Abstract

Red Hat Developer Toolset is a Red Hat offering for developers on the Red Hat Enterprise Linux platform. The Red Hat Developer Toolset User Guide provides an overview of this product, explains how to invoke and use the Red Hat Developer Toolset versions of the tools, and links to resources with more in-depth information.

APPENDIX B. REVISION HISTORY

Table of Contents
1.1. ABOUT RED HAT DEVELOPER TOOLSET

Red Hat Developer Toolset is a Red Hat offering for developers on the Red Hat Enterprise Linux platform. It provides a complete set of development and performance analysis tools that can be installed and used on multiple versions of Red Hat Enterprise Linux. Executables built with the Red Hat Developer Toolset toolchain can then also be deployed and run on multiple versions of Red Hat Enterprise Linux. For detailed compatibility information, see Section 1.3, “Compatibility”.

Red Hat Developer Toolset does not replace the default system tools provided with Red Hat Enterprise Linux 6 or 7 when installed on those platforms. Instead, a parallel set of developer tools provides an alternative, newer version of those tools for optional use by developers. The default compiler and debugger, for example, remain those provided by the base Red Hat Enterprise Linux system.

What Is New in Red Hat Developer Toolset 7.1

Since Red Hat Developer Toolset 4.1, the Red Hat Developer Toolset content is also available in the ISO format together with the rest of Red Hat Software Collections content at https://access.redhat.com/downloads, specifically for Server and Workstation. Note that packages that require the Optional channel, which are discussed in Section 1.5.3, “Installing Optional Packages”, cannot be installed from the ISO image.

Red Hat Developer Toolset differs from "Technology Preview" compiler releases previously supplied in Red Hat Enterprise Linux in two important respects:

1. Red Hat Developer Toolset can be used on multiple major and minor releases of Red Hat Enterprise Linux, as detailed in Section 1.3, "Compatibility".

2. Unlike Technology Preview compilers and other tools shipped in earlier Red Hat Enterprise Linux, Red Hat Developer Toolset is fully supported under Red Hat Enterprise Linux Subscription Level Agreements, is functionally complete, and is intended for production use.

Important bug fixes and security errata are issued to Red Hat Developer Toolset subscribers in a similar manner to Red Hat Enterprise Linux for two years from the release of each major version release. A new major version of Red Hat Developer Toolset is released annually, providing significant updates for existing components and adding major new components. A single minor release, issued six months after each new major version release, provides a smaller update of bug fixes, security errata, and new minor components.

Additionally, the Red Hat Enterprise Linux Application Compatibility Specification also applies to Red Hat Developer Toolset (subject to some constraints on the use of newer C++11 language features, detailed in Section 2.2.4, "C++ Compatibility").

**IMPORTANT**

Applications and libraries provided by Red Hat Developer Toolset do not replace the Red Hat Enterprise Linux system versions, nor are they used in preference to the system versions. Using a framework called Software Collections, an additional set of developer tools is installed into the /opt/ directory and is explicitly enabled by the user on demand using the scl utility.

### 1.2. MAIN FEATURES

Red Hat Developer Toolset 7.1 brings the following changes:

- The Red Hat Developer Toolset version of the GNU Compiler Collection (GCC) has been upgraded to version 7.3.1 with many new features and bug fixes.
The Red Hat Developer Toolset version of the GNU Debugger (GDB) has been upgraded to version 8.0.1 with many new features and bug fixes.

For a full list of changes and features introduced in this release, see Section A.1, “Changes in Version 7.1”.

1.3. COMPATIBILITY

Red Hat Developer Toolset 7.1 is available for Red Hat Enterprise Linux 6 and 7 for a number of architectures. Figure 1.1, “Red Hat Developer Toolset 7.1 Compatibility Matrix” illustrates the support for binaries built with Red Hat Developer Toolset on a certain version of Red Hat Enterprise Linux when those binaries are run on various other versions of this system.

For ABI compatibility information, see Section 2.2.4, “C++ Compatibility”.

Architecture support
Red Hat Developer Toolset is available on the following architectures:

- The 64-bit Intel and AMD architectures
- The 64-bit ARM architecture
- The IBM POWER architecture
- The little-endian variant of IBM POWER architecture
- The IBM z Systems architecture

1.4. GETTING ACCESS TO RED HAT DEVELOPER TOOLSET

Red Hat Developer Toolset is an offering that is distributed as a part of the following content sets:
CHAPTER 1. RED HAT DEVELOPER TOOLSET

Red Hat Software Collections
This content set is available to customers with Red Hat Enterprise Linux 6 and 7 subscriptions listed at https://access.redhat.com/solutions/472793.

Red Hat Developer Tools
This content set is available to customers with deployments of Red Hat Enterprise Linux 7.

NOTE
Please note the difference: Red Hat Developer Toolset is an offering distributed as a part of the Red Hat Developer Tools content set.

Enable Red Hat Developer Toolset by using the Red Hat Subscription Management. For information on how to register your system with this subscription management service, see the Red Hat Subscription Management collection of guides.

1.4.1. Using Red Hat Software Collections
Complete the following steps to attach a subscription that provides access to the repository for Red Hat Software Collections (which includes Red Hat Developer Toolset), and then enable that repository:

1. Determine the pool ID of a subscription that provides Red Hat Software Collections (and thus also Red Hat Developer Toolset). To do so, display a list of all subscriptions that are available for your system:

   # subscription-manager list --available

   For each available subscription, this command displays its name, unique identifier, expiration date, and other details related to your subscription. The pool ID is listed on a line beginning with Pool ID.

   For a complete list of subscriptions that provide access to Red Hat Developer Toolset, see https://access.redhat.com/solutions/472793.

2. Attach the appropriate subscription to your system:

   # subscription-manager attach --pool=pool_id

   Replace pool_id with the pool ID you determined in the previous step. To verify the list of subscriptions your system has currently attached, at any time:

   # subscription-manager list --consumed

3. Determine the exact name of the Red Hat Software Collections repository. Retrieve repository metadata and to display a list of available Yum repositories:

   # subscription-manager repos --list

   The repository names depend on the specific version of Red Hat Enterprise Linux you are using and are in the following format:

   rhel-variant-rhscl-version-rpms
   rhel-variant-rhscl-version-debug-rpms
rhel-variant-rhscl-version-source-rpms

In addition, certain packages, such as devtoolset-7-gcc-plugin-devel, depend on packages that are only available in the Optional channel. The repository names with these packages use the following format:

rhel-version-variant-optional-rpms
rhel-version-variant-optional-debug-rpms
rhel-version-variant-optional-source-rpms

For both the regular repositories and optional repositories, replace variant with the Red Hat Enterprise Linux system variant (server or workstation), and version with the Red Hat Enterprise Linux system version (6-eus, 6, or 7).

4. Enable the repositories from step no. 3:

```bash
# subscription-manager repos --enable repository
```

Replace repository with the name of the repository to enable.

Once the subscription is attached to the system, you can install Red Hat Developer Toolset as described in Section 1.5, “Installing Red Hat Developer Toolset”. For more information on how to register your system using Red Hat Subscription Management and associate it with subscriptions, see the Red Hat Subscription Management collection of guides.

### 1.4.2. Using Red Hat Developer Tools

1. Enable the rhel-7-variant-devtools-rpms repository:

```bash
# subscription-manager repos --enable rhel-7-variant-devtools-rpms
```

Replace variant with the Red Hat Enterprise Linux system variant (server or workstation).

2. Add the Red Hat Developer Tools key to your system:

```bash
# cd /etc/pki/rpm-gpg
# wget -O RPM-GPG-KEY-redhat-devel https://www.redhat.com/security/data/a5787476.txt
# rpm --import RPM-GPG-KEY-redhat-devel
```

Once the subscription is attached to the system, you can install Red Hat Developer Toolset as described in Section 1.5, “Installing Red Hat Developer Toolset”. For more information on how to register your system using Red Hat Subscription Management and associate it with subscriptions, see the Red Hat Subscription Management collection of guides.

### 1.5. INSTALLING RED HAT DEVELOPER TOOLSET

Red Hat Developer Toolset is distributed as a collection of RPM packages that can be installed, updated, uninstalled, and inspected by using the standard package management tools that are included in Red Hat Enterprise Linux. Note that a valid subscription that provides access to the Red Hat Software Collections content set is required in order to install Red Hat Developer Toolset on your system. For detailed instructions on how to associate your system with an appropriate subscription and get access to Red Hat Developer Toolset, see Section 1.4, “Getting Access to Red Hat Developer Toolset”.

12
1.5.1. Installing All Available Components

To install all components that are included in Red Hat Developer Toolset, install the `devtoolset-7` package:

```
# yum install devtoolset-7
```

This installs all development, debugging, and performance monitoring tools, and other dependent packages to the system. Alternatively, you can choose to install only a selected package group as described in Section 1.5.2, “Installing Individual Package Groups”.

1.5.2. Installing Individual Package Groups

To make it easier to install only certain components, such as the integrated development environment or the software development toolchain, Red Hat Developer Toolset is distributed with a number of meta packages that allow you to install selected package groups as described in Table 1.2, “Red Hat Developer Toolset Meta Packages”.

<table>
<thead>
<tr>
<th>Package Name</th>
<th>Description</th>
<th>Installed Components</th>
</tr>
</thead>
<tbody>
<tr>
<td>devtoolset-7-perftools</td>
<td>Performance monitoring tools</td>
<td>SystemTap, Valgrind, OProfile, Dyninst</td>
</tr>
<tr>
<td>devtoolset-7-toolchain</td>
<td>Development and debugging tools</td>
<td>GCC, make, GDB, binutils, elfutils, dwz, memstomp, strace, ltrace</td>
</tr>
</tbody>
</table>

To install any of these meta packages:

```
# yum install package_name
```

Replace `package_name` with a space-separated list of meta packages you want to install. For example, to install only the development and debugging toolchain and packages that depend on it:

```
# yum install devtoolset-7-toolchain
```

Alternatively, you can choose to install all available components as described in Section 1.5.1, “Installing All Available Components”.

---

**IMPORTANT**

Before installing Red Hat Developer Toolset, install all available Red Hat Enterprise Linux updates.

**NOTE**

Note that since Red Hat Developer Toolset 3.0, the `scl-utils` package is not a part of Red Hat Developer Toolset, which is a change from preceding versions where the `scl` utility was installed along with the Red Hat Developer Toolset software collection.
1.5.3. Installing Optional Packages

Red Hat Developer Toolset is distributed with a number of optional packages that are not installed by default. To list all Red Hat Developer Toolset packages that are available to you but not installed on your system:

```
$ yum list available devtoolset-7-\*
```

To install any of these optional packages:

```
# yum install package_name
```

Replace `package_name` with a space-separated list of packages that you want to install. For example, to install the `devtoolset-7-gdb-gdbserver` and `devtoolset-7-gdb-doc` packages:

```
# yum install devtoolset-7-gdb-gdbserver devtoolset-7-gdb-doc
```

1.5.4. Installing Debugging Information

To install debugging information for any of the Red Hat Developer Toolset packages, make sure that the `yum-utils` package is installed and run:

```
# debuginfo-install package_name
```

For example, to install debugging information for the `devtoolset-7-dwz` package:

```
# debuginfo-install devtoolset-7-dwz
```

Note that in order to use this command, you need to have access to the repository with these packages. If your system is registered with Red Hat Subscription Management, enable the `rhel-variant-rhscl-version-debug-rpms` repository as described in Section 1.4, “Getting Access to Red Hat Developer Toolset”. For more information on how to get access to debuginfo packages, see https://access.redhat.com/site/solutions/9907.

NOTE

The `devtoolset-7-package_name-debuginfo` packages can conflict with the corresponding packages from the base Red Hat Enterprise Linux system or from other versions of Red Hat Developer Toolset. This conflict also occurs in a multilib environment, where 64-bit debuginfo packages conflict with 32-bit debuginfo packages.

Manually uninstall the conflicting debuginfo packages prior to installing Red Hat Developer Toolset 7.1 and install only relevant debuginfo packages when necessary.

1.6. UPDATING RED HAT DEVELOPER TOOLSET

1.6.1. Updating to a Minor Version

When a new minor version of Red Hat Developer Toolset is available, update your Red Hat Enterprise Linux installation:

```
# yum update
```
This updates all packages on your Red Hat Enterprise Linux system, including the Red Hat Developer Toolset versions of development, debugging, and performance monitoring tools, and other dependent packages.

**IMPORTANT**

Use of Red Hat Developer Toolset requires the removal of any earlier pre-release versions of it. Additionally, it is not possible to update to Red Hat Developer Toolset 7.1 from a pre-release version of Red Hat Developer Toolset, including beta releases. If you have previously installed any pre-release version of Red Hat Developer Toolset, uninstall it from your system as described in Section 1.7, “Uninstalling Red Hat Developer Toolset” and install the new version as documented in Section 1.5, “Installing Red Hat Developer Toolset”.

### 1.6.2. Updating to a Major Version

When a new major version of Red Hat Developer Toolset is available, you can install it in parallel with the previous version. For detailed instructions on how to install Red Hat Developer Toolset on your system, see Section 1.5, “Installing Red Hat Developer Toolset”.

### 1.7. UNINSTALLING RED HAT DEVELOPER TOOLSET

To uninstall Red Hat Developer Toolset packages from your system:

```
# yum remove devtoolset-7\* libasan libatomic libcilkrts libitm liblsan libtsan libubsan
```

This removes the GNU Compiler Collection, GNU Debugger, binutils, and other packages that are a part of Red Hat Developer Toolset from the system.

**NOTE**

Red Hat Developer Toolset 7.1 for Red Hat Enterprise Linux 7 no longer includes the libatomic and libitm libraries, which the above command attempts to remove, because they are not required for a proper function of Red Hat Developer Toolset components on that system. Nevertheless, the above command works as expected even on Red Hat Enterprise Linux 7.

Note that the uninstallation of the tools provided by Red Hat Developer Toolset does not affect the Red Hat Enterprise Linux system versions of these tools.

### 1.8. USING RED HAT DEVELOPER TOOLSET CONTAINER IMAGES

Docker-formatted container images can be used to run Red Hat Developer Toolset components inside virtual software containers, thus isolating them from the host system and allowing for their rapid deployment. For detailed description of the Red Hat Developer Toolset docker-formatted container images and Red Hat Developer Toolset Dockerfiles, see Using Red Hat Software Collections Container Images.
NOTE

The `docker` package, which contains the `Docker` daemon, command-line tool, and other necessary components for building and using docker-formatted container images, is currently available only for the Server variant of the Red Hat Enterprise Linux 7 product. Docker-formatted container images cannot be run on Red Hat Enterprise Linux 6, and Red Hat Developer Toolset Dockerfiles are not distributed for Red Hat Enterprise Linux 6.

Follow the instructions outlined at [Getting Docker in RHEL 7](#) to set up an environment for building and using docker-formatted container images.

PART II. DEVELOPMENT TOOLS
The GNU Compiler Collection, commonly abbreviated GCC, is a portable compiler suite with support for a wide selection of programming languages.

Red Hat Developer Toolset is distributed with GCC 7.3.1. This version is more recent than the version included in Red Hat Enterprise Linux and provides a number of bug fixes and enhancements.

2.1. GNU C COMPILER

2.1.1. Installing the C Compiler

In Red Hat Developer Toolset, the GNU C compiler is provided by the devtoolset-7-gcc package and is automatically installed with devtoolset-7-toolchain as described in Section 1.5, “Installing Red Hat Developer Toolset”.

2.1.2. Using the C Compiler

To compile a C program on the command line, run the gcc compiler as follows:

```bash
$ scl enable devtoolset-7 'gcc -o output_file source_file...'
```

This creates a binary file named output_file in the current working directory. If the -o option is omitted, the compiler creates a file named a.out by default.

When you are working on a project that consists of several source files, it is common to compile an object file for each of the source files first and then link these object files together. This way, when you change a single source file, you can recompile only this file without having to compile the entire project. To compile an object file on the command line:

```bash
$ scl enable devtoolset-7 'gcc -o object_file -c source_file'
```

This creates an object file named object_file. If the -o option is omitted, the compiler creates a file named after the source file with the .o file extension. To link object files together and create a binary file:

```bash
$ scl enable devtoolset-7 'gcc -o output_file object_file...'
```

Note that you can execute any command using the scl utility, causing it to be run with the Red Hat Developer Toolset binaries used in preference to the Red Hat Enterprise Linux system equivalent. This allows you to run a shell session with Red Hat Developer Toolset gcc as default:

```bash
$ scl enable devtoolset-7 'bash'
```
NOTE
To verify the version of gcc you are using at any point:

```bash
$ which gcc
```

Red Hat Developer Toolset’s gcc executable path will begin with `/opt`. Alternatively, you can use the following command to confirm that the version number matches that for Red Hat Developer Toolset gcc:

```bash
$ gcc -v
```

Example 2.1. Compiling a C Program on the Command Line
Consider a source file named `hello.c` with the following contents:

```c
#include <stdio.h>

int main(int argc, char *argv[]) {
    printf("Hello, World!\n");
    return 0;
}
```

Compile this source code on the command line by using the gcc compiler from Red Hat Developer Toolset:

```bash
$ scl enable devtoolset-7 'gcc -o hello hello.c'
```

This creates a new binary file called `hello` in the current working directory.

2.1.3. Running a C Program
When gcc compiles a program, it creates an executable binary file. To run this program on the command line, change to the directory with the executable file and run it:

```bash
$ ./file_name
```

Example 2.2. Running a C Program on the Command Line
Assuming that you have successfully compiled the `hello` binary file as shown in Example 2.1, “Compiling a C Program on the Command Line”, you can run it by typing the following at a shell prompt:

```bash
$ ./hello
Hello, World!
```

2.2. GNU C++ COMPILER
2.2.1. Installing the C++ Compiler

In Red Hat Developer Toolset, the GNU C++ compiler is provided by the devtoolset-7-gcc-c++ package and is automatically installed with the devtoolset-7-toolchain package as described in Section 1.5, “Installing Red Hat Developer Toolset”.

2.2.2. Using the C++ Compiler

To compile a C++ program on the command line, run the g++ compiler as follows:

```bash
$ scl enable devtoolset-7 'g++ -o output_file source_file...'
```

This creates a binary file named `output_file` in the current working directory. If the `-o` option is omitted, the `g++` compiler creates a file named `a.out` by default.

When you are working on a project that consists of several source files, it is common to compile an object file for each of the source files first and then link these object files together. This way, when you change a single source file, you can recompile only this file without having to compile the entire project.

To compile an object file on the command line:

```bash
$ scl enable devtoolset-7 'g++ -o object_file -c source_file'
```

This creates an object file named `object_file`. If the `-o` option is omitted, the `g++` compiler creates a file named after the source file with the `.o` file extension. To link object files together and create a binary file:

```bash
$ scl enable devtoolset-7 'g++ -o output_file object_file...'
```

Note that you can execute any command using the `scl` utility, causing it to be run with the Red Hat Developer Toolset binaries used in preference to the Red Hat Enterprise Linux system equivalent. This allows you to run a shell session with Red Hat Developer Toolset `g++` as default:

```bash
$ scl enable devtoolset-7 'bash'
```

**NOTE**

To verify the version of `g++` you are using at any point:

```bash
$ which g++
```

Red Hat Developer Toolset’s `g++` executable path will begin with `/opt`. Alternatively, you can use the following command to confirm that the version number matches that for Red Hat Developer Toolset `g++`:

```bash
$ g++ -v
```

**Example 2.3. Compiling a C++ Program on the Command Line**

Consider a source file named `hello.cpp` with the following contents:

```cpp
#include <iostream>
```
using namespace std;

int main(int argc, char *argv[]) {
    cout << "Hello, World!" << endl;
    return 0;
}

Compile this source code on the command line by using the `g++` compiler from Red Hat Developer Toolset:

```
$ scl enable devtoolset-7 'g++ -o hello hello.cpp'
```

This creates a new binary file called `hello` in the current working directory.

### 2.2.3. Running a C++ Program

When `g++` compiles a program, it creates an executable binary file. To run this program on the command line, change to the directory with the executable file and run it:

```
$ ./file_name
```

**Example 2.4. Running a C++ Program on the Command Line**

Assuming that you have successfully compiled the `hello` binary file as shown in Example 2.3, “Compiling a C++ Program on the Command Line”, you can run it:

```
$ ./hello
Hello, World!
```

### 2.2.4. C++ Compatibility

All compilers from Red Hat Enterprise Linux versions 5, 6, and 7 and from Red Hat Developer Toolset versions 1, 2, 3, 4, and 6 in any `-std` mode are compatible with any other of those compilers in C++98 mode.

A compiler in C++11 or C++14 mode is only guaranteed to be compatible with another compiler in C++11 or C++14 mode if they are from the same release series (for example from Red Hat Developer Toolset 6.x).

**IMPORTANT**

All compatibility information mentioned in this section is relevant only for Red Hat-supplied versions of the GCC C++ compiler.

#### 2.2.4.1. C++ ABI

Any C++98-compliant binaries or libraries built explicitly with `-std=c++98` or `-std=gnu++98` can be freely mixed with binaries and shared libraries built by the Red Hat Enterprise Linux 5, 6 or 7 system toolchain GCC. Red Hat recommends use of the `-std=c++98` or `-std=gnu++98` modes for production software development.
The default language standard setting for Red Hat Developer Toolset is C++14 with GNU extensions, equivalent to explicitly using option `-std=gnu++14`.

Using and mixing the C++11, C++14, and C++17 language versions is supported in Red Hat Developer Toolset only when all C++ objects compiled with the respective flag have been built using the same major version of GCC. As later major versions of Red Hat Developer Toolset may use a later major release of GCC, forward-compatibility of objects, binaries, and libraries built with the options `-std=c++11`, `-std=gnu++11`, `-std=c++14`, `-std=gnu++14`, `-std=c++17`, and `-std=gnu++17` options cannot be guaranteed, and so is not supported.

**IMPORTANT**

Use of C++11, C++14 and C++17 features in your application requires careful consideration of the above ABI compatibility information.

The mixing of objects, binaries and libraries, built by the Red Hat Enterprise Linux 6 or 7 system toolchain GCC using the `-std=c++0x` or `-std=gnu++0x` flags, with those built with the `-std=c++11` or `-std=gnu++11` or `-std=c++14` or `-std=gnu++14` or `-std=c++17` or `-std=gnu++17` flags using the GCC in Red Hat Developer Toolset is explicitly not supported.

Aside from the C++11, C++14 and C++17 ABI, discussed above, the Red Hat Enterprise Linux Application Compatibility Specification is unchanged for Red Hat Developer Toolset. When mixing objects built with Red Hat Developer Toolset with those built with the Red Hat Enterprise Linux 6 or 7 toolchain (particularly `.o/.a` files), the Red Hat Developer Toolset toolchain should be used for any linkage. This ensures any newer library features provided only by Red Hat Developer Toolset are resolved at link-time.

A new standard mangling for SIMD vector types has been added to avoid name clashes on systems with vectors of varying lengths. The compiler in Red Hat Developer Toolset uses the new mangling by default. It is possible to use the previous standard mangling by adding the `-fabi-version=2` or `-fabi-version=3` options to GCC C++ compiler calls. To display a warning about code that uses the old mangling, use the `-Wabi` option.

On Red Hat Enterprise Linux 7, the GCC C++ compiler still uses the old mangling by default, but emits aliases with the new mangling on targets that support strong aliases. It is possible to use the new standard mangling by adding the `-fabi-version=4` option to compiler calls. To display a warning about code that uses the old mangling, use the `-Wabi` option.

On Red Hat Enterprise Linux 6, the GCC C++ compiler supports only the previous standard mangling.

### 2.3. GNU FORTRAN COMPILER

#### 2.3.1. Installing the Fortran Compiler

In Red Hat Developer Toolset, the GNU Fortran compiler is provided by the `devtoolset-7-gcc-gfortran` package and is automatically installed with `devtoolset-7-toolchain` as described in Section 1.5, “Installing Red Hat Developer Toolset”.

#### 2.3.2. Using the Fortran Compiler

To compile a Fortran program on the command line, run the `gfortran` compiler as follows:

```bash
$ scl enable devtoolset-7 'gfortran -o output_file source_file...
```
This creates a binary file named `output_file` in the current working directory. If the `-o` option is omitted, the compiler creates a file named `a.out` by default.

When you are working on a project that consists of several source files, it is common to compile an object file for each of the source files first and then link these object files together. This way, when you change a single source file, you can recompile only this file without having to compile the entire project. To compile an object file on the command line:

```
$ scl enable devtoolset-7 'gfortran -o object_file -c source_file'
```

This creates an object file named `object_file`. If the `-o` option is omitted, the compiler creates a file named after the source file with the `.o` file extension. To link object files together and create a binary file:

```
$ scl enable devtoolset-7 'gfortran -o output_file object_file...'
```

Note that you can execute any command using the `scl` utility, causing it to be run with the Red Hat Developer Toolset binaries used in preference to the Red Hat Enterprise Linux system equivalent. This allows you to run a shell session with Red Hat Developer Toolset `gfortran` as default:

```
$ scl enable devtoolset-7 'bash'
```

NOTE
To verify the version of `gfortran` you are using at any point:

```
$ which gfortran
```

Red Hat Developer Toolset's `gfortran` executable path will begin with `/opt`. Alternatively, you can use the following command to confirm that the version number matches that for Red Hat Developer Toolset `gfortran`:

```
$ gfortran -v
```

Example 2.5. Compiling a Fortran Program on the Command Line
Consider a source file named `hello.f` with the following contents:

```fortran
program hello
    print *, "Hello, World!"
end program hello
```

Compile this source code on the command line by using the `gfortran` compiler from Red Hat Developer Toolset:

```
$ scl enable devtoolset-7 'gfortran -o hello hello.f'
```

This creates a new binary file called `hello` in the current working directory.

2.3.3. Running a Fortran Program
When `gfortran` compiles a program, it creates an executable binary file. To run this program on the command line, change to the directory with the executable file and run it:

```
$ ./file_name
```

### Example 2.6. Running a Fortran Program on the Command Line

Assuming that you have successfully compiled the `hello` binary file as shown in Example 2.5, “Compiling a Fortran Program on the Command Line”, you can run it:

```
$ ./hello
Hello, World!
```

## 2.4. SPECIFICS OF GCC IN RED HAT DEVELOPER TOOLSET

### Static linking of libraries

Certain more recent library features are statically linked into applications built with Red Hat Developer Toolset to support execution on multiple versions of Red Hat Enterprise Linux. This creates an additional minor security risk as standard Red Hat Enterprise Linux errata do not change this code. If the need arises for developers to rebuild their applications due to this risk, Red Hat will communicate this using a security erratum.

**IMPORTANT**

Because of this additional security risk, developers are strongly advised not to statically link their entire application for the same reasons.

### Specify libraries after object files when linking

In Red Hat Developer Toolset, libraries are linked using linker scripts which might specify some symbols through static archives. This is required to ensure compatibility with multiple versions of Red Hat Enterprise Linux. However, the linker scripts use the names of the respective shared object files. As a consequence, the linker uses different symbol handling rules than expected, and does not recognize symbols required by object files when the option adding the library is specified before options specifying the object files:

```
$ scl enable devtoolset-7 'gcc -lsomelib objfile.o'
```

Using a library from the Red Hat Developer Toolset in this manner results in the linker error message `undefined reference to symbol`. To prevent this problem, follow the standard linking practice, and specify the option adding the library after the options specifying the object files:

```
$ scl enable devtoolset-7 'gcc objfile.o -lsomelib'
```

Note that this recommendation also applies when using the base Red Hat Enterprise Linux version of GCC.

CHAPTER 3. GNU MAKE

The GNU make utility, commonly abbreviated make, is a tool for controlling the generation of executables from source files. make automatically determines which parts of a complex program have changed and need to be recompiled. make uses configuration files called Makefiles to control the way programs are built.

Red Hat Developer Toolset is distributed with make 4.2.1. This version is more recent than the version included in Red Hat Enterprise Linux and provides a number of bug fixes and enhancements.

3.1. INSTALLING MAKE

In Red Hat Developer Toolset, GNU make is provided by the devtoolset-7-make package and is automatically installed with devtoolset-7-toolchain as described in Section 1.5, “Installing Red Hat Developer Toolset”.

3.2. USING MAKE

To build a program without using a Makefile, run the make tool as follows:

```
$ scl enable devtoolset-7 'make source_file_without_extension'
```

This command makes use of implicit rules that are defined for a number of programming languages, including C, C++, and Fortran. The result is a binary file named `source_file_without_extension` in the current working directory.

Note that you can execute any command using the scl utility, causing it to be run with the Red Hat Developer Toolset binaries used in preference to the Red Hat Enterprise Linux system equivalent. This allows you to run a shell session with Red Hat Developer Toolset make as default:

```
$ scl enable devtoolset-7 'bash'
```

**NOTE**

To verify the version of make you are using at any point:

```
$ which make
```

Red Hat Developer Toolset’s make executable path will begin with `/opt`. Alternatively, you can use the following command to confirm that the version number matches that for Red Hat Developer Toolset make:

```
$ make -v
```

**Example 3.1. Building a C Program Using make**

Consider a source file named `hello.c` with the following contents:

```c
#include <stdio.h>

int main(int argc, char *argv[]) {
```
Build this source code using the implicit rules defined by the make utility from Red Hat Developer Toolset:

```bash
$ scl enable devtoolset-7 'make hello'
cc hello.c -o hello
```

This creates a new binary file called `hello` in the current working directory.

### 3.3. USING MAKEFILES

To build complex programs that consist of a number of source files, make uses configuration files called `Makefiles` that control how to compile the components of a program and build the final executable. Makefiles can also contain instructions for cleaning the working directory, installing and uninstalling program files, and other operations.

Make automatically uses files named `GNUmakefile`, `makefile`, or `Makefile` in the current directory. To specify another file name, use the `-f` option:

```bash
$ make -f make_file
```

Describing the details of Makefile syntax is beyond the scope of this guide. See `GNU make`, the official GNU make manual, which provides an in-depth description of the GNU make utility, Makefile syntax, and their usage.

The full make manual is also available in the Texinfo format as a part of your installation. To view this manual:

```bash
$ scl enable devtoolset-7 'info make'
```

#### Example 3.2. Building a C Program Using a Makefile

Consider the following universal Makefile named `Makefile` for building the simple C program introduced in Example 3.1, “Building a C Program Using make”. The Makefile defines some variables and specifies four `rules`, which consist of `targets` and their `recipes`. Note that the lines with recipes must start with the TAB character:

```make
CC=gcc
CFLAGS=-c -Wall
SOURCE=hello.c
OBJ=$(SOURCE:.c=.o)
EXE=hello

all: $(SOURCE) $(EXE)

$(EXE): $(OBJ)
 $(CC) $(OBJ) -o $@

.o: .c
```
To build the `hello.c` program using this Makefile, run the `make` utility:

```
$ scl enable devtoolset-7 'make'
gcc -c -Wall hello.c -o hello.o
gcc hello.o -o hello
```

This creates a new object file `hello.o` and a new binary file called `hello` in the current working directory.

To clean the working directory, run:

```
$ scl enable devtoolset-7 'make clean'
rm -rf hello.o hello
```

This removes the object and binary files from the working directory.

binutils is a collection of various binary tools, such as the GNU linker, GNU assembler, and other utilities that allow you to inspect and manipulate object files and binaries. See Table 4.1, “Tools Included in binutils for Red Hat Developer Toolset” for a complete list of binary tools that are distributed with the Red Hat Developer Toolset version of binutils.

Red Hat Developer Toolset is distributed with binutils 2.28. This version is more recent than the version included in Red Hat Enterprise Linux and the previous release of Red Hat Developer Toolset and provides bug fixes and enhancements.

### 4.1. INSTALLING BINUTILS

In Red Hat Developer Toolset, binutils are provided by the devtoolset-7-binutils package and are automatically installed with devtoolset-7-toolchain as described in Section 1.5, “Installing Red Hat Developer Toolset”.

### 4.2. USING THE GNU ASSEMBLER

To produce an object file from an assembly language program, run the `as` tool as follows:

```
$ scl enable devtoolset-7 'as option ... -o object_file source_file'
```

This creates an object file named `object_file` in the current working directory.

Note that you can execute any command using the `scl` utility, causing it to be run with the Red Hat Developer Toolset binaries used in preference to the Red Hat Enterprise Linux system equivalent. This allows you to run a shell session with Red Hat Developer Toolset as default:

```
$ scl enable devtoolset-7 'bash'
```

**NOTE**

To verify the version of `as` you are using at any point:

```
$ which as
```

Red Hat Developer Toolset’s `as` executable path will begin with `/opt`. Alternatively, you can use the following command to confirm that the version number matches that for Red Hat Developer Toolset `as`:

```
$ as -v
```

### 4.3. USING THE GNU LINKER

To create an executable binary file or a library from object files, run the `ld` tool as follows:

```
$ scl enable devtoolset-7 'ld option ... -o output_file object_file ...'
```

This creates a binary file named `output_file` in the current working directory. If the `-o` option is omitted, the compiler creates a file named `a.out` by default.
Note that you can execute any command using the `scl` utility, causing it to be run with the Red Hat Developer Toolset binaries used in preference to the Red Hat Enterprise Linux system equivalent. This allows you to run a shell session with Red Hat Developer Toolset `ld` as default:

```bash
$ scl enable devtoolset-7 'bash'
```

### NOTE

To verify the version of `ld` you are using at any point:

```bash
$ which ld
```

Red Hat Developer Toolset's `ld` executable path will begin with `/opt`. Alternatively, you can use the following command to confirm that the version number matches that for Red Hat Developer Toolset `ld`:

```bash
$ ld -v
```

## 4.4. USING OTHER BINARY TOOLS

The `binutils` provide many binary tools other than a linker and an assembler. For a complete list of these tools, see Table 4.1, “Tools Included in `binutils` for Red Hat Developer Toolset”.

To execute any of the tools that are a part of `binutils`:

```bash
$ scl enable devtoolset-7 'tool option ... file_name'
```

See Table 4.1, “Tools Included in `binutils` for Red Hat Developer Toolset” for a list of tools that are distributed with `binutils`. For example, to use the `objdump` tool to inspect an object file:

```bash
$ scl enable devtoolset-7 'objdump option ... object_file'
```

Note that you can execute any command using the `scl` utility, causing it to be run with the Red Hat Developer Toolset binaries used in preference to the Red Hat Enterprise Linux system equivalent. This allows you to run a shell session with Red Hat Developer Toolset binary tools as default:

```bash
$ scl enable devtoolset-7 'bash'
```

### NOTE

To verify the version of `binutils` you are using at any point:

```bash
$ which objdump
```

Red Hat Developer Toolset's `objdump` executable path will begin with `/opt`. Alternatively, you can use the following command to confirm that the version number matches that for Red Hat Developer Toolset `objdump`:

```bash
$ objdump -v
```
4.5. SPECIFICS OF BINUTILS IN RED HAT DEVELOPER TOOLSET

**Static linking of libraries**

**Specify libraries after object files when linking**

In Red Hat Developer Toolset, libraries are linked using linker scripts which might specify some symbols through static archives. This is required to ensure compatibility with multiple versions of Red Hat Enterprise Linux. However, the linker scripts use the names of the respective shared object files. As a consequence, the linker uses different symbol handling rules than expected, and does not recognize symbols required by object files when the option adding the library is specified before options specifying the object files:

```
$ scl enable devtoolset-7 'ld -lsomelib objfile.o'
```

Using a library from the Red Hat Developer Toolset in this manner results in the linker error message `undefined reference to symbol`. To prevent this problem, follow the standard linking practice, and specify the option adding the library after the options specifying the object files:

```
$ scl enable devtoolset-7 'ld objfile.o -lsomelib'
```

Note that this recommendation also applies when using the base Red Hat Enterprise Linux version of `binutils`.

5.1. INSTALLING ELFUTILS

In Red Hat Developer Toolset, elfutils is provided by the devtoolset-7-elfutils package and is automatically installed with devtoolset-7-toolchain as described in Section 1.5, “Installing Red Hat Developer Toolset”.

5.2. USING ELFUTILS

To execute any of the tools that are part of elfutils, run the tool as follows:

```
$ scl enable devtoolset-7 'tool option ... file_name'
```

See Table 5.1, “Tools Included in elfutils for Red Hat Developer Toolset” for a list of tools that are distributed with elfutils. For example, to use the eu-objdump tool to inspect an object file:

```
$ scl enable devtoolset-7 'eu-objdump option ... object_file'
```

Note that you can execute any command using the scl utility, causing it to be run with the Red Hat Developer Toolset binaries used in preference to the Red Hat Enterprise Linux system equivalent. This allows you to run a shell session with Red Hat Developer Toolset binary tools as default:

```
$ scl enable devtoolset-7 'bash'
```

NOTE

To verify the version of elfutils you are using at any point:

```
$ which eu-objdump
```

Red Hat Developer Toolset’s eu-objdump executable path will begin with /opt. Alternatively, you can use the following command to confirm that the version number matches that for Red Hat Developer Toolset eu-objdump:

```
$ eu-objdump -V
```

CHAPTER 6. DWZ

**dwz** is a command line tool that attempts to optimize DWARF debugging information contained in **ELF** shared libraries and **ELF** executables for size. To do so, **dwz** replaces DWARF information representation with equivalent smaller representation where possible and reduces the amount of duplication by using techniques from **Appendix E** of the **DWARF Standard**.

Red Hat Developer Toolset is distributed with **dwz 0.12**.

6.1. INSTALLING DWZ

In Red Hat Developer Toolset, the **dwz** utility is provided by the **devtoolset-7-dwz** package and is automatically installed with **devtoolset-7-toolchain** as described in Section 1.5, “Installing Red Hat Developer Toolset”.

6.2. USING DWZ

To optimize DWARF debugging information in a binary file, run the **dwz** tool as follows:

```
$ scl enable devtoolset-7 'dwz option... file_name'
```

Note that you can execute any command using the **scl** utility, causing it to be run with the Red Hat Developer Toolset binaries used in preference to the Red Hat Enterprise Linux system equivalent. This allows you to run a shell session with Red Hat Developer Toolset **dwz** as default:

```
$ scl enable devtoolset-7 'bash'
```

**NOTE**

To verify the version of **dwz** you are using at any point:

```
$ which dwz
```

Red Hat Developer Toolset’s **dwz** executable path will begin with **/opt**. Alternatively, you can use the following command to confirm that the version number matches that for Red Hat Developer Toolset **dwz**:

```
$ dwz -v
```

PART III. DEBUGGING TOOLS
CHAPTER 7. GNU DEBUGGER (GDB)

The GNU Debugger, commonly abbreviated as GDB, is a command line tool that can be used to debug programs written in various programming languages. It allows you to inspect memory within the code being debugged, control the execution state of the code, detect the execution of particular sections of code, and much more.

Red Hat Developer Toolset is distributed with GDB 8.0.1. This version is more recent than the version included in Red Hat Enterprise Linux and the previous release of Red Hat Developer Toolset and provides some enhancements and numerous bug fixes.

7.1. INSTALLING THE GNU DEBUGGER

In Red Hat Developer Toolset, the GNU Debugger is provided by the devtoolset-7-gdb package and is automatically installed with devtoolset-7-toolchain as described in Section 1.5, "Installing Red Hat Developer Toolset".

7.2. PREPARING A PROGRAM FOR DEBUGGING

Compiling Programs with Debugging Information

To compile a C program with debugging information that can be read by the GNU Debugger, make sure the gcc compiler is run with the -g option:

```
$ scl enable devtoolset-7 'gcc -g -o output_file input_file...'
```

Similarly, to compile a C++ program with debugging information:

```
$ scl enable devtoolset-7 'g++ -g -o output_file input_file...'
```

Example 7.1. Compiling a C Program With Debugging Information

Consider a source file named fibonacci.c that has the following contents:

```c
#include <stdio.h>
#include <limits.h>

int main (int argc, char *argv[]) {
    unsigned long int a = 0;
    unsigned long int b = 1;
    unsigned long int sum;

    while (b < LONG_MAX) {
        printf("%ld ", b);
        sum = a + b;
        a = b;
        b = sum;
    }
    return 0;
}
```

Compile this program on the command line using GCC from Red Hat Developer Toolset with debugging information for the GNU Debugger:
$ scl enable devtoolset-7 'gcc -g -o fibonacci fibonacci.c'

This creates a new binary file called `fibonacci` in the current working directory.

### Installing Debugging Information for Existing Packages

To install debugging information for a package that is already installed on the system:

```
# debuginfo-install package_name
```

Note that the `yum-utils` package must be installed for the `debuginfo-install` utility to be available on your system.

**Example 7.2. Installing Debugging Information for the glibc Package**

Install debugging information for the `glibc` package:

```
# debuginfo-install glibc
```

```
Loaded plugins: product-id, refresh-packagekit, subscription-manager
--> Running transaction check
---> Package glibc-debuginfo.x86_64 0:2.17-105.el7 will be installed
...```

### 7.3. RUNNING THE GNU DEBUGGER

To run the GNU Debugger on a program you want to debug:

```
$ scl enable devtoolset-7 'gdb file_name'
```

This starts the `gdb` debugger in interactive mode and displays the default prompt, `(gdb)`. To quit the debugging session and return to the shell prompt, run the following command at any time:

```
(gdb) quit
```

Note that you can execute any command using the `scl` utility, causing it to be run with the Red Hat Developer Toolset binaries used in preference to the Red Hat Enterprise Linux system equivalent. This allows you to run a shell session with Red Hat Developer Toolset `gdb` as default:

```
$ scl enable devtoolset-7 'bash'
```
NOTE

To verify the version of `gdb` you are using at any point:

```
$ which gdb
```

Red Hat Developer Toolset's `gdb` executable path will begin with `/opt`. Alternatively, you can use the following command to confirm that the version number matches that for Red Hat Developer Toolset `gdb`:

```
$ gdb -v
```

Example 7.3. Running the gdb Utility on the fibonacci Binary File

This example assumes that you have successfully compiled the `fibonacci` binary file as shown in Example 7.1, "Compiling a C Program With Debugging Information".

Start debugging `fibonacci` with `gdb`:

```
$ scl enable devtoolset-7 'gdb fibonacci'

Reading symbols from fibonacci...done.
(gdb)
```

7.4. LISTING SOURCE CODE

To view the source code of the program you are debugging:

```
(gdb) list
```

Before you start the execution of the program you are debugging, `gdb` displays the first ten lines of the source code, and any subsequent use of this command lists another ten lines. Once you start the execution, `gdb` displays the lines that are surrounding the line on which the execution stops, typically when you set a breakpoint.

You can also display the code that is surrounding a particular line:
Similarly, to display the code that is surrounding the beginning of a particular function:

```
(gdb) list file_name:function_name
```

Note that you can change the number of lines the `list` command displays:

```
(gdb) set listsize number
```

**Example 7.4. Listing the Source Code of the fibonacci Binary File**

The `fibonacci.c` file listed in Example 7.1, “Compiling a C Program With Debugging Information” has exactly 17 lines. Assuming that you have compiled it with debugging information and you want the `gdb` utility to be capable of listing the entire source code, you can run the following command to change the number of listed lines to 20:

```
(gdb) set listsize 20
```

You can now display the entire source code of the file you are debugging by running the `list` command with no additional arguments:

```
(gdb) list
1       #include <stdio.h>
2       #include <limits.h>
3
4       int main (int argc, char *argv[]) {
5         unsigned long int a = 0;
6         unsigned long int b = 1;
7         unsigned long int sum;
8
9         while (b < LONG_MAX) {
10           printf("%ld ", b);
11           sum = a + b;
12           a = b;
13           b = sum;
14         }
15
16         return 0;
17      }
```

### 7.5. SETTING BREAKPOINTS

**Setting a New Breakpoint**

To set a new breakpoint at a certain line:

```
(gdb) break file_name:line_number
```

You can also set a breakpoint on a certain function:

```
(gdb) break file_name:function_name
```
Example 7.5. Setting a New Breakpoint

This example assumes that you have compiled the `fibonacci.c` file listed in Example 7.1, “Compiling a C Program With Debugging Information” with debugging information.

Set a new breakpoint at line 10:

```
(gdb) break 10
Breakpoint 1 at 0x4004e5: file fibonacci.c, line 10.
```

Listing Breakpoints

To display a list of currently set breakpoints:

```
(gdb) info breakpoints
```

Example 7.6. Listing Breakpoints

This example assumes that you have followed the instructions in Example 7.5, “Setting a New Breakpoint”.

Display the list of currently set breakpoints:

```
(gdb) info breakpoints
Num Type          Disp Enb Address            What
 1  breakpoint     keep y  0x00000000004004e5 in main at fibonacci.c:10
```

Deleting Existing Breakpoints

To delete a breakpoint that is set at a certain line:

```
(gdb) clear line_number
```

Similarly, to delete a breakpoint that is set on a certain function:

```
(gdb) clear function_name
```

Example 7.7. Deleting an Existing Breakpoint

This example assumes that you have compiled the `fibonacci.c` file listed in Example 7.1, “Compiling a C Program With Debugging Information” with debugging information.

Set a new breakpoint at line 7:

```
(gdb) break 7
Breakpoint 2 at 0x4004e3: file fibonacci.c, line 7.
```

Remove this breakpoint:
7.6. STARTING EXECUTION

To start an execution of the program you are debugging:

(gdb) run

If the program accepts any command line arguments, you can provide them as arguments to the `run` command:

(gdb) run argument...

The execution stops when the first breakpoint (if any) is reached, when an error occurs, or when the program terminates.

**Example 7.8. Executing the fibonacci Binary File**

This example assumes that you have followed the instructions in Example 7.5, “Setting a New Breakpoint”.

Execute the `fibonacci` binary file:

(gdb) run
Starting program: /home/john/fibonacci

Breakpoint 1, main (argc=1, argv=0x7fffffffe4d8) at fibonacci.c:10
10          printf("%ld ", b);

7.7. DISPLAYING CURRENT VALUES

The `gdb` utility allows you to display the value of almost anything that is relevant to the program, from a variable of any complexity to a valid expression or even a library function. However, the most common task is to display the value of a variable.

To display the current value of a certain variable:

(gdb) print variable_name

**Example 7.9. Displaying the Current Values of Variables**

This example assumes that you have followed the instructions in Example 7.8, “Executing the fibonacci Binary File” and the execution of the `fibonacci` binary stopped after reaching the breakpoint at line 10.

Display the current values of variables `a` and `b`:

(gdb) print a
7.8. CONTINUING EXECUTION

To resume the execution of the program you are debugging after it reached a breakpoint:

\[ (gdb) \text{continue} \]

The execution stops again when another breakpoint is reached. To skip a certain number of breakpoints (typically when you are debugging a loop):

\[ (gdb) \text{continue number} \]

The \texttt{gdb} utility also allows you to stop the execution after executing a single line of code:

\[ (gdb) \text{step} \]

Finally, you can execute a certain number of lines:

\[ (gdb) \text{step number} \]

Example 7.10. Continuing the Execution of the fibonacci Binary File

This example assumes that you have followed the instructions in Example 7.8, “Executing the fibonacci Binary File”, and the execution of the \texttt{fibonacci} binary stopped after reaching the breakpoint at line 10.

Resume the execution:

\[ (gdb) \text{continue} \]

Continuing.

Breakpoint 1, main (argc=1, argv=0x7fffffffe4d8) at fibonacci.c:10
10 \hspace{1em} printf("%ld ", b);

The execution stops the next time the breakpoint is reached.

Execute the next three lines of code:

\[ (gdb) \text{step 3} \]

13 \hspace{1em} b = sum;

This allows you to verify the current value of the \texttt{sum} variable before it is assigned to \texttt{b}:

\[ (gdb) \text{print sum} \]

$3 = 2$

CHAPTER 8. STRACE

`strace` is a diagnostic and debugging tool for the command line that can be used to trace system calls that are made and received by a running process. It records the name of each system call, its arguments, and its return value, as well as signals received by the process and other interactions with the kernel, and prints this record to standard error output or a selected file.

Red Hat Developer Toolset is distributed with `strace 4.17`.

8.1. INSTALLING STRACE

In Red Hat Enterprise Linux, the `strace` utility is provided by the `devtoolset-7-strace` package and is automatically installed with `devtoolset-7-toolchain` as described in Section 1.5, “Installing Red Hat Developer Toolset”.

8.2. USING STRACE

To run the `strace` utility on a program you want to analyze:

```
$ scl enable devtoolset-7 'strace program argument...'
```

Replace `program` with the name of the program you want to analyze, and `argument` with any command line options and arguments you want to supply to this program. Alternatively, you can run the utility on an already running process by using the `-p` command line option followed by the process ID:

```
$ scl enable devtoolset-7 'strace -p process_id'
```

Note that you can execute any command using the `scl` utility, causing it to be run with the Red Hat Developer Toolset binaries used in preference to the Red Hat Enterprise Linux system equivalent. This allows you to run a shell session with Red Hat Developer Toolset `strace` as default:

```
$ scl enable devtoolset-7 'bash'
```

**NOTE**

To verify the version of `strace` you are using at any point:

```
$ which strace
```

Red Hat Developer Toolset’s `strace` executable path will begin with `/opt`. Alternatively, you can use the following command to confirm that the version number matches that for Red Hat Developer Toolset `strace`:

```
$ strace -V
```

8.2.1. Redirecting Output to a File

By default, `strace` prints the name of each system call, its arguments and the return value to standard error output. To redirect this output to a file, use the `-o` command line option followed by the file name:

```
$ scl enable devtoolset-7 'strace -o file_name program argument...'
```
Example 8.1. Redirecting Output to a File

Consider a slightly modified version of the `fibonacci` file from Example 7.1, “Compiling a C Program With Debugging Information”. This executable file displays the Fibonacci sequence and optionally allows you to specify how many members of this sequence to list. Run the `strace` utility on this file and redirect the trace output to `fibonacci.log`:

```
$ scl enable devtoolset-7 'strace -o fibonacci.log ./fibonacci 20'
```

```
1 1 2 3 5 8 13 21 34 55 89 144 233 377 610 987 1597 2584 4181 6765
```

This creates a new plain-text file called `fibonacci.log` in the current working directory.

8.2.2. Tracing Selected System Calls

To trace only a selected set of system calls, run the `strace` utility with the `-e` command line option:

```
$ scl enable devtoolset-7 'strace -e expression program argument...'
```

Replace `expression` with a comma-separated list of system calls to trace or any of the keywords listed in Table 8.1, “Commonly Used Values of the -e Option”. For a detailed description of all available values, see the `strace(1)` manual page.

### Table 8.1. Commonly Used Values of the -e Option

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>%file</td>
<td>System calls that accept a file name as an argument.</td>
</tr>
<tr>
<td>%process</td>
<td>System calls that are related to process management.</td>
</tr>
<tr>
<td>%network</td>
<td>System calls that are related to networking.</td>
</tr>
<tr>
<td>%signal</td>
<td>System calls that are related to signal management.</td>
</tr>
<tr>
<td>%ipc</td>
<td>System calls that are related to inter-process communication (IPC).</td>
</tr>
<tr>
<td>%desc</td>
<td>System calls that are related to file descriptors.</td>
</tr>
</tbody>
</table>

Note that the syntax `-e expression` is a shorthand for the full form `-e trace=expression`.

Example 8.2. Tracing Selected System Calls

Consider the `employee` file from Example 10.1, “Using memstomp”. Run the `strace` utility on this executable file and trace only the `mmap` and `munmap` system calls:
8.2.3. Displaying Time Stamps

To prefix each line of the trace with the exact time of the day in hours, minutes, and seconds, run the `strace` utility with the `-t` command line option:

```
$ scl enable devtoolset-7 'strace -t program argument...'
```

To also display milliseconds, supply the `-t` option twice:

```
$ scl enable devtoolset-7 'strace -tt program argument...'
```

To prefix each line of the trace with the time required to execute the respective system call, use the `-r` command line option:

```
$ scl enable devtoolset-7 'strace -r program argument...'
```

Example 8.3. Displaying Time Stamps

Consider an executable file named `pwd`. Run the `strace` utility on this file and include time stamps in the output:

```
$ scl enable devtoolset-7 'strace -tt pwd'
19:43:28.011815 execve("./pwd", ["./pwd"], /* 36 vars */) = 0
19:43:28.012128 brk(0) = 0xcd3000
19:43:28.012174 mmap(NULL, 4096, PROT_READ|PROT_WRITE, MAP_PRIVATE|MAP_ANONYMOUS, -1, 0) = 0x7fc869cb0000
19:43:28.012427 open("/etc/ld.so.cache", O_RDONLY) = 3
19:43:28.012446 fstat(3, {st_mode=S_IFREG|0644, st_size=61239, ...}) = 0
19:43:28.012464 mmap(NULL, 61239, PROT_READ, MAP_PRIVATE, 3, 0) = 0x7fc869ca1000
```
8.2.4. Displaying a Summary

To display a summary of how much time was required to execute each system call, how many times were these system calls executed, and how many errors were encountered during their execution, run the `strace` utility with the `-c` command line option:

```
$ scl enable devtoolset-7 'strace -c program argument...'
```

Example 8.4. Displaying a Summary

Consider an executable file named `lsblk`. Run the `strace` utility on this file and display a trace summary:

```
$ scl enable devtoolset-7 'strace -c lsblk > /dev/null'
% time     seconds  usecs/call     calls    errors syscall
------ ----------- ----------- --------- --------- ----------------
80.88    0.000055           1       106        16 open
19.12    0.000013           0       140           munmap

8.2.5. Tampering with System Call Results

Simulating errors returned from system calls can help identify missing error handling in programs.

To make a program receive a generic error as the result of a particular system call, run the `strace` utility with the `-e fault=` option and supply the system call:

```
$ scl enable devtoolset-7 'strace -e fault=syscall program argument...'
```

To specify the error type or return value, use the `-e inject=` option:

```
$ scl enable devtoolset-7 'strace -e inject=syscall:retval=return-value program argument'
$ scl enable devtoolset-7 'strace -e inject=syscall:error=error-type program argument'
```

Note that specifying the error type and return value is mutually exclusive.

Example 8.5. Tampering with System Call Results
Consider an executable file named \texttt{lsblk}. Run the \texttt{strace} utility on this file and make the \texttt{mmap()} system call return an error:

```
$ scl enable devtoolset-7 'strace -e fault=mmap:error=EPERM lsblk > /dev/null'
execve("/usr/bin/lsblk", ["lsblk"], 0x7ffe1c0e2a0 /* 54 vars */) = 0
brk(NULL)                               = 0x55d9e8b43000
mmap(NULL, 8192, PROT_READ|PROT_WRITE, MAP_PRIVATE|MAP_ANONYMOUS, -1, 0) = -1 EPERM (Operation not permitted) (INJECTED)
writev(2, [{iov_base="lsblk", iov_len=5}, {iov_base=": ", iov_len=2},
          {iov_base="error while loading shared libra"..., iov_len=36},
          {iov_base=": ", iov_len=2}, {iov_base="error while loading shared libra"..., iov_len=36},
          {iov_base="error while loading shared libra"..., iov_len=36},
          {iov_base=": ", iov_len=2}, {iov_base="error while loading shared libra"..., iov_len=36},
          {iov_base=": ", iov_len=2}, {iov_base="error while loading shared libra"..., iov_len=36}], 10)
lsblk: error while loading shared libraries: cannot create cache for search path: Cannot allocate memory
) = 105
exit_group(127)                         = ?
+++ exited with 127 +++
```

CHAPTER 9. LTRACE

`ltrace` is a diagnostic and debugging tool for the command line that can be used to display calls that are made to shared libraries. It uses the dynamic library hooking mechanism, which prevents it from tracing calls to statically linked libraries. `ltrace` also displays return values of the library calls. The output is printed to standard error output or to a selected file.

Red Hat Developer Toolset is distributed with `ltrace 0.7.91`. While the base version `ltrace` remains the same as in the previous release of Red Hat Developer Toolset, various enhancements and bug fixes have ported.

9.1. INSTALLING LTRACE

In Red Hat Enterprise Linux, the `ltrace` utility is provided by the `devtoolset-7-ltrace` package and is automatically installed with `devtoolset-7-toolchain` as described in Section 1.5, “Installing Red Hat Developer Toolset”.

9.2. USING LTRACE

To run the `ltrace` utility on a program you want to analyze:

```
$ scl enable devtoolset-7 'ltrace program argument...'
```

Replace `program` with the name of the program you want to analyze, and `argument` with any command line options and arguments you want to supply to this program. Alternatively, you can run the utility on an already running process by using the `-p` command line option followed by the process ID:

```
$ scl enable devtoolset-7 'ltrace -p process_id'
```

Note that you can execute any command using the `scl` utility, causing it to be run with the Red Hat Developer Toolset binaries used in preference to the Red Hat Enterprise Linux system equivalent. This allows you to run a shell session with Red Hat Developer Toolset `ltrace` as default:

```
$ scl enable devtoolset-7 'bash'
```

NOTE

To verify the version of `ltrace` you are using at any point:

```
$ which ltrace
```

Red Hat Developer Toolset’s `ltrace` executable path will begin with `/opt`. Alternatively, you can use the following command to confirm that the version number matches that for Red Hat Developer Toolset `ltrace`:

```
$ ltrace -V
```

9.2.1. Redirecting Output to a File

By default, `ltrace` prints the name of each system call, its arguments and the return value to standard error output. To redirect this output to a file, use the `-o` command line option followed by the file name:
$ scl enable devtoolset-7 'ltrace -o file_name program argument...

Replace *file_name* with the name of the file.

**Example 9.1. Redirecting Output to a File**

Consider a slightly modified version of the *fibonacci* file from Example 7.1, “Compiling a C Program With Debugging Information”. This executable file displays the Fibonacci sequence and optionally allows you to specify how many members of this sequence to list. Run the *ltrace* utility on this file and redirect the trace output to *fibonacci.log*:

```bash
$ scl enable devtoolset-7 'ltrace -o fibonacci.log ./fibonacci 20'
```

```
1 1 2 3 5 8 13 21 34 55 89 144 233 377 610 987 1597 2584 4181 6765
```

This creates a new plain-text file called *fibonacci.log* in the current working directory.

**9.2.2. Tracing Selected Library Calls**

To trace only a selected set of library calls, run the *ltrace* utility with the *-e* command line option:

```bash
$ scl enable devtoolset-7 'ltrace -e expression program argument...

Replace *expression* with a chain of rules to specify the library calls to trace. The rules can consist of patterns that identify symbol names (such as *malloc* or *free*) and patterns that identify library SONAMES (such as *libc.so*). For example, to trace call to the *malloc* and *free* function but to omit those that are done by the *libc* library:

```bash
$ scl enable devtoolset-7 'ltrace -e malloc+free-@libc.so* program'
```

**Example 9.2. Tracing Selected Library Calls**

Consider the *ls* command. Run the *ltrace* utility on this program and trace only the *opendir*, *readdir*, and *closedir* function calls:

```bash
$ scl enable devtoolset-7 'ltrace -e opendir+readdir+closedir ls'
```

```
ls->opendir(".") = { 3 }
ls->readdir({ 3 }) = { 61533, "." }
ls->readdir({ 3 }) = { 131, ".." }
ls->readdir({ 3 }) = { 67185100, "BUILDROOT" }
ls->readdir({ 3 }) = { 202390772, "SOURCES" }
ls->readdir({ 3 }) = { 60249, "SPECS" }
ls->readdir({ 3 }) = { 67130110, "BUILD" }
ls->readdir({ 3 }) = { 136599168, "RPMS" }
ls->readdir({ 3 }) = { 202383274, "SRPMS" }
ls->readdir({ 3 }) = nil
ls->closedir({ 3 }) = 0
BUILD BUILDROOT RPMS SOURCES SPECS SRPMS
+++ exited (status 0) +++
```

For a detailed description of available filter expressions, see the *ltrace(1)* manual page.
9.2.3. Displaying Time Stamps

To prefix each line of the trace with the exact time of the day in hours, minutes, and seconds, run the `ltrace` utility with the `-t` command line option:

```
$ scl enable devtoolset-7 'ltrace -t program argument...'
```

To also display milliseconds, supply the `-t` option twice:

```
$ scl enable devtoolset-7 'ltrace -tt program argument...'
```

To prefix each line of the trace with the time required to execute the respective system call, use the `-r` command line option:

```
$ scl enable devtoolset-7 'ltrace -r program argument...'
```

**Example 9.3. Displaying Time Stamps**

Consider the `pwd` command. Run the `ltrace` utility on this program and include time stamps in the output:

```
$ scl enable devtoolset-7 'ltrace -tt pwd'
13:27:19.631371 __libc_start_main([ "pwd"] <unfinished ...>
13:27:19.632240 getenv("POSIXLY_CORRECT") = nil
13:27:19.632520 strrchr("pwd", '/') = nil
13:27:19.632786 setlocale(LC_ALL, "") = "en_US.UTF-8"
13:27:19.633220 bindtextdomain("coreutils", "/usr/share/locale") = "/usr/share/locale"
13:27:19.633471 textdomain("coreutils") = "coreutils"
(...)
13:27:19.637110 exited (status 0)
```

9.2.4. Displaying a Summary

To display a summary of how much time was required to execute each system call and how many times were these system calls executed, run the `ltrace` utility with the `-c` command line option:

```
$ scl enable devtoolset-7 'ltrace -c program argument...'
```

**Example 9.4. Displaying a Summary**

Consider the `lsblk` command. Run the `ltrace` utility on this program and display a trace summary:

```
$ scl enable devtoolset-7 'ltrace -c lsblk > /dev/null'
```

```
% time   seconds  uses/call  calls  function
-------- --------- ---------- -------- ---------------------
 53.60   0.261644  261644     1 __libc_start_main
  4.48   0.021848    58        374 mbrtowc
  4.41   0.021524    57        374 wcwidth
```
9.3. ADDITIONAL RESOURCES

**CHAPTER 10. MEMSTOMP**

*memstomp* is a command line tool that can be used to identify function calls with overlapping memory regions in situations when such an overlap is not permitted by various standards. It intercepts calls to the library functions listed in Table 10.1, “Function Calls Inspected by memstomp” and for each memory overlap, it displays a detailed backtrace to help you debug the problem.

Similarly to *Valgrind*, the *memstomp* utility inspects applications without the need to recompile them. However, it is much faster than this tool and therefore serves as a convenient alternative to it.

Red Hat Developer Toolset is distributed with *memstomp 0.1.5*.

### 10.1. INSTALLING MEMSTOMP

In Red Hat Developer Toolset, the `memstomp` utility is provided by the `devtoolset-7-memstomp` package and is automatically installed with `devtoolset-7-toolchain` as described in Section 1.5, "Installing Red Hat Developer Toolset".

### 10.2. USING MEMSTOMP

To run the `memstomp` utility on a program you want to analyze:

```
$ scl enable devtoolset-7 'memstomp program argument...'
```

To immediately terminate the analyzed program when a problem is detected, run the utility with the `--kill` (or `-k` for short) command line option:

```
$ scl enable devtoolset-7 'memstomp --kill program argument...'
```

The use of the `--kill` option is especially recommended if you are analyzing a multi-threaded program; the internal implementation of backtraces is not thread-safe and running the `memstomp` utility on a multi-threaded program without this command line option can therefore produce unreliable results.

Additionally, if you have compiled the analyzed program with the debugging information or this debugging information is available to you, you can use the `--debug-info` (or `-d`) command line option to produce a more detailed backtrace:

```
$ scl enable devtoolset-7 'memstomp --debug-info program argument...'
```

For detailed instructions on how to compile your program with the debugging information built in the binary file, see Section 7.2, "Preparing a Program for Debugging". For information on how to install
debugging information for any of the Red Hat Developer Toolset packages, see Section 1.5.4, "Installing Debugging Information".

Note that you can execute any command using the `scl` utility, causing it to be run with the Red Hat Developer Toolset binaries used in preference to the Red Hat Enterprise Linux system equivalent. This allows you to run a shell session with Red Hat Developer Toolset `memstomp` as default:

```bash
$ scl enable devtoolset-7 'bash'
```

**Example 10.1. Using memstomp**

In the current working directory, create a source file named `employee.c` with the following contents:

```c
#include <stdio.h>
#include <string.h>

#define BUFSIZE 80

int main(int argc, char *argv[]) {
    char employee[BUFSIZE] = "John,Doe,john@example.com";
    char name[BUFSIZE] = {0};
    char surname[BUFSIZE] = {0};
    char *email;
    size_t length;

    /* Extract the information: */
    memccpy(name, employee, ',', BUFSIZE);
    length = strlen(name);
    memccpy(surname, employee + length, ',', BUFSIZE);
    length += strlen(surname);
    email = employee + length;

    /* Compose the new entry: */
    strcat(employee, surname);
    strcpy(employee, name);
    strcat(employee, email);

    /* Print the result: */
    puts(employee);

    return 0;
}
```

Compile this program into a binary file named `employee`:

```bash
$ scl enable devtoolset-7 'gcc -rdynamic -g -o employee employee.c'
```

To identify erroneous function calls with overlapping memory regions:

```bash
$ scl enable devtoolset-7 'memstomp --debug-info ./employee'
memstomp: 0.1.4 successfully initialized for process employee (pid 14887).
strcat(dest=0x7fff13afc265, src=0x7fff13afc269, bytes=21) overlap for
```

PART IV. PERFORMANCE MONITORING TOOLS
CHAPTER 11. SYSTEMTAP

**SystemTap** is a tracing and probing tool that allows users to monitor the activities of the entire system without needing to instrument, recompile, install, and reboot. It is programmable with a custom scripting language, which gives it expressiveness (to trace, filter, and analyze) and reach (to look into the running kernel and applications).

**SystemTap** can monitor various types of events, such as function calls within the kernel or applications, timers, tracepoints, performance counters, and so on. Some included example scripts produce output similar to `netstat`, `ps`, `top`, and `iostat`, others include pretty-printed function callgraph traces or tools for working around security bugs.

Red Hat Developer Toolset is distributed with **SystemTap 3.1**. This version is more recent than the version included in the previous release of Red Hat Developer Toolset and provides numerous bug fixes and enhancements.

11.1. INSTALLED SYSTEMTAP

In Red Hat Developer Toolset, **SystemTap** is provided by the `devtoolset-7-systemtap` package and is automatically installed with `devtoolset-7-perftools` as described in Section 1.5, “Installing Red Hat Developer Toolset”.

64
NOTE

The Red Hat Developer Toolset version of SystemTap is available for both Red Hat Enterprise Linux 6 and Red Hat Enterprise Linux 7, but some new features are only offered by the Red Hat Developer Toolset version of SystemTap for Red Hat Enterprise Linux 7.

In order to place instrumentation into the Linux kernel, SystemTap may also require installation of additional packages with debugging information. To determine which packages to install, run the stap-prep utility as follows:

```
$ scl enable devtoolset-7 'stap-prep'
```

Note that if you execute this command as the root user, the utility automatically offers the packages for installation. For more information on how to install these packages on your system, see the Red Hat Enterprise Linux 6 SystemTap Beginners Guide or the Red Hat Enterprise Linux 7 SystemTap Beginners Guide.

11.2. USING SYSTEMTAP

To execute any of the tools that are part of SystemTap:

```
$ scl enable devtoolset-7 'tool option...'
```

See Table 11.1, “Tools Distributed with SystemTap for Red Hat Developer Toolset” for a list of tools that are distributed with SystemTap. For example, to run the stap tool to build an instrumentation module:

```
$ scl enable devtoolset-7 'stap option... argument...'
```

Note that you can execute any command using the scl utility, causing it to be run with the Red Hat Developer Toolset binaries used in preference to the Red Hat Enterprise Linux system equivalent. This allows you to run a shell session with Red Hat Developer Toolset SystemTap as default:

```
$ scl enable devtoolset-7 'bash'
```

NOTE

To verify the version of SystemTap you are using at any point:

```
$ which stap
```

Red Hat Developer Toolset’s stap executable path will begin with /opt. Alternatively, you can use the following command to confirm that the version number matches that for Red Hat Developer Toolset SystemTap:

```
$ stap -V
```

CHAPTER 12. VALGRIND

Valgrind is an instrumentation framework that ships with a number of tools for profiling applications. It can be used to detect various memory errors and memory-management problems, such as the use of uninitialized memory or an improper allocation and freeing of memory, or to identify the use of improper arguments in system calls. For a complete list of profiling tools that are distributed with the Red Hat Developer Toolset version of Valgrind, see Table 12.1, “Tools Distributed with Valgrind for Red Hat Developer Toolset”.

Valgrind profiles an application by rewriting it and instrumenting the rewritten binary. This allows you to profile your application without the need to recompile it, but it also makes Valgrind significantly slower than other profilers, especially when performing extremely detailed runs. It is therefore not suited to debugging time-specific issues, or kernel-space debugging.

Red Hat Developer Toolset is distributed with Valgrind 3.13.0. This version is more recent than the version included in the previous release of Red Hat Developer Toolset and provides numerous bug fixes and enhancements.

12.1. INSTALLING VALGRIND

In Red Hat Developer Toolset, Valgrind is provided by the devtoolset-7-valgrind package and is automatically installed with devtoolset-7-perftools.

For detailed instructions on how to install Red Hat Developer Toolset and related packages to your system, see Section 1.5, “Installing Red Hat Developer Toolset”.

NOTE

Note that if you use Valgrind in combination with the GNU Debugger, it is recommended that you use the version of GDB that is included in Red Hat Developer Toolset to ensure that all features are fully supported.
12.2. USING VALGRIND

To run any of the Valgrind tools on a program you want to profile:

$ scl enable devtoolset-7 'valgrind --tool=tool program argument...'

See Table 12.1, “Tools Distributed with Valgrind for Red Hat Developer Toolset” for a list of tools that are distributed with Valgrind. The argument of the --tool command line option must be specified in lower case, and if this option is omitted, Valgrind uses Memcheck by default. For example, to run Cachegrind on a program to identify the sources of cache misses:

$ scl enable devtoolset-7 'valgrind --tool=cachegrind program argument...'

Note that you can execute any command using the scl utility, causing it to be run with the Red Hat Developer Toolset binaries used in preference to the Red Hat Enterprise Linux system equivalent. This allows you to run a shell session with Red Hat Developer Toolset Valgrind as default:

$ scl enable devtoolset-7 'bash'

NOTE

To verify the version of Valgrind you are using at any point:

$ which valgrind

Red Hat Developer Toolset’s valgrind executable path will begin with /opt. Alternatively, you can use the following command to confirm that the version number matches that for Red Hat Developer Toolset Valgrind:

$ valgrind --version

CHAPTER 13. OPROFILE

OProfile is a low overhead, system-wide profiler that uses the performance-monitoring hardware on the processor to retrieve information about the kernel and executables on the system, such as when memory is referenced, the number of level 2 cache (L2) requests, and the number of hardware interrupts received. It consists of a configuration utility, a daemon for collecting data, and a number of tools that can be used to transform the data into a human-readable form. For a complete list of tools that are distributed with the Red Hat Developer Toolset version of OProfile, see Table 13.1, “Tools Distributed with OProfile for Red Hat Developer Toolset”.

OProfile profiles an application without adding any instrumentation by recording the details of every nth event. This allows it to consume fewer resources than Valgrind, but it also causes its samples to be less precise. Unlike Valgrind, which only collects data for a single process and its children in user-space, OProfile is well suited to collect system-wide data on both user-space and kernel-space processes, and requires root privileges to run.

Red Hat Developer Toolset is distributed with OProfile 1.2.0.

13.1. INSTALLING OPROFILE

In Red Hat Developer Toolset, OProfile is provided by the devtoolset-7-oprofile package and is automatically installed with devtoolset-7-perftools as described in Section 1.5, “Installing Red Hat Developer Toolset”.

13.2. USING OPROFILE

To run any of the tools that are distributed with OProfile:
See Table 13.1, “Tools Distributed with OProfile for Red Hat Developer Toolset” for a list of tools that are distributed with OProfile. For example, to use the ophelp command to list available events in the XML format:

```bash
$ scl enable devtoolset-7 'ophelp -X'
```

Note that you can execute any command using the `scl` utility, causing it to be run with the Red Hat Developer Toolset binaries used in preference to the Red Hat Enterprise Linux system equivalent. This allows you to run a shell session with Red Hat Developer Toolset OProfile as default:

```bash
$ scl enable devtoolset-7 'bash'
```

### NOTE

To verify the version of OProfile you are using at any point:

```bash
$ which operf
```

Red Hat Developer Toolset's `operf` executable path will begin with `/opt`. Alternatively, you can use the following command to confirm that the version number matches that for Red Hat Developer Toolset OProfile:

```bash
# operf --version
```

CHAPTER 14. DYNINST

The Dyninst library provides an application programming interface (API) for instrumenting and working with user-space executables during their execution. It can be used to insert code into a running program, change certain subroutine calls, or even remove them from the program. It serves as a valuable debugging and performance-monitoring tool. The Dyninst API is also commonly used along with SystemTap to allow non-root users to instrument user-space executables.

Red Hat Developer Toolset is distributed with Dyninst 9.3.2.

14.1. INSTALLING DYNINST

In Red Hat Developer Toolset, the Dyninst library is provided by the devtoolset-7-dyninst package and is automatically installed with devtoolset-7-perftools as described in Section 1.5, “Installing Red Hat Developer Toolset”. In addition, it is recommended that you also install the GNU Compiler Collection provided by the devtoolset-7-toolchain package.

If you intend to write a custom instrumentation for binaries, install the relevant header files:

```
# yum install devtoolset-7-dyninst-devel
```

You can also install API documentation for this library:

```
# yum install devtoolset-7-dyninst-doc
```

For a complete list of documents that are included in the devtoolset-7-dyninst-doc package, see Section 14.3, “Additional Resources”. For detailed instructions on how to install optional packages to your system, see Section 1.5, “Installing Red Hat Developer Toolset”.

14.2. USING DYNINST

14.2.1. Using Dyninst with SystemTap

To use Dyninst along with SystemTap to allow non-root users to instrument user-space executables, run the stap command with the --dyninst (or --runtime=dyninst) command line option. This tells stap to translate a SystemTap script into C code that uses the Dyninst library, compile this C code into a shared library, and then load the shared library and run the script. Note that when executed like this, the stap command also requires the -c or -x command line option to be specified.

To use the Dyninst runtime to instrument an executable file:

```
$ scl enable devtoolset-7 "stap --dyninst -c 'command' option... argument..."
```

Similarly, to use the Dyninst runtime to instrument a user's process:

```
$ scl enable devtoolset-7 "stap --dyninst -x process_id option... argument..."
```

Example 14.1. Using Dyninst with SystemTap

Consider a source file named `exercise.C` that has the following contents:

```c
#include <stdio.h>

void print_iteration(int value) {
    printf("Iteration number %d\n", value);
}

int main(int argc, char **argv) {
    int i;
    printf("Enter the starting number: ");
    scanf("%d", &i);
    for(; i>0; --i)
        print_iteration(i);
    return 0;
}
```

This program prompts the user to enter a starting number and then counts down to 1, calling the `print_iteration()` function for each iteration in order to print the number to the standard output. Compile this program on the command line using the `g++` compiler from Red Hat Developer Toolset:

```
$ scl enable devtoolset-7 'g++ -g -o exercise exercise.C'
```

Now consider another source file named `count.stp` with the following contents:

```bash
#!/usr/bin/stap

global count = 0

probe process.function("print_iteration") {
    count++
}

probe end {
    printf("Function executed %d times.\n", count)
}
```

This `SystemTap` script prints the total number of times the `print_iteration()` function was called during the execution of a process. Run this script on the `exercise` binary file:

```
$ scl enable devtoolset-7 "stap --dyninst -c './exercise' count.stp"
```

```bash
Enter the starting number: 5
Iteration number 5
Iteration number 4
Iteration number 3
Iteration number 2
Iteration number 1
Function executed 5 times.
```

14.2.2. Using Dyninst as a Stand-alone Library
Before using the Dyninst library as a part of your application, set the value of the DYNINSTAPI_RT_LIB environment variable to the path to the runtime library file:

```
$ export DYNINSTAPI_RT_LIB=/opt/rh/devtoolset-7/root/usr/lib64/dyninst/libdyninstAPI_RT.so
```

This sets the DYNINSTAPI_RT_LIB environment variable in the current shell session.

Example 14.2, "Using Dyninst as a Stand-alone Application" illustrates how to write and build a program to monitor the execution of a user-space process. For a detailed explanation of how to use Dyninst, see the resources listed in Section 14.3, "Additional Resources".

**Example 14.2. Using Dyninst as a Stand-alone Application**

Consider the `exercise.C` source file from Example 14.1, "Using Dyninst with SystemTap": this program prompts the user to enter a starting number and then counts down to 1, calling the `print_iteration()` function for each iteration in order to print the number to standard output.

Now consider another source file named `count.C` with the following contents:

```c
#include <stdio.h>
#include <fcntl.h>
#include "BPatch.h"
#include "BPatch_process.h"
#include "BPatch_function.h"
#include "BPatch_Vector.h"
#include "BPatch_thread.h"
#include "BPatch_point.h"

void usage() {
    fprintf(stderr, "Usage: count <process_id> <function>\n");
}

// Global information for counter
BPatch_variableExpr *counter = NULL;

void createCounter(BPatch_process *app, BPatch_image *appImage) {
    int zero = 0;
    counter = app->malloc(*appImage->findType("int"));
    counter->writeValue(&zero);
}

bool interceptfunc(BPatch_process *app,
    BPatch_image *appImage,
    char *funcName) {
    BPatch_Vector<BPatch_function *> func;
    appImage->findFunction(funcName, func);
    if(func.size() == 0) {
        fprintf(stderr, "Unable to find function to instrument()\n");
        exit (-1);
    }
    BPatch_Vector<BPatch_snippet *> incCount;
    BPatch_Vector<BPatch_point *> *points;
    points = func[0]->findPoint(BPatch_entry);
    if (**points.size() == 0) {
```
Note that a client application is expected to destroy all `BPatch` objects before any of the `Dyninst` library destructors are called. Otherwise the mutator might terminate unexpectedly with a segmentation fault. To work around this problem, set the `BPatch` object of the mutator as a local variable in the `main()` function. Or, if you need to use `BPatch` as a global variable, manually detach all the mutatee processes before the mutator exits.

This program accepts a process ID and a function name as command line arguments and then prints the total number of times the function was called during the execution of the process. You can use the following `Makefile` to build these two files:

```makefile
DTS      = /opt/rh/devtoolset-4/root
CXXFLAGS = -g -I$(DTS)/usr/include/dyninst
LBITS    := $(shell getconf LONG_BIT)
ifeq ($(LBITS),64)
    DYNINSTLIBS = $(DTS)/usr/lib64/dyninst
else
    DYNINSTLIBS = $(DTS)/usr/lib64/dyninst
```

```c
int main(int argc, char *argv[]) {
    int pid;
    BPatch bpatch;
    if (argc != 3) {
        usage();
        exit(1);
    }
    pid = atoi(argv[1]);
    BPatch_process *app = bpatch.processAttach(NULL, pid);
    if (!app) exit (-1);
    BPatch_image *appImage = app->getImage();
    createCounter(app, appImage);
    fprintf(stderr, "Finding function %s(): ", argv[2]);
    BPatch_Vector<BPatch_function*> countFuncs;
    fprintf(stderr, "OK
Instrumenting function %s(): ", argv[2]);
    interceptfunc(app, appImage, argv[2]);
    bpatch.registerExitCallback(printCount);
    fprintf(stderr, "OK
Waiting for process %d to exit...
", pid);
    app->continueExecution();
    while (!app->isTerminated())
        bpatch.waitForStatusChange();
    return 0;
}
```

```c
void printCount(BPatch_thread *thread, BPatch_exitType) {
    int val = 0;
    counter->readValue(&val, sizeof(int));
    fprintf(stderr, "Function executed %d times.\n", val);
}
```
To compile the two programs on the command line using the `g++` compiler from Red Hat Developer Toolset, run the `make` utility:

```
$ scl enable devtoolset-7 make
```

This creates new binary files called `exercise` and `count` in the current working directory.

In one shell session, execute the `exercise` binary file as follows and wait for it to prompt you to enter the starting number:

```
$ ./exercise
Enter the starting number:
```

Do not enter this number. Instead, start another shell session and type the following at its prompt to set the `DYNINSTAPI_RT_LIB` environment variable and execute the `count` binary file:

```
$ export DYNINSTAPI_RT_LIB=/opt/rh/devtoolset-7/root/usr/lib64/dyninst/libdyninstAPI_RT.so
$ ./count `pidof exercise` print_iteration
Finding function print_iteration(): OK
Instrumenting function print_iteration(): OK
Waiting for process 8607 to exit...
```

Now switch back to the first shell session and enter the starting number as requested by the `exercise` program. For example:

```
Enter the starting number: 5
Iteration number 5
Iteration number 4
```
When the `exercise` program terminates, the `count` program displays the number of times the `print_iteration()` function was executed:

```
Function executed 5 times.
```

### 14.3. ADDITIONAL RESOURCES

CHAPTER 18. ACCESSING RED HAT PRODUCT DOCUMENTATION

Red Hat Product Documentation located at https://access.redhat.com/site/documentation/ serves as a central source of information. It is currently translated in 23 languages, and for each product, it provides different kinds of books from release and technical notes to installation, user, and reference guides in HTML, PDF, and EPUB formats.

Below is a brief list of documents that are directly or indirectly relevant to this book.

Red Hat Developer Toolset

- Using Red Hat Software Collections Container Images — The Using Red Hat Software Collections Container Images provides instructions for obtaining, configuring, and using container images that are shipped with Red Hat Software Collections, including the Red Hat Developer Toolset container images.

- Red Hat Software Collections Packaging Guide — The Software Collections Packaging Guide explains the concept of Software Collections and documents how to create, build, and extend them.

Red Hat Enterprise Linux

- Red Hat Enterprise Linux 6 Installation Guide — The Installation Guide for Red Hat Enterprise Linux 6 explains how to obtain, install, and update the system.

- Red Hat Enterprise Linux 6 Installation Guide and Red Hat Enterprise Linux 7 Installation Guide — The Installation Guides for Red Hat Enterprise Linux 6 an 7 explain how to obtain, install, and update the system.

CHAPTER 19. CONTACTING GLOBAL SUPPORT SERVICES

Unless you have a Self-Support subscription, when both the Red Hat Documentation website and Customer Portal fail to provide the answers to your questions, you can contact *Global Support Services* (*GSS*).

19.1. GATHERING REQUIRED INFORMATION

Several items of information should be gathered before contacting *GSS*.

**Background Information**

Ensure you have the following background information at hand before calling *GSS*:

- Hardware type, make, and model on which the product runs
- Software version
- Latest upgrades
- Any recent changes to the system
- An explanation of the problem and the symptoms
- Any messages or significant information about the issue

**NOTE**

If you ever forget your Red Hat login information, it can be recovered at https://access.redhat.com/site/help/LoginAssistance.html.

**Diagnostics**

The diagnostics report for Red Hat Enterprise Linux is required as well. This report is also known as a *sosreport* and the program to create the report is provided by the *sos* package. To install the *sos* package and all its dependencies on your system:

```
# yum install sos
```

To generate the report:

```
# sosreport
```

For more information, access the Knowledgebase article at https://access.redhat.com/kb/docs/DOC-3593.

**Account and Contact Information**

In order to help you, *GSS* requires your account information to customize their support, as well contact information to get back to you. When you contact *GSS* ensure you have your:

- Red Hat customer number or Red Hat Network (RHN) login name
- Company name
- Contact name
• Preferred method of contact (phone or email) and contact information (phone number or email address)

**Issue Severity**

Determining an issue’s severity is important to allow the GSS team to prioritize their work. There are four levels of severity.

**Severity 1 (urgent)**

A problem that severely impacts your use of the software for production purposes. It halts your business operations and has no procedural workaround.

**Severity 2 (high)**

A problem where the software is functioning, but production is severely reduced. It causes a high impact to business operations, and no workaround exists.

**Severity 3 (medium)**

A problem that involves partial, non-critical loss of the use of the software. There is a medium to low impact on your business, and business continues to function by utilizing a workaround.

**Severity 4 (low)**

A general usage question, report of a documentation error, or a recommendation for a future product improvement.

For more information on determining the severity level of an issue, see [https://access.redhat.com/support/policy/severity](https://access.redhat.com/support/policy/severity).

Once the issue severity has been determined, submit a service request through the Customer Portal under the Connect option, or at [https://access.redhat.com/support/contact/technicalSupport.html](https://access.redhat.com/support/contact/technicalSupport.html). Note that you need your Red Hat login details in order to submit service requests.

If the severity is level 1 or 2, then follow up your service request with a phone call. Contact information and business hours are found at [https://access.redhat.com/support/contact/technicalSupport.html](https://access.redhat.com/support/contact/technicalSupport.html).

If you have a premium subscription, then after hours support is available for Severity 1 and 2 cases.

Turn-around rates for both premium subscriptions and standard subscription can be found at [https://access.redhat.com/support/offerings/production/sla.html](https://access.redhat.com/support/offerings/production/sla.html).

**19.2. ESCALATING AN ISSUE**

If you feel an issue is not being handled correctly or adequately, you can escalate it. There are two types of escalations:

**Technical escalation**

If an issue is not being resolved appropriately or if you need a more senior resource to attend to it.

**Management escalation**

If the issue has become more severe or you believe it requires a higher priority.

More information on escalation, including contacts, is available at [https://access.redhat.com/support/policy/mgt_escalation.html](https://access.redhat.com/support/policy/mgt_escalation.html).

**19.3. RE-OPENING A SERVICE REQUEST**

If there is more relevant information regarding a closed service request (such as the problem reoccurring), you can re-open the request via the Red Hat Customer Portal at
IMPORTANT

In order to re-open a service request, you need the original service-request number.

19.4. ADDITIONAL RESOURCES

For more information, see the resources listed below.

Online Documentation

- **Getting Started** — The *Getting Started* page serves as a starting point for people who purchased a Red Hat subscription and offers the *Red Hat Welcome Kit* and the *Quick Guide to Red Hat Support* for download.

APPENDIX A. CHANGES IN RED HAT DEVELOPER TOOLSET

A.1. CHANGES IN VERSION 7.1

The sections below document features and compatibility changes introduced in Red Hat Developer Toolset 7.1.

A.1.1. Changes in GCC

Red Hat Developer Toolset 7.1 is distributed with GCC 7.3.1, which provides a number of bug fixes and improvements over the version included in the previous release of Red Hat Developer Toolset.

A.1.1.1. Changes Since Red Hat Developer Toolset 7.0

The following changes have been made since the release of GCC included in Red Hat Developer Toolset 7.0:

- The `-fstack-clash-protection` option has been added to the GCC compiler to generate additional code guarding against stack clash. As a result, applications can be hardened against this type of attacks. For more details, see the manual page for GCC. (BZ#1500856)

- Previously, the GCC compiler handled the Debugging Information Entries (DIE) incorrectly when generating them for a C++ class method nested in another class method. As a consequence, the compiler might terminate unexpectedly when compiling such C++ code. Handling of DIE in this situation has been corrected and the problem no longer occurs. (BZ#1525304)

- Previously, the GCC compiler did not emit the `DW_AT_linkage_name` and `DW_AT_MIPS_linkage_name` linkage name attributes for inline functions in debug information. As a consequence, applications using the DWARF debug information, such as the GDB debugger, could not use this information. GCC has been changed to include these attributes even for inline functions with no out-of-line copies and this information is available for GDB and other tools. (BZ#977960)

- Previously, the code for the `std::promise` and `std::future` C++ standard library class templates contained a data race. The code has been fixed and the race condition no longer exists. (BZ#1512587)

- Previously, the `devtoolset-7-gcc` package did not contain a symbolic link to the `objcopy` utility installed by the `devtoolset-7-binutils` package. As a consequence, GCC from Red Hat Developer Toolset used the system version of `objcopy` which lacked some features, such as the `-gsplit-dwarf` option. The symbolic link has been added and the correct version of `objcopy` is now used. (BZ#1501355)

- Previously, some symbols in the `libstdc++_nonshared.a` static library file used incorrect visibility. As a consequence, linking some C++ programs failed. This bug has been fixed and no longer occurs. (BZ#1519073)

A.1.2. Changes in GDB

Red Hat Developer Toolset 7.1 is distributed with GDB 8.0.1, which provides a number of bug fixes and enhancements over the version included in the previous release of Red Hat Developer Toolset.

A.1.2.1. Changes Since Red Hat Developer Toolset 7.0
The following changes have been added since the release of GDB included in Red Hat Developer Toolset 7.0:

- Previously, the GDB debugger showed caller function names instead of inlined callee function names when listing breakpoints. As a consequence, GDB users were not able to identify breakpoints placed on inline functions from the function name. GDB has been extended to store names of inline callee functions when breakpoints are placed. As a result, GDB now correctly displays names of inline functions when listing breakpoints. (BZ#1228556)

- Support for accessing the IBM z14 processor Guarded Storage Facility hardware control registers and software based broadcast control registers has been added to GDB. As a result, GDB can now display the described registers of the IBM z Systems architecture z14 machines, and enables users to investigate more easily boundary check violations on these machines. (BZ#1498758)

A.1.3. Changes in elfutils

Red Hat Developer Toolset 7.1 is distributed with elfutils 0.170, which provides a number of bug fixes and feature enhancements over the version included in the previous release of Red Hat Developer Toolset.

A.1.3.1. Changes Since Red Hat Developer Toolset 7.0

The following bugs have been fixed since the release of elfutils included in Red Hat Developer Toolset 7.0:

- Previously, the dwarf_aggregate_size() calculated wrong size for multidimensional arrays. The function has been fixed and correctly reports sizes of multidimensional arrays. (BZ#1527966)

A.1.3.2. Changes Since Red Hat Enterprise Linux 7.5

The elfutils version in Red Hat Developer Toolset 7.1 is the same as the version included in Red Hat Enterprise Linux 7.5.

A.1.4. Changes in Valgrind

Red Hat Developer Toolset 7.1 is distributed with Valgrind 3.13.0, which provides numerous enhancements over the version included in the previous release of Red Hat Developer Toolset.

A.1.4.1. Changes Since Red Hat Developer Toolset 7.0

The following bugs have been fixed in Valgrind in Red Hat Developer Toolset version 7.1:

- The 64-bit timebase register of the PowerPC architecture is no longer modeled by Valgrind as only 32-bit. (BZ#1523871)

- Previously, Valgrind closed immediately the socket used for output when the option --xml-socket was used. Consequently, using this option caused Valgrind to report an error. This bug has been fixed and the option can be used again.

- Support for the IBM Power Systems architecture has been extended to include the ISA 3.0B specification.

- Previously, the memcheck tool could produce a warning "conditional jump or move depends on
A.1.4.2. Changes Since Red Hat Enterprise Linux 7.5

The Valgrind version in Red Hat Developer Toolset 7.1 is the same as the version included in Red Hat Enterprise Linux 7.5.

A.2. CHANGES IN VERSION 7.0

The sections below document features and compatibility changes introduced in Red Hat Developer Toolset 7.0.

A.2.1. Changes in binutils

Red Hat Developer Toolset 7.0 is distributed with binutils 2.28, which provides numerous enhancements over the version included in Red Hat Enterprise Linux and the previous version of Red Hat Developer Toolset.

A.2.1.1. Changes Since Red Hat Developer Toolset 6.1

The following features have been added since the release of binutils included in Red Hat Developer Toolset 6.1:

- The ld linker has been extended:
  - Support for creating Secure Gateway Veneers in applications for the ARM architectures has been added.
  - The --no-eh-frame-hdr option has been added to disable generation of .eh_frame_hdr sections in ELF executable files. This results in smaller application size when exception handling is not required.

- The ld.gold linker has been extended to support the HIDDEN command in linker scripts and generation of executable files for the big-endian ARM architectures.

- The nm tool --with-version-strings option has been added to display symbol version information.

- The objcopy tool options --remove-section and --only-section have been extended to accept regular expressions.

- Support for locating separate debug information files using the build-id method has been added.

GNU Build Notes

The binutils tools in Red Hat Developer Toolset 7.0 contain support for the GNU Build Notes feature. This enables compilers to record additional information in object files:

- How the object file was built
- What tests were run when building the object file
- What are the requirements of the object file for the runtime system
When the linker creates an executable file or a library file, these notes are combined and added. Various tools can extract this information from the resulting file to find out more about it.

**Architecture and processor support**

- Support for the IBM Power Systems architecture has been extended.
- Support for the Scalable Vector Extensions (SVE) on the 64-bit ARM architecture has been added.
- Support for additional instructions on the IBM z Systems architecture has been added.
- Support for the ARM Cortex M23 and M33 processors has been added.

**A.2.1.2. Changes Since Red Hat Enterprise Linux 7.4**

The changes in **binutils** since the version included in Red Hat Enterprise Linux 7.4 are equivalent to the above listed changes since the version included in Red Hat Developer Toolset 6.1.

**A.2.2. Changes in dyninst**

Red Hat Developer Toolset 7.0 is distributed with **Dyninst 9.3.2**, which provides enhancements over the version included in the previous version of Red Hat Developer Toolset.

**A.2.2.1. Changes Since Red Hat Developer Toolset 6.1**

The following features have been added since the release of **Dyninst** included in Red Hat Developer Toolset 6.1:

- Relocation and instrumentation of code containing C++ exceptions has been implemented.
- Stack analysis on the 32-bit Intel and AMD architecture has been improved.

**A.2.3. Changes in elfutils**

Red Hat Developer Toolset 7.0 is distributed with **elfutils 0.170**, which provides a number of bug fixes and feature enhancements over the version included in the previous release of Red Hat Developer Toolset.

**A.2.3.1. Changes Since Red Hat Developer Toolset 6.1**

The following features have been added since the release of **elfutils** included in Red Hat Developer Toolset 6.1:

- The back ends for 32 and 64-bit Intel and AMD architectures, the 64-bit ARM architecture, and the IBM Power Systems architecture have been extended with a fallback for unwinding based on the frame pointer. As a result, the **eu-stack** utility and the functions **dwfl_thread_getframes** and **dwfl_getthread_frames** from the **libdw** library can unwind code even if the **DWARF**-based call frame information is not present. (BZ#1472979)
- The **dwarf.h** header file from the **libdw** library has been extended to enable recognition of **DWARF** format version 5 attributes, tags, character encodings, language codes, calling conventions, defaulted member functions, and macro constants. This enables the **eu-readelf** tool to show **DWARF** version 5 extensions in non-strict **DWARF** mode (version 4 format with version 5 extensions). (BZ#1472979)
Two new functions have been added to the `libdw` library: `dwarf_default_lower_bound` and `dwarf_line_file`.

The `eu-strip` tool has been extended with options `-R`, `--remove-section=section`, and `--keep-section=section` to control handling of sections.

The `eu-objdump` option `-d` has been extended to support disassembling Extended Berkeley Packet Filter (eBPF) code in ELF files by default.

The version of `elfutils` included in Red Hat Developer Toolset 7.0 includes two bug fixes:

- Previously, using the `eu-strip` utility could leave an unused .shstrtab section in the executable file. As a consequence, the optimization resulted in an unoptimized executable file. The utility has been fixed and as a result, `eu-strip` always removes unused .shstrtab sections. (BZ#1455687)

- Previously, the `eu-strip` utility produced empty files if there was no action possible. As a consequence, `eu-strip` created empty executable files when the file was already optimized, and empty debug files with the `-f` option if no debug information was found. The utility has been extended to recognize the situation. As a result, `eu-strip` produces executable file identical to the input when the input is already optimized, and does not write an empty debug file with the `-f` option if no debug information is found. (BZ#1455620)

### A.2.3.2. Changes Since Red Hat Enterprise Linux 7.4

The changes in `elfutils` since the version included in Red Hat Enterprise Linux 7.4 are equivalent to the above listed changes since the version included in Red Hat Developer Toolset 6.1.

### A.2.4. Changes in GCC

Red Hat Developer Toolset 7.0 is distributed with GCC 7.2.1, which provides numerous enhancements over the version included in the previous release of Red Hat Developer Toolset.

#### A.2.4.1. Changes Since Red Hat Developer Toolset 6.1

The following features have been added since the release of GCC included in Red Hat Developer Toolset 6.1:

- Support for the DWARF 5 debug information format has been added.

- A sanitizer to detect variables whose address was taken and used outside the variable’s scope has been added and is available under the `-fsanitize-address-use-after-scope` option.

- New warnings for statically detecting certain common types of programming errors have been added. Apart from others, the detected errors include:
  - implicit fall through in `switch` statements
  - pointer comparison with a zero character constant
  - identical branches of an `if-else` statement
  - wrong usage of restrict-qualified parameters
  - suspicious arguments to a `memset` call
- suspicious uses of integer values in boolean contexts
- unreachable statements in a `switch` statement
- unbounded uses of variable-length arrays

- The spell-checker has been improved and is now able to detect many more cases.
- Various compile-time checks for buffer overflows and invalid memory access have been added.
- Support for the `_FloatN` and `_FloatNx` type names specified by the ISO/IEC TS 18661-3:2015 standard has been added to the C front end.
- The C++ front end fix-it hints have been improved.
- Experimental support for C17 has been added to the C standard library and the C++ front end.

**Optimization Improvements**

- A store merging optimization pass for reducing store operations has been added. This optimization merges constant stores to adjacent memory locations.
- Better optimization of `sprintf` function family return values has been added. The function calls can be completely folded into a constant.
- The code hoisting optimization has been extended to enable moving the expressions evaluated on all paths to the function exit, to the front of the function’s code. This further reduces the code size.
- The optimization of interprocedural constant propagation has been improved. Information about which bits of variables are known to be zero and ranges of integral variables can be propagated.
- A new loop splitting optimization pass has been added to better optimize loops which contain a condition that is always true or always false for a certain range of the iteration variable.
- The shrink-wrapping optimization has been improved.

**Architecture support**

- Support for the z14 processor of the IBM z Systems architecture has been added.
- Support for the ARMv8.2-A and ARMv8.3-A architecture variants and the ARMv8.2-A 16-bit Floating-Point Extensions has been added.
- Support for the latest revision of the AAPCS64 procedure call standard on the 64-bit ARM architecture has been added.
- Support for the following ISA extensions for the Intel 64 architecture has been added:
  - AVX-512 Fused Multiply Accumulation Packed Single precision (4FMAPS)
  - AVX-512 Vector Neural Network Instructions Word variable precision (4VNNIW)
  - AVX-512 Vector Population Count (VPOPCNTDQ)
  - Software Guard Extensions (SGX)

**Deprecated Features**
The Cilk+ extensions have been deprecated. Support of Cilk++ in future versions of GCC is not guaranteed.

A.2.5. Changes in GDB

Red Hat Developer Toolset 7.0 is distributed with GDB 8.0.1, which provides a number of enhancements over the version included in the previous release of Red Hat Developer Toolset.

A.2.5.1. Changes Since Red Hat Developer Toolset 6.1

The following features have been added since the release of GDB included in Red Hat Developer Toolset 6.1:

- Support for C++11 R-value references has been added.
- Python scripting has been extended with functions to start, stop, and access a running btrace recording. Additionally, support for R-value references has been added to gdb.Type.
- Support for recording and replaying rdrand and rdseed instructions of the 64-bit Intel architecture has been added.
- User commands have been extended to accept an unlimited number of arguments instead of the previous maximum of ten.
- The eval command has been extended to expand user-defined command arguments.
- Support for the debug information format DWARF version 5 has been added. However, the .debug_names index is not yet supported.
- The options set disassembler-options and show disassembler-options have been added to control the passing of target-specific information to the disassembler. Multiple disassembler options can be specified as a comma-separated list. Currently, this feature is supported for ARM, PowerPC, and System/390 targets.
- A new MI command -file-list-shared-libraries has been added to list the shared libraries in the program.

A.2.6. Changes in make

Red Hat Developer Toolset 7.0 is distributed with make 4.2.1, which provides a number of bug fixes and feature enhancements over the version included in the previous release of Red Hat Developer Toolset.

A.2.6.1. Changes Since Red Hat Developer Toolset 6.1

The following changes have been added since the release of make included in Red Hat Developer Toolset 6.1:

- Previously, running the make tool without arguments resulted in a segmentation fault when the pseudo-terminal /dev/pts was not mounted. The tool has been extended to use the default terminal in such cases. As a result, make no longer produces a segmentation fault when /dev/pts is not present. (BZ#1451452)
- The functionality of the internal option --jobserver-fds has been made available with the option --jobserver-auth. The former name --jobserver-fds has been removed.
A.2.6.2. Changes Since Red Hat Enterprise Linux 7.4

Since the release of make included in Red Hat Enterprise Linux, the following changes have been made in addition to the changes listed above:

- Integration with GNU Guile versions 1.8 as well as 2.0 and later is supported.
- When the special target .POSIX is specified, make adheres to the POSIX requirements for handling backslash and newline. This changes how make handles backslash and newline in non-recipe lines:
  - Trailing spaces before the backslash are preserved
  - Each backslash and newline, including subsequent white space, is converted to single space
- The BSD != shell assignment operator is now supported as an alternative to the $(shell ...) function. As a consequence, variable names ending in an exclamation mark, defined as myvariable!= somevalue, are now interpreted as shell assignments. To restore the previous behaviour, add white space after the intended variable name, such as myvariable! = somevalue.

A.2.7. Changes in OProfile

Red Hat Developer Toolset 7.0 is distributed with OProfile 1.2.0, which provides a number of bug fixes and feature enhancements over the version included in the previous release of Red Hat Developer Toolset.

A.2.7.1. Changes Since Red Hat Developer Toolset 6.1

Since the release of OProfile included in Red Hat Developer Toolset 6.1, support for the following processors and architectures has been improved:

- The 8NV and NVL variants of the IBM Power architecture
- The z14 processor of the IBM z Systems architecture
- 2nd generation Intel Xeon Phi

A.2.7.2. Changes Since Red Hat Enterprise Linux 7.4

Since the release of OProfile included in Red Hat Enterprise Linux 7.4, the following changes have been made in addition to the changes listed above:

- The deprecated opcontrol andoprof_start commands have been removed. The operf command should be used in their place. The opreport command is still used to analyze data stored in the oprofile_data/ directory by operf.
- Fixes have been included to avoid dropping samples from Java programs using Just-In-Time (JIT) translation due to use of anonymous hugepages and changes in the anonymous page mappings.
- The search logic has been corrected to properly store data in an archive and make use of the archive data.
operf now only starts the command to be measured if the performance monitoring hardware is properly set up. This fixes a bug that caused operf to start the command that is to be measured regardless of whether the performance monitoring set up was successful.

Changes in OProfile processor support since Red Hat Enterprise Linux 7.4 are identical to the changes in processor support since Red Hat Developer Toolset 6.1 listed above.

A.2.8. Changes in strace

Red Hat Developer Toolset 7.0 is distributed with strace 4.17, which provides numerous bug fixes and feature enhancements over the version included in the previous release of Red Hat Developer Toolset.

A.2.8.1. Changes Since Red Hat Developer Toolset 6.1

The following enhancements have been added since the release of strace included in Red Hat Developer Toolset 6.1:

- System call tampering and fault injection capability has been added. This function allows users to specify the system call to intercept, a return value or error code to return as a result of the call, a signal to send, and a condition for the call order. The -e fault=specification and -e inject=specification options allows specifying the details. Multiple fault injections can be specified. For more details, see the strace manual page.

- Support for tracing 32-bit executable files with the 64-bit strace version has been improved.

- Time stamp output has been changed to conform to the ISO 8601 specification.

- A general netlink socket parser and improved decoding of socket addresses have been added.

- The system call classes %stat, %lstat, %fstat, %stat, %statfs, %fstatfs, and %%statfs have been added to allow filtering of system calls used to query file system information. For more details, see the strace manual page.

System Call Specification Changes

The way in which system calls are specified has been significantly changed and extended:

- Specifying classes of system calls for tracing now uses a % prefix:

  ```
  strace -e trace=%class
  ```

  The old specification style without % is deprecated but still supported.

- Specifying system calls for tracing has been extended to support regular expressions. To use a regular expression, prepend the system call specification with a forward slash:

  ```
  strace -e trace=/regexp
  ```

- Error suppression for cases where no system calls match the provided specification has been added. To use the error suppression, prepend the system call specification with a question mark:

  ```
  strace -e trace=?function
  ```

Decoding Improvements
The following improvements to decoding of system calls, their parameters, and return values have been implemented:

- Improvements have been made to decoding of several `ioctl` call classes:
  - Decoding of the `DM_*` and `NS_*` commands has been implemented.
  - Decoding of the `SG_*` and `V4L2` commands has been improved.
  - Decoding of the `sg_io_hdr` and `sg_io_v4` structures has been improved.

- Decoding of the following system calls has been improved: `futex`, `keyctl`, `quotactl`, `timerfd_settime`, `bpf`, `accept`, `accept4`, `bind`, `getpeername`, `getsockname`, `ipc`, `recvfrom`, `recvmsg`, `recvmmsg`, `sendto`, `sendmmsg`, `socketcall`, `sched_attr` and the POSIX asynchronous I/O (`aio`) system call family.

- Decoding of the following system calls has been implemented: `statx`, `pkey_alloc`, `pkey_free`, `pkey_mprotect`, and `ustat`.

- Decoding of the `perf_event_open` call parameter `attr` has been implemented.

- Decoding of the message structures `cmsghdr`, `msghdr`, and `mmsghdr` has been improved.

- Display of `mode_t`, `umode_t`, and `umask` types has been fixed.

### A.2.8.2. Changes Since Red Hat Enterprise Linux 7.4

The changes in `strace` since the version included in Red Hat Enterprise Linux 7.4 are equivalent to the above listed changes since the version included in Red Hat Developer Toolset 6.1.

### A.2.9. Changes in SystemTap

Red Hat Developer Toolset 7.0 is distributed with SystemTap 3.1, which provides a number of bug fixes and feature enhancements over the version included in the previous release of Red Hat Developer Toolset.

#### A.2.9.1. Changes Since Red Hat Developer Toolset 6.1

The following features have been added since the release of SystemTap included in Red Hat Developer Toolset 6.1:

- The probes for system calls no longer default to being based on debuginfo information.
- Support for probing Python functions has been added.
- Access to Java function parameters has been made more uniform.
- The performance of statistical aggregate variables has been improved.
- A new statistics operator `@variance` has been added.
- More options for fetching and setting user-space values have been added.
- NFS monitoring has been improved with sample scripts and tapset compatibility fixes.
A.2.9.2. Changes Since Red Hat Enterprise Linux 7.4

The SystemTap version included in Red Hat Developer Toolset 7.0 is the same as the version included in Red Hat Enterprise Linux 7.4.

A.2.10. Changes in Valgrind

Red Hat Developer Toolset 7.0 is distributed with Valgrind 3.13.0, which provides numerous enhancements over the version included in the previous release of Red Hat Developer Toolset.

A.2.10.1. Changes Since Red Hat Developer Toolset 6.1

The following features have been added since the release of Valgrind included in Red Hat Developer Toolset 6.1:

- **Valgrind** has been extended in several ways to run large programs:
  - The translation cache size has been increased. The maximum number of sectors has been increased from 24 to 48 and the default number of sectors from 16 to 32.
  - The amount of memory usable by Valgrind has been increased from 64 GB to 128 GB. As a consequence, the Memcheck tool supports running applications that allocate up to approximately 60 GB.
  - The default load address of Valgrind has been changed from 0x38000000 to 0x58000000. As a consequence, Valgrind can load executable files 1200 MB in size.

- A new representation of stack traces called XTree has been added. An XTree is a tree of stack traces and data associated with these stack traces. The tools Memcheck, Helgrind, and Massif can use this representation to report heap consumption of the analyzed application. Reporting is controlled by the new options --xtree-memory and --xtree-memory-file. Additionally, Valgrind’s internal gdbserver has been extended for the XTrees:
  - A report can be produced on demand by issuing the command xtmemory filename in the external gdb monitor.
  - The Memcheck monitor command leak_check accepts a new option xt-leak to produce the leak report in an XTree file. For more information consult the Valgrind manual installed on your system. See Section 12.3, “Additional Resources”.

- The symbol demangler has been updated to support the C++11 standard as well as the Rust programming language.

- File name template argument format has been extended with a new letter %n which is replaced by a sequentially increased number. This is useful for processes that produce several files from the same filename template and can be used as an alternative to the process id letter %p.

**Architecture updates**

- Failures with long blocks of code using AVX2 instructions on the Intel and AMD 64-bit architecture have been fixed.

- Recognition of Intel Control Flow Enforcement (CET) on the Intel and AMD 64-bit architecture has been added.
● Support for the IBM Power Systems architecture has been extended to include the ISA 3.0B specification.

● An alternative implementation of Load-Linked and Store-Conditional instructions for the 64-bit ARM architecture has been added. The alternative implementation is enabled automatically when required. To enable the alternative implementation manually, use the `--sim-hints=fallback-llsc` option.

A.2.10.2. Changes Since Red Hat Enterprise Linux 7.4

The changes in Valgrind since the version included in Red Hat Enterprise Linux 7.4 are equivalent to the above listed changes since the version included in Red Hat Developer Toolset 6.1.

A.2.11. Changes in devtoolset-7-perftools-rhel7

Red Hat Developer Toolset 7.0 is distributed with devtoolset-7-perftools-rhel7, a pre-built docker image that includes other Red Hat Developer Toolset components. The image is available as a package devtoolset-7-perftools-docker.

A.2.11.1. Changes Since Red Hat Developer Toolset 6.1

Since the release of devtoolset-6-perftools-rhel7 included in Red Hat Developer Toolset 6.1, the following tools have been added to the container image:

● dwz
● ltrace
● make
● memstomp
● strace

For the changes in application features since the release of devtoolset-6-perftools-rhel7 included in Red Hat Developer Toolset 6.1, see the sections describing changes in the individual tools:

● Section A.2.2, “Changes in dyninst”
● Section A.2.3, “Changes in elfutils”
● Section A.2.7, “Changes in OProfile”
● Section A.2.9, “Changes in SystemTap”
● Section A.2.10, “Changes in Valgrind”
● Section A.2.6, “Changes in make”

A.2.12. Changes in devtoolset-7-toolchain-rhel7

Red Hat Developer Toolset 7.0 is distributed with devtoolset-7-toolchain-rhel7, a pre-built docker image that includes other Red Hat Developer Toolset components. The image is available as a package devtoolset-7-toolchain-docker.
A.2.12.1. Changes Since Red Hat Developer Toolset 6.1

For the changes since the release of devtoolset-6-toolchain-rhel7 included in Red Hat Developer Toolset 6.1, see the sections describing changes to the individual tools:

- Section A.2.1, “Changes in binutils”
- Section A.2.4, “Changes in GCC”
- Section A.2.5, “Changes in GDB”
