CHAPTER 1. OVERVIEW

This guide provides procedures and examples for how to enhance your OpenShift Container Platform cluster performance and conduct scaling at different levels of an OpenShift Container Platform production stack. It includes recommended practices for building, scaling, and tuning OpenShift Container Platform clusters.

Tuning considerations can vary depending on your cluster setup, and be advised that any performance recommendations in this guide might come with trade-offs.
CHAPTER 2. RECOMMENDED INSTALLATION PRACTICES

2.1. PRE-INSTALLING DEPENDENCIES

A node host will access the network to install any RPMs dependencies, such as `atomic-openshift-*`, `iptables`, and `docker`. Pre-installing these dependencies, creates a more efficient install, because the RPMs are only accessed when necessary, instead of a number of times per host during the install.

This is also useful for machines that cannot access the registry for security purposes.

2.2. ANSIBLE INSTALL OPTIMIZATION

The OpenShift Container Platform install method uses Ansible. Ansible is useful for running parallel operations, meaning a fast and efficient installation. However, these can be improved upon with additional tuning options. See the Configuring Ansible section for a list of available Ansible configuration options.

**IMPORTANT**

Parallel behavior can overwhelm a content source, such as your image registry or Red Hat Satellite server. Preparing your server’s infrastructure pods and operating system patches can help prevent this issue.

Run the installer from the lowest-possible latency control node (LAN speeds). Running over a wide area network (WAN) is not advised, neither is running the installation over a lossy network connection.

Ansible provides its own guidance for performance and scaling, including using RHEL 6.6 or later to ensure the version of OpenSSH supports `ControlPersist`, and running the installer from the same LAN as the cluster, but not running it from a machine in the cluster.

The following is an example Ansible configuration for large cluster installation and administration that incorporates the recommendations documented by Ansible:

```bash
# cat /etc/ansible/ansible.cfg
# config file for ansible -- http://ansible.com/
# ==============
[defaults]
forks = 20
host_key_checking = False
remote_user = root
roles_path = roles/
gathering = smart
fact_caching = jsonfile
fact_caching_connection = $HOME/ansible/facts
fact_caching_timeout = 600
log_path = $HOME/ansible.log
nocows = 1
callback_whitelist = profile_tasks

[privilege_escalation]
become = False

[ssh_connection]
```
ssh_args = -o ControlMaster=auto -o ControlPersist=600s -o ServerAliveInterval=60
control_path = %%(directory)s/%%(h-%%r
pipelining = True
timeout = 10

1. 20 forks is ideal, because larger forks can lead to installations failing.
2. Pipelining reduces the number of connections between control and target nodes, helping to improve installer performance.

2.3. NETWORKING CONSIDERATIONS

Network subnets can be changed post-install, but with difficulty. It is much easier to consider the network subnet size prior to installation, because underestimating the size can create problems with growing clusters.

See the Network Optimization topic for recommended network subnetting practices.
CHAPTER 3. RECOMMENDED HOST PRACTICES

3.1. RECOMMENDED PRACTICES FOR OPENSHIFT CONTAINER PLATFORM MASTER HOSTS

In addition to pod traffic, the most-used data-path in an OpenShift Container Platform infrastructure is between the OpenShift Container Platform master hosts and etcd. The OpenShift Container Platform API server (part of the master binary) consults etcd for node status, network configuration, secrets, and more.

Optimize this traffic path by:

- Co-locating master hosts and etcd servers.
- Ensuring an uncongested, low latency LAN communication link between master hosts.

The OpenShift Container Platform master caches deserialized versions of resources aggressively to ease CPU load. However, in smaller clusters of less than 1000 pods, this cache can waste a lot of memory for negligible CPU load reduction. The default cache size is 50,000 entries, which, depending on the size of your resources, can grow to occupy 1 to 2 GB of memory. This cache size can be reduced using the following setting in `/etc/origin/master/master-config.yaml`:

```yaml
kubernetesMasterConfig:
  apiServerArguments:
    deserialization-cache-size:
      - "1000"
```

3.2. RECOMMENDED PRACTICES FOR OPENSHIFT CONTAINER PLATFORM NODE HOSTS

The OpenShift Container Platform node configuration file at `/etc/origin/node/node-config.yaml` contains important options, such as the iptables synchronization period, the Maximum Transmission Unit (MTU) of the SDN network, and the proxy-mode.

The node configuration file allows you to pass arguments to the kubelet (node) process. You can view a list of possible options by running `kubelet --help`.

**NOTE**

Not all kubelet options are supported by OpenShift Container Platform, and are used in the upstream Kubernetes. This means certain options are in limited support.

**NOTE**

See the [Cluster Limits](#) page for the maximum supported limits for each version of OpenShift Container Platform.

In the `/etc/origin/node/node-config.yaml` file, two parameters control the maximum number of pods that can be scheduled to a node: `pods-per-core` and `max-pods`. When both options are in use, the lower of the two limits the number of pods on a node. Exceeding these values can result in:

- Increased CPU utilization on both OpenShift Container Platform and Docker.
- Slow pod scheduling.
- Potential out-of-memory scenarios (depends on the amount of memory in the node).
- Exhausting the pool of IP addresses.
- Resource overcommitting, leading to poor user application performance.

**NOTE**

In Kubernetes, a pod that is holding a single container actually uses two containers. The second container is used to set up networking prior to the actual container starting. Therefore, a system running 10 pods will actually have 20 containers running.

**pods-per-core** sets the number of pods the node can run based on the number of processor cores on the node. For example, if **pods-per-core** is set to 10 on a node with 4 processor cores, the maximum number of pods allowed on the node will be 40.

```kubernetes
kubeletArguments:
pods-per-core:
  - "10"
```

**NOTE**

Setting **pods-per-core** to 0 disables this limit.

**max-pods** sets the number of pods the node can run to a fixed value, regardless of the properties of the node. *Cluster Limits* documents maximum supported values for **max-pods**.

```kubernetes
kubeletArguments:
max-pods:
  - "250"
```

Using the above example, the default value for **pods-per-core** is 10 and the default value for **max-pods** is 250. This means that unless the node has 25 cores or more, by default, **pods-per-core** will be the limiting factor.

See the *Sizing Considerations* section in the installation documentation for the recommended limits for an OpenShift Container Platform cluster. The recommended sizing accounts for OpenShift Container Platform and Docker coordination for container status updates. This coordination puts CPU pressure on the master and docker processes, which can include writing a large amount of log data.

### 3.3. RECOMMENDED PRACTICES FOR OPENShift CONTAINER PLATFORM ETCD HOSTS

etcd is a distributed key-value store that OpenShift Container Platform uses for configuration.

<table>
<thead>
<tr>
<th>OpenShift Container Platform Version</th>
<th>etcd version</th>
<th>storage schema version</th>
</tr>
</thead>
<tbody>
<tr>
<td>3.3 and earlier</td>
<td>2.x</td>
<td>v2</td>
</tr>
</tbody>
</table>
etcd 3.x introduces important scalability and performance improvements that reduce CPU, memory, network, and disk requirements for any size cluster. etcd 3.x also implements a backwards compatible storage API that facilitates a two-step migration of the on-disk etcd database. For migration purposes, the storage mode used by etcd 3.x in OpenShift Container Platform 3.5 remained in v2 mode. As of OpenShift Container Platform 3.6, new installs will use storage mode v3. Upgrades from previous versions of OpenShift Container Platform will not automatically migrate data from v2 to v3. You must use the supplied playbooks and follow the documented process to migrate the data.

Version 3 of etcd implements a backwards compatible storage API that facilitates a two-step migration of the on-disk etcd database. For migration purposes, the storage mode used by etcd 3.x in OpenShift Container Platform 3.5 remained in v2 mode. As of OpenShift Container Platform 3.6, new installs will use storage mode v3. In order to provide customers time to prepare for migrating the etcd schema from v2 to v3 (and associated downtime and verification), OpenShift Container Platform 3.6 does not enforce this upgrade. However, based on extensive test results Red Hat strongly recommends migrating existing OpenShift Container Platform clusters to etcd 3.x storage mode v3. This is particularly relevant in larger clusters, or in scenarios where SSD storage is not available.

**IMPORTANT**

etcd schema migration will be required by future OpenShift Container Platform upgrades.

In addition to changing the storage mode for new installs to v3, OpenShift Container Platform 3.6 also begins enforcing **quorum reads** for all OpenShift Container Platform types. This is done to ensure that queries against etcd do not return stale data. In single-node etcd clusters, stale data is not a concern. In highly available etcd deployments typically found in production clusters, quorum reads ensure valid query results. A quorum read is **linearizable** in database terms - every client sees the latest updated state of the cluster, and all clients see the same sequence of reads and writes. See the etcd 3.1 announcement for more information on performance improvements.

It is important to note that OpenShift Container Platform uses etcd for storing additional information beyond what Kubernetes itself requires. For example, OpenShift Container Platform stores information about images, builds, and other components in etcd, as is required by features that OpenShift Container Platform adds on top of Kubernetes. Ultimately, this means that guidance around performance and sizing for etcd hosts will differ from Kubernetes and other recommendations in salient ways. Red Hat tests etcd scalability and performance with the OpenShift Container Platform use-case and parameters in mind to generate the most accurate recommendations.

Performance improvements were quantified using a 300-node OpenShift Container Platform 3.6 cluster using the cluster-loader utility. Comparing etcd 3.x (storage mode v2) versus etcd 3.x (storage mode v3), clear improvements are identified in the charts below.

Storage IOPS under load is significantly reduced:
Storage IOPS in steady state is also significantly reduced:

Viewing the same I/O data, plotting the average IOPS in both modes:
CPU utilization by both the API server (master) and etcd processes is reduced:

Memory utilization by both the API server (master) and etcd processes is also reduced:
IMPORTANT

After profiling etcd under OpenShift Container Platform, etcd frequently performs small amounts of storage input and output. Using etcd with storage that handles small read/write operations quickly, such as SSD, is highly recommended.

Looking at the size I/O operations done by a 3-node cluster of etcd 3.1 (using storage v3 mode and with quorum reads enforced), read sizes are as follows:

And writes:
etcd processes are typically memory intensive. Master / API server processes are CPU intensive. This makes them a reasonable co-location pair within a single machine or virtual machine (VM). Optimize communication between etcd and master hosts either by co-locating them on the same host, or providing a dedicated network.

### 3.3.1. Providing Storage to an etcd Node Using PCI Passthrough with OpenStack

To provide fast storage to an etcd node so that etcd is stable at large scale, use PCI passthrough to pass a non-volatile memory express (NVMe) device directly to the etcd node. To set this up with Red Hat OpenStack 11 or later, complete the following on the OpenStack compute nodes where the PCI device exists.

1. Ensure Intel Vt-x is enabled in BIOS.

2. Enable the input–output memory management unit (IOMMU). In the `/etc/sysconfig/grub` file, add `intel_iommu=on iommu=pt` to the end of the `GRUB_CMDLINX_LINUX` line, within the quotation marks.

3. Regenerate `/etc/grub2.cfg` by running:

   ```bash
   $ grub2-mkconfig -o /etc/grub2.cfg
   ```

4. Reboot the system.

5. On controllers in `/etc/nova.conf`:

   ```
   [filter_scheduler]
   available_filters=nova.scheduler.filters.all_filters
   ```
6. Restart `nova-api` and `nova-scheduler` on the controllers.

7. On compute nodes in `/etc/nova/nova.conf`:

```
[pci]

passthrough_whitelist = { "address": "0000:06:00.0" }

alias = { "vendor_id":"144d", "product_id":"a820", "device_type":"type-PCI", "name":"nvme" }
```

To retrieve the required `address`, `vendor_id`, and `product_id` values of the NVMe device you want to passthrough, run:

```bash
# lspci -nn | grep devicename
```

8. Restart `nova-compute` on the compute nodes.

9. Configure the OpenStack version you are running to use the NVMe and launch the etcd node.

### 3.4. SCALING HOSTS USING THE TUNED PROFILE

**Tuned** is a tuning profile delivery mechanism enabled by default in Red Hat Enterprise Linux (RHEL) and other Red Hat products. **Tuned** customizes Linux settings, such as sysctls, power management, and kernel command line options, to optimize the operating system for different workload performance and scalability requirements.

OpenShift Container Platform leverages the tuned daemon and includes Tuned profiles called `openshift`, `openshift-node` and `openshift-control-plane`. These profiles safely increase some of the commonly encountered vertical scaling limits present in the kernel, and are automatically applied to your system during installation.

The Tuned profiles support inheritance between profiles. They also support an auto-parent functionality which selects a parent profile based on whether the profile is used in a virtual environment. The openshift profile uses both of these features and is a parent of openshift-node and openshift-control-plane profiles. It contains tuning relevant to both OpenShift Container Platform application nodes and control plane nodes respectively. The openshift-node and openshift-control-plane profiles are set on application and control plane nodes respectively.

The profile hierarchy with the openshift profile as a parent ensures the tuning delivered to the OpenShift Container Platform system is a union of throughput-performance (the default for RHEL) for bare metal hosts and virtual-guest for RHEL and atomic-guest for RHEL Atomic Host nodes.

To see which Tuned profile is enabled on your system, run:

```bash
# tuned-adm active
Current active profile: openshift-node
```

See the [Red Hat Enterprise Linux Performance Tuning Guide](#) for more information about Tuned.
CHAPTER 4. OPTIMIZING COMPUTE RESOURCES

4.1. OVERCOMMITTING

You can use overcommit procedures so that resources such as CPU and memory are more accessible to the parts of your cluster that need them.

**IMPORTANT**

To avoid erratic cluster behavior due to scheduling collisions between the hypervisor and Kubernetes, do not overcommit at the hypervisor level.

Note that when you overcommit, there is a risk that another application may not have access to the resources it requires when it needs them, which will result in reduced performance. However, this may be an acceptable trade-off in favor of increased density and reduced costs. For example, development, quality assurance (QA), or test environments may be overcommitted, whereas production might not be.

OpenShift Container Platform implements resource management through the compute resource model and quota system. See the documentation for more information about the [OpenShift resource model](#).

For more information and strategies for overcommitting, see the [Overcommitting documentation in the Cluster Administration Guide](#).

4.2. IMAGE CONSIDERATIONS

4.2.1. Using a Pre-deployed Image to Improve Efficiency

You can create a base OpenShift Container Platform image with a number of tasks built-in to improve efficiency, maintain configuration consistency on all node hosts, and reduce repetitive tasks. This is known as a pre-deployed image.

For example, because every node requires the `ose-pod` image in order to run pods, each node has to periodically connect to the Docker registry in order to pull the latest image. This can become problematic when you have 100 nodes attempting this at the same time, and can lead to resource contention on the image registry, waste of network bandwidth, and increased pod launch times.

To build a pre-deployed image:

- Create an instance of the type and size required.
- Ensure a dedicated storage device is available for Docker local image or container storage, separate from any persistent volumes for containers.
- Fully update the system, and ensure Docker is installed.
- Ensure the host has access to all yum repositories.
- Set up thin-provisioned LVM storage.
- Pre-seed your commonly used images (such as the `rhel7` base image), as well as OpenShift Container Platform infrastructure container images (`ose-pod`, `ose-deployer`, etc.) into your pre-deployed image.
Ensure that pre-deployed images are configured for any appropriate cluster configurations, such as being able to run on OpenStack, or AWS, as well as any other cluster configurations.

4.2.2. Pre-pulling Images

To efficiently produce images, you can pre-pull any necessary container images to all node hosts. This means the image does not have to be initially pulled, which saves time and performance over slow connections, especially for images, such as S2I, metrics, and logging, which can be large.

This is also useful for machines that cannot access the registry for security purposes.

Alternatively, you can use a local image instead of the default of a specified registry. To do this:

1. Pull from local images by setting the `imagePullPolicy` parameter of a pod configuration to `IfNotPresent` or `Never`.
2. Ensure that all nodes in the cluster have the same images saved locally.

**NOTE**

Pulling from a local registry is suitable if you can control node configuration. However, it will not work reliably on cloud providers that do not replace nodes automatically, such as GCE. If you are running on Google Container Engine (GKE), there will already be a `.dockercfg` file on each node with Google Container Registry credentials.

4.3. DEBUGGING USING THE RHEL TOOLS CONTAINER IMAGE

Red Hat distributes a `rhel-tools` container image, packaging tools that aid in debugging scaling or performance problems. This container image:

- Allows users to deploy minimal footprint container hosts by moving packages out of the base distribution and into this support container.
- Provides debugging capabilities for Red Hat Enterprise Linux 7 Atomic Host, which has an immutable package tree. `rhel-tools` includes utilities such as tcpdump, sosreport, git, gdb, perf, and many more common system administration utilities.

Use the `rhel-tools` container with the following:

```
# atomic run rhel7/rhel-tools
```

See the [RHEL Tools Container documentation](https://access.redhat.com/documentation) for more information.

4.4. DEBUGGING USING ANSIBLE-BASED HEALTH CHECKS

Additional diagnostic health checks are available through the [Ansible-based tooling](https://access.redhat.com/documentation) used to install and manage OpenShift Container Platform clusters. They can report common deployment problems for the current OpenShift Container Platform installation.

These checks can be run either using the `ansible-playbook` command (the same method used during Advanced Installation) or as a containerized version of `openshift-ansible`. For the `ansible-playbook` method, the checks are provided by the `atomic-openshift-utils` RPM package. For the containerized method, the `openshift3/ose-ansible` container image is distributed via the [Red Hat Container Registry](https://access.redhat.com/documentation).
See Ansible-based Health Checks in the Cluster Administration guide for information on the available health checks and example usage.
CHAPTER 5. OPTIMIZING STORAGE

5.1. OVERVIEW

Optimizing storage helps to minimize storage use across all resources. By optimizing storage, administrators help ensure that existing storage resources are working in an efficient manner.

5.2. GENERAL STORAGE GUIDELINES

The following table lists the available persistent storage technologies for OpenShift Container Platform.

Table 5.1. Available storage options

<table>
<thead>
<tr>
<th>Storage Type</th>
<th>Description</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>Block</td>
<td>- Presented to the operating system (OS) as a block device</td>

[a] ReadOnlyMany

[b] ReadWriteMany

[c] This does not apply to physical disk, VM physical disk, VMDK, loopback over NFS, AWS EBS, and Azure Disk.

[d] For metrics, it is an anti-pattern to use any shared storage and a single volume (RWX). By default, metrics deploys with one volume per Cassandra Replica.

[e] For logging, using any shared storage would be an anti-pattern. One volume per logging-es is required.

[f] Object storage is not consumed through OpenShift Container Platform’s PVs/persistent volume claims (PVCs). Apps must integrate with the object storage REST API.

---

**NOTE**

As of OpenShift Container Platform 3.6.1, Container-Native Storage (CNS) GlusterFS (a hyperconverged or cluster-hosted storage solution) and Container-Ready Storage (CRS) GlusterFS (an externally hosted storage solution) provides interfaces for block, file, and object storage for the purpose of the OpenShift Container Platform registry, logging, and metrics.

---

**5.3. STORAGE RECOMMENDATIONS**

The following table summarizes the recommended and configurable storage technologies for the given OpenShift Container Platform cluster application.

[a] ReadOnlyMany

[b] ReadWriteMany

[c] This does not apply to physical disk, VM physical disk, VMDK, loopback over NFS, AWS EBS, and Azure Disk.

[d] For metrics, it is an anti-pattern to use any shared storage and a single volume (RWX). By default, metrics deploys with one volume per Cassandra Replica.

[e] For logging, using any shared storage would be an anti-pattern. One volume per logging-es is required.

[f] Object storage is not consumed through OpenShift Container Platform’s PVs/persistent volume claims (PVCs). Apps must integrate with the object storage REST API.
NOTE
A scaled registry is an OpenShift Container Platform registry where three or more pod replicas are running.

5.3.1. Specific Application and Storage Recommendations

IMPORTANT
Testing shows issues with using the RHEL NFS server as a storage backend for the container image registry. This includes the OpenShift Container Registry and Quay, Cassandra for metrics storage, and ElasticSearch for logging storage. Therefore, using the RHEL NFS server to back PVs used by core services is not recommended. Other NFS implementations on the marketplace might not have these issues. Contact the individual NFS implementation vendor for more information on any testing that was possibly completed against these OpenShift core components.

5.3.1.1. Registry
In a non-scaled/high-availability (HA) OpenShift Container Platform registry cluster deployment:

- The preferred storage technology is object storage followed by block storage. The storage technology does not need to support RWX access mode.
- The storage technology must ensure read-after-write consistency. All NAS storage (excluding CNS/CRS GlusterFS as it uses an object storage interface) are not recommended for OpenShift Container Platform Registry cluster deployment with production workloads.
- While hostPath volumes are configurable for a non-scaled/HA OpenShift Container Platform Registry, they are not recommended for cluster deployment.

5.3.1.2. Scaled Registry
In a scaled/HA OpenShift Container Platform registry cluster deployment:

- The preferred storage technology is object storage. The storage technology must support RWX access mode and must ensure read-after-write consistency.
- File storage and block storage are not recommended for a scaled/HA OpenShift Container Platform registry cluster deployment with production workloads.
- All NAS storage (excluding CNS/CRS GlusterFS as it uses an object storage interface) are not recommended for OpenShift Container Platform Registry cluster deployment with production workloads.

5.3.1.3. Metrics
In an OpenShift Container Platform hosted metrics cluster deployment:

- The preferred storage technology is block storage.
- It is not recommended to use NAS storage (excluding CNS/CRS GlusterFS as it uses a block storage interface from iSCSI) for hosted metrics cluster deployment with production workloads.
5.3.1.4. Logging

In an OpenShift Container Platform hosted logging cluster deployment:

- The preferred storage technology is block storage.
- It is not recommended to use NAS storage (excluding CNS/CRS GlusterFS as it uses a block storage interface from iSCSI) for hosted metrics cluster deployment with production workloads.

5.3.1.5. Applications

Application use cases vary from application to application, as described in the following examples:

- Storage technologies that support dynamic PV provisioning have low mount time latencies, and are not tied to nodes to support a healthy cluster.
- Application developers are responsible for knowing and understanding the storage requirements for their application, and how it works with the provided storage to ensure that issues do not occur when an application scales or interacts with the storage layer.

5.3.1.6. Other Specific Application Storage Recommendations

- OpenShift Container Platform Internal etcd: For the best etcd reliability, the lowest consistent latency storage technology is preferable.
- OpenStack Cinder: OpenStack Cinder tends to be adept in ROX access mode use cases.
- Databases: Databases (RDBMSs, NoSQL DBs, etc.) tend to perform best with dedicated block storage.

5.4. CHOOSING A GRAPH DRIVER

Container runtimes store images and containers in a graph driver (a pluggable storage technology), such as DeviceMapper and OverlayFS. Each has advantages and disadvantages.
For more information about OverlayFS, including supportability and usage caveats, see the Red Hat Enterprise Linux (RHEL) 7 Release Notes for your version.

### Table 5.3. Graph Driver Comparisons

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Benefits</th>
<th>Limitations</th>
</tr>
</thead>
<tbody>
<tr>
<td>OverlayFS</td>
<td>Combines a lower (parent) and upper (child) filesystem and a working directory (on the same filesystem as the child). The lower filesystem is the base image, and when you create new containers, a new upper filesystem is created containing the deltas.</td>
<td>- Faster than Device Mapper at starting and stopping containers. The startup time difference between Device Mapper and Overlay is generally less than one second.</td>
<td>Not POSIX compliant.</td>
</tr>
<tr>
<td></td>
<td>• overlay</td>
<td>- Allows for page cache sharing.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• overlay2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Device Mapper Thin Provisioning</td>
<td>Uses LVM, Device Mapper, and the dm-thinp kernel module. It differs by removing the loopback device, talking straight to a raw partition (no filesystem).</td>
<td>- There are measurable performance advantages at moderate load and high density.</td>
<td>- You have to have a dedicated partition for it.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- It gives you per-container limits for capacity (10G by default).</td>
<td>- It is not set up by default in Red Hat Enterprise Linux (RHEL).</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>- All containers and images share the same pool of capacity. It cannot be resized without destroying and re-creating the pool.</td>
</tr>
</tbody>
</table>
Device Mapper loop-lvm

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Benefits</th>
<th>Limitations</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Uses the Device Mapper thin provisioning module (dm-thin-pool) to implement copy-on-write (CoW) snapshots. For each device mapper graph location, thin pool is created based on two block devices, one for data and one for metadata. By default, these block devices are created automatically by using loopback mounts of automatically created sparse files.</td>
<td>It works out of the box, so it is useful for prototyping and development purposes.</td>
<td>- Not all Portable Operating System Interface for Unix (POSIX) features work (for example, O_DIRECT). Most importantly, this mode is unsupported for production workloads. - All containers and images share the same pool of capacity. It cannot be resized without destroying and re-creating the pool.</td>
</tr>
</tbody>
</table>

For better performance, Red Hat strongly recommends using the overlayFS storage driver over Device Mapper. However, if you are already using Device Mapper in a production environment, Red Hat strongly recommends using thin provisioning for container images and container root file systems. Otherwise, always use overlayfs2 for Docker engine or overlayFS for CRI-O.

Using a loop device can affect performance issues. While you can still continue to use it, the following warning message is logged:

```
devmapper: Usage of loopback devices is strongly discouraged for production use. Please use `--storage-opt dm.thinpooldev` or use `man docker` to refer to dm.thinpooldev section.
```

To ease storage configuration, use the `docker-storage-setup` utility, which automates much of the configuration details:

1. Edit the the `/etc/sysconfig/docker-storage-setup` file to specify the device driver:

```
STORAGE_DRIVER=devicemapper
```

Or

```
STORAGE_DRIVER=overlay2
```
NOTE
If using CRI-O specify \texttt{STORAGE\_DRIVER=overlay} to use overlay2.

2. If you had a separate disk drive dedicated to Docker storage (for example, \texttt{/dev/xvdb}), add the following to the \texttt{/etc/sysconfig/docker-storage-setup} file:

\begin{verbatim}
DEVS=/dev/xvdb
VG=docker_vg
\end{verbatim}

3. Restart the docker-storage-setup service:

\begin{verbatim}
# systemctl restart docker-storage-setup
\end{verbatim}

After the restart, docker-storage-setup sets up a volume group named docker_vg and creates a thin-pool logical volume. Documentation for thin provisioning on RHEL is available in the LVM Administrator Guide. View the newly created volumes with the \texttt{lsblk} command:

\begin{verbatim}
# lsblk /dev/xvdb
NAME MAJ:MIN RM SIZE RO TYPE MOUNTPOINT
xvdb 202:16 0 20G 0 disk
└─xvdb1 202:17 0 10G 0 part
  └─docker_vg-docker--pool_tmeta 253:0 0 12M 0 lvm
  └─docker_vg-docker--pool 253:2 0 6.9G 0 lvm
  └─docker_vg-docker--pool_tdata 253:1 0 6.9G 0 lvm
  └─docker_vg-docker--pool 253:2 0 6.9G 0 lvm
\end{verbatim}

NOTE
Thin-provisioned volumes are not mounted and have no file system (individual containers do have an XFS file system), thus they do not show up in \texttt{df} output.

4. To verify that Docker is using an LVM thin pool, and to monitor disk space use, run the docker \texttt{info} command:

\begin{verbatim}
# docker info | egrep -i 'storage|pool|space|filesystem'
Storage Driver: overlay2
Backing Filesystem: extfs
\end{verbatim}

1 The \texttt{docker info} output when using overlay2.

\begin{verbatim}
# docker info | egrep -i 'storage|pool|space|filesystem'
Storage Driver: devicemapper
Pool Name: docker_vg-docker--pool
Pool Blocksize: 524.3 kB
Backing Filesystem: xfs
Data Space Used: 62.39 MB
Data Space Total: 6.434 GB
Data Space Available: 6.372 GB
Metadata Space Used: 40.96 kB
Metadata Space Total: 16.78 MB
Metadata Space Available: 16.74 MB
\end{verbatim}
The `docker info` output when using `devicemapper`.

Corresponds to the VG you specified in `/etc/sysconfig/docker-storage-setup`.

By default, a thin pool is configured to use 40% of the underlying block device. As you use the storage, LVM automatically extends the thin pool up to 100%. This is why the `Data Space Total` value does not match the full size of the underlying LVM device. This auto-extend technique was used to unify the storage approach taken in both Red Hat Enterprise Linux and Red Hat Atomic Host, which only uses a single partition.

In development, Docker in Red Hat distributions defaults to a loopback mounted sparse file. To see if your system is using the loopback mode:

```
# docker info | grep loop0
Data file: /dev/loop0
```

**IMPORTANT**

Red Hat strongly recommends using the `overlay2` storage driver in thin-pool mode for production workloads.

OverlayFS is also supported for container runtimes use cases as of Red Hat Enterprise Linux 7.2, and provides faster start up time and page cache sharing, which can potentially improve density by reducing overall memory utilization.

### 5.4.1. Benefits of Using the OverlayFS Versus DeviceMapper with SELinux

The main advantage of the OverlayFS graph is Linux page cache sharing among containers that share an image on the same node. This attribute of OverlayFS leads to reduced input/output (I/O) during container startup (and, thus, faster container startup time by several hundred milliseconds), as well as reduced memory usage when similar images are running on a node. Both of these results are beneficial in many environments, especially those with the goal of optimizing for density and have high container churn rate (such as a build farm), or those that have significant overlap in image content.

Page cache sharing is not possible with DeviceMapper because thin-provisioned devices are allocated on a per-container basis.

**NOTE**

DeviceMapper is the default Docker storage configuration on Red Hat Enterprise Linux. The use of OverlayFS as the container storage technology is under evaluation and moving Red Hat Enterprise Linux to OverlayFS as the default in future releases is under consideration.

### 5.4.2. Comparing the Overlay Versus overlay2 Graph Drivers

OverlayFS is a type of union file system. It allows you to overlay one file system on top of another. Changes are recorded in the upper file system, while the lower file system remains unmodified. This allows multiple users to share a file-system image, such as a container or a DVD-ROM, where the base image is on read-only media.

OverlayFS layers two directories on a single Linux host and presents them as a single directory. These directories are called layers, and the unification process is referred to as a union mount.
OverlayFS uses one of two graph drivers, overlay or overlay2. As of Red Hat Enterprise Linux 7.2, overlay became a supported graph driver. As of Red Hat Enterprise Linux 7.4, overlay2 became supported. SELinux on the docker daemon became supported in Red Hat Enterprise Linux 7.4. See the Red Hat Enterprise Linux release notes for information on using OverlayFS with your version of RHEL, including supportability and usage caveats.

The overlay2 driver natively supports up to 128 lower OverlayFS layers but, the overlay driver works only with a single lower OverlayFS layer. Because of this capability, the overlay2 driver provides better performance for layer-related Docker commands, such as docker build, and consumes fewer inodes on the backing filesystem.

Because the overlay driver works with a single lower OverlayFS layer, you cannot implement multi-layered images as multiple OverlayFS layers. Instead, each image layer is implemented as its own directory under /var/lib/docker/overlay. Hard links are then used as a space-efficient way to reference data shared with lower layers.

Docker recommends using the overlay2 driver with OverlayFS rather than the overlay driver, because it is more efficient in terms of inode utilization.

**NOTE**

You need version 3.10.0-693 or higher of the kernel to use overlay2 with RHEL or CentOS.
CHAPTER 6. NETWORK OPTIMIZATION

6.1. OPTIMIZING NETWORK PERFORMANCE

The OpenShift SDN uses OpenvSwitch, virtual extensible LAN (VXLAN) tunnels, OpenFlow rules, and iptables. This network can be tuned by using jumbo frames, network interface cards (NIC) offloads, multi-queue, and ethtool settings.

VXLAN provides benefits over VLANs, such as an increase in networks from 4096 to over 16 million, and layer 2 connectivity across physical networks. This allows for all pods behind a service to communicate with each other, even if they are running on different systems.

VXLAN encapsulates all tunneled traffic in user datagram protocol (UDP) packets. However, this leads to increased CPU utilization. Both these outer- and inner-packets are subject to normal checksumming rules to guarantee data has not been corrupted during transit. Depending on CPU performance, this additional processing overhead can cause a reduction in throughput and increased latency when compared to traditional, non-overlay networks.

Cloud, VM, and bare metal CPU performance can be capable of handling much more than one Gbps network throughput. When using higher bandwidth links such as 10 or 40 Gbps, reduced performance can occur. This is a known issue in VXLAN-based environments and is not specific to containers or OpenShift Container Platform. Any network that relies on VXLAN tunnels will perform similarly because of the VXLAN implementation.

If you are looking to push beyond one Gbps, you can:

- Use **Native Container Routing**. This option has important operational caveats that do not exist when using OpenShift SDN, such as updating routing tables on a router.
- Evaluate network plug-ins that implement different routing techniques, such as border gateway protocol (BGP).
- Use VXLAN-offload capable network adapters. VXLAN-offload moves the packet checksum calculation and associated CPU overhead off of the system CPU and onto dedicated hardware on the network adapter. This frees up CPU cycles for use by pods and applications, and allows users to utilize the full bandwidth of their network infrastructure.

VXLAN-offload does not reduce latency. However, CPU utilization is reduced even in latency tests.

6.1.1. Optimizing the MTU for Your Network

There are two important maximum transmission units (MTUs): the network interface card (NIC) MTU and the SDN overlay’s MTU.

The NIC MTU must be less than or equal to the maximum supported value of the NIC of your network. If you are optimizing for throughput, pick the largest possible value. If you are optimizing for lowest latency, pick a lower value.

The SDN overlay’s MTU must be less than the NIC MTU by 50 bytes at a minimum. This accounts for the SDN overlay header. So, on a normal ethernet network, set this to 1450. On a jumbo frame ethernet network, set this to 8950.
NOTE

This 50 byte overlay header is relevant to the OpenShift SDN. Other SDN solutions might require the value to be more or less.

To configure the MTU, edit the node configuration file at `/etc/origin/node/node-config.yaml`, and edit the following:

```
networkConfig:
  mtu: 1450
  networkPluginName: "redhat/openshift-ovs-subnet"
```

1. Maximum transmission unit (MTU) for the pod overlay network.
2. Set to `redhat/openshift-ovs-subnet` for the `ovs-subnet` plug-in, `redhat/openshift-ovs-multitenant` for the `ovs-multitenant` plug-in, or `redhat/openshift-ovs-networkpolicy` for the `ovs-networkpolicy` plug-in. This can also be set to any other CNI-compatible plug-in as well.

NOTE

You must change the MTU size on all masters and nodes that are part of the OpenShift Container Platform SDN. Also, the MTU size of the tun0 interface must be the same across all nodes that are part of the cluster.

### 6.2. CONFIGURING NETWORK SUBNETS

OpenShift Container Platform provides IP address management for both pods and services. The default values allow for:

- A maximum cluster size of 1024 nodes
- Each of the 1024 nodes having a /23 allocated to it (510 usable IPs for pods)
- Around 65,536 IP addresses for services

Under most circumstances, these networks cannot be changed after deployment. So, planning ahead for growth is important.

Restrictions for resizing networks are documented in the [Configuring SDN documentation](#).

To plan for a larger environment, the following are suggested values to consider adding to the `[OSE3:vars]` section in your Ansible inventory file:

```
[OSE3:vars]
  osm_cluster_network_cidr=10.128.0.0/10
```

This will allow for 8192 nodes, each with 510 usable IP addresses.

See the supportability limits in the OpenShift Container Platform documentation for node/pod limits for the version of software you are installing.

### 6.3. OPTIMIZING IPSEC
Because encrypting and decrypting node hosts uses CPU power, performance is affected both in throughput and CPU usage on the nodes when encryption is enabled, regardless of the IP security system being used.

IPSec encrypts traffic at the IP payload level, before it hits the NIC, protecting fields that would otherwise be used for NIC offloading. This means that some NIC acceleration features may not be usable when IPSec is enabled and will lead to decreased throughput and increased CPU usage.
CHAPTER 7. ROUTING OPTIMIZATION

7.1. SCALING OPENSHIFT CONTAINER PLATFORM HAPROXY ROUTER

7.1.1. Baseline Performance

The OpenShift Container Platform router is the ingress point for all external traffic destined for OpenShift Container Platform services.

On an public cloud instance of size 4 vCPU/16GB RAM, a single HAProxy router is able to handle between 7000–32000 HTTP keep-alive requests depending on encryption, page size, and the number of connections used. For example, when using TLS edge or re-encryption terminations with large page sizes and a high numbers of connections, expect to see results in the lower range. With HTTP keep-alive, a single HAProxy router is capable of saturating 1 Gbit NIC at page sizes as small as 8 kB.

The table below shows HTTP keep-alive performance on such a public cloud instance with a single HAProxy and 100 routes:

<table>
<thead>
<tr>
<th>Encryption</th>
<th>Page size</th>
<th>HTTP(s) requests per second</th>
</tr>
</thead>
<tbody>
<tr>
<td>none</td>
<td>1kB</td>
<td>15435</td>
</tr>
<tr>
<td>none</td>
<td>4kB</td>
<td>11947</td>
</tr>
<tr>
<td>edge</td>
<td>1kB</td>
<td>7467</td>
</tr>
<tr>
<td>edge</td>
<td>4kB</td>
<td>7678</td>
</tr>
<tr>
<td>passthrough</td>
<td>1kB</td>
<td>25789</td>
</tr>
<tr>
<td>passthrough</td>
<td>4kB</td>
<td>17876</td>
</tr>
<tr>
<td>re-encrypt</td>
<td>1kB</td>
<td>7611</td>
</tr>
<tr>
<td>re-encrypt</td>
<td>4kB</td>
<td>7395</td>
</tr>
</tbody>
</table>

When running on bare metal with modern processors, you can expect roughly twice the performance of the public cloud instance above. This overhead is introduced by the virtualization layer in place on public clouds and holds mostly true for private cloud-based virtualization as well. The following table is a guide on how many applications to use behind the router:

<table>
<thead>
<tr>
<th>Number of applications</th>
<th>Application type</th>
</tr>
</thead>
<tbody>
<tr>
<td>5-10</td>
<td>static file/web server or caching proxy</td>
</tr>
<tr>
<td>100-1000</td>
<td>applications generating dynamic content</td>
</tr>
</tbody>
</table>
In general, HAProxy can saturate about 5-1000 applications, depending on the technology in use. The number will typically be lower for applications serving only static content.

**Router sharding** should be used to serve more routes towards applications and help horizontally scale the routing tier.

### 7.1.2. Performance Optimizations

#### 7.1.2.1. Setting the Maximum Number of Connections

One of the most important tunable parameters for HAProxy scalability is the `maxconn` parameter, which sets the maximum per-process number of concurrent connections to a given number. Adjust this parameter by editing the `ROUTER_MAX_CONNECTIONS` environment variable in the OpenShift Container Platform HAProxy router’s deployment configuration file.

**NOTE**

A connection includes the frontend and internal backend. This counts as two connections. Be sure to set `ROUTER_MAX_CONNECTIONS` to double than the number of connections you intend to create.

#### 7.1.2.2. CPU and Interrupt Affinity

In OpenShift Container Platform, the HAProxy router runs as a single process. The OpenShift Container Platform HAProxy router typically performs better on a system with fewer but high frequency cores, rather than on a symmetric multiprocessing (SMP) system with a high number of lower frequency cores.

Pinning the HAProxy process to one CPU core and the network interrupts to another CPU core tends to increase network performance. Having processes and interrupts on the same non-uniform memory access (NUMA) node helps avoid memory accesses by ensuring a shared L3 cache. However, this level of control is generally not possible on a public cloud environment. On bare metal hosts, `irqbalance` automatically handles peripheral component interconnect (PCI) locality and NUMA affinity for interrupt request lines (IRQs). On a cloud environment, this level of information is generally not provided to the operating system.

CPU pinning is performed either by `taskset` or by using HAProxy’s `cpu-map` parameter. This directive takes two arguments: the process ID and the CPU core ID. For example, to pin HAProxy process 1 onto CPU core 0, add the following line to the global section of HAProxy’s configuration file:

```
cpu-map 1 0
```

To modify the HAProxy configuration file, refer to [Deploying a Customized HAProxy Router](#).

#### 7.1.2.3. Impacts of Buffer Increases

The OpenShift Container Platform HAProxy router request buffer configuration limits the size of headers in incoming requests and responses from applications. The HAProxy parameter `tune.bufsize` can be increased to allow processing of larger headers and to allow applications with very large cookies to work, such as those accepted by load balancers provided by many public cloud providers. However, this affects the total memory use, especially when large numbers of connections are open. With very large numbers of open connections, the memory usage will be nearly proportionate to the increase of this tunable parameter.
7.1.2.4. Optimizations for HAProxy Reloads

Long-lasting connections, such as WebSocket connections, combined with long client/server HAProxy timeouts and short HAProxy reload intervals, can cause instantiation of many HAProxy processes. These processes must handle old connections, which were started before the HAProxy configuration reload. A large number of these processes is undesirable, as it will exert unnecessary load on the system and can lead to issues, such as out of memory conditions.

Router environment variables affecting this behavior are `ROUTER_DEFAULT_TUNNEL_TIMEOUT`, `ROUTER_DEFAULT_CLIENT_TIMEOUT`, `ROUTER_DEFAULT_SERVER_TIMEOUT`, and `RELOAD_INTERVAL` in particular.
CHAPTER 8. SCALING CLUSTER METRICS

8.1. OVERVIEW

OpenShift Container Platform exposes metrics that can be collected and stored in back-ends by Heapster. As an OpenShift Container Platform administrator, you can view containers and components metrics in one user interface. These metrics are also used by horizontal pod autoscalers in order to determine when and how to scale.

This topic provides information for scaling the metrics components.

NOTE

Autoscaling the metrics components, such as Hawkular and Heapster, is not supported by OpenShift Container Platform.

8.2. RECOMMENDATIONS FOR OPENSHIFT CONTAINER PLATFORM VERSION 3.9

- Run metrics pods on dedicated OpenShift Container Platform infrastructure nodes.
- Use persistent storage when configuring metrics. Set `USE_PERSISTENT_STORAGE=true`.
- Keep the `METRICS_RESOLUTION=30` parameter in OpenShift Container Platform metrics deployments. Using a value lower than the default value of 30 for `METRICS_RESOLUTION` is not recommended. When using the Ansible metrics installation procedure, this is the `openshift_metrics_resolution` parameter.
- Closely monitor OpenShift Container Platform nodes with host metrics pods to detect early capacity shortages (CPU and memory) on the host system. These capacity shortages can cause problems for metrics pods.
- In OpenShift Container Platform version 3.7 testing, test cases up to 25,000 pods were monitored in a OpenShift Container Platform cluster.

8.3. CAPACITY PLANNING FOR CLUSTER METRICS

In tests performed with 210 and 990 OpenShift Container Platform nodes, where 10500 pods and 11000 pods were monitored respectively, the Cassandra database grew at the speed shown in the table below:

<table>
<thead>
<tr>
<th>Number of Nodes</th>
<th>Number of Pods</th>
<th>Cassandra Storage growth speed</th>
<th>Cassandra storage growth per day</th>
<th>Cassandra storage growth per week</th>
</tr>
</thead>
<tbody>
<tr>
<td>210</td>
<td>10500</td>
<td>500 MB per hour</td>
<td>15 GB</td>
<td>75 GB</td>
</tr>
<tr>
<td>990</td>
<td>11000</td>
<td>1 GB per hour</td>
<td>30 GB</td>
<td>210 GB</td>
</tr>
</tbody>
</table>

In the above calculation, approximately 20 percent of the expected size was added as overhead to ensure that the storage requirements do not exceed calculated value.
If the `METRICS_DURATION` and `METRICS_RESOLUTION` values are kept at the default (7 days and 15 seconds respectively), it is safe to plan Cassandra storage size requirements for week, as in the values above.

**WARNING**

Because OpenShift Container Platform metrics uses the Cassandra database as a datastore for metrics data, if `USE_PERSISTENT_STORAGE=true` is set during the metrics set up process, PV will be on top in the network storage, with NFS as the default. However, using network storage in combination with Cassandra is not recommended.

If you use a Cassandra database as a datastore for metrics data, see the Cassandra documentation for their recommendations.

---

### 8.4. SCALING OPENSHIFT CONTAINER PLATFORM METRICS PODS

One set of metrics pods (Cassandra/Hawkular/Heapster) is able to monitor at least 25,000 pods.

**CAUTION**

Pay attention to system load on nodes where OpenShift Container Platform metrics pods run. Use that information to determine if it is necessary to scale out a number of OpenShift Container Platform metrics pods and spread the load across multiple OpenShift Container Platform nodes. Scaling OpenShift Container Platform metrics heapster pods is not recommended.

#### 8.4.1. Prerequisites

If persistent storage was used to deploy OpenShift Container Platform metrics, then you must create a persistent volume (PV) for the new Cassandra pod to use before you can scale out the number of OpenShift Container Platform metrics Cassandra pods. However, if Cassandra was deployed with dynamically provisioned PVs, then this step is not necessary.

#### 8.4.2. Scaling the Cassandra Components

Cassandra nodes use persistent storage. Therefore, scaling up or down is not possible with replication controllers.

Scaling a Cassandra cluster requires modifying the `openshift_metrics_cassandra_replicas` variable and re-running the deployment. By default, the Cassandra cluster is a single-node cluster.

To scale up the number of OpenShift Container Platform metrics hawkular pods to two replicas, run:

```
# oc scale -n openshift-infra --replicas=2 rc hawkular-metrics
```

Alternatively, update your inventory file and re-run the deployment.
NOTE

If you add a new node to or remove an existing node from a Cassandra cluster, the data stored in the cluster rebalances across the cluster.

To scale down:

1. If remotely accessing the container, run the following for the Cassandra node you want to remove:

   ```bash
   $ oc exec -it <hawkular-cassandra-pod> nodetool decommission
   
   If locally accessing the container, run the following instead:
   
   ```bash
   $ oc rsh <hawkular-cassandra-pod> nodetool decommission
   ```

   This command can take a while to run since it copies data across the cluster. You can monitor the decommission progress with `nodetool netstats -H`.

2. Once the previous command succeeds, scale down the `rc` for the Cassandra instance to 0.

   ```bash
   # oc scale -n openshift-infra --replicas=0 rc <hawkular-cassandra-rc>
   ```

   This will remove the Cassandra pod.

IMPORTANT

If the scale down process completed and the existing Cassandra nodes are functioning as expected, you can also delete the `rc` for this Cassandra instance and its corresponding persistent volume claim (PVC). Deleting the PVC can permanently delete any data associated with this Cassandra instance, so if the scale down did not fully and successfully complete, you will not be able to recover the lost data.
CHAPTER 9. CLUSTER LIMITS

9.1. OVERVIEW

This topic summarizes the limits for objects in OpenShift Container Platform.

In most cases, exceeding these thresholds results in lower overall performance. It does not necessarily mean that the cluster will fail.

Some of the limits represented in this topic are given for the largest possible cluster. For smaller clusters, the limits are proportionally lower.

There are many factors that influence the stated thresholds, including the etcd version or storage data format.

9.2. OPENSHIFT CONTAINER PLATFORM CLUSTER LIMITS

<table>
<thead>
<tr>
<th>Limit Type</th>
<th>3.7 Limit</th>
<th>3.9 Limit</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>
### 9.3. PLANNING YOUR ENVIRONMENT ACCORDING TO CLUSTER LIMITS

**IMPORTANT**

Oversubscribing the physical resources on a node affects resource guarantees the Kubernetes scheduler makes during pod placement. Learn what measures you can take to avoid memory swapping.

While planning your environment, determine how many pods are expected to fit per node:

\[
\text{Maximum Pods per Cluster / Expected Pods per Node} = \text{Total Number of Nodes}
\]

The number of pods expected to fit on a node is dependent on the application itself. Consider the application’s memory, CPU, and storage requirements.

**Example Scenario**

If you want to scope your cluster for 2200 pods per cluster, you would need at least nine nodes, assuming that there are 250 maximum pods per node:

\[
2200 / 250 = 8.8
\]

If you increase the number of nodes to 20, then the pod distribution changes to 110 pods per node:

\[
2200 / 20 = 110
\]

### 9.4. PLANNING YOUR ENVIRONMENT ACCORDING TO APPLICATION REQUIREMENTS

Consider an example application environment:

<table>
<thead>
<tr>
<th>Pod Type</th>
<th>Pod Quantity</th>
<th>Max Memory</th>
<th>CPU Cores</th>
<th>Persistent Storage</th>
</tr>
</thead>
<tbody>
<tr>
<td>apache</td>
<td>100</td>
<td>500MB</td>
<td>0.5</td>
<td>1GB</td>
</tr>
<tr>
<td>Pod Type</td>
<td>Pod Quantity</td>
<td>Max Memory</td>
<td>CPU Cores</td>
<td>Persistent Storage</td>
</tr>
<tr>
<td>------------</td>
<td>--------------</td>
<td>------------</td>
<td>-----------</td>
<td>--------------------</td>
</tr>
<tr>
<td>node.js</td>
<td>200</td>
<td>1GB</td>
<td>1</td>
<td>1GB</td>
</tr>
<tr>
<td>postgresql</td>
<td>100</td>
<td>1GB</td>
<td>2</td>
<td>10GB</td>
</tr>
<tr>
<td>JBoss EAP</td>
<td>100</td>
<td>1GB</td>
<td>1</td>
<td>1GB</td>
</tr>
</tbody>
</table>

Extrapolated requirements: 550 CPU cores, 450GB RAM, and 1.4TB storage.

Instance size for nodes can be modulated up or down, depending on your preference. Nodes are often resource overcommitted. In this deployment scenario, you can choose to run additional smaller nodes or fewer larger nodes to provide the same amount of resources. Factors such as operational agility and cost-per-instance should be considered.

<table>
<thead>
<tr>
<th>Node Type</th>
<th>Quantity</th>
<th>CPUs</th>
<th>RAM (GB)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Nodes (option 1)</td>
<td>100</td>
<td>4</td>
<td>16</td>
</tr>
<tr>
<td>Nodes (option 2)</td>
<td>50</td>
<td>8</td>
<td>32</td>
</tr>
<tr>
<td>Nodes (option 3)</td>
<td>25</td>
<td>16</td>
<td>64</td>
</tr>
</tbody>
</table>

Some applications lend themselves well to overcommitted environments, and some do not. Most Java applications and applications that use huge pages are examples of applications that would not allow for overcommitment. That memory can not be used for other applications. In the example above, the environment would be roughly 30 percent overcommitted, a common ratio.
10.1. WHAT CLUSTER LOADER DOES

Cluster Loader is a tool that deploys large numbers of various objects to a cluster, which creates user-defined cluster objects. Build, configure, and run Cluster Loader to measure performance metrics of your OpenShift Container Platform deployment at various cluster states.

10.2. INSTALLING CLUSTER LOADER

Cluster Loader is included in the atomic-openshift-tests package. To install it, run:

```
$ yum install atomic-openshift-tests
```

After installation, the test executable extended.test is located in /usr/libexec/atomic-openshift/extended.test.

10.3. RUNNING CLUSTER LOADER

1. Set the KUBECONFIG variable to the location of the administrator kubeconfig:

```
$ export KUBECONFIG=${KUBECONFIG-$HOME/.kube/config}
```

2. Execute Cluster Loader using the built-in test configuration, which deploys five template builds and waits for them to complete:

```
$ cd /usr/libexec/atomic-openshift/
$ ./extended.test --ginkgo.focus="Load cluster"
```

Alternatively, execute Cluster Loader with a user-defined configuration by adding the flag for --viper-config:

```
$ ./extended.test --ginkgo.focus="Load cluster" --viper-config=config/test
```

In this example, there is a subdirectory called config/ with a configuration file called test.yml. In the command line, exclude the extension of the configuration file, as the tool will automatically determine the file type and extension.

10.4. CONFIGURING CLUSTER LOADER

Create multiple namespaces (projects), which contain multiple templates or pods.

Locate the configuration files for Cluster Loader in the config/subdirectory. The pod files and template files referenced in these configuration examples are found in the content/subdirectory.

10.4.1. Configuration Fields

Table 10.1. Top-level Cluster Loader Fields
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cleanup</td>
<td>Set to <code>true</code> or <code>false</code>. One definition per configuration. If set to <code>true</code>, <code>cleanup</code> will delete all namespaces (projects) created by Cluster Loader at the end of the test.</td>
</tr>
<tr>
<td>projects</td>
<td>A sub-object with one or many definition(s). Under <code>projects</code>, each namespace to create is defined and <code>projects</code> has several mandatory subheadings.</td>
</tr>
<tr>
<td>tuningset</td>
<td>A sub-object with one definition per configuration. <code>tuningset</code> allows the user to define a tuning set to add configurable timing to project or object creation (pods, templates, and so on).</td>
</tr>
<tr>
<td>sync</td>
<td>An optional sub-object with one definition per configuration. Adds synchronization possibilities during object creation.</td>
</tr>
</tbody>
</table>

Table 10.2. Fields under `projects`

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>num</td>
<td>An integer. One definition of the count of how many projects to create.</td>
</tr>
<tr>
<td>basename</td>
<td>A string. One definition of the base name for the project. The count of identical namespaces will be appended to <code>basename</code> to prevent collisions.</td>
</tr>
<tr>
<td>tuning</td>
<td>A string. One definition of what tuning set you want to apply to the objects, which you deploy inside this namespace.</td>
</tr>
<tr>
<td>ifexists</td>
<td>A string containing either <code>reuse</code> or <code>delete</code>. Defines what the tool does if it finds a project or namespace that has the same name of the project or namespace it creates during execution.</td>
</tr>
<tr>
<td>configmaps</td>
<td>A list of key-value pairs. The key is the ConfigMap name and the value is a path to a file from which you create the ConfigMap.</td>
</tr>
<tr>
<td>secrets</td>
<td>A list of key-value pairs. The key is the secret name and the value is a path to a file from which you create the secret.</td>
</tr>
<tr>
<td>pods</td>
<td>A sub-object with one or many definition(s) of pods to deploy.</td>
</tr>
</tbody>
</table>
### Table 10.3. Fields under pods and templates

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>total</strong></td>
<td>This field is not used.</td>
</tr>
<tr>
<td><strong>num</strong></td>
<td>An integer. The number of pods or templates to deploy.</td>
</tr>
<tr>
<td><strong>image</strong></td>
<td>A string. The docker image URL to a repository where it can be pulled.</td>
</tr>
<tr>
<td><strong>basename</strong></td>
<td>A string. One definition of the base name for the template (or pod) that you want to create.</td>
</tr>
<tr>
<td><strong>file</strong></td>
<td>A string. The path to a local file, which is either a PodSpec or template to be created.</td>
</tr>
<tr>
<td><strong>parameters</strong></td>
<td>Key-value pairs. Under <code>parameters</code>, you can specify a list of values to override in the pod or template.</td>
</tr>
</tbody>
</table>

### Table 10.4. Fields under tuningset

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>name</strong></td>
<td>A string. The name of the tuning set which will match the name specified when defining a tuning in a project.</td>
</tr>
<tr>
<td><strong>pods</strong></td>
<td>A sub-object identifying the <code>tuningset</code> that will apply to pods.</td>
</tr>
<tr>
<td><strong>templates</strong></td>
<td>A sub-object identifying the <code>tuningset</code> that will apply to templates.</td>
</tr>
</tbody>
</table>

### Table 10.5. Fields under tuningset pods or tuningset templates
### Table 10.6. Fields under `tuningset pods` or `tuningset templates`, `stepping`

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>stepping</strong></td>
<td>A sub-object. A stepping configuration used if you want to create an object in a step creation pattern.</td>
</tr>
<tr>
<td><strong>rate_limit</strong></td>
<td>A sub-object. A rate-limiting tuning set configuration to limit the object creation rate.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>stepsize</strong></td>
<td>An integer. How many objects to create before pausing object creation.</td>
</tr>
<tr>
<td><strong>pause</strong></td>
<td>An integer. How many seconds to pause after creating the number of objects defined in <code>stepsize</code>.</td>
</tr>
<tr>
<td><strong>timeout</strong></td>
<td>An integer. How many seconds to wait before failure if the object creation is not successful.</td>
</tr>
<tr>
<td><strong>delay</strong></td>
<td>An integer. How many milliseconds (ms) to wait between creation requests.</td>
</tr>
</tbody>
</table>

### Table 10.7. Fields under `sync`

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>server</strong></td>
<td>A sub-object with <code>enabled</code> and <code>port</code> fields. The boolean <code>enabled</code> defines whether to start a HTTP server for pod synchronization. The integer <code>port</code> defines the HTTP server port to listen on (<code>9090</code> by default).</td>
</tr>
<tr>
<td><strong>running</strong></td>
<td>A boolean. Wait for pods with labels matching <code>selectors</code> to go into <code>Running</code> state.</td>
</tr>
<tr>
<td><strong>succeeded</strong></td>
<td>A boolean. Wait for pods with labels matching <code>selectors</code> to go into <code>Completed</code> state.</td>
</tr>
<tr>
<td><strong>selectors</strong></td>
<td>A list of selectors to match pods in <code>Running</code> or <code>Completed</code> states.</td>
</tr>
<tr>
<td><strong>timeout</strong></td>
<td>A string. The synchronization timeout period to wait for pods in <code>Running</code> or <code>Completed</code> states. For values that are not <code>0</code>, use units: [ns</td>
</tr>
</tbody>
</table>
10.4.2. Example Cluster Loader Configuration File

Cluster Loader’s configuration file is a basic YAML file:

```
provider: local
ClusterLoader:
cleanup: true
projects:
  - num: 1
    basename: clusterloader-cakephp-mysql
tuning: default
ifexists: reuse
templates:
  - num: 1
    file: ./examples/quickstarts/cakephp-mysql.json
- num: 1
  basename: clusterloader-dancer-mysql
tuning: default
ifexists: reuse
templates:
  - num: 1
    file: ./examples/quickstarts/dancer-mysql.json
- num: 1
  basename: clusterloader-django-postgresql
tuning: default
ifexists: reuse
templates:
  - num: 1
    file: ./examples/quickstarts/django-postgresql.json
- num: 1
  basename: clusterloader-nodejs-mongodb
tuning: default
ifexists: reuse
templates:
  - num: 1
    file: ./examples/quickstarts/nodejs-mongodb.json
- num: 1
  basename: clusterloader-rails-postgresql
tuning: default
templates:
  - num: 1
    file: ./examples/quickstarts/rails-postgresql.json

tuningset:
  - name: default
pods:
  stepping: 3
  stepsize: 5
  pause: 0 s
  rate_limit: 4
  delay: 0 ms
```
1. Optional setting for end-to-end tests. Set to local to avoid extra log messages.

2. The tuning sets allow rate limiting and stepping, the ability to create several batches of pods while pausing in between sets. Cluster Loader monitors completion of the previous step before continuing.

3. Stepping will pause for $M$ seconds after each $N$ objects are created.

4. Rate limiting will wait $M$ milliseconds between the creation of objects.

10.5. KNOWN ISSUES

If the IDENTIFIER parameter is not defined in user templates, template creation fails with error: unknown parameter name "IDENTIFIER". If you deploy templates, add this parameter to your template to avoid this error:

```json
{
    "name": "IDENTIFIER",
    "description": "Number to append to the name of resources",
    "value": "1"
}
```

If you deploy pods, adding the parameter is unnecessary.
CHAPTER 11. USING CPU MANAGER

11.1. WHAT CPU MANAGER DOES

IMPORTANT

CPU Manager is a Technology Preview feature. Technology Preview features are not supported with Red Hat production service level agreements (SLAs), might not be functionally complete, and Red Hat does not recommend to use them for production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information on Red Hat Technology Preview features support scope, see https://access.redhat.com/support/offerings/techpreview/.

CPU Manager manages groups of CPUs and constrains workloads to specific CPUs.

CPU Manager is useful for workloads that have some of these attributes:

- Require as much CPU time as possible.
- Are sensitive to processor cache misses.
- Are low-latency network applications.
- Coordinate with other processes and benefit from sharing a single processor cache.

11.2. SETTING UP CPU MANAGER

To set up CPU Manager:

1. Optionally, label a node:

```bash
# oc label node perf-node.example.com cpumanager=true
```

2. Enable CPU manager support on the target node:

```bash
# cat /etc/origin/node/node-config.yaml
...
kubeletArguments:
...
feature-gates:
- CPUManager=true
cpu-manager-policy:
- static
cpu-manager-reconcile-period:
- 5s
kube-reserved:
1
- cpu=500m

# systemctl restart atomic-openshift-node
```
**kube-reserved** is a required setting. The value may need to be adjusted depending on your environment.

3. Create a pod that requests a core or multiple cores. Both limits and requests must have their CPU value set to a whole integer. That is the number of cores that will be dedicated to this pod:

```yaml
# cat cpumanager.yaml
apiVersion: v1
kind: Pod
metadata:
generateName: cpumanager-
spec:
containers:
- name: cpumanager
  image: gcr.io/google_containers/pause-amd64:3.0
  resources:
  requests:
    cpu: 1
    memory: "1G"
  limits:
    cpu: 1
    memory: "1G"
nodeSelector:
cpumanager: "true"
```

4. Create the pod:

```
# oc create -f cpumanager.yaml
```

5. Verify that the pod is scheduled to the node that you labeled:

```
# oc describe pod cpumanager
Name: cpumanager-4gdtn
Namespace: test
Node: perf-node.example.com/172.31.62.105
...
Limits:
cpu: 1
memory: 1G
Requests:
cpu: 1
memory: 1G
...
QoS Class: Guaranteed
Node-Selectors: cpumanager=true
          region=primary
```

6. Verify that the cgroups are set up correctly. Get the PID of the pause process:

```
# systemd-cgls -l
└─1 /usr/lib/systemd/systemd --system --deserialize 20
    └─kubepods.slice
        └─kubepods-pod0ec1ab8b_e1c4_11e7_bb22_027b30990a24.slice
```
Pods of QoS tier Guaranteed are placed within the kubepods.slice. Pods of other QoS tiers end up in child cgroups of kubepods.

# cd /sys/fs/cgroup/cpuset/kubepods.slice/kubepods-pod0ec1ab8b_e1c4_11e7_bbb2_027b30990a24.slice/docker-b24e29bc4021064057f941dc5f3538595c317d294f2c8e448b5e61a29c026d1c.scope
# for i in `ls cpuset.cpus tasks` ; do echo -n "$i " ; cat $i ; done
cpuset.cpus 2
tasks 44216

7. Check the allowed CPU list for the task:

# grep ^Cpus_allowed_list /proc/44216/status
Cpus_allowed_list: 2

8. Verify that another pod (in this case, the pod in the burstable QoS tier) on the system cannot run on the core allocated for the Guaranteed pod:

# cat /sys/fs/cgroup/cpuset/kubepods.slice/kubepods-burstable.slice/kubepods-burstable-podbe76ff22_dead_11e7_b99e_027b30990a24.slice/docker-da621bea7569704fc39f84385a179923309ab9d32f6360cccbff102e73f9557.scope/cpuset.cpus
0-1,3

# oc describe node perf-node.example.com
... Capacity:
cpu: 4
memory: 16266720Ki
pods: 40
Allocatable:
cpu: 3500m
memory: 16164320Ki
pods: 40
---
<table>
<thead>
<tr>
<th>Namespace</th>
<th>Name</th>
<th>CPU Requests</th>
<th>CPU Limits</th>
<th>Memory Requests</th>
<th>Memory Limits</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>cpumanager-4gdtn</td>
<td>1 (28%)</td>
<td>1 (28%)</td>
<td>1G (6%)</td>
<td>1G (6%)</td>
</tr>
<tr>
<td></td>
<td>cpumanager-hczts</td>
<td>1 (28%)</td>
<td>1 (28%)</td>
<td>1G (6%)</td>
<td>1G (6%)</td>
</tr>
<tr>
<td></td>
<td>cpumanager-r9wrq</td>
<td>1 (28%)</td>
<td>1 (28%)</td>
<td>1G (6%)</td>
<td>1G (6%)</td>
</tr>
</tbody>
</table>
... Allocated resources:
(Total limits may be over 100 percent, i.e., overcommitted.)
CPU Requests CPU Limits Memory Requests Memory Limits
----------- ----------- --------------- ----------- -----------
3 (85%)      3 (85%)    5437500k (32%)  9250M (55%) This VM has four CPU cores. You set kube-reserved to 500 millicores, meaning half of one core is subtracted from the total capacity of the node to arrive at the Node Allocatable amount.
You can see that **Allocatable CPU** is 3500 millicores. This means we can run three of our CPU manager pods since each will take one whole core. A whole core is equivalent to 1000 millicores.

If you try to schedule a fourth pod, the system will accept the pod, but it will never be scheduled:

```
# oc get pods --all-namespaces |grep test
  test  cpumanager-4gdtn   1/1   Running   0    8m
  test  cpumanager-hczts   1/1   Running   0    8m
  test  cpumanager-nb9d5   0/1   Pending   0    8m
  test  cpumanager-r9wrq   1/1   Running   0    8m
```
12.1. WHAT HUGE PAGES DO

IMPORTANT

Managing huge pages is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs), might not be functionally complete, and Red Hat does not recommend to use them for production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information on Red Hat Technology Preview features support scope, see https://access.redhat.com/support/offerings/techpreview/.

Memory is managed in blocks known as pages. On most systems, a page is 4Ki. 1Mi of memory is equal to 256 pages; 1Gi of memory is 262,144 pages, and so on. CPUs have a built-in memory management unit that manages a list of these pages in hardware. The Translation Lookaside Buffer (TLB) is a small hardware cache of virtual-to-physical page mappings. If the virtual address passed in a hardware instruction can be found in the TLB, the mapping can be determined quickly. If not, a TLB miss occurs, and the system falls back to slower, software-based address translation, resulting in performance issues. Since the size of the TLB is fixed, the only way to reduce the chance of a TLB miss is to increase the page size.

A huge page is a memory page that is larger than 4Ki. On x86_64 architectures, there are two common huge page sizes: 2Mi and 1Gi. Sizes vary on other architectures. In order to use huge pages, code must be written so that applications are aware of them. Transparent Huge Pages (THP) attempt to automate the management of huge pages without application knowledge, but they have limitations. In particular, they are limited to 2Mi page sizes. THP can lead to performance degradation on nodes with high memory utilization or fragmentation due to defragmenting efforts of THP, which can lock memory pages. For this reason, some applications may be designed to (or recommend) usage of pre-allocated huge pages instead of THP.

In OpenShift Container Platform, applications in a pod can allocate and consume pre-allocated huge pages. This topic describes how.

12.2. PREREQUISITES

1. Nodes must pre-allocate huge pages in order for the node to report its huge page capacity. A node can only pre-allocate huge pages for a single size.

2. `HugePages` must be set to `true` across the system:

   ```bash
   # cat /etc/origin/node/node-config.yaml
   ...
   kubeletArguments:
   ...
   feature-gates:
   - HugePages=true
   # systemctl restart atomic-openshift-node
   ``

3. The master API must be enabled for `feature-gates` with `HugePages=true`:
12.3. CONSUMING HUGE PAGES

Huge pages can be consumed via container level resource requirements using the resource name hugepages-<size>, where size is the most compact binary notation using integer values supported on a particular node. For example, if a node supports 2048KiB page sizes, it will expose a schedulable resource hugepages-2Mi. Unlike CPU or memory, huge pages do not support overcommitment.

```yaml
kind: Pod
metadata:
  generateName: hugepages-volume-
spec:
  containers:
    - securityContext:
      privileged: true
    image: rhel7:latest
    command:
    - sleep
    - inf
    name: example
    volumeMounts:
    - mountPath: /hugepages
      name: hugepage
    resources:
      limits:
        hugepages-2Mi: 100Mi
    volumes:
    - name: hugepage
      emptyDir:
      medium: HugePages
```

Specify the amount of memory for hugepages as the exact amount to be allocated. Do not specify this value as the amount of memory for hugepages multiplied by the size of the page. For example, given a huge page size of 2MB, if you want to use 100MB of huge-page-backed RAM for your application, then you would allocate 50 huge pages. OpenShift Container Platform handles the math for you. As in the above example, you can specify 100MB directly.

Some platforms support multiple huge page sizes. To allocate huge pages of a specific size, precede the huge pages boot command parameters with a huge page size selection parameter hugepagesz=<size>. The <size> value must be specified in bytes with an optional scale suffix [kKmMgG]. The default huge page size can be defined with the default_hugepagesz=<size> boot parameter. See Configuring Transparent Huge Pages for more information.

Huge page requests must equal the limits. This is the default if limits are specified, but requests are not.
Huge pages are isolated at a pod scope. Container isolation is planned in a future iteration.

**EmptyDir** volumes backed by huge pages must not consume more huge page memory than the pod request.

Applications that consume huge pages via `shmget()` with `SHM_HUGETLB` must run with a supplemental group that matches `proc/sys/vm/hugepages/hugepage_shm_group`.
