### 17.2.10.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

#### Table 17.3. Network parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>networking</strong></td>
<td>The configuration for the cluster network.</td>
<td><strong>Object</strong></td>
</tr>
<tr>
<td><strong>networking.network</strong></td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either <strong>OpenShiftSDN</strong> or <strong>OVNKubernetes</strong>. The default value is <strong>OpenShiftSDN</strong>.</td>
</tr>
</tbody>
</table>
| **networking.clusterNetwork** | The IP address blocks for pods. The default value is **10.128.0.0/14** with a host prefix of /23. If you specify multiple IP address blocks, the blocks must not overlap. | An array of objects. For example: ```json
  networking:
  clusterNetwork:
  - cidr: 10.128.0.0/14
    hostPrefix: 23
``` |
### Parameter Description Values

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking.clusterNetwork.cidr</td>
<td>Required if you use networking.clusterNetwork. An IP address block. An IPv4 network.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td>networking.clusterNetwork.hostPrefix</td>
<td>The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given cidr. A hostPrefix value of 23 provides 510 (2^(32 - 23) - 2) pod IP addresses.</td>
<td>A subnet prefix. The default value is 23.</td>
</tr>
<tr>
<td>networking.serviceNetwork</td>
<td>The IP address block for services. The default value is 172.30.0.0/16. The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.</td>
<td>An array with an IP address block in CIDR format. For example:</td>
</tr>
<tr>
<td>networking.serviceNetwork</td>
<td></td>
<td>networking: serviceNetwork: - 172.30.0.0/16</td>
</tr>
<tr>
<td>networking.machineNetwork</td>
<td>The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap. If you specify multiple IP kernel arguments, the machineNetwork.cidr value must be the CIDR of the primary network.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td>networking.machineNetwork</td>
<td></td>
<td>networking: machineNetwork: - cidr: 10.0.0.0/16</td>
</tr>
<tr>
<td>networking.machineNetwork.cidr</td>
<td>Required if you use networking.machineNetwork. An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24.</td>
<td>An IP network block in CIDR notation. For example, 10.0.0.0/16.</td>
</tr>
</tbody>
</table>

#### 17.2.10.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:
### Table 17.4. Optional parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>cgroupsV2</td>
<td>Enables Linux control groups version 2 (cgroups v2) on specific nodes in your cluster. The OpenShift Container Platform process for enabling cgroups v2 disables all cgroup version 1 controllers and hierarchies. The OpenShift Container Platform cgroups version 2 feature is in Developer Preview and is not supported by Red Hat at this time.</td>
<td>true</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of MachinePool objects.</td>
</tr>
<tr>
<td>compute.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are s390x (the default).</td>
<td>String</td>
</tr>
<tr>
<td>compute.hyperthreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>compute.name</td>
<td>Required if you use <code>compute</code>. The name of the machine pool.</td>
<td>worker</td>
</tr>
</tbody>
</table>

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>compute.platform</td>
<td>Required if you use compute. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the controlPlane.platform parameter value.</td>
<td>alibaba, aws, azure, gcp, ibmcloud, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td>compute.replicas</td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td>controlPlane</td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of MachinePool objects.</td>
</tr>
<tr>
<td>controlPlane.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are s390x (the default).</td>
<td>String</td>
</tr>
<tr>
<td>controlPlane.hypertreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>IMPORTANT</td>
<td>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td></td>
</tr>
<tr>
<td>controlPlane.name</td>
<td>Required if you use controlPlane. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use controlPlane. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the compute.platform parameter value.</td>
<td>alibaba, aws, azure, gcp, ibmcloud, openstack, ovirt, vsphere, or {}</td>
</tr>
</tbody>
</table>
### Parameter Description Values

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (&quot;&quot;&quot;).</td>
</tr>
</tbody>
</table>

**NOTE**

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the *Cloud Credential Operator* entry in the *Platform Operators reference* content.

</tbody>
</table>
How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.

**publish**

How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.

**Internal** or **External**. The default value is **External**.

Setting this field to **Internal** is not supported on non-cloud platforms and IBM Cloud.

**IMPORTANT**

If the value of the field is set to **Internal**, the cluster will become non-functional. For more information, refer to [BZ#1953035](#).

**sshKey**

The SSH key or keys to authenticate access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

One or more keys. For example:

```yaml
sshKey:
  - <key1>
  - <key2>
  - <key3>
```

### 17.2.10.4. Additional Red Hat OpenStack Platform (RHOSP) configuration parameters

Additional RHOSP configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>compute.platform.openstack.rootVolume.size</code></td>
<td>For compute machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.</td>
<td>Integer, for example <strong>30</strong>.</td>
</tr>
<tr>
<td><code>compute.platform.openstack.rootVolume.type</code></td>
<td>For compute machines, the root volume’s type.</td>
<td>String, for example <strong>performance</strong>.</td>
</tr>
</tbody>
</table>
### Parameter | Description | Values
--- | --- | ---
**controlPlane.platform.openstack.rootVolume.size** | For control plane machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage. | Integer, for example 30.

**controlPlane.platform.openstack.rootVolume.type** | For control plane machines, the root volume’s type. | String, for example **performance**.

**platform.openstack.cloud** | The name of the RHOSP cloud to use from the list of clouds in the *clouds.yaml* file. | String, for example **MyCloud**.

**platform.openstack.externalNetwork** | The RHOSP external network name to be used for installation. | String, for example **external**.

**platform.openstack.computeFlavor** | The RHOSP flavor to use for control plane and compute machines. **This property is deprecated.** To use a flavor as the default for all machine pools, add it as the value of the **type** key in the **platform.openstack.defaultMachinePlatform** property. You can also set a flavor value for each machine pool individually. | String, for example **m1.xlarge**.

### 17.2.10.5. Optional RHOSP configuration parameters

Optional RHOSP configuration parameters are described in the following table:

#### Table 17.6. Optional RHOSP parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>compute.platform.openstack.additionalNetworkIDs</strong></td>
<td>Additional networks that are associated with compute machines. Allowed address pairs are not created for additional networks.</td>
<td>A list of one or more UUIDs as strings. For example, <strong>fa806b2f-ac49-4bce-b9db-124bc64209bf</strong>.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>

<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td>platform.openstack.clusterOSImage</td>
<td>The location from which the installer downloads the RHCOS image. You must set this parameter to perform an installation in a restricted network.</td>
<td>An HTTP or HTTPS URL, optionally with an SHA-256 checksum. For example, <a href="http://mirror.example.com/images/rhcos-43.81.201912131630.0-openstack.x86_64.qcow2.gz?sha256=ffebeb68e8a1f2a245ca19522c16c86f67f9ac8e4e0c1f0a812b068b16f7265d">http://mirror.example.com/images/rhcos-43.81.201912131630.0-openstack.x86_64.qcow2.gz?sha256=ffebeb68e8a1f2a245ca19522c16c86f67f9ac8e4e0c1f0a812b068b16f7265d</a>. The value can also be the name of an existing Glance image, for example my-rhcos.</td>
</tr>
<tr>
<td>platform.openstack.clusterOSImageProperties</td>
<td>Properties to add to the installer-uploaded ClusterOSImage in Glance. This property is ignored if platform.openstack.clusterOSImage is set to an existing Glance image. You can use this property to exceed the default persistent volume (PV) limit for RHOSP of 26 PVs per node. To exceed the limit, set the hw_scsi_model property value to virtio-scsi and the hw_disk_bus value to scsi. You can also use this property to enable the QEMU guest agent by including the hw_qemu_guest_agent property with a value of yes.</td>
<td>A list of key-value string pairs. For example, [&quot;hw_scsi_model&quot;: &quot;virtio-scsi&quot;, &quot;hw_disk_bus&quot;: &quot;scsi&quot;].</td>
</tr>
<tr>
<td>platform.openstack.defaultMachinePlatform</td>
<td>The default machine pool platform configuration.</td>
<td>{ &quot;type&quot;: &quot;ml.large&quot;, &quot;rootVolume&quot;: { &quot;size&quot;: 30, &quot;type&quot;: &quot;performance&quot; } }</td>
</tr>
<tr>
<td>platform.openstack.ingressFloatingIP</td>
<td>An existing floating IP address to associate with the Ingress port. To use this property, you must also define the platform.openstack.externalNetwork property.</td>
<td>An IP address, for example 128.0.0.1.</td>
</tr>
</tbody>
</table>
## 17.2.10.6. Custom subnets in RHOSP deployments

Optionally, you can deploy a cluster on a Red Hat OpenStack Platform (RHOSP) subnet of your choice. The subnet’s GUID is passed as the value of `platform.openstack.machinesSubnet` in the `install-config.yaml` file.

This subnet is used as the cluster’s primary subnet. By default, nodes and ports are created on it. You can create nodes and ports on a different RHOSP subnet by setting the value of the `platform.openstack.machinesSubnet` property to the subnet’s UUID.

Before you run the OpenShift Container Platform installer with a custom subnet, verify that your configuration meets the following requirements:

- The subnet that is used by `platform.openstack.machinesSubnet` has DHCP enabled.
- The CIDR of `platform.openstack.machinesSubnet` matches the CIDR of `networking.machineNetwork`.
- The installation program user has permission to create ports on this network, including ports with fixed IP addresses.

Clusters that use custom subnets have the following limitations:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>platform.openstack.apiFloatingIP</code></td>
<td>An existing floating IP address to associate with the API load balancer. To use this property, you must also define the <code>platform.openstack.externalNetwork</code> property.</td>
<td>An IP address, for example 128.0.0.1.</td>
</tr>
<tr>
<td><code>platform.openstack.externalDNS</code></td>
<td>IP addresses for external DNS servers that cluster instances use for DNS resolution.</td>
<td>A list of IP addresses as strings. For example, [&quot;8.8.8.8&quot;, &quot;192.168.1.12&quot;].</td>
</tr>
<tr>
<td><code>platform.openstack.machinesSubnet</code></td>
<td>The UUID of a RHOSP subnet that the cluster’s nodes use. Nodes and virtual IP (VIP) ports are created on this subnet. If you deploy to a custom subnet, you cannot specify an external DNS server to the OpenShift Container Platform installer. Instead, add DNS to the subnet in RHOSP.</td>
<td>A UUID as a string. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf.</td>
</tr>
</tbody>
</table>
If you plan to install a cluster that uses floating IP addresses, the `platform.openstack.machinesSubnet` subnet must be attached to a router that is connected to the `externalNetwork` network.

If the `platform.openstack.machinesSubnet` value is set in the `install-config.yaml` file, the installation program does not create a private network or subnet for your RHOSP machines.

You cannot use the `platform.openstack.externalDNS` property at the same time as a custom subnet. To add DNS to a cluster that uses a custom subnet, configure DNS on the RHOSP network.

**NOTE**

By default, the API VIP takes x.x.x.5 and the Ingress VIP takes x.x.x.7 from your network’s CIDR block. To override these default values, set values for `platform.openstack.apiVIP` and `platform.openstack.ingressVIP` that are outside of the DHCP allocation pool.

17.2.10.7. Deploying a cluster with bare metal machines

If you want your cluster to use bare metal machines, modify the `install-config.yaml` file. Your cluster can have both control plane and compute machines running on bare metal, or just compute machines.

Bare-metal compute machines are not supported on clusters that use Kuryr.

**NOTE**

Be sure that your `install-config.yaml` file reflects whether the RHOSP network that you use for bare metal workers supports floating IP addresses or not.

**Prerequisites**

- The RHOSP Bare Metal service (Ironic) is enabled and accessible via the RHOSP Compute API.
- Bare metal is available as a RHOSP flavor.
- The RHOSP network supports both VM and bare metal server attachment.
- Your network configuration does not rely on a provider network. Provider networks are not supported.
- If you want to deploy the machines on a pre-existing network, a RHOSP subnet is provisioned.
- If you want to deploy the machines on an installer-provisioned network, the RHOSP Bare Metal service (Ironic) is able to listen for and interact with Preboot eXecution Environment (PXE) boot machines that run on tenant networks.
- You created an `install-config.yaml` file as part of the OpenShift Container Platform installation process.

**Procedure**

1. In the `install-config.yaml` file, edit the flavors for machines:
   
   a. If you want to use bare-metal control plane machines, change the value of `controlPlane.platform.openstack.type` to a bare metal flavor.
b. Change the value of `compute.platform.openstack.type` to a bare metal flavor.

c. If you want to deploy your machines on a pre-existing network, change the value of `platform.openstack.machinesSubnet` to the RHOSP subnet UUID of the network. Control plane and compute machines must use the same subnet.

An example bare metal `install-config.yaml` file

```yaml
controlPlane:
  platform:
    openstack:
      type: <bare_metal_control_plane_flavor> ❶

compute:
  - architecture: amd64
    hypervirshc: Enabled
    name: worker
    platform:
      openstack:
        type: <bare_metal_compute_flavor> ❷
    replicas: 3

platform:
  openstack:
    machinesSubnet: <subnet_UUID> ❸
```

1. If you want to have bare-metal control plane machines, change this value to a bare metal flavor.

2. Change this value to a bare metal flavor to use for compute machines.

3. If you want to use a pre-existing network, change this value to the UUID of the RHOSP subnet.

Use the updated `install-config.yaml` file to complete the installation process. The compute machines that are created during deployment use the flavor that you added to the file.

**NOTE**

The installer may time out while waiting for bare metal machines to boot.

If the installer times out, restart and then complete the deployment by using the `wait-for` command of the installer. For example:

```bash
./openshift-install wait-for install-complete --log-level debug
```

### 17.2.10.8. Cluster deployment on RHOSP provider networks

You can deploy your OpenShift Container Platform clusters on Red Hat OpenStack Platform (RHOSP) with a primary network interface on a provider network. Provider networks are commonly used to give
projects direct access to a public network that can be used to reach the internet. You can also share provider networks among projects as part of the network creation process.

RHOSP provider networks map directly to an existing physical network in the data center. A RHOSP administrator must create them.

In the following example, OpenShift Container Platform workloads are connected to a data center by using a provider network:

OpenShift Container Platform clusters that are installed on provider networks do not require tenant networks or floating IP addresses. The installer does not create these resources during installation.

Example provider network types include flat (untagged) and VLAN (802.1Q tagged).

NOTE

A cluster can support as many provider network connections as the network type allows. For example, VLAN networks typically support up to 4096 connections.

You can learn more about provider and tenant networks in the RHOSP documentation.
Before you install an OpenShift Container Platform cluster, your Red Hat OpenStack Platform (RHOSP) deployment and provider network must meet a number of conditions:

- The RHOSP networking service (Neutron) is enabled and accessible through the RHOSP networking API.
- The RHOSP networking service has the port security and allowed address pairs extensions enabled.
- The provider network can be shared with other tenants.

TIP

Use the `openstack network create` command with the `--share` flag to create a network that can be shared.

- The RHOSP project that you use to install the cluster must own the provider network, as well as an appropriate subnet.

TIP

To create a network for a project that is named "openshift," enter the following command:

```bash
$ openstack network create --project openshift
```

To create a subnet for a project that is named "openshift," enter the following command:

```bash
$ openstack subnet create --project openshift
```

To learn more about creating networks on RHOSP, read the provider networks documentation.

If the cluster is owned by the `admin` user, you must run the installer as that user to create ports on the network.

IMPORTANT

Provider networks must be owned by the RHOSP project that is used to create the cluster. If they are not, the RHOSP Compute service (Nova) cannot request a port from that network.

- Verify that the provider network can reach the RHOSP metadata service IP address, which is `169.254.169.254` by default.

Depending on your RHOSP SDN and networking service configuration, you might need to provide the route when you create the subnet. For example:

```bash
$ openstack subnet create --dhcp --host-route
destination=169.254.169.254/32,gateway=192.0.2.2 ...
```

- Optional: To secure the network, create role-based access control (RBAC) rules that limit network access to a single project.
17.2.10.8.2. Deploying a cluster that has a primary interface on a provider network

You can deploy an OpenShift Container Platform cluster that has its primary network interface on an Red Hat OpenStack Platform (RHOSP) provider network. 

Prerequisites

- Your Red Hat OpenStack Platform (RHOSP) deployment is configured as described by "RHOSP provider network requirements for cluster installation".

Procedure

1. In a text editor, open the *install-config.yaml* file.

2. Set the value of the `platform.openstack.apiVIP` property to the IP address for the API VIP.

3. Set the value of the `platform.openstack.ingressVIP` property to the IP address for the Ingress VIP.

4. Set the value of the `platform.openstack.machinesSubnet` property to the UUID of the provider network subnet.

5. Set the value of the `networking.machineNetwork.cidr` property to the CIDR block of the provider network subnet.

**IMPORTANT**

The `platform.openstack.apiVIP` and `platform.openstack.ingressVIP` properties must both be unassigned IP addresses from the `networking.machineNetwork.cidr` block.

Section of an installation configuration file for a cluster that relies on a RHOSP provider network

```yaml
...  
platform:  
  openstack:  
    apiVIP: 192.0.2.13  
    ingressVIP: 192.0.2.23  
    machinesSubnet: fa806b2f-ac49-4bce-b9db-124bc64209bf  
    # ...  
  networking:  
    machineNetwork:  
    - cidr: 192.0.2.0/24
```

**WARNING**

You cannot set the `platform.openstack.externalNetwork` or `platform.openstack.externalDNS` parameters while using a provider network for the primary network interface.

When you deploy the cluster, the installer uses the *install-config.yaml* file to deploy the cluster on the provider network.
TIP

You can add additional networks, including provider networks, to the `platform.openstack.additionalNetworkIDs` list.

After you deploy your cluster, you can attach pods to additional networks. For more information, see [Understanding multiple networks](#).

17.2.10.9. Sample customized `install-config.yaml` file for RHOSP

This sample `install-config.yaml` demonstrates all of the possible Red Hat OpenStack Platform (RHOSP) customization options.

```
apiVersion: v1
baseDomain: example.com
controlPlane:
  name: master
  platform: {}
  replicas: 3
compute:
  - name: worker
    platform:
      openstack:
        type: m1.large
        replicas: 3
metadata:
  name: example
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
      hostPrefix: 23
  machineNetwork:
    - cidr: 10.0.0.0/16
  serviceNetwork:
    - 172.30.0.0/16
networkType: OpenShiftSDN
platform:
  openstack:
    cloud: mycloud
    externalNetwork: external
    computeFlavor: m1.xlarge
    apiFloatingIP: 128.0.0.1
  fips: false
  pullSecret: '{"auths": ...}"
  sshKey: ssh-ed25519 AAAA...
```

17.2.11. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the
installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The ./openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N '' -f <path>/<file_name>  
   ```

   **Note**
   Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

2. View the public SSH key:

   ```bash
   $ cat <path>/<file_name>.pub
   ```

   For example, run the following to view the ~/.ssh/id_rsa.pub public key:

   ```bash
   $ cat ~/.ssh/id_rsa.pub
   ```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the ./openshift-install gather command.

   **NOTE**

   On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.
a. If the `ssh-agent` process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

**Example output**

Agent pid 31874

**NOTE**

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the `ssh-agent`:

```
$ ssh-add <path>/<file_name>
```

Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

**Example output**

Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

### 17.2.12. Enabling access to the environment

At deployment, all OpenShift Container Platform machines are created in a Red Hat OpenStack Platform (RHOSP)-tenant network. Therefore, they are not accessible directly in most RHOSP deployments.

You can configure OpenShift Container Platform API and application access by using floating IP addresses (FIPs) during installation. You can also complete an installation without configuring FIPs, but the installer will not configure a way to reach the API or applications externally.

#### 17.2.12.1. Enabling access with floating IP addresses

Create floating IP (FIP) addresses for external access to the OpenShift Container Platform API and cluster applications.

**Procedure**

1. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the API FIP:

```
$ openstack floating ip create --description "API <cluster_name>.<base_domain>" <external_network>
```
2. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the apps, or Ingress, FIP:

```
$ openstack floating ip create --description "Ingress <cluster_name>.<base_domain>"
<external_network>
```

3. Add records that follow these patterns to your DNS server for the API and Ingress FIPs:

```
api.<cluster_name>.<base_domain>. IN A <API_FIP>
*.apps.<cluster_name>.<base_domain>. IN A <apps_FIP>
```

**NOTE**

If you do not control the DNS server, you can add the record to your `/etc/hosts` file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

4. Add the FIPs to the `install-config.yaml` file as the values of the following parameters:

- `platform.openstack.ingressFloatingIP`
- `platform.openstack.apiFloatingIP`

If you use these values, you must also enter an external network as the value of the `platform.openstack.externalNetwork` parameter in the `install-config.yaml` file.

**TIP**

You can make OpenShift Container Platform resources available outside of the cluster by assigning a floating IP address and updating your firewall configuration.

17.2.12.2. Completing installation without floating IP addresses

You can install OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) without providing floating IP addresses.

In the `install-config.yaml` file, do not define the following parameters:

- `platform.openstack.ingressFloatingIP`
- `platform.openstack.apiFloatingIP`

If you cannot provide an external network, you can also leave `platform.openstack.externalNetwork` blank. If you do not provide a value for `platform.openstack.externalNetwork`, a router is not created for you, and, without additional action, the installer will fail to retrieve an image from Glance. You must configure external connectivity on your own.

If you run the installer from a system that cannot reach the cluster API due to a lack of floating IP addresses or name resolution, installation fails. To prevent installation failure in these cases, you can use a proxy network or run the installer from a system that is on the same network as your machines.
NOTE
You can enable name resolution by creating DNS records for the API and Ingress ports. For example:

```
api.<cluster_name>.<base_domain>. IN A <api_port_IP>
*.apps.<cluster_name>.<base_domain>. IN A <ingress_port_IP>
```

If you do not control the DNS server, you can add the record to your /etc/hosts file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

17.2.13. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

IMPORTANT
You can run the create cluster command of the installation program only once, during initial installation.

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Change to the directory that contains the installation program and initialize the cluster deployment:

```
$ ./openshift-install create cluster --dir <installation_directory> \ 1
  --log-level=info 2
```

   1 For <installation_directory>, specify the location of your customized ./install-config.yaml file.

   2 To view different installation details, specify warn, debug, or error instead of info.

NOTE
If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.

When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the kubeadmin user, display in your terminal.

Example output

```
... INFO Install complete!
```
NOTE

The cluster access and credential information also outputs to
<installation_directory>/openshift_install.log when an installation succeeds.

IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

IMPORTANT

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

17.2.14. Verifying cluster status

You can verify your OpenShift Container Platform cluster’s status during or after installation.

Procedure

1. In the cluster environment, export the administrator’s kubeconfig file:

   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig

   For <installation_directory>, specify the path to the directory that you stored the installation files in.

   The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server.

2. View the control plane and compute machines created after a deployment:
$ oc get nodes

3. View your cluster’s version:

$ oc get clusterversion

4. View your Operators’ status:

$ oc get clusteroperator

5. View all running pods in the cluster:

$ oc get pods -A

17.2.15. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadm` credentials:

   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   $ oc whoami

   **Example output**

   system:admin

**Additional resources**

- See [Accessing the web console](#) for more details about accessing and understanding the OpenShift Container Platform web console.

17.2.16. Telemetry access for OpenShift Container Platform
In OpenShift Container Platform 4.10, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources
- See About remote health monitoring for more information about the Telemetry service

17.2.17. Next steps
- Customize your cluster.
- If necessary, you can opt out of remote health reporting .
- If you need to enable external access to node ports, configure ingress cluster traffic by using a node port.
- If you did not configure RHOSP to accept application traffic over floating IP addresses, configure RHOSP access with floating IP addresses .

17.3. INSTALLING A CLUSTER ON OPENSTACK WITH KURYR

In OpenShift Container Platform version 4.10, you can install a customized cluster on Red Hat OpenStack Platform (RHOSP) that uses Kuryr SDN. To customize the installation, modify parameters in the install-config.yaml before you install the cluster.

17.3.1. Prerequisites
- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You verified that OpenShift Container Platform 4.10 is compatible with your RHOSP version by using the Supported platforms for OpenShift clusters section. You can also compare platform support across different versions by viewing the OpenShift Container Platform on RHOSP support matrix.
- You have a storage service installed in RHOSP, such as block storage (Cinder) or object storage (Swift). Object storage is the recommended storage technology for OpenShift Container Platform registry cluster deployment. For more information, see Optimizing storage.

17.3.2. About Kuryr SDN
Kuryr is a container network interface (CNI) plug-in solution that uses the Neutron and Octavia Red Hat OpenStack Platform (RHOSP) services to provide networking for pods and Services.

Kuryr and OpenShift Container Platform integration is primarily designed for OpenShift Container Platform clusters running on RHOSP VMs. Kuryr improves the network performance by plugging OpenShift Container Platform pods into RHOSP SDN. In addition, it provides interconnectivity between
pods and RHOSP virtual instances.

Kuryr components are installed as pods in OpenShift Container Platform using the *openshift-kuryr* namespace:

- **kuryr-controller** - a single service instance installed on a master node. This is modeled in OpenShift Container Platform as a *Deployment* object.

- **kuryr-cni** - a container installing and configuring Kuryr as a CNI driver on each OpenShift Container Platform node. This is modeled in OpenShift Container Platform as a *DaemonSet* object.

The Kuryr controller watches the OpenShift Container Platform API server for pod, service, and namespace create, update, and delete events. It maps the OpenShift Container Platform API calls to corresponding objects in Neutron and Octavia. This means that every network solution that implements the Neutron trunk port functionality can be used to back OpenShift Container Platform via Kuryr. This includes open source solutions such as Open vSwitch (OVS) and Open Virtual Network (OVN) as well as Neutron-compatible commercial SDNs.

Kuryr is recommended for OpenShift Container Platform deployments on encapsulated RHOSP tenant networks to avoid double encapsulation, such as running an encapsulated OpenShift Container Platform SDN over an RHOSP network.

If you use provider networks or tenant VLANs, you do not need to use Kuryr to avoid double encapsulation. The performance benefit is negligible. Depending on your configuration, though, using Kuryr to avoid having two overlays might still be beneficial.

Kuryr is not recommended in deployments where all of the following criteria are true:

- The RHOSP version is less than 16.
- The deployment uses UDP services, or a large number of TCP services on few hypervisors.

or

- The *ovn-octavia* Octavia driver is disabled.
- The deployment uses a large number of TCP services on few hypervisors.

17.3.3. Resource guidelines for installing OpenShift Container Platform on RHOSP with Kuryr

When using Kuryr SDN, the pods, services, namespaces, and network policies are using resources from the RHOSP quota; this increases the minimum requirements. Kuryr also has some additional requirements on top of what a default install requires.

Use the following quota to satisfy a default cluster’s minimum requirements:

**Table 17.7. Recommended resources for a default OpenShift Container Platform cluster on RHOSP with Kuryr**

<table>
<thead>
<tr>
<th>Resource</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Floating IP addresses</td>
<td>3 - plus the expected number of Services of LoadBalancer type</td>
</tr>
<tr>
<td>Resource</td>
<td>Value</td>
</tr>
<tr>
<td>-------------------</td>
<td>-------------------------------------------------</td>
</tr>
<tr>
<td>Ports</td>
<td>1500 - 1 needed per Pod</td>
</tr>
<tr>
<td>Routers</td>
<td>1</td>
</tr>
<tr>
<td>Subnets</td>
<td>250 - 1 needed per Namespace/Project</td>
</tr>
<tr>
<td>Networks</td>
<td>250 - 1 needed per Namespace/Project</td>
</tr>
<tr>
<td>RAM</td>
<td>112 GB</td>
</tr>
<tr>
<td>vCPUs</td>
<td>28</td>
</tr>
<tr>
<td>Volume storage</td>
<td>275 GB</td>
</tr>
<tr>
<td>Instances</td>
<td>7</td>
</tr>
<tr>
<td>Security groups</td>
<td>250 - 1 needed per Service and per NetworkPolicy</td>
</tr>
<tr>
<td>Security group rules</td>
<td>1000</td>
</tr>
<tr>
<td>Server groups</td>
<td>2 - plus 1 for each additional availability zone in each machine pool</td>
</tr>
<tr>
<td>Load balancers</td>
<td>100 - 1 needed per Service</td>
</tr>
<tr>
<td>Load balancer listeners</td>
<td>500 - 1 needed per Service-exposed port</td>
</tr>
<tr>
<td>Load balancer pools</td>
<td>500 - 1 needed per Service-exposed port</td>
</tr>
</tbody>
</table>

A cluster might function with fewer than recommended resources, but its performance is not guaranteed.

**IMPORTANT**

If RHOSP object storage (Swift) is available and operated by a user account with the `swiftoperator` role, it is used as the default backend for the OpenShift Container Platform image registry. In this case, the volume storage requirement is 175 GB. Swift space requirements vary depending on the size of the image registry.

**IMPORTANT**

If you are using Red Hat OpenStack Platform (RHOSP) version 16 with the Amphora driver rather than the OVN Octavia driver, security groups are associated with service accounts instead of user projects.

Take the following notes into consideration when setting resources:
- The number of ports that are required is larger than the number of pods. Kuryr uses ports pools to have pre-created ports ready to be used by pods and speed up the pods’ booting time.

- Each network policy is mapped into an RHOSP security group, and depending on the NetworkPolicy spec, one or more rules are added to the security group.

- Each service is mapped to an RHOSP load balancer. Consider this requirement when estimating the number of security groups required for the quota. If you are using RHOSP version 15 or earlier, or the ovn-octavia driver, each load balancer has a security group with the user project.

- The quota does not account for load balancer resources (such as VM resources), but you must consider these resources when you decide the RHOSP deployment’s size. The default installation will have more than 50 load balancers; the clusters must be able to accommodate them.
  
  If you are using RHOSP version 16 with the OVN Octavia driver enabled, only one load balancer VM is generated; services are load balanced through OVN flows.

An OpenShift Container Platform deployment comprises control plane machines, compute machines, and a bootstrap machine.

To enable Kuryr SDN, your environment must meet the following requirements:

- Run RHOSP 13+.

- Have Overcloud with Octavia.

- Use Neutron Trunk ports extension.

- Use openvswitch firewall driver if ML2/OVS Neutron driver is used instead of ovs-hybrid.

### 17.3.3.1. Increasing quota

When using Kuryr SDN, you must increase quotas to satisfy the Red Hat OpenStack Platform (RHOSP) resources used by pods, services, namespaces, and network policies.

**Procedure**

- Increase the quotas for a project by running the following command:

  ```
  $ sudo openstack quota set --secgroups 250 --secgroup-rules 1000 --ports 1500 --subnets 250 --networks 250 <project>
  ```

### 17.3.3.2. Configuring Neutron

Kuryr CNI leverages the Neutron Trunks extension to plug containers into the Red Hat OpenStack Platform (RHOSP) SDN, so you must use the trunks extension for Kuryr to properly work.

In addition, if you leverage the default ML2/OVS Neutron driver, the firewall must be set to openvswitch instead of ovs_hybrid so that security groups are enforced on trunk subports and Kuryr can properly handle network policies.

### 17.3.3.3. Configuring Octavia

...
Kuryr SDN uses Red Hat OpenStack Platform (RHOSP)’s Octavia LBaaS to implement OpenShift Container Platform services. Thus, you must install and configure Octavia components in RHOSP to use Kuryr SDN.

To enable Octavia, you must include the Octavia service during the installation of the RHOSP Overcloud, or upgrade the Octavia service if the Overcloud already exists. The following steps for enabling Octavia apply to both a clean install of the Overcloud or an Overcloud update.

**NOTE**

The following steps only capture the key pieces required during the deployment of RHOSP when dealing with Octavia. It is also important to note that registry methods vary.

This example uses the local registry method.

**Procedure**

1. If you are using the local registry, create a template to upload the images to the registry. For example:

   ```bash
   (undercloud) $ openstack overcloud container image prepare
   -e /usr/share/openstack-tripleo-heat-templates/environments/services-docker/octavia.yaml
   --namespace=registry.access.redhat.com/rhosp13
   --push-destination=<local-ip-from-undercloud.conf>:8787
   --prefix=openstack-
   --tag-from-label {version}-{product-version}
   --output-env-file=/home/stack/templates/overcloud_images.yaml
   --output-images-file /home/stack/local_registry_images.yaml
   ...
   - imagename: registry.access.redhat.com/rhosp13/openstack-octavia-api:13.0-43
     push_destination: <local-ip-from-undercloud.conf>:8787
   - imagename: registry.access.redhat.com/rhosp13/openstack-octavia-health-manager:13.0-45
     push_destination: <local-ip-from-undercloud.conf>:8787
   - imagename: registry.access.redhat.com/rhosp13/openstack-octavia-housekeeping:13.0-45
     push_destination: <local-ip-from-undercloud.conf>:8787
   - imagename: registry.access.redhat.com/rhosp13/openstack-octavia-worker:13.0-44
     push_destination: <local-ip-from-undercloud.conf>:8787
   (undercloud) $ sudo openstack overcloud container image upload
   --config-file /home/stack/local_registry_images.yaml
   --verbose
   ```

   This may take some time depending on the speed of your network and Undercloud disk.

   **NOTE**

   The Octavia container versions vary depending upon the specific RHOSP release installed.

2. Verify that the `local_registry_images.yaml` file contains the Octavia images. For example:

   ```yaml
   ...
   - imagename: registry.access.redhat.com/rhosp13/openstack-octavia-api:13.0-43
     push_destination: <local-ip-from-undercloud.conf>:8787
   - imagename: registry.access.redhat.com/rhosp13/openstack-octavia-health-manager:13.0-45
     push_destination: <local-ip-from-undercloud.conf>:8787
   - imagename: registry.access.redhat.com/rhosp13/openstack-octavia-housekeeping:13.0-45
     push_destination: <local-ip-from-undercloud.conf>:8787
   - imagename: registry.access.redhat.com/rhosp13/openstack-octavia-worker:13.0-44
     push_destination: <local-ip-from-undercloud.conf>:8787
   ```

3. Pull the container images from `registry.redhat.io` to the Undercloud node:

   ```bash
   (undercloud) $ sudo openstack overcloud container image upload
   --config-file /home/stack/local_registry_images.yaml
   --verbose
   ```

   This may take some time depending on the speed of your network and Undercloud disk.
4. Since an Octavia load balancer is used to access the OpenShift Container Platform API, you must increase their listeners’ default timeouts for the connections. The default timeout is 50 seconds. Increase the timeout to 20 minutes by passing the following file to the Overcloud deploy command:

   ```yaml
   (undercloud) $ cat octavia_timeouts.yaml
   parameter_defaults:
     OctaviaTimeoutClientData: 1200000
     OctaviaTimeoutMemberData: 1200000
   ```

   **NOTE**
   This is not needed for RHOSP 13.0.13+.

5. Install or update your Overcloud environment with Octavia:

   ```bash
   $ openstack overcloud deploy --templates \
   -e /usr/share/openstack-tripleo-heat-templates/environments/services-docker/octavia.yaml \
   -e octavia_timeouts.yaml
   ```

   **NOTE**
   This command only includes the files associated with Octavia; it varies based on your specific installation of RHOSP. See the RHOSP documentation for further information. For more information on customizing your Octavia installation, see installation of Octavia using Director.

   **NOTE**
   When leveraging Kuryr SDN, the Overcloud installation requires the Neutron trunk extension. This is available by default on director deployments. Use the opensvswitch firewall instead of the default ovs-hybrid when the Neutron backend is ML2/OVS. There is no need for modifications if the backend is ML2/OVN.

6. In RHOSP versions earlier than 13.0.13, add the project ID to the octavia.conf configuration file after you create the project.

   - To enforce network policies across services, like when traffic goes through the Octavia load balancer, you must ensure Octavia creates the Amphora VM security groups on the user project.
     This change ensures that required load balancer security groups belong to that project, and that they can be updated to enforce services isolation.

   **NOTE**
   This task is unnecessary in RHOSP version 13.0.13 or later.

   Octavia implements a new ACL API that restricts access to the load balancers VIP.

   a. Get the project ID
b. Add the project ID to `octavia.conf` for the controllers.

i. Source the `stackrc` file:

   ```
   $ source stackrc  # Undercloud credentials
   ```

ii. List the Overcloud controllers:

   ```
   $ openstack server list
   ```

   **Example output**

   ```
   +--------------------------------------+--------------+--------+-----------------------+-------+
   | ID                                   | Name         | Status | Networks              |-------+
   | Image | Flavor               |          |                        |-------+
   +--------------------------------------+--------------+--------+-----------------------+-------+
   | 6bef8e73-2ba5-4860-a0b1-3937f8ca7e01 | controller-0 | ACTIVE | ctlplane=192.168.24.8 | overcloud-full | controller |
   | dda3173a-ab26-47f8-a2dc-8473b4a67ab9 | compute-0 | ACTIVE | ctlplane=192.168.24.6 | overcloud-full | compute |
   +--------------------------------------+--------------+--------+-----------------------+-------+
   ```

iii. SSH into the controller(s).

   ```
   $ ssh heat-admin@192.168.24.8
   ```

iv. Edit the `octavia.conf` file to add the project into the list of projects where Amphora security groups are on the user’s account.

```
# List of project IDs that are allowed to have Load balancer security groups belonging to them.
amp_secgroup_allowed_projects = PROJECT_ID

c. Restart the Octavia worker so the new configuration loads.
controller-0$ sudo docker restart octavia_worker

**NOTE**
Depending on your RHOSP environment, Octavia might not support UDP listeners. If you use Kuryr SDN on RHOSP version 13.0.13 or earlier, UDP services are not supported. RHOSP version 16 or later support UDP.

17.3.3.1. The Octavia OVN Driver

Octavia supports multiple provider drivers through the Octavia API.

To see all available Octavia provider drivers, on a command line, enter:

```
$ openstack loadbalancer provider list
```

**Example output**

```
+---------+-------------------------------------------------+
| name    | description                                     |
+---------+-------------------------------------------------+
| amphora | The Octavia Amphora driver.                     |
| octavia | Deprecated alias of the Octavia Amphora driver. |
| ovn     | Octavia OVN driver.                             |
+---------+-------------------------------------------------+
```

Beginning with RHOSP version 16, the Octavia OVN provider driver (**ovn**) is supported on OpenShift Container Platform on RHOSP deployments.

**ovn** is an integration driver for the load balancing that Octavia and OVN provide. It supports basic load balancing capabilities, and is based on OpenFlow rules. The driver is automatically enabled in Octavia by Director on deployments that use OVN Neutron ML2.

The Amphora provider driver is the default driver. If **ovn** is enabled, however, Kuryr uses it.

If Kuryr uses **ovn** instead of Amphora, it offers the following benefits:

- Decreased resource requirements. Kuryr does not require a load balancer VM for each service.
- Reduced network latency.
- Increased service creation speed by using OpenFlow rules instead of a VM for each service.
- Distributed load balancing actions across all nodes instead of centralized on Amphora VMs.

You can **configure your cluster to use the Octavia OVN driver** after your RHOSP cloud is upgraded from version 13 to version 16.
17.3.3.4. Known limitations of installing with Kuryr

Using OpenShift Container Platform with Kuryr SDN has several known limitations.

**RHOSP general limitations**
Using OpenShift Container Platform with Kuryr SDN has several limitations that apply to all versions and environments:

- **Service** objects with the **NodePort** type are not supported.

- Clusters that use the OVN Octavia provider driver support **Service** objects for which the `.spec.selector` property is unspecified only if the `.subsets.addresses` property of the **Endpoints** object includes the subnet of the nodes or pods.

- If the subnet on which machines are created is not connected to a router, or if the subnet is connected, but the router has no external gateway set, Kuryr cannot create floating IPs for **Service** objects with type **LoadBalancer**.

- Configuring the `sessionAffinity=ClientIP` property on **Service** objects does not have an effect. Kuryr does not support this setting.

**RHOSP version limitations**
Using OpenShift Container Platform with Kuryr SDN has several limitations that depend on the RHOSP version.

- RHOSP versions before 16 use the default Octavia load balancer driver (Amphora). This driver requires that one Amphora load balancer VM is deployed per OpenShift Container Platform service. Creating too many services can cause you to run out of resources. Deployments of later versions of RHOSP that have the OVN Octavia driver disabled also use the Amphora driver. They are subject to the same resource concerns as earlier versions of RHOSP.

- Octavia RHOSP versions before 13.0.13 do not support UDP listeners. Therefore, OpenShift Container Platform UDP services are not supported.

- Octavia RHOSP versions before 13.0.13 cannot listen to multiple protocols on the same port. Services that expose the same port to different protocols, like TCP and UDP, are not supported.

- Kuryr SDN does not support automatic unidling by a service.

**RHOSP environment limitations**
There are limitations when using Kuryr SDN that depend on your deployment environment.

Because of Octavia’s lack of support for the UDP protocol and multiple listeners, if the RHOSP version is earlier than 13.0.13, Kuryr forces pods to use TCP for DNS resolution.

In Go versions 1.12 and earlier, applications that are compiled with CGO support disabled use UDP only. In this case, the native Go resolver does not recognize the `use-vc` option in `resolv.conf`, which controls whether TCP is forced for DNS resolution. As a result, UDP is still used for DNS resolution, which fails.

To ensure that TCP forcing is allowed, compile applications either with the environment variable `CGO_ENABLED` set to 1, i.e. `CGO_ENABLED=1`, or ensure that the variable is absent.

In Go versions 1.13 and later, TCP is used automatically if DNS resolution using UDP fails.
NOTE

musl-based containers, including Alpine-based containers, do not support the use-vc option.

RHOSP upgrade limitations
As a result of the RHOSP upgrade process, the Octavia API might be changed, and upgrades to the Amphora images that are used for load balancers might be required.

You can address API changes on an individual basis.

If the Amphora image is upgraded, the RHOSP operator can handle existing load balancer VMs in two ways:

- Upgrade each VM by triggering a load balancer failover.
- Leave responsibility for upgrading the VMs to users.

If the operator takes the first option, there might be short downtimes during failovers.

If the operator takes the second option, the existing load balancers will not support upgraded Octavia API features, like UDP listeners. In this case, users must recreate their Services to use these features.

IMPORTANT

If OpenShift Container Platform detects a new Octavia version that supports UDP load balancing, it recreates the DNS service automatically. The service recreation ensures that the service default supports UDP load balancing.

The recreation causes the DNS service approximately one minute of downtime.

17.3.3.5. Control plane and compute machines

By default, the OpenShift Container Platform installation process stands up three control plane and three compute machines.

Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 25 GB storage space

TIP

Compute machines host the applications that you run on OpenShift Container Platform; aim to run as many as you can.

17.3.3.6. Bootstrap machine

During installation, a bootstrap machine is temporarily provisioned to stand up the control plane. After the production control plane is ready, the bootstrap machine is deprovisioned.

The bootstrap machine requires:
17.3.4. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.10, you require access to the internet to obtain the images that are necessary to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

17.3.5. Enabling Swift on RHOSP

Swift is operated by a user account with the `swiftoperator` role. Add the role to an account before you run the installation program.

**IMPORTANT**

If the Red Hat OpenStack Platform (RHOSP) object storage service, commonly known as Swift, is available, OpenShift Container Platform uses it as the image registry storage. If it is unavailable, the installation program relies on the RHOSP block storage service, commonly known as Cinder.

If Swift is present and you want to use it, you must enable access to it. If it is not present, or if you do not want to use it, skip this section.

**Prerequisites**

- You have a RHOSP administrator account on the target environment.
- The Swift service is installed.
- On Ceph RGW, the `account in url` option is enabled.

**Procedure**

To enable Swift on RHOSP:
1. As an administrator in the RHOSP CLI, add the **swiftoperator** role to the account that will access Swift:

   ```bash
   $ openstack role add --user <user> --project <project> swiftoperator
   ```

   Your RHOSP deployment can now use Swift for the image registry.

### 17.3.6. Verifying external network access

The OpenShift Container Platform installation process requires external network access. You must provide an external network value to it, or deployment fails. Before you begin the process, verify that a network with the external router type exists in Red Hat OpenStack Platform (RHOSP).

**Prerequisites**

- Configure OpenStack’s networking service to have DHCP agents forward instances' DNS queries

**Procedure**

1. Using the RHOSP CLI, verify the name and ID of the 'External' network:

   ```bash
   $ openstack network list --long -c ID -c Name -c "Router Type"
   ```

   **Example output**

   ```
   +--------------------------------------+----------------+-------------+
   | ID                                   | Name           | Router Type |
   +--------------------------------------+----------------+-------------+
   | 148a8023-62a7-4672-b018-003462f8d7dc | public_network | External    |
   +--------------------------------------+----------------+-------------+
   ```

   A network with an external router type appears in the network list. If at least one does not, see Creating a default floating IP network and Creating a default provider network.

**IMPORTANT**

If the external network’s CIDR range overlaps one of the default network ranges, you must change the matching network ranges in the `install-config.yaml` file before you start the installation process.

The default network ranges are:

<table>
<thead>
<tr>
<th>Network</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>machineNetwork</td>
<td>10.0.0.0/16</td>
</tr>
<tr>
<td>serviceNetwork</td>
<td>172.30.0.0/16</td>
</tr>
<tr>
<td>clusterNetwork</td>
<td>10.128.0.0/14</td>
</tr>
</tbody>
</table>
WARNING

If the installation program finds multiple networks with the same name, it sets one of them at random. To avoid this behavior, create unique names for resources in RHOSP.

NOTE

If the Neutron trunk service plug-in is enabled, a trunk port is created by default. For more information, see Neutron trunk port.

17.3.7. Defining parameters for the installation program

The OpenShift Container Platform installation program relies on a file that is called clouds.yaml. The file describes Red Hat OpenStack Platform (RHOSP) configuration parameters, including the project name, log in information, and authorization service URLs.

Procedure

1. Create the clouds.yaml file:

   - If your RHOSP distribution includes the Horizon web UI, generate a clouds.yaml file in it.

     IMPORTANT

     Remember to add a password to the auth field. You can also keep secrets in a separate file from clouds.yaml.

   - If your RHOSP distribution does not include the Horizon web UI, or you do not want to use Horizon, create the file yourself. For detailed information about clouds.yaml, see Config files in the RHOSP documentation.

```yaml
clouds:
  shiftstack:
    auth:
      auth_url: http://10.10.42.5000/v3
      project_name: shiftstack
      username: shiftstack_user
      password: XXX
      user_domain_name: Default
      project_domain_name: Default
  dev-env:
    region_name: RegionOne
    auth:
      username: 'devuser'
      password: XXX
      project_name: 'devonly'
      auth_url: 'https://10.10.22:5001/v2.0'
```
2. If your RHOSP installation uses self-signed certificate authority (CA) certificates for endpoint authentication:
   a. Copy the certificate authority file to your machine.
   b. Add the `cacerts` key to the `clouds.yaml` file. The value must be an absolute, non-root-accessible path to the CA certificate:

```yaml
clouds:
  shiftstack:
    ...
  cacert: "/etc/pki/ca-trust/source/anchors/ca.crt.pem"
```

**TIP**

After you run the installer with a custom CA certificate, you can update the certificate by editing the value of the `ca-cert.pem` key in the `cloud-provider-config` keymap. On a command line, run:

```
$ oc edit configmap -n openshift-config cloud-provider-config
```

3. Place the `clouds.yaml` file in one of the following locations:
   a. The value of the `OS_CLIENT_CONFIG_FILE` environment variable
   b. The current directory
   c. A Unix-specific user configuration directory, for example `~/.config/openstack/clouds.yaml`
   d. A Unix-specific site configuration directory, for example `/etc/openstack/clouds.yaml`

The installation program searches for `clouds.yaml` in that order.

### 17.3.8. Setting cloud provider options

Optionally, you can edit the cloud provider configuration for your cluster. The cloud provider configuration controls how OpenShift Container Platform interacts with Red Hat OpenStack Platform (RHOSP).

For a complete list of cloud provider configuration parameters, see the `cloud.conf` specification.

#### Procedure

1. If you have not already generated manifest files for your cluster, generate them by running the following command:

   ```
   $ openshift-install --dir <destination_directory> create manifests
   ```

2. In a text editor, open the cloud-provider configuration manifest file. For example:

   ```
   $ vi openshift/manifests/cloud-provider-config.yaml
   ```

3. Modify the options based on the `cloud.conf` specification.
   Configuring Octavia for load balancing is a common case. For example:

   ```yaml
clouds:
  shiftstack:
    ...
  octavia:
    enable: true
    loadbalancers:
      - name: lb-name
        vip: 10.10.10.10
        pool: pool-name
        members:
          - name: server-name
            ip: 10.10.10.11
            port: 80
```
This property enables Octavia integration.

This property sets the Octavia provider that your load balancer uses. It accepts "ovn" or "amphora" as values. If you choose to use OVN, you must also set lb-method to SOURCE_IP_PORT.

This property is required if you want to use multiple external networks with your cluster. The cloud provider creates floating IP addresses on the network that is specified here.

**IMPORTANT**

Prior to saving your changes, verify that the file is structured correctly. Clusters might fail if properties are not placed in the appropriate section.

4. Save the changes to the file and proceed with installation.

TIP

You can update your cloud provider configuration after you run the installer. On a command line, run:

```
$ oc edit configmap -n openshift-config cloud-provider-config
```

After you save your changes, your cluster will take some time to reconfigure itself. The process is complete if none of your nodes have a `SchedulingDisabled` status.

### 17.3.9. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the mirror host.

**Prerequisites**

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space

**Procedure**

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.
IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```bash
$ tar -xvf openshift-install-linux.tar.gz
```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

17.3.10. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Red Hat OpenStack Platform (RHOSP).

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster. For a restricted network installation, these files are on your mirror host.
- Have the `imageContentSources` values that were generated during mirror registry creation.
- Obtain the contents of the certificate for your mirror registry.
- Retrieve a Red Hat Enterprise Linux CoreOS (RHCOS) image and upload it to an accessible location.
- Obtain service principal permissions at the subscription level.

Procedure

1. Create the `install-config.yaml` file.
   
a. Change to the directory that contains the installation program and run the following command:

```bash
$ ./openshift-install create install-config --dir <installation_directory>
```

   1. For `<installation_directory>`, specify the directory name to store the files that the installation program creates.
IMPORTANT

Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

b. At the prompts, provide the configuration details for your cloud:

   i. Optional: Select an SSH key to use to access your cluster machines.

   NOTE

   For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

   ii. Select openstack as the platform to target.

   iii. Specify the Red Hat OpenStack Platform (RHOSP) external network name to use for installing the cluster.

   iv. Specify the floating IP address to use for external access to the OpenShift API.

   v. Specify a RHOSP flavor with at least 16 GB RAM to use for control plane and compute nodes.

   vi. Select the base domain to deploy the cluster to. All DNS records will be sub-domains of this base and will also include the cluster name.

   vii. Enter a name for your cluster. The name must be 14 or fewer characters long.

   viii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

2. In the install-config.yaml file, set the value of platform.openstack.clusterOSImage to the image location or name. For example:

   ```yaml
   platform:
   openstack:
    clusterOSImage: http://mirror.example.com/images/rhcos-43.81.201912131630.0-
                       openstack.x86_64.qcow2.gz?
    sha256=febb68e8a1f2a245ca19522c16c86f67f9ac8e4e0c1f0a812b068b16f7265d
   ```

3. Edit the install-config.yaml file to provide the additional information that is required for an installation in a restricted network.

   a. Update the pullSecret value to contain the authentication information for your registry:

   ```yaml
   pullSecret: "{"auths":<{mirror_host_name>:5000>: {"auth": "<credentials>","email":
                             "you@example.com"}}"
   ```

For <mirror_host_name> specify the registry domain name that you specified in the
For `<mirror_host_name>`, specify the registry domain name that you specified in the certificate for your mirror registry, and for `<credentials>`, specify the base64-encoded user name and password for your mirror registry.

b. Add the `additionalTrustBundle` parameter and value.

```
additionalTrustBundle: |
-----BEGIN CERTIFICATE-----
ZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZ
-----END CERTIFICATE-----
```

The value must be the contents of the certificate file that you used for your mirror registry, which can be an existing, trusted certificate authority or the self-signed certificate that you generated for the mirror registry.

c. Add the image content resources, which look like this excerpt:

```
imageContentSources:
  - mirrors:
    - <mirror_host_name>:5000/<repo_name>/release
      source: quay.example.com/openshift-release-dev/ocp-release
    - mirrors:
      - <mirror_host_name>:5000/<repo_name>/release
      source: registry.example.com/ocp/release
```

To complete these values, use the `imageContentSources` that you recorded during mirror registry creation.

4. Make any other modifications to the `install-config.yaml` file that you require. You can find more information about the available parameters in the Installation configuration parameters section.

5. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

**IMPORTANT**

The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

17.3.10.1. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**NOTE**

Kuryr installations default to HTTP proxies.

**Prerequisites**

- For Kuryr installations on restricted networks that use the `Proxy` object, the proxy must be able to reply to the router that the cluster uses. To add a static route for the proxy configuration, from a command line as the root user, enter:
$ ip route add <cluster_network_cidr> via <installer_subnet_gateway>

- The restricted subnet must have a gateway that is defined and available to be linked to the **Router** resource that Kuryr creates.

- You have an existing **install-config.yaml** file.

- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object’s **spec.noProxy** field to bypass the proxy if necessary.

**NOTE**

The **Proxy** object **status.noProxy** field is populated with the values of the networking.machineNetwork[].cidr, networking.clusterNetwork[].cidr, and networking.serviceNetwork[] fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (169.254.169.254).

**Procedure**

1. Edit your **install-config.yaml** file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port>  # 1
  httpsProxy: https://<username>:<pswd>@<ip>:<port>  # 2
  noProxy: example.com  # 3
additionalTrustBundle: |
  -----BEGIN CERTIFICATE-----
  <MY_TRUSTED_CA_CERT>
  -----END CERTIFICATE-----

# 1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.
# 2 A proxy URL to use for creating HTTPS connections outside the cluster.
# 3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.
# 4 If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the **trustedCA** field of the **Proxy** object. The **additionalTrustBundle** field is required unless
```
the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

NOTE
The installation program does not support the proxy `readinessEndpoints` field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

NOTE
Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

### 17.3.11. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide a customized `install-config.yaml` installation configuration file that describes the details for your environment.

NOTE
After installation, you cannot modify these parameters in the `install-config.yaml` file.

### 17.3.11.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

**Table 17.8. Required parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is <code>v1</code>. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the baseDomain and metadata.name parameter values that uses the &lt;metadata.name&gt;.&lt;baseDomain&gt; format.</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
</tr>
<tr>
<td>metadata</td>
<td>Kubernetes resource ObjectMeta, from which only the name parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of {{metadata.name}}.&lt;baseDomain&gt;.</td>
<td>String of lowercase letters, hyphens (-), and periods (.), such as dev. The string must be 14 characters or fewer long.</td>
</tr>
<tr>
<td>platform</td>
<td>The configuration for the specific platform upon which to perform the installation: alibabacloud, aws, baremetal, azure, ibmcloud, openstack, ovirt, vsphere, or {}. For additional information about platform.&lt;platform&gt; parameters, consult the table for your specific platform that follows.</td>
<td>Object</td>
</tr>
</tbody>
</table>
Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.

### Parameter: pullSecret

Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.

```json
{
   "auths":{
      "cloud.openshift.com":{
         "auth":"b3Blb=",
         "email":"you@example.com"
      },
      "quay.io":{
         "auth":"b3Blb=",
         "email":"you@example.com"
      }
   }
}
```

#### 17.3.11.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

**Table 17.9. Network parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong></td>
<td>You cannot modify parameters specified by the networking object after installation.</td>
</tr>
<tr>
<td>networking.networkType</td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN.</td>
</tr>
<tr>
<td>networking.clusterNetwork</td>
<td>The IP address blocks for pods.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td>The default value is 10.128.0.0/14 with a host prefix of /23.</td>
<td>networking:</td>
</tr>
<tr>
<td></td>
<td>If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td>clusterNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- cidr: 10.128.0.0/14</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- hostPrefix: 23</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>----------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------</td>
</tr>
<tr>
<td>networking.clusterNetwork.cidr</td>
<td>Required if you use <code>networking.clusterNetwork</code>. An IP address block.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td>networking.clusterNetwork.hostPrefix</td>
<td>The subnet prefix length to assign to each individual node. For example, if <code>hostPrefix</code> is set to 23 then each node is assigned a /23 subnet out of the given <code>cidr</code>. A <code>hostPrefix</code> value of 23 provides 510 ((2^{32 - 23}) - 2) pod IP addresses.</td>
<td>A subnet prefix. The default value is 23.</td>
</tr>
<tr>
<td>networking.serviceNetwork</td>
<td>The IP address block for services. The default value is 172.30.0.0/16.</td>
<td>An array with an IP address block in CIDR format. For example:</td>
</tr>
<tr>
<td></td>
<td>The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.</td>
<td>networking: serviceNetwork: - 172.30.0.0/16</td>
</tr>
<tr>
<td>networking.machineNetwork</td>
<td>The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap. If you specify multiple IP kernel arguments, the <code>machineNetwork.cidr</code> value must be the CIDR of the primary network.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td>An array of objects. For example:</td>
<td>networking: machineNetwork: - cidr: 10.0.0.0/16</td>
</tr>
<tr>
<td>networking.machineNetwork.cidr</td>
<td>Required if you use <code>networking.machineNetwork</code>. An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24.</td>
<td>An IP network block in CIDR notation. For example, 10.0.0.0/16.</td>

### 17.3.11.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>cgroupsV2</td>
<td>Enables Linux control groups version 2 (cgroups v2) on specific nodes in your cluster. The OpenShift Container Platform process for enabling cgroups v2 disables all cgroup version 1 controllers and hierarchies. The OpenShift Container Platform cgroups version 2 feature is in Developer Preview and is not supported by Red Hat at this time.</td>
<td>true</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of MachinePool objects.</td>
</tr>
<tr>
<td>compute.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are s390x (the default).</td>
<td>String</td>
</tr>
<tr>
<td>compute.hyperthreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>compute.name</td>
<td>Required if you use compute. The name of the machine pool.</td>
<td>worker</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------</td>
</tr>
<tr>
<td>compute.platform</td>
<td>Required if you use compute. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the controlPlane.platform parameter value.</td>
<td>alibaba, aws, azure, gcp, ibmcloud, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td>compute.replicas</td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td>controlPlane</td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of MachinePool objects.</td>
</tr>
<tr>
<td>controlPlane.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are s390x (the default).</td>
<td>String</td>
</tr>
<tr>
<td>controlPlane.hypertreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>controlPlane.name</td>
<td>Required if you use controlPlane. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use controlPlane. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the compute.platform parameter value.</td>
<td>alibaba, aws, azure, gcp, ibmcloud, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>----------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------------------------------------------</td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (&quot;&quot;).</td>
</tr>
</tbody>
</table>

**NOTE**

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the *Cloud Credential Operator* entry in the *Platform Operators reference content*. 
<table>

</tr>
<tr>
<td>imageContentSources.source</td>
<td>Required if you use <strong>imageContentSources</strong>. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td><strong>String</strong></td>
</tr>
<tr>
<td>imageContentSources.mirrors</td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td><strong>Array of strings</strong></td>
</tr>
</tbody>
</table>
How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.

**Internal** or **External**. The default value is **External**.

Setting this field to **Internal** is not supported on non-cloud platforms and IBM Cloud.

**IMPORTANT**

If the value of the field is set to **Internal**, the cluster will become non-functional. For more information, refer to [BZ#1953035](#).

The SSH key or keys to authenticate access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

One or more keys. For example:

```
sshKey:
  - <key1>
  - <key2>
  - <key3>
```

### 17.3.11.4. Additional Red Hat OpenStack Platform (RHOSP) configuration parameters

Additional RHOSP configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>compute.platform.openstack.rootVolume.size</code></td>
<td>For compute machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.</td>
<td>Integer, for example <strong>30</strong>.</td>
</tr>
<tr>
<td><code>compute.platform.openstack.rootVolume.type</code></td>
<td>For compute machines, the root volume’s type.</td>
<td>String, for example <strong>performance</strong>.</td>
</tr>
</tbody>
</table>
For control plane machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.

- controlPlane.platform.openstack.rootVolume.size
  - Integer, for example 30.

For control plane machines, the root volume’s type.

- controlPlane.platform.openstack.rootVolume.type
  - String, for example performance.

The name of the RHOSP cloud to use from the list of clouds in the clouds.yaml file.

- platform.openstack.cloud
  - String, for example MyCloud.

The RHOSP external network name to be used for installation.

- platform.openstack.externalNetwork
  - String, for example external.

The RHOSP flavor to use for control plane and compute machines.

- platform.openstack.computeFlavor
  - String, for example m1.xlarge.

This property is deprecated. To use a flavor as the default for all machine pools, add it as the value of the type key in the platform.openstack.defaultMachinePlatform property. You can also set a flavor value for each machine pool individually.

### 17.3.11.5. Optional RHOSP configuration parameters

Optional RHOSP configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>compute.platform.openstack.additionalNetworkIDs</td>
<td>Additional networks that are associated with compute machines. Allowed address pairs are not created for additional networks.</td>
<td>A list of one or more UUIDs as strings. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>------------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>compute.platform.openstack.additionalSecurityGroupIDs</code></td>
<td>Additional security groups that are associated with compute machines.</td>
<td>A list of one or more UUIDs as strings. For example, 7ee219f3-d2e9-48a1-96c2-e7429f1b0da7.</td>
</tr>
<tr>
<td><code>compute.platform.openstack.zones</code></td>
<td>RHOSP Compute (Nova) availability zones (AZs) to install machines on. If this parameter is not set, the installer relies on the default settings for Nova that the RHOSP administrator configured. On clusters that use Kuryr, RHOSP Octavia does not support availability zones. Load balancers and, if you are using the Amphora provider driver, OpenShift Container Platform services that rely on Amphora VMs, are not created according to the value of this property.</td>
<td>A list of strings. For example, [&quot;zone-1&quot;, &quot;zone-2&quot;].</td>
</tr>
<tr>
<td><code>compute.platform.openstack.rootVolume.zones</code></td>
<td>For compute machines, the availability zone to install root volumes on. If you do not set a value for this parameter, the installer selects the default availability zone.</td>
<td>A list of strings, for example [&quot;zone-1&quot;, &quot;zone-2&quot;].</td>
</tr>
</tbody>
</table>
### Parameter | Description | Values
---|---|---
**compute.platform.openstack.serverGroupPolicy** | Server group policy to apply to the group that will contain the compute machines in the pool. You cannot change server group policies or affiliations after creation. Supported options include **anti-affinity**, **soft-affinity**, and **soft-anti-affinity**. The default value is **soft-anti-affinity**. An **affinity** policy prevents migrations and therefore affects RHOSP upgrades. The **affinity** policy is not supported. If you use a strict **anti-affinity** policy, an additional RHOSP host is required during instance migration. | A server group policy to apply to the machine pool. For example, **soft-affinity**.

**controlPlane.platform.openstack.additionalNetworkIDs** | Additional networks that are associated with control plane machines. Allowed address pairs are not created for additional networks. | A list of one or more UUIDs as strings. For example, `fa806b2f-ac49-4bce-b9db-124bc64209bf`.

**controlPlane.platform.openstack.additionalSecurityGroupIDs** | Additional security groups that are associated with control plane machines. | A list of one or more UUIDs as strings. For example, `7ee219f3-d2e9-48a1-96c2-e7429f1b0da7`.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
</table>
| `controlPlane.plat form.openstack.zones`      | RHOSP Compute (Nova) availability zones (AZs) to install machines on. If this parameter is not set, the installer relies on the default settings for Nova that the RHOSP administrator configured.  
On clusters that use Kuryr, RHOSP Octavia does not support availability zones. Load balancers and, if you are using the Amphora provider driver, OpenShift Container Platform services that rely on Amphora VMs, are not created according to the value of this property. | A list of strings. For example, ["zone-1", "zone-2"]. |
| `controlPlane.plat form.openstack.rootVolume.zones` | For control plane machines, the availability zone to install root volumes on. If you do not set this value, the installer selects the default availability zone.                                                                 | A list of strings, for example ["zone-1", "zone-2"]. |
| `controlPlane.plat form.openstack.serverGroupPolicy` | Server group policy to apply to the group that will contain the control plane machines in the pool. You cannot change server group policies or affiliations after creation. Supported options include anti-affinity, soft-affinity, and soft-anti-affinity. The default value is soft-anti-affinity.  
An affinity policy prevents migrations, and therefore affects RHOSP upgrades. The affinity policy is not supported.  
If you use a strict anti-affinity policy, an additional RHOSP host is required during instance migration. | A server group policy to apply to the machine pool. For example, soft-affinity. |
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>platform.openstack.clusterOSImage</td>
<td>The location from which the installer downloads the RHCOS image. You must set this parameter to perform an installation in a restricted network.</td>
<td>An HTTP or HTTPS URL, optionally with an SHA-256 checksum. For example, <a href="http://mirror.example.com/images/rhcos-43.81.201912131630.0-openstack.x86_64.qcow2.gz?sha256=ffebbd68e8a1f2a245ca19522c16c86f67f9ac8e4e0c1f0a812b068b16f7265d">http://mirror.example.com/images/rhcos-43.81.201912131630.0-openstack.x86_64.qcow2.gz?sha256=ffebbd68e8a1f2a245ca19522c16c86f67f9ac8e4e0c1f0a812b068b16f7265d</a>. The value can also be the name of an existing Glance image, for example my-rhcos.</td>
</tr>
<tr>
<td>platform.openstack.clusterOSImageProperties</td>
<td>Properties to add to the installer-uploaded ClusterOSImage in Glance. This property is ignored if platform.openstack.clusterOSImage is set to an existing Glance image. You can use this property to exceed the default persistent volume (PV) limit for RHOSP of 26 PVs per node. To exceed the limit, set the hw_scsi_model property value to virtio-scsi and the hw_disk_bus value to scsi. You can also use this property to enable the QEMU guest agent by including the hw_qemu_guest_agent property with a value of yes.</td>
<td>A list of key-value string pairs. For example, [&quot;hw_scsi_model&quot;: &quot;virtio-scsi&quot;, &quot;hw_disk_bus&quot;: &quot;scsi&quot;].</td>
</tr>
<tr>
<td>platform.openstack.defaultMachinePlatform</td>
<td>The default machine pool platform configuration.</td>
<td>{ &quot;type&quot;: &quot;ml.large&quot;, &quot;rootVolume&quot;: { &quot;size&quot;: 30, &quot;type&quot;: &quot;performance&quot; } }</td>
</tr>
<tr>
<td>platform.openstack.ingressFloatingIP</td>
<td>An existing floating IP address to associate with the Ingress port. To use this property, you must also define the platform.openstack.externalNetwork property.</td>
<td>An IP address, for example 128.0.0.1.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>------------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>platform.openstack.apiFloatingIP</strong></td>
<td>An existing floating IP address to associate with the API load balancer. To use this property, you must also define the <strong>platform.openstack.externalNetwork</strong> property.</td>
<td>An IP address, for example <strong>128.0.0.1</strong>.</td>
</tr>
<tr>
<td><strong>platform.openstack.externalDNS</strong></td>
<td>IP addresses for external DNS servers that cluster instances use for DNS resolution.</td>
<td>A list of IP addresses as strings. For example, [&quot;8.8.8.8&quot;, &quot;192.168.1.12&quot;].</td>
</tr>
<tr>
<td><strong>platform.openstack.machinesSubnet</strong></td>
<td>The UUID of a RHOSP subnet that the cluster’s nodes use. Nodes and virtual IP (VIP) ports are created on this subnet.</td>
<td>A UUID as a string. For example, <strong>fa806b2f-ac49-4bce-b9db-124bc64209bf</strong>.</td>
</tr>
<tr>
<td></td>
<td>The first item in <strong>networking.machineNetwork</strong> must match the value of <strong>machinesSubnet</strong>.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you deploy to a custom subnet, you cannot specify an external DNS server to the OpenShift Container Platform installer. Instead, add DNS to the subnet in RHOSP.</td>
<td></td>
</tr>
</tbody>
</table>

### 17.3.11.6. Custom subnets in RHOSP deployments

Optionally, you can deploy a cluster on a Red Hat OpenStack Platform (RHOSP) subnet of your choice. The subnet’s GUID is passed as the value of **platform.openstack.machinesSubnet** in the **install-config.yaml** file.

This subnet is used as the cluster’s primary subnet. By default, nodes and ports are created on it. You can create nodes and ports on a different RHOSP subnet by setting the value of the **platform.openstack.machinesSubnet** property to the subnet’s UUID.

Before you run the OpenShift Container Platform installer with a custom subnet, verify that your configuration meets the following requirements:

- The subnet that is used by **platform.openstack.machinesSubnet** has DHCP enabled.
- The CIDR of **platform.openstack.machinesSubnet** matches the CIDR of **networking.machineNetwork**.
- The installation program user has permission to create ports on this network, including ports with fixed IP addresses.

Clusters that use custom subnets have the following limitations:
• If you plan to install a cluster that uses floating IP addresses, the `platform.openstack.machinesSubnet` subnet must be attached to a router that is connected to the `externalNetwork` network.

• If the `platform.openstack.machinesSubnet` value is set in the `install-config.yaml` file, the installation program does not create a private network or subnet for your RHOSP machines.

• You cannot use the `platform.openstack.externalDNS` property at the same time as a custom subnet. To add DNS to a cluster that uses a custom subnet, configure DNS on the RHOSP network.

**NOTE**

By default, the API VIP takes `x.x.x.5` and the Ingress VIP takes `x.x.x.7` from your network’s CIDR block. To override these default values, set values for `platform.openstack.apiVIP` and `platform.openstack.ingressVIP` that are outside of the DHCP allocation pool.

17.3.11.7. Sample customized `install-config.yaml` file for RHOSP with Kuryr

To deploy with Kuryr SDN instead of the default OpenShift SDN, you must modify the `install-config.yaml` file to include Kuryr as the desired `networking.networkType` and proceed with the default OpenShift Container Platform SDN installation steps. This sample `install-config.yaml` demonstrates all of the possible Red Hat OpenStack Platform (RHOSP) customization options.

**IMPORTANT**

This sample file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program.

```yaml
apiVersion: v1
baseDomain: example.com
controlPlane:
  name: master
  platform: {}
  replicas: 3
compute:
  - name: worker
    platform:
      openstack:
        type: ml.large
        replicas: 3
    metadata:
      name: example
    networking:
      clusterNetwork:
        - cidr: 10.128.0.0/14
        hostPrefix: 23
      machineNetwork:
        - cidr: 10.0.0.0/16
      serviceNetwork:
        - 172.30.0.0/16
      networkType: Kuryr
    platform:
      openstack:
```

1

```yaml
platform.openstack:
```

CHAPTER 17. INSTALLING ON OPENSTACK

2121
The Amphora Octavia driver creates two ports per load balancer. As a result, the service subnet that the installer creates is twice the size of the CIDR that is specified as the value of the `serviceNetwork` property. The larger range is required to prevent IP address conflicts.

Both `trunkSupport` and `octaviaSupport` are automatically discovered by the installer, so there is no need to set them. But if your environment does not meet both requirements, Kuryr SDN will not properly work. Trunks are needed to connect the pods to the RHOSP network and Octavia is required to create the OpenShift Container Platform services.

17.3.11.8. Cluster deployment on RHOSP provider networks

You can deploy your OpenShift Container Platform clusters on Red Hat OpenStack Platform (RHOSP) with a primary network interface on a provider network. Provider networks are commonly used to give projects direct access to a public network that can be used to reach the internet. You can also share provider networks among projects as part of the network creation process.

RHOSP provider networks map directly to an existing physical network in the data center. A RHOSP administrator must create them.

In the following example, OpenShift Container Platform workloads are connected to a data center by using a provider network:
OpenShift Container Platform clusters that are installed on provider networks do not require tenant networks or floating IP addresses. The installer does not create these resources during installation.

Example provider network types include flat (untagged) and VLAN (802.1Q tagged).

**NOTE**

A cluster can support as many provider network connections as the network type allows. For example, VLAN networks typically support up to 4096 connections.

You can learn more about provider and tenant networks in the RHOSP documentation.

### 17.3.11.8.1. RHOSP provider network requirements for cluster installation

Before you install an OpenShift Container Platform cluster, your Red Hat OpenStack Platform (RHOSP) deployment and provider network must meet a number of conditions:

- The RHOP networking service (Neutron) is enabled and accessible through the RHOSP networking API.
- The RHOSP networking service has the port security and allowed address pairs extensions enabled.
- The provider network can be shared with other tenants.

**TIP**

Use the `openstack network create` command with the `--share` flag to create a network that can be shared.

- The RHOSP project that you use to install the cluster must own the provider network, as well as an appropriate subnet.

**TIP**

To create a network for a project that is named "openshift," enter the following command:

```
$ openstack network create --project openshift
```

To create a subnet for a project that is named "openshift," enter the following command:

```
$ openstack subnet create --project openshift
```

To learn more about creating networks on RHOSP, read the provider networks documentation.

If the cluster is owned by the `admin` user, you must run the installer as that user to create ports on the network.

**IMPORTANT**

Provider networks must be owned by the RHOSP project that is used to create the cluster. If they are not, the RHOSP Compute service (Nova) cannot request a port from that network.

- Verify that the provider network can reach the RHOSP metadata service IP address, which is `169.254.169.254` by default.

  Depending on your RHOSP SDN and networking service configuration, you might need to provide the route when you create the subnet. For example:

  ```
  $ openstack subnet create --dhcp --host-route destination=169.254.169.254/32,gateway=192.0.2.2 ...
  ```

- Optional: To secure the network, create role-based access control (RBAC) rules that limit network access to a single project.

17.3.11.8.2. Deploying a cluster that has a primary interface on a provider network

You can deploy an OpenShift Container Platform cluster that has its primary network interface on an Red Hat OpenStack Platform (RHOSP) provider network. Prerequisites

- Your Red Hat OpenStack Platform (RHOSP) deployment is configured as described by "RHOSP provider network requirements for cluster installation".
1. In a text editor, open the `install-config.yaml` file.

2. Set the value of the `platform.openstack.apiVIP` property to the IP address for the API VIP.

3. Set the value of the `platform.openstack.ingressVIP` property to the IP address for the Ingress VIP.

4. Set the value of the `platform.openstack.machinesSubnet` property to the UUID of the provider network subnet.

5. Set the value of the `networking.machineNetwork.cidr` property to the CIDR block of the provider network subnet.

**IMPORTANT**

The `platform.openstack.apiVIP` and `platform.openstack.ingressVIP` properties must both be unassigned IP addresses from the `networking.machineNetwork.cidr` block.

Section of an installation configuration file for a cluster that relies on a RHOSP provider network

```yaml
...  
platform:
  openstack:
    apiVIP: 192.0.2.13
    ingressVIP: 192.0.2.23
    machinesSubnet: fa806b2f-ac49-4bce-b9db-124bc64209bf
    # ...
  networking:
    machineNetwork:
    - cidr: 192.0.2.0/24
```

**WARNING**

You cannot set the `platform.openstack.externalNetwork` or `platform.openstack.externalDNS` parameters while using a provider network for the primary network interface.

When you deploy the cluster, the installer uses the `install-config.yaml` file to deploy the cluster on the provider network.

**TIP**

You can add additional networks, including provider networks, to the `platform.openstack.additionalNetworkIDs` list.

After you deploy your cluster, you can attach pods to additional networks. For more information, see [Understanding multiple networks](#).
17.3.11.9. Kuryr ports pools

A Kuryr ports pool maintains a number of ports on standby for pod creation. Keeping ports on standby minimizes pod creation time. Without ports pools, Kuryr must explicitly request port creation or deletion whenever a pod is created or deleted.

The Neutron ports that Kuryr uses are created in subnets that are tied to namespaces. These pod ports are also added as subports to the primary port of OpenShift Container Platform cluster nodes. Because Kuryr keeps each namespace in a separate subnet, a separate ports pool is maintained for each namespace-worker pair.

Prior to installing a cluster, you can set the following parameters in the `cluster-network-03-config.yml` manifest file to configure ports pool behavior:

- The `enablePortPoolsPrepopulation` parameter controls pool prepopulation, which forces Kuryr to add Neutron ports to the pools when the first pod that is configured to use the dedicated network for pods is created in a namespace. The default value is `false`.
- The `poolMinPorts` parameter is the minimum number of free ports that are kept in the pool. The default value is `1`.
- The `poolMaxPorts` parameter is the maximum number of free ports that are kept in the pool. A value of `0` disables that upper bound. This is the default setting. If your OpenStack port quota is low, or you have a limited number of IP addresses on the pod network, consider setting this option to ensure that unneeded ports are deleted.
- The `poolBatchPorts` parameter defines the maximum number of Neutron ports that can be created at once. The default value is `3`.

17.3.11.10. Adjusting Kuryr ports pools during installation

During installation, you can configure how Kuryr manages Red Hat OpenStack Platform (RHOSP) Neutron ports to control the speed and efficiency of pod creation.

Prerequisites

- Create and modify the `install-config.yaml` file.

Procedure

1. From a command line, create the manifest files:

   ```
   $ ./openshift-install create manifests --dir <installation_directory>
   $ touch <installation_directory>/manifests/cluster-network-03-config.yml
   ```

   For `<installation_directory>`, specify the name of the directory that contains the `install-config.yaml` file for your cluster.

2. Create a file that is named `cluster-network-03-config.yml` in the `<installation_directory>/manifests/` directory:

   ```
   $ touch <installation_directory>/manifests/cluster-network-03-config.yml
   ```
For `<installation_directory>`, specify the directory name that contains the `manifests/` directory for your cluster.

After creating the file, several network configuration files are in the `manifests/` directory, as shown:

```
$ ls <installation_directory>/manifests/cluster-network-*
```

**Example output**

```
cluster-network-01-crd.yml
cluster-network-02-config.yml
cluster-network-03-config.yml
```

3. Open the `cluster-network-03-config.yml` file in an editor, and enter a custom resource (CR) that describes the Cluster Network Operator configuration that you want:

```
$ oc edit networks.operator.openshift.io cluster
```

4. Edit the settings to meet your requirements. The following file is provided as an example:

```
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
  name: cluster
spec:
  clusterNetwork:
    - cidr: 10.128.0.0/14
      hostPrefix: 23
  serviceNetwork:
    - 172.30.0.0/16
  defaultNetwork:
    type: Kuryr
    kuryrConfig:
      enablePortPoolsPrepopulation: false
      poolMinPorts: 1
      poolBatchPorts: 3
      poolMaxPorts: 5
      openstackServiceNetwork: 172.30.0.0/15
```

1. Set `enablePortPoolsPrepopulation` to `true` to make Kuryr create new Neutron ports when the first pod on the network for pods is created in a namespace. This setting raises the Neutron ports quota but can reduce the time that is required to spawn pods. The default value is `false`.

2. Kuryr creates new ports for a pool if the number of free ports in that pool is lower than the value of `poolMinPorts`. The default value is `1`.

3. `poolBatchPorts` controls the number of new ports that are created if the number of free ports is lower than the value of `poolMinPorts`. The default value is `3`.

4. If the number of free ports in a pool is higher than the value of `poolMaxPorts`, Kuryr
The `openStackServiceNetwork` parameter defines the CIDR range of the network from which IP addresses are allocated to RHOSP Octavia’s LoadBalancers.

If this parameter is used with the Amphora driver, Octavia takes two IP addresses from this network for each load balancer: one for OpenShift and the other for VRRP connections. Because these IP addresses are managed by OpenShift Container Platform and Neutron respectively, they must come from different pools. Therefore, the value of `openStackServiceNetwork` must be at least twice the size of the value of `serviceNetwork`, and the value of `serviceNetwork` must overlap entirely with the range that is defined by `openStackServiceNetwork`.

The CNO verifies that VRRP IP addresses that are taken from the range that is defined by this parameter do not overlap with the range that is defined by the `serviceNetwork` parameter.

If this parameter is not set, the CNO uses an expanded value of `serviceNetwork` that is determined by decrementing the prefix size by 1.

5. Save the `cluster-network-03-config.yml` file, and exit the text editor.

6. Optional: Back up the `manifests/cluster-network-03-config.yml` file. The installation program deletes the `manifests/` directory while creating the cluster.

17.3.12. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the `core` user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user `core`. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N " -f <path>/<file_name>
   ```

   Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.
NOTE
If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the ~/.ssh/id_rsa.pub public key:

```
$ cat ~/.ssh/id_rsa.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the ./openshift-install gather command.

NOTE
On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.

a. If the ssh-agent process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

Example output

```
Agent pid 31874
```

NOTE
If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the ssh-agent:

```
$ ssh-add <path>/<file_name> 1
```

Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

Next steps
When you install OpenShift Container Platform, provide the SSH public key to the installation program.

17.3.13. Enabling access to the environment

At deployment, all OpenShift Container Platform machines are created in a Red Hat OpenStack Platform (RHOSP)-tenant network. Therefore, they are not accessible directly in most RHOSP deployments.

You can configure OpenShift Container Platform API and application access by using floating IP addresses (FIPs) during installation. You can also complete an installation without configuring FIPs, but the installer will not configure a way to reach the API or applications externally.

17.3.13.1. Enabling access with floating IP addresses

Create floating IP (FIP) addresses for external access to the OpenShift Container Platform API and cluster applications.

Procedure

1. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the API FIP:

   ```
   $ openstack floating ip create --description "API <cluster_name>.<base_domain>" <external_network>
   ```

2. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the apps, or Ingress, FIP:

   ```
   $ openstack floating ip create --description "Ingress <cluster_name>.<base_domain>" <external_network>
   ```

3. Add records that follow these patterns to your DNS server for the API and Ingress FIPs:

   ```
   api.<cluster_name>.<base_domain>. IN A <API_FIP>
   *.apps.<cluster_name>.<base_domain>. IN A <apps_FIP>
   ```

   **NOTE**

   If you do not control the DNS server, you can add the record to your `/etc/hosts` file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

4. Add the FIPs to the `install-config.yaml` file as the values of the following parameters:

   - `platform.openstack.ingressFloatingIP`
   - `platform.openstack.apiFloatingIP`

   If you use these values, you must also enter an external network as the value of the `platform.openstack.externalNetwork` parameter in the `install-config.yaml` file.
TIP

You can make OpenShift Container Platform resources available outside of the cluster by assigning a floating IP address and updating your firewall configuration.

17.3.13.2. Completing installation without floating IP addresses

You can install OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) without providing floating IP addresses.

In the install-config.yaml file, do not define the following parameters:

- platform.openstack.ingressFloatingIP
- platform.openstack.apiFloatingIP

If you cannot provide an external network, you can also leave platform.openstack.externalNetwork blank. If you do not provide a value for platform.openstack.externalNetwork, a router is not created for you, and, without additional action, the installer will fail to retrieve an image from Glance. You must configure external connectivity on your own.

If you run the installer from a system that cannot reach the cluster API due to a lack of floating IP addresses or name resolution, installation fails. To prevent installation failure in these cases, you can use a proxy network or run the installer from a system that is on the same network as your machines.

NOTE

You can enable name resolution by creating DNS records for the API and Ingress ports. For example:

```
api.<cluster_name>.<base_domain>. IN A <api_port_IP>
*.apps.<cluster_name>.<base_domain>. IN A <ingress_port_IP>
```

If you do not control the DNS server, you can add the record to your /etc/hosts file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

17.3.14. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

IMPORTANT

You can run the create cluster command of the installation program only once, during initial installation.

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure
1. Change to the directory that contains the installation program and initialize the cluster deployment:

```
$ ./openshift-install create cluster --dir <installation_directory> \
  --log-level=info
```

1. For `<installation_directory>`, specify the location of your customized `./install-config.yaml` file.

2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

**NOTE**

If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.

When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the `kubeadmin` user, display in your terminal.

**Example output**

```
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-Wt5AL"
INFO Time elapsed: 36m22s
```

**NOTE**

The cluster access and credential information also outputs to `<installation_directory>/.openshift_install.log` when an installation succeeds.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for `Recovering from expired control plane certificates` for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.
17.3.15. Verifying cluster status

You can verify your OpenShift Container Platform cluster’s status during or after installation.

Procedure

1. In the cluster environment, export the administrator’s kubeconfig file:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server.

2. View the control plane and compute machines created after a deployment:

   ```bash
   $ oc get nodes
   $$
   $ oc get clusterversion
   $ oc get clusteroperator
   $ oc get pods -A
   $ oc get pods -A
   ```

17.3.16. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

Procedure
1. Export the `kubeadmin` credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   ```

   **Example output**

   ```text
   system:admin
   ```

   **Additional resources**

   - See [Accessing the web console](#) for more details about accessing and understanding the OpenShift Container Platform web console.

### 17.3.17. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.10, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use `subscription watch` to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- See [About remote health monitoring](#) for more information about the Telemetry service

### 17.3.18. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- If you need to enable external access to node ports, configure ingress cluster traffic by using a node port.
- If you did not configure RHOSP to accept application traffic over floating IP addresses, configure RHOSP access with floating IP addresses.

### 17.4. INSTALLING A CLUSTER ON OPENSTACK THAT SUPPORTS SR-IOV-CONNECTED COMPUTE MACHINES

In OpenShift Container Platform version 4.10, you can install a cluster on Red Hat OpenStack Platform (RHOSP) that can use compute machines with single-root I/O virtualization (SR-IOV) technology.
17.4.1. Prerequisites

- Review details about the OpenShift Container Platform installation and update processes.
  - Verify that OpenShift Container Platform 4.10 is compatible with your RHOSP version by using the "Supported platforms for OpenShift clusters" section. You can also compare platform support across different versions by viewing the OpenShift Container Platform on RHOSP support matrix.

- Verify that your network configuration does not rely on a provider network. Provider networks are not supported.

- Have a storage service installed in RHOSP, like block storage (Cinder) or object storage (Swift). Object storage is the recommended storage technology for OpenShift Container Platform registry cluster deployment. For more information, see Optimizing storage.

- Have metadata service enabled in RHOSP

17.4.2. Resource guidelines for installing OpenShift Container Platform on RHOSP

To support an OpenShift Container Platform installation, your Red Hat OpenStack Platform (RHOSP) quota must meet the following requirements:

<table>
<thead>
<tr>
<th>Resource</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Floating IP addresses</td>
<td>3</td>
</tr>
<tr>
<td>Ports</td>
<td>15</td>
</tr>
<tr>
<td>Routers</td>
<td>1</td>
</tr>
<tr>
<td>Subnets</td>
<td>1</td>
</tr>
<tr>
<td>RAM</td>
<td>112 GB</td>
</tr>
<tr>
<td>vCPUs</td>
<td>28</td>
</tr>
<tr>
<td>Volume storage</td>
<td>275 GB</td>
</tr>
<tr>
<td>Instances</td>
<td>7</td>
</tr>
<tr>
<td>Security groups</td>
<td>3</td>
</tr>
<tr>
<td>Security group rules</td>
<td>60</td>
</tr>
<tr>
<td>Server groups</td>
<td>2 - plus 1 for each additional availability zone in each machine pool</td>
</tr>
</tbody>
</table>
A cluster might function with fewer than recommended resources, but its performance is not guaranteed.

**IMPORTANT**

If RHOSP object storage (Swift) is available and operated by a user account with the `swiftoperator` role, it is used as the default backend for the OpenShift Container Platform image registry. In this case, the volume storage requirement is 175 GB. Swift space requirements vary depending on the size of the image registry.

**NOTE**

By default, your security group and security group rule quotas might be low. If you encounter problems, run `openstack quota set --secgroups 3 --secgroup-rules 60 <project>` as an administrator to increase them.

An OpenShift Container Platform deployment comprises control plane machines, compute machines, and a bootstrap machine.

**17.4.2.1. Control plane and compute machines**

By default, the OpenShift Container Platform installation process stands up three control plane and three compute machines.

Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 25 GB storage space

**TIP**

Compute machines host the applications that you run on OpenShift Container Platform; aim to run as many as you can.

Additionally, for clusters that use single-root input/output virtualization (SR-IOV), RHOSP compute nodes require a flavor that supports huge pages.

**IMPORTANT**

SR-IOV deployments often employ performance optimizations, such as dedicated or isolated CPUs. For maximum performance, configure your underlying RHOSP deployment to use these optimizations, and then run OpenShift Container Platform compute machines on the optimized infrastructure.

**Additional resources**

- For more information about configuring performant RHOSP compute nodes, see Configuring Compute nodes for performance.

**17.4.2.2. Bootstrap machine**
During installation, a bootstrap machine is temporarily provisioned to stand up the control plane. After the production control plane is ready, the bootstrap machine is deprovisioned.

The bootstrap machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 25 GB storage space

### 17.4.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.10, you require access to the internet to obtain the images that are necessary to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 17.4.4. Enabling Swift on RHOSP

Swift is operated by a user account with the `swiftoperator` role. Add the role to an account before you run the installation program.

**IMPORTANT**

If the Red Hat OpenStack Platform (RHOSP) object storage service, commonly known as Swift, is available, OpenShift Container Platform uses it as the image registry storage. If it is unavailable, the installation program relies on the RHOSP block storage service, commonly known as Cinder.

If Swift is present and you want to use it, you must enable access to it. If it is not present, or if you do not want to use it, skip this section.

**Prerequisites**

- You have a RHOSP administrator account on the target environment.
- The Swift service is installed.
On Ceph RGW, the account in url option is enabled.

Procedure

To enable Swift on RHOSP:

1. As an administrator in the RHOSP CLI, add the `swiftoperator` role to the account that will access Swift:

   ```
   $ openstack role add --user <user> --project <project> swiftoperator
   ```

Your RHOSP deployment can now use Swift for the image registry.

17.4.5. Verifying external network access

The OpenShift Container Platform installation process requires external network access. You must provide an external network value to it, or deployment fails. Before you begin the process, verify that a network with the external router type exists in Red Hat OpenStack Platform (RHOSP).

Prerequisites

- Configure OpenStack’s networking service to have DHCP agents forward instances’ DNS queries

Procedure

1. Using the RHOSP CLI, verify the name and ID of the 'External' network:

   ```
   $ openstack network list --long -c ID -c Name -c "Router Type"
   ```

   **Example output**

   ```
   +--------------------------------------+----------------+-------------+
   | ID                                   | Name           | Router Type |
   +--------------------------------------+----------------+-------------+
   | 148a8023-62a7-4672-b018-003462f8d7dc | public_network | External    |
   +--------------------------------------+----------------+-------------+
   ```

   A network with an external router type appears in the network list. If at least one does not, see Creating a default floating IP network and Creating a default provider network.

   **NOTE**

   If the Neutron trunk service plug-in is enabled, a trunk port is created by default. For more information, see Neutron trunk port.

17.4.6. Defining parameters for the installation program

The OpenShift Container Platform installation program relies on a file that is called `clouds.yaml`. The file describes Red Hat OpenStack Platform (RHOSP) configuration parameters, including the project name, log in information, and authorization service URLs.

Procedure
1. Create the **clouds.yaml** file:

   - If your RHOSP distribution includes the Horizon web UI, generate a **clouds.yaml** file in it.

     **IMPORTANT**
     
     Remember to add a password to the **auth** field. You can also keep secrets in a separate file from **clouds.yaml**.

   - If your RHOSP distribution does not include the Horizon web UI, or you do not want to use Horizon, create the file yourself. For detailed information about **clouds.yaml**, see Config files in the RHOSP documentation.

```yaml
clouds:
    shiftstack:
        auth:
            project_name: shiftstack
            username: shiftstack_user
            password: XXX
            user_domain_name: Default
            project_domain_name: Default
    dev-env:
        region_name: RegionOne
        auth:
            username: 'devuser'
            password: XXX
            project_name: 'devonly'
```

2. If your RHOSP installation uses self-signed certificate authority (CA) certificates for endpoint authentication:

   a. Copy the certificate authority file to your machine.

   b. Add the **cacerts** key to the **clouds.yaml** file. The value must be an absolute, non-root-accessible path to the CA certificate:

```yaml
clouds:
    shiftstack:
        ... 
    cacert: "/etc/pki/ca-trust/source/anchors/ca.crt.pem"
```

**TIP**

After you run the installer with a custom CA certificate, you can update the certificate by editing the value of the **ca-cert.pem** key in the **cloud-provider-config** keymap. On a command line, run:

```
$ oc edit configmap -n openshift-config cloud-provider-config
```

3. Place the **clouds.yaml** file in one of the following locations:

   a. The value of the **OS_CLIENT_CONFIG_FILE** environment variable
b. The current directory

c. A Unix-specific user configuration directory, for example `~/.config/openstack/clouds.yaml`

d. A Unix-specific site configuration directory, for example `/etc/openstack/clouds.yaml`

The installation program searches for `clouds.yaml` in that order.

17.4.7. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the mirror host.

Prerequisites

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

**IMPORTANT**

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

17.4.8. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on
Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster. For a restricted network installation, these files are on your mirror host.

- Have the imageContentSources values that were generated during mirror registry creation.

- Obtain the contents of the certificate for your mirror registry.

- Retrieve a Red Hat Enterprise Linux CoreOS (RHCOS) image and upload it to an accessible location.

- Obtain service principal permissions at the subscription level.

Procedure

1. Create the install-config.yaml file.

   a. Change to the directory that contains the installation program and run the following command:

   ```
   $ ./openshift-install create install-config --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

   IMPORTANT

   Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

   b. At the prompts, provide the configuration details for your cloud:

      i. Optional: Select an SSH key to use to access your cluster machines.

      NOTE

      For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

      ii. Enter a descriptive name for your cluster.

      iii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

2. Edit the install-config.yaml file to provide the additional information that is required for an installation in a restricted network.

   a. Update the pullSecret value to contain the authentication information for your registry:
For `<mirror_host_name>`, specify the registry domain name that you specified in the certificate for your mirror registry, and for `<credentials>`, specify the base64-encoded user name and password for your mirror registry.

b. Add the `additionalTrustBundle` parameter and value.

```
additionalTrustBundle: |
-----BEGIN CERTIFICATE-----
ZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZ
-----END CERTIFICATE-----
```

The value must be the contents of the certificate file that you used for your mirror registry, which can be an existing, trusted certificate authority or the self-signed certificate that you generated for the mirror registry.

c. Add the image content resources, which look like this excerpt:

```
imageContentSources:
- mirrors:
  - `<mirror_host_name>:5000`/<repo_name>/release
    source: quay.example.com/openshift-release-dev/ocp-release
  - mirrors:
    - `<mirror_host_name>:5000`/<repo_name>/release
      source: registry.example.com/ocp/release
```

To complete these values, use the `imageContentSources` that you recorded during mirror registry creation.

3. Make any other modifications to the `install-config.yaml` file that you require. You can find more information about the available parameters in the `Installation configuration parameters` section.

4. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

**IMPORTANT**

The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

### 17.4.8.1. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**Prerequisites**

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to...
hosting cloud provider APIs. You added sites to the Proxy object’s spec.noProxy field to bypass the proxy if necessary.

NOTE

The Proxy object status.noProxy field is populated with the values of the networking.machineNetwork[].cidr, networking.clusterNetwork[].cidr, and networking.serviceNetwork[] fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object status.noProxy field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your install-config.yaml file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
     httpProxy: http://<username>:@<ip>:<port>
     httpsProxy: https://<username>:@<ip>:<port>
     noProxy: example.com
     additionalTrustBundle:
       -----BEGIN CERTIFICATE-----
       <MY_TRUSTED_CA_CERT>
       -----END CERTIFICATE-----
       ...
   ```

   1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.
   2. A proxy URL to use for creating HTTPS connections outside the cluster.
   3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.
   4. If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the trustedCA field of the Proxy object. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

NOTE

The installation program does not support the proxy readinessEndpoints field.

2. Save the file and reference it when installing OpenShift Container Platform.
The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

**NOTE**

Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

17.4.9. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide a customized `install-config.yaml` installation configuration file that describes the details for your environment.

**NOTE**

After installation, you cannot modify these parameters in the `install-config.yaml` file.

17.4.9.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

Table 17.14. Required parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is v1. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the <code>baseDomain</code> and <code>metadata.name</code> parameter values that uses the <code>&lt;metadata.name&gt;..&lt;baseDomain&gt;</code> format.</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
</tr>
<tr>
<td>metadata</td>
<td>Kubernetes resource <code>ObjectMeta</code>, from which only the <code>name</code> parameter is consumed.</td>
<td>Object</td>
</tr>
</tbody>
</table>
### Parameter | Description | Values
--- | --- | ---
metadata.name | The name of the cluster. DNS records for the cluster are all subdomains of `.metadata.name`. `.baseDomain`. | String of lowercase letters, hyphens (-), and periods (.), such as dev.

platform | The configuration for the specific platform upon which to perform the installation: alibabacloud, aws, baremetal, azure, ibmcloud, openstack, ovirt, vsphere, or {}. For additional information about platform.<platform> parameters, consult the table for your specific platform that follows. | Object

**pullSecret** | Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io. | ```
{
  "auths":{
    "cloud.openshift.com":{
      "auth":"b3Blb=",
      "email":"you@example.com"
    },
    "quay.io":{
      "auth":"b3Blb=",
      "email":"you@example.com"
    }
  }
}
```

### 17.4.9.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

**Table 17.15. Network parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong></td>
<td>You cannot modify parameters specified by the <code>networking</code> object after installation.</td>
</tr>
<tr>
<td>networking.network Type</td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN.</td>
</tr>
<tr>
<td>networking.clusterNetwork</td>
<td>The IP address blocks for pods.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td>The default value is <strong>10.128.0.0/14</strong> with a host prefix of /23.</td>
<td>networking:</td>
</tr>
<tr>
<td></td>
<td>If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td>- clusterNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- cidr: <strong>10.128.0.0/14</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>hostPrefix: <strong>23</strong></td>
</tr>
<tr>
<td>networking.clusterNetwork.cidr</td>
<td>Required if you use <code>networking.clusterNetwork</code>. An IP address block.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td></td>
<td>An IPv4 network.</td>
<td></td>
</tr>
<tr>
<td>networking.clusterNetwork.hostPrefix</td>
<td>The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to <strong>23</strong> then each node is assigned a /23 subnet out of the given cidr. A hostPrefix value of <strong>23</strong> provides 510 (2^(32 - 23) - 2) pod IP addresses.</td>
<td>A subnet prefix.</td>
</tr>
<tr>
<td></td>
<td>The default value is <strong>23</strong>.</td>
<td></td>
</tr>
<tr>
<td>networking.serviceNetwork</td>
<td>The IP address block for services. The default value is <strong>172.30.0.0/16</strong>.</td>
<td>An array with an IP address block in CIDR format. For example:</td>
</tr>
<tr>
<td></td>
<td>The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.</td>
<td>networking:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- serviceNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- <strong>172.30.0.0/16</strong></td>
</tr>
</tbody>
</table>
### networking.machine

#### machineNetwork

The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap. If you specify multiple IP kernel arguments, the `machineNetwork.cidr` value must be the CIDR of the primary network.

An array of objects. For example:

```yaml
networking:
machineNetwork:
  - cidr: 10.0.0.0/16
```

#### networking.machineNetwork.cidr

Required if you use `networking.machineNetwork`. An IP address block. The default value is `10.0.0.0/16` for all platforms other than `libvirt`. For `libvirt`, the default value is `192.168.126.0/24`.

An IP network block in CIDR notation. For example, `10.0.0.0/16`.

**NOTE**

Set the `networking.machineNetwork` to match the CIDR that the preferred NIC resides in.

### 17.4.9.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

**Table 17.16. Optional parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>additionalTrustBundle</code></td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td><code>cgroupsV2</code></td>
<td>Enables Linux control groups version 2 (cgroups v2) on specific nodes in your cluster. The OpenShift Container Platform process for enabling cgroups v2 disables all cgroup version 1 controllers and hierarchies. The OpenShift Container Platform cgroups version 2 feature is in Developer Preview and is not supported by Red Hat at this time.</td>
<td>true</td>
</tr>
<tr>
<td><code>compute</code></td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of <code>MachinePool</code> objects.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>----------------------------</td>
</tr>
<tr>
<td>compute.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>s390x</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td>compute.hyperthreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>compute.name</td>
<td>Required if you use compute. The name of the machine pool.</td>
<td>worker</td>
</tr>
<tr>
<td>compute.platform</td>
<td>Required if you use compute. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the controlPlane.platform parameter value.</td>
<td>alibaba, aws, azure, gcp, ibmcloud, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td>compute.replicas</td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td>controlPlane</td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of MachinePool objects.</td>
</tr>
<tr>
<td>controlPlane.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>s390x</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-------------------------</td>
</tr>
<tr>
<td>controlPlane.hypertreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>controlPlane.name</td>
<td>Required if you use controlPlane. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use controlPlane. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the compute.platform parameter value.</td>
<td>alibaba, aws, azure, gcp, ibmcloud, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (“”).</td>
</tr>
</tbody>
</table>

**IMPORTANT**
If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.

**NOTE**
Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Platform Operators reference content.
Enable or disable FIPS mode. The default is **false** (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the **x86_64** architecture.

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>fips</strong></td>
<td>Sources and repositories for the release–image content.</td>
<td><strong>false</strong> or <strong>true</strong></td>
</tr>
<tr>
<td><strong>imageContentSources</strong></td>
<td>Sources and repositories for the release–image content.</td>
<td>Array of objects. Includes a <strong>source</strong> and, optionally, <strong>mirrors</strong>, as described in the following rows of this table.</td>
</tr>
<tr>
<td><strong>imageContentSources.source</strong></td>
<td>Required if you use <strong>imageContentSources</strong>. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td><strong>String</strong></td>
</tr>
<tr>
<td><strong>imageContentSources.mirrors</strong></td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
</tbody>
</table>
17.4.9.4. Custom subnets in RHOSP deployments

 Optionally, you can deploy a cluster on a Red Hat OpenStack Platform (RHOSP) subnet of your choice. The subnet’s GUID is passed as the value of `platform.openstack.machinesSubnet` in the `install-config.yaml` file.

 This subnet is used as the cluster’s primary subnet. By default, nodes and ports are created on it. You can create nodes and ports on a different RHOSP subnet by setting the value of the `platform.openstack.machinesSubnet` property to the subnet’s UUID.

 Before you run the OpenShift Container Platform installer with a custom subnet, verify that your configuration meets the following requirements:

 - The subnet that is used by `platform.openstack.machinesSubnet` has DHCP enabled.
 - The CIDR of `platform.openstack.machinesSubnet` matches the CIDR of `networking.machineNetwork`.

---

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>publish</td>
<td>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</td>
<td><code>Internal</code> or <code>External</code>. The default value is <code>External</code>. Setting this field to <code>Internal</code> is not supported on non-cloud platforms and IBM Cloud. <strong>IMPORTANT</strong> If the value of the field is set to <code>Internal</code>, the cluster will become non-functional. For more information, refer to BZ#1953035.</td>
</tr>
<tr>
<td>sshKey</td>
<td>The SSH key or keys to authenticate access your cluster machines. <strong>NOTE</strong> For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your <code>ssh-agent</code> process uses.</td>
<td>One or more keys. For example: <code>sshKey: &lt;key1&gt; &lt;key2&gt; &lt;key3&gt;</code></td>
</tr>
</tbody>
</table>
The installation program user has permission to create ports on this network, including ports with fixed IP addresses.

Clusters that use custom subnets have the following limitations:

- If you plan to install a cluster that uses floating IP addresses, the `platform.openstack.machinesSubnet` subnet must be attached to a router that is connected to the `externalNetwork` network.

- If the `platform.openstack.machinesSubnet` value is set in the `install-config.yaml` file, the installation program does not create a private network or subnet for your RHOSP machines.

- You cannot use the `platform.openstack.externalDNS` property at the same time as a custom subnet. To add DNS to a cluster that uses a custom subnet, configure DNS on the RHOSP network.

**NOTE**

By default, the API VIP takes x.x.x.5 and the Ingress VIP takes x.x.x.7 from your network’s CIDR block. To override these default values, set values for `platform.openstack.apiVIP` and `platform.openstack.ingressVIP` that are outside of the DHCP allocation pool.

17.4.9.5. Deploying a cluster with bare metal machines

If you want your cluster to use bare metal machines, modify the `inventory.yaml` file. Your cluster can have both control plane and compute machines running on bare metal, or just compute machines.

Bare-metal compute machines are not supported on clusters that use Kuryr.

**NOTE**

Be sure that your `install-config.yaml` file reflects whether the RHOSP network that you use for bare metal workers supports floating IP addresses or not.

**Prerequisites**

- The RHOSP Bare Metal service (Ironic) is enabled and accessible via the RHOSP Compute API.

- Bare metal is available as a RHOSP flavor.

- The RHOSP network supports both VM and bare metal server attachment.

- Your network configuration does not rely on a provider network. Provider networks are not supported.

- If you want to deploy the machines on a pre-existing network, a RHOSP subnet is provisioned.

- If you want to deploy the machines on an installer-provisioned network, the RHOSP Bare Metal service (Ironic) is able to listen for and interact with Preboot eXecution Environment (PXE) boot machines that run on tenant networks.

- You created an `inventory.yaml` file as part of the OpenShift Container Platform installation process.

**Procedure**
1. In the **inventory.yaml** file, edit the flavors for machines:

   a. If you want to use bare-metal control plane machines, change the value of `os_flavor_master` to a bare metal flavor.

   b. Change the value of `os_flavor_worker` to a bare metal flavor.

   **An example bare metal inventory.yaml file**

   ```yaml
   all:
     hosts:
       localhost:
         ansible_connection: local
         ansible_python_interpreter: "{{ansible_playbook_python}}"

   # User-provided values
   os_subnet_range: '10.0.0.0/16'
   os_flavor_master: 'my-bare-metal-flavor'
   os_flavor_worker: 'my-bare-metal-flavor'
   os_image_rhcos: 'rhcos'
   os_external_network: 'external'
   ...
   
   1. If you want to have bare-metal control plane machines, change this value to a bare metal flavor.
   
   2. Change this value to a bare metal flavor to use for compute machines.

   Use the updated **inventory.yaml** file to complete the installation process. Machines that are created during deployment use the flavor that you added to the file.

   **NOTE**

   The installer may time out while waiting for bare metal machines to boot.

   If the installer times out, restart and then complete the deployment by using the **wait-for** command of the installer. For example:

   ```bash
   ./openshift-install wait-for install-complete --log-level debug
   ```

   **17.4.9.6. Sample customized install-config.yaml file for RHOSP**

   This sample **install-config.yaml** demonstrates all of the possible Red Hat OpenStack Platform (RHOSP) customization options.

   **IMPORTANT**

   This sample file is provided for reference only. You must obtain your **install-config.yaml** file by using the installation program.
17.4.10. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the `core` user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user `core`. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**Procedure**
1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N " -f <path>/<file_name>  
```

Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

**NOTE**

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the `x86_64` architecture, do not create a key that uses the `ed25519` algorithm. Instead, create a key that uses the `rsa` or `ecdsa` algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_rsa.pub` public key:

```
$ cat ~/.ssh/id_rsa.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `.openshift-install gather` command.

**NOTE**

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

a. If the `ssh-agent` process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

**Example output**

Agent pid 31874

**NOTE**

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the `ssh-agent`:

```
$ ssh-add <path>/<file_name>
```

```
Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

Example output

Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

17.4.11. Enabling access to the environment

At deployment, all OpenShift Container Platform machines are created in a Red Hat OpenStack Platform (RHOSP)-tenant network. Therefore, they are not accessible directly in most RHOSP deployments.

You can configure OpenShift Container Platform API and application access by using floating IP addresses (FIPs) during installation. You can also complete an installation without configuring FIPs, but the installer will not configure a way to reach the API or applications externally.

17.4.11.1. Enabling access with floating IP addresses

Create floating IP (FIP) addresses for external access to the OpenShift Container Platform API and cluster applications.

Procedure

1. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the API FIP:

   $ openstack floating ip create --description "API <cluster_name>.<base_domain>" <external_network>

2. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the apps, or Ingress, FIP:

   $ openstack floating ip create --description "Ingress <cluster_name>.<base_domain>" <external_network>

3. Add records that follow these patterns to your DNS server for the API and Ingress FIPs:

   api.<cluster_name>.<base_domain>. IN A <API_FIP>
   *.apps.<cluster_name>.<base_domain>. IN A <apps_FIP>

   NOTE

   If you do not control the DNS server, you can add the record to your /etc/hosts file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

4. Add the FIPs to the install-config.yaml file as the values of the following parameters:

   - platform.openstack.ingressFloatingIP
If you use these values, you must also enter an external network as the value of the `platform.openstack.externalNetwork` parameter in the `install-config.yaml` file.

**TIP**

You can make OpenShift Container Platform resources available outside of the cluster by assigning a floating IP address and updating your firewall configuration.

### 17.4.11.2. Completing installation without floating IP addresses

You can install OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) without providing floating IP addresses.

In the file, do not define the following:

If you run the installer from a system that cannot reach the cluster API due to a lack of floating IP addresses or name resolution, installation fails. To prevent installation failure in these cases, you can use a proxy network or run the installer from a system that is on the same network as your machines.

**NOTE**

You can enable name resolution by creating DNS records for the API and Ingress ports. For example:

```text
api.<cluster_name>.<base_domain>. IN A <api_port_IP>
*.apps.<cluster_name>.<base_domain>. IN A <ingress_port_IP>
```

If you do not control the DNS server, you can add the record to your `/etc/hosts` file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

### 17.4.12. Creating SR-IOV networks for compute machines

If your Red Hat OpenStack Platform (RHOSP) deployment supports single root I/O virtualization (SR-IOV), you can provision SR-IOV networks that compute machines run on.

**NOTE**

The following instructions entail creating an external flat network and an external, VLAN-based network that can be attached to a compute machine. Depending on your RHOSP deployment, other network types might be required.

**Prerequisites**

- Your cluster supports SR-IOV.

**NOTE**

If you are unsure about what your cluster supports, review the OpenShift Container Platform SR-IOV hardware networks documentation.
You created radio and uplink provider networks as part of your RHOSP deployment. The names \textit{radio} and \textit{uplink} are used in all example commands to represent these networks.

\textbf{Procedure}

1. On a command line, create a radio RHOSP network:

   \begin{verbatim}
   $ openstack network create radio --provider-physical-network radio --provider-network-type flat --external
   \end{verbatim}

2. Create an uplink RHOSP network:

   \begin{verbatim}
   $ openstack network create uplink --provider-physical-network uplink --provider-network-type vlan --external
   \end{verbatim}

3. Create a subnet for the radio network:

   \begin{verbatim}
   $ openstack subnet create --network radio --subnet-range <radio_network_subnet_range> radio
   \end{verbatim}

4. Create a subnet for the uplink network:

   \begin{verbatim}
   $ openstack subnet create --network uplink --subnet-range <uplink_network_subnet_range> uplink
   \end{verbatim}

\textbf{17.4.13. Deploying the cluster}

You can install OpenShift Container Platform on a compatible cloud platform.

\begin{itemize}
\item \textbf{IMPORTANT}
\end{itemize}

\begin{itemize}
\item You can run the \texttt{create cluster} command of the installation program only once, during initial installation.
\end{itemize}

\textbf{Prerequisites}

- Configure an account with the cloud platform that hosts your cluster.
- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

\textbf{Procedure}

1. Change to the directory that contains the installation program and initialize the cluster deployment:

   \begin{verbatim}
   $ ./openshift-install create cluster --dir <installation_directory> \
   --log-level=info
   \end{verbatim}

   For \texttt{<installation_directory>}, specify the

   \begin{verbatim}
   2
   \end{verbatim}

   To view different installation details, specify \texttt{warn}, \texttt{debug}, or \texttt{error} instead of \texttt{info}.
NOTE

If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.

When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the **kubeadmin** user, display in your terminal.

**Example output**

```text
... INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-yMBZj-Wt5AL"
INFO Time elapsed: 36m22s
```

NOTE

The cluster access and credential information also outputs to `<installation_directory>/.openshift_install.log` when an installation succeeds.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

**IMPORTANT**

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

17.4.14. Verifying cluster status

You can verify your OpenShift Container Platform cluster’s status during or after installation.

**Procedure**
1. In the cluster environment, export the administrator’s kubeconfig file:

   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server.

2. View the control plane and compute machines created after a deployment:

   $ oc get nodes

3. View your cluster's version:

   $ oc get clusterversion

4. View your Operators' status:

   $ oc get clusteroperator

5. View all running pods in the cluster:

   $ oc get pods -A

17.4.15. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

Procedure

1. Export the `kubeadmin` credentials:

   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   $ oc whoami
Example output

system:admin

The cluster is operational. Before you can add SR-IOV compute machines though, you must perform additional tasks.

17.4.16. Preparing a cluster that runs on RHOSP for SR-IOV

Before you use single root I/O virtualization (SR-IOV) on a cluster that runs on Red Hat OpenStack Platform (RHOSP), make the RHOSP metadata service mountable as a drive and enable the No-IOMMU Operator for the virtual function I/O (VFIO) driver.

17.4.16.1. Enabling the RHOSP metadata service as a mountable drive

You can apply a machine config to your machine pool that makes the Red Hat OpenStack Platform (RHOSP) metadata service available as a mountable drive.

The following machine config enables the display of RHOSP network UUIDs from within the SR-IOV Network Operator. This configuration simplifies the association of SR-IOV resources to cluster SR-IOV resources.

Procedure

1. Create a machine config file from the following template:

A mountable metadata service machine config file

```
kind: MachineConfig
apiVersion: machineconfiguration.openshift.io/v1
metadata:
  name: 20-mount-config
labels:
  machineconfiguration.openshift.io/role: worker
spec:
  config:
    ignition:
      version: 3.2.0
    systemd:
      units:
        - name: create-mountpoint-var-config.service
          enabled: true
          contents: |
            [Unit]
            Description=Create mountpoint /var/config
            Before=kubelet.service
            
            [Service]
            ExecStart=/bin/mkdir -p /var/config
            
            [Install]
            WantedBy=var-config.mount
          - name: var-config.mount
```
You can substitute a name of your choice.

2. From a command line, apply the machine config:

```bash
$ oc apply -f <machine_config_file_name>.yaml
```

17.4.16.2. Enabling the No-IOMMU feature for the RHOSP VFIO driver

You can apply a machine config to your machine pool that enables the No-IOMMU feature for the Red Hat OpenStack Platform (RHOSP) virtual function I/O (VFIO) driver. The RHOSP vfio-pci driver requires this feature.

**Procedure**

1. Create a machine config file from the following template:

   **A No-IOMMU VFIO machine config file**

   ```yaml
   kind: MachineConfig
   apiVersion: machineconfiguration.openshift.io/v1
   metadata:
     name: 99-vfio-noiommu
   labels:
     machineconfiguration.openshift.io/role: worker
   spec:
     config:
       ignition:
         version: 3.2.0
       storage:
         files:
           - path: /etc/modprobe.d/vfio-noiommu.conf
             mode: 0644
             contents:
               source: data;base64,b3B0aW9ucyB2ZmlvIGVuYWJsZV91bnNhZmVfVfVfbm9pb21tdV9tb2RIPETEK
   
   You can substitute a name of your choice.
   
   2. From a command line, apply the machine config:

   ```bash
   $ oc apply -f <machine_config_file_name>.yaml
   ```
The cluster is installed and prepared for SR-IOV configuration. Complete the post-installation SR-IOV tasks that are listed in the “Next steps” section.

17.4.17. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.10, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service

17.4.18. Next steps

- To complete SR-IOV configuration for your cluster:
  - Install the Performance Addon Operator.
  - Configure the Performance Addon Operator with huge pages support.
  - Install the SR-IOV Operator.
  - Configure your SR-IOV network device.
  - Add an SR-IOV compute machine set.
- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- If you need to enable external access to node ports, configure ingress cluster traffic by using a node port.
- If you did not configure RHOSP to accept application traffic over floating IP addresses, configure RHOSP access with floating IP addresses.

17.5. INSTALLING A CLUSTER ON OPENSTACK THAT SUPPORTS OVS-DPDK-CONNECTED COMPUTE MACHINES

If your Red Hat OpenStack Platform (RHOSP) deployment has Open vSwitch with the Data Plane Development Kit (OVS-DPDK) enabled, you can install an OpenShift Container Platform cluster on it. Clusters that run on such RHOSP deployments use OVS-DPDK features by providing access to poll mode drivers.

17.5.1. Prerequisites

- Review details about the OpenShift Container Platform installation and update processes.
  - Verify that OpenShift Container Platform 4.10 is compatible with your RHOSP version by using the “Supported platforms for OpenShift clusters” section. You can also compare
platform support across different versions by viewing the OpenShift Container Platform on RHOSP support matrix.

- Have a storage service installed in RHOSP, like block storage (Cinder) or object storage (Swift). Object storage is the recommended storage technology for OpenShift Container Platform registry cluster deployment. For more information, see Optimizing storage.

- Have the metadata service enabled in RHOSP.

- Plan your RHOSP OVS-DPDK deployment by referring to Planning your OVS-DPDK deployment in the Network Functions Virtualization Planning and Configuration Guide.

- Configure your RHOSP OVS-DPDK deployment according to Configuring an OVS-DPDK deployment in the Network Functions Virtualization Planning and Configuration Guide.
  - You must complete Creating a flavor and deploying an instance for OVS-DPDK before you install a cluster on RHOSP.

### 17.5.2. Resource guidelines for installing OpenShift Container Platform on RHOSP

To support an OpenShift Container Platform installation, your Red Hat OpenStack Platform (RHOSP) quota must meet the following requirements:

<table>
<thead>
<tr>
<th>Resource</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Floating IP addresses</td>
<td>3</td>
</tr>
<tr>
<td>Ports</td>
<td>15</td>
</tr>
<tr>
<td>Routers</td>
<td>1</td>
</tr>
<tr>
<td>Subnets</td>
<td>1</td>
</tr>
<tr>
<td>RAM</td>
<td>112 GB</td>
</tr>
<tr>
<td>vCPUs</td>
<td>28</td>
</tr>
<tr>
<td>Volume storage</td>
<td>275 GB</td>
</tr>
<tr>
<td>Instances</td>
<td>7</td>
</tr>
<tr>
<td>Security groups</td>
<td>3</td>
</tr>
<tr>
<td>Security group rules</td>
<td>60</td>
</tr>
<tr>
<td>Server groups</td>
<td>2 - plus 1 for each additional availability zone in each machine pool</td>
</tr>
</tbody>
</table>
A cluster might function with fewer than recommended resources, but its performance is not guaranteed.

**IMPORTANT**

If RHOSP object storage (Swift) is available and operated by a user account with the **swiftoperator** role, it is used as the default backend for the OpenShift Container Platform image registry. In this case, the volume storage requirement is 175 GB. Swift space requirements vary depending on the size of the image registry.

**NOTE**

By default, your security group and security group rule quotas might be low. If you encounter problems, run `openstack quota set --secgroups 3 --secgroup-rules 60 <project>` as an administrator to increase them.

An OpenShift Container Platform deployment comprises control plane machines, compute machines, and a bootstrap machine.

### 17.5.2.1. Control plane and compute machines

By default, the OpenShift Container Platform installation process stands up three control plane and three compute machines.

Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 25 GB storage space

**TIP**

Compute machines host the applications that you run on OpenShift Container Platform; aim to run as many as you can.

Additionally, for clusters that use single-root input/output virtualization (SR-IOV), RHOSP compute nodes require a flavor that supports huge pages.

**IMPORTANT**

SR-IOV deployments often employ performance optimizations, such as dedicated or isolated CPUs. For maximum performance, configure your underlying RHOSP deployment to use these optimizations, and then run OpenShift Container Platform compute machines on the optimized infrastructure.

**Additional resources**

- For more information about configuring performant RHOSP compute nodes, see Configuring Compute nodes for performance.

### 17.5.2.2. Bootstrap machine
During installation, a bootstrap machine is temporarily provisioned to stand up the control plane. After the production control plane is ready, the bootstrap machine is deprovisioned.

The bootstrap machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 25 GB storage space

17.5.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.10, you require access to the internet to obtain the images that are necessary to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

17.5.4. Enabling Swift on RHOSP

Swift is operated by a user account with the `swiftoperator` role. Add the role to an account before you run the installation program.

IMPORTANT

If the Red Hat OpenStack Platform (RHOSP) object storage service, commonly known as Swift, is available, OpenShift Container Platform uses it as the image registry storage. If it is unavailable, the installation program relies on the RHOSP block storage service, commonly known as Cinder.

If Swift is present and you want to use it, you must enable access to it. If it is not present, or if you do not want to use it, skip this section.

Prerequisites

- You have a RHOSP administrator account on the target environment.
- The Swift service is installed.
On Ceph RGW, the account in url option is enabled.

**Procedure**

To enable Swift on RHOSP:

1. As an administrator in the RHOSP CLI, add the `swiftoperator` role to the account that will access Swift:

   ```
   $ openstack role add --user <user> --project <project> swiftoperator
   ```

Your RHOSP deployment can now use Swift for the image registry.

17.5.5. Verifying external network access

The OpenShift Container Platform installation process requires external network access. You must provide an external network value to it, or deployment fails. Before you begin the process, verify that a network with the external router type exists in Red Hat OpenStack Platform (RHOSP).

**Prerequisites**

- Configure OpenStack’s networking service to have DHCP agents forward instances’ DNS queries

**Procedure**

1. Using the RHOSP CLI, verify the name and ID of the 'External' network:

   ```
   $ openstack network list --long -c ID -c Name -c "Router Type"
   ```

   **Example output**

   ```
   +--------------------------------------+----------------+-------------+
   | ID                                   | Name           | Router Type |
   +--------------------------------------+----------------+-------------+
   | 148a8023-62a7-4672-b018-003462f8d7dc | public_network | External    |
   +--------------------------------------+----------------+-------------+
   ```

   A network with an external router type appears in the network list. If at least one does not, see Creating a default floating IP network and Creating a default provider network.

   **NOTE**

   If the Neutron trunk service plug-in is enabled, a trunk port is created by default. For more information, see Neutron trunk port.

17.5.6. Defining parameters for the installation program

The OpenShift Container Platform installation program relies on a file that is called `clouds.yaml`. The file describes Red Hat OpenStack Platform (RHOSP) configuration parameters, including the project name, log in information, and authorization service URLs.

**Procedure**
1. Create the `clouds.yaml` file:

- If your RHOSP distribution includes the Horizon web UI, generate a `clouds.yaml` file in it.

  **IMPORTANT**

  Remember to add a password to the `auth` field. You can also keep secrets in a separate file from `clouds.yaml`.

- If your RHOSP distribution does not include the Horizon web UI, or you do not want to use Horizon, create the file yourself. For detailed information about `clouds.yaml`, see Config files in the RHOSP documentation.

```yaml
clouds:
  shiftstack:
    auth:
      project_name: shiftstack
      username: shiftstack_user
      password: XXX
      user_domain_name: Default
      project_domain_name: Default
  dev-env:
    region_name: RegionOne
    auth:
      username: 'devuser'
      password: XXX
      project_name: 'devonly'
```

2. If your RHOSP installation uses self-signed certificate authority (CA) certificates for endpoint authentication:

   a. Copy the certificate authority file to your machine.

   b. Add the `cacerts` key to the `clouds.yaml` file. The value must be an absolute, non-root-accessible path to the CA certificate:

```yaml
clouds:
  shiftstack:
    ... 
  cacert: "/etc/pki/ca-trust/source/anchors/ca.crt.pem"
```

**TIP**

After you run the installer with a custom CA certificate, you can update the certificate by editing the value of the `ca-cert.pem` key in the `cloud-provider-config` keymap. On a command line, run:

```
$ oc edit configmap -n openshift-config cloud-provider-config
```

3. Place the `clouds.yaml` file in one of the following locations:

   a. The value of the `OS_CLIENT_CONFIG_FILE` environment variable
b. The current directory

c. A Unix-specific user configuration directory, for example `~/.config/openstack/clouds.yaml`

d. A Unix-specific site configuration directory, for example `/etc/openstack/clouds.yaml`

The installation program searches for `clouds.yaml` in that order.

17.5.7. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the mirror host.

Prerequisites

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

   IMPORTANT

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   IMPORTANT

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ tar -xvf openshift-install-linux.tar.gz
   ```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

17.5.8. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on
Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster. For a restricted network installation, these files are on your mirror host.

- Have the **imageContentSources** values that were generated during mirror registry creation.

- Obtain the contents of the certificate for your mirror registry.

- Retrieve a Red Hat Enterprise Linux CoreOS (RHCOS) image and upload it to an accessible location.

- Obtain service principal permissions at the subscription level.

Procedure

1. Create the **install-config.yaml** file.
   
   a. Change to the directory that contains the installation program and run the following command:

   ```bash
   $ ./openshift-install create install-config --dir <installation_directory>
   ```

   **1** For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

   IMPORTANT

   Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

   b. At the prompts, provide the configuration details for your cloud:

      i. Optional: Select an SSH key to use to access your cluster machines.

      **NOTE**

      For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

      ii. Enter a descriptive name for your cluster.

      iii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

2. Edit the **install-config.yaml** file to provide the additional information that is required for an installation in a restricted network.

   a. Update the **pullSecret** value to contain the authentication information for your registry:
For `<mirror_host_name>`, specify the registry domain name that you specified in the certificate for your mirror registry, and for `<credentials>`, specify the base64-encoded user name and password for your mirror registry.

b. Add the `additionalTrustBundle` parameter and value.

```
additionalTrustBundle: |
   -----BEGIN CERTIFICATE-----
   ZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZ
   -----END CERTIFICATE-----
```

The value must be the contents of the certificate file that you used for your mirror registry, which can be an existing, trusted certificate authority or the self-signed certificate that you generated for the mirror registry.

c. Add the image content resources, which look like this excerpt:

```
imageContentSources:
- mirrors:
  - `<mirror_host_name>:`5000/<repo_name>/release
    source: quay.example.com/openshift-release-dev/ocp-release
  - mirrors:
    - `<mirror_host_name>:`5000/<repo_name>/release
      source: registry.example.com/ocp/release
```

To complete these values, use the `imageContentSources` that you recorded during mirror registry creation.

3. Make any other modifications to the `install-config.yaml` file that you require. You can find more information about the available parameters in the `Installation configuration parameters` section.

4. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

**IMPORTANT**

The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

### 17.5.8.1. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**Prerequisites**

- You have an existing `install-config.yaml` file.

- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to
hosting cloud provider APIs. You added sites to the **Proxy** object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The **Proxy** object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object `status.noProxy` field is also populated with the instance metadata endpoint (`169.254.169.254`).

**Procedure**

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port>  # 1
  httpsProxy: https://<username>:<pswd>@<ip>:<port>  # 2
  noProxy: example.com  # 3
additionalTrustBundle: |
  -----BEGIN CERTIFICATE-----
  <MY_TRUSTED_CA_CERT>
  -----END CERTIFICATE-----
...  # 4
```

   1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.
   2. A proxy URL to use for creating HTTPS connections outside the cluster.
   3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, `.y.com` matches `x.y.com`, but not `y.com`. Use * to bypass the proxy for all destinations.
   4. If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the `trustedCA` field of the **Proxy** object. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

**NOTE**

The installation program does not support the proxy `readinessEndpoints` field.

2. Save the file and reference it when installing OpenShift Container Platform.
The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

**NOTE**

Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

### 17.5.9. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide a customized `install-config.yaml` installation configuration file that describes the details for your environment.

**NOTE**

After installation, you cannot modify these parameters in the `install-config.yaml` file.

#### 17.5.9.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>apiVersion</code></td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is <code>v1</code>. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td><code>baseDomain</code></td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the <code>baseDomain</code> and <code>metadata.name</code> parameter values that uses the <code>&lt;metadata.name&gt;.&lt;baseDomain&gt;</code> format.</td>
<td>A fully-qualified domain or subdomain name, such as <code>example.com</code>.</td>
</tr>
<tr>
<td><code>metadata</code></td>
<td>Kubernetes resource <code>ObjectMeta</code>, from which only the <code>name</code> parameter is consumed.</td>
<td>Object</td>
</tr>
</tbody>
</table>
The name of the cluster. DNS records for the cluster are all subdomains of {{.metadata.name}}. {{.baseDomain}}.

String of lowercase letters, hyphens (-), and periods (.), such as dev.

The configuration for the specific platform upon which to perform the installation: alibabacloud, aws, baremetal, azure, ibmcloud, openstack, ovirt, vsphere, or {}. For additional information about platform.<platform> parameters, consult the table for your specific platform that follows.

Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.

```
{
  "auths":{
    "cloud.openshift.com":{
      "auth":"b3Blb=",
      "email":"you@example.com"
    },
    "quay.io":{
      "auth":"b3Blb=",
      "email":"you@example.com"
    }
  }
}
```

### 17.5.9.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

**Table 17.19. Network parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of {{.metadata.name}}. {{.baseDomain}}.</td>
<td>String of lowercase letters, hyphens (-), and periods (.), such as dev.</td>
</tr>
<tr>
<td>platform</td>
<td>The configuration for the specific platform upon which to perform the installation: alibabacloud, aws, baremetal, azure, ibmcloud, openstack, ovirt, vsphere, or {}. For additional information about platform.&lt;platform&gt; parameters, consult the table for your specific platform that follows.</td>
<td>Object</td>
</tr>
</tbody>
</table>
| pullSecret    | Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io. | {"auths":{ "cloud.openshift.com":{ "auth":"b3Blb=",
"email":"you@example.com"
 },
"quay.io":{ "auth":"b3Blb=",
"email":"you@example.com"

<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td><strong>NOTE</strong></td>
<td>You cannot modify parameters specified by the <code>networking</code> object after installation.</td>
<td></td>
</tr>
<tr>
<td>networking.network</td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN.</td>
</tr>
</tbody>
</table>
| networking.clusterNetwork | The IP address blocks for pods. The default value is 10.128.0.0/14 with a host prefix of /23. If you specify multiple IP address blocks, the blocks must not overlap. | An array of objects. For example: ```
- networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
    hostPrefix: 23``` |
| networking.clusterNetwork.cidr | Required if you use `networking.clusterNetwork`. An IP address block. An IPv4 network. | An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32. |
| networking.clusterNetwork.hostPrefix | The subnet prefix length to assign to each individual node. For example, if `hostPrefix` is set to 23 then each node is assigned a /23 subnet out of the given `cidr`. A `hostPrefix` value of 23 provides 510 (2^(32 - 23) - 2) pod IP addresses. | A subnet prefix. The default value is 23. |
| networking.serviceNetwork | The IP address block for services. The default value is 172.30.0.0/16. The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network. | An array with an IP address block in CIDR format. For example: ```
- networking:
  serviceNetwork:
    - 172.30.0.0/16``` |
networking.machine

The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap. If you specify multiple IP kernel arguments, the `machineNetwork.cidr` value must be the CIDR of the primary network.

networking.machineNetwork.cidr

Required if you use `networking.machineNetwork`. An IP address block. The default value is `10.0.0.0/16` for all platforms other than libvirt. For libvirt, the default value is `192.168.126.0/24`.

NOTE

Set the `networking.machineNetwork` to match the CIDR that the preferred NIC resides in.

17.5.9.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

Table 17.20. Optional parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>cgroupsV2</td>
<td>Enables Linux control groups version 2 (cgroups v2) on specific nodes in your cluster. The OpenShift Container Platform process for enabling cgroups v2 disables all cgroup version 1 controllers and hierarchies. The OpenShift Container Platform cgroups version 2 feature is in Developer Preview and is not supported by Red Hat at this time.</td>
<td>true</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of <code>MachinePool</code> objects.</td>

<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are s390x (the default).</td>
<td>String</td>
</tr>
<tr>
<td>compute.hyperthreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td></td>
</tr>
<tr>
<td>compute.name</td>
<td>Required if you use compute. The name of the machine pool.</td>
<td>worker</td>
</tr>
<tr>
<td>compute.platform</td>
<td>Required if you use compute. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the controlPlane.platform parameter value.</td>
<td>alibaba, aws, azure, gcp, ibmcloud, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td>compute.replicas</td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td>controlPlane</td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of MachinePool objects.</td>
</tr>
<tr>
<td>controlPlane.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are s390x (the default).</td>
<td>String</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>----------------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-------------------------</td>
</tr>
<tr>
<td><strong>controlPlane.hypertreading</strong></td>
<td>Whether to enable or disable simultaneous multithreading, or <em>hypertreading</em>, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td></td>
</tr>
<tr>
<td><strong>controlPlane.name</strong></td>
<td>Required if you use <strong>controlPlane</strong>. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td><strong>controlPlane.platform</strong></td>
<td>Required if you use <strong>controlPlane</strong>. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the <strong>compute.platform</strong> parameter value.</td>
<td>alibaba, aws, azure, gcp, ibmcloud, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td><strong>controlPlane.replicas</strong></td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
<tr>
<td><strong>credentialsMode</strong></td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (“”)</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-----------------------------</td>
</tr>
<tr>
<td>fips</td>
<td>Enable or disable FIPS mode. The default is false (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</td>
<td>false or true</td>
</tr>
</tbody>
</table>

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>imageContentSources</td>
<td>Sources and repositories for the release–image content.</td>
<td>Array of objects. Includes a source and, optionally, mirrors, as described in the following rows of this table.</td>
</tr>
<tr>
<td>imageContentSources.source</td>
<td>Required if you use imageContentSources. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td>imageContentSources.mirrors</td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>

<tr>
<td>publish</td>
<td>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</td>
<td><strong>Internal</strong> or <strong>External</strong>. The default value is <strong>External</strong>. Setting this field to <strong>Internal</strong> is not supported on non-cloud platforms and IBM Cloud. <strong>IMPORTANT</strong> If the value of the field is set to <strong>Internal</strong>, the cluster will become non-functional. For more information, refer to <a href="#">BZ#1953035</a>.</td>
</tr>
<tr>
<td>sshKey</td>
<td>The SSH key or keys to authenticate access your cluster machines.</td>
<td>One or more keys. For example: sshKey: &lt;key1&gt; &lt;key2&gt; &lt;key3&gt;</td>
</tr>
</tbody>
</table>

### 17.5.9.4. Custom subnets in RHOSP deployments

Optionally, you can deploy a cluster on a Red Hat OpenStack Platform (RHOSP) subnet of your choice. The subnet’s GUID is passed as the value of `platform.openstack.machinesSubnet` in the `install-config.yaml` file.

This subnet is used as the cluster’s primary subnet. By default, nodes and ports are created on it. You can create nodes and ports on a different RHOSP subnet by setting the value of the `platform.openstack.machinesSubnet` property to the subnet’s UUID.

Before you run the OpenShift Container Platform installer with a custom subnet, verify that your configuration meets the following requirements:

- The subnet that is used by `platform.openstack.machinesSubnet` has DHCP enabled.
- The CIDR of `platform.openstack.machinesSubnet` matches the CIDR of `networking.machineNetwork`. 

---

2180
The installation program user has permission to create ports on this network, including ports with fixed IP addresses.

Clusters that use custom subnets have the following limitations:

- If you plan to install a cluster that uses floating IP addresses, the `platform.openstack.machinesSubnet` subnet must be attached to a router that is connected to the `externalNetwork` network.

- If the `platform.openstack.machinesSubnet` value is set in the `install-config.yaml` file, the installation program does not create a private network or subnet for your RHOSP machines.

- You cannot use the `platform.openstack.externalDNS` property at the same time as a custom subnet. To add DNS to a cluster that uses a custom subnet, configure DNS on the RHOSP network.

**NOTE**

By default, the API VIP takes x.x.x.5 and the Ingress VIP takes x.x.x.7 from your network’s CIDR block. To override these default values, set values for `platform.openstack.apiVIP` and `platform.openstack.ingressVIP` that are outside of the DHCP allocation pool.

### 17.5.9.5. Deploying a cluster with bare metal machines

If you want your cluster to use bare metal machines, modify the `inventory.yaml` file. Your cluster can have both control plane and compute machines running on bare metal, or just compute machines.

Bare-metal compute machines are not supported on clusters that use Kuryr.

**NOTE**

Be sure that your `install-config.yaml` file reflects whether the RHOSP network that you use for bare metal workers supports floating IP addresses or not.

**Prerequisites**

- The RHOSP [Bare Metal service (Ironic)](https://github.com/openstack/ironic) is enabled and accessible via the RHOSP Compute API.

- Bare metal is available as a RHOSP flavor.

- The RHOSP network supports both VM and bare metal server attachment.

- Your network configuration does not rely on a provider network. Provider networks are not supported.

- If you want to deploy the machines on a pre-existing network, a RHOSP subnet is provisioned.

- If you want to deploy the machines on an installer-provisioned network, the RHOSP Bare Metal service (Ironic) is able to listen for and interact with Preboot eXecution Environment (PXE) boot machines that run on tenant networks.

- You created an `inventory.yaml` file as part of the OpenShift Container Platform installation process.

**Procedure**
1. In the `inventory.yaml` file, edit the flavors for machines:

   a. If you want to use bare-metal control plane machines, change the value of `os_flavor_master` to a bare metal flavor.

   b. Change the value of `os_flavor_worker` to a bare metal flavor.

   **An example bare metal `inventory.yaml` file**

   ```yaml
   all:
     hosts:
       localhost:
         ansible_connection: local
         ansible_python_interpreter: "{{ansible_playbook_python}}"

   # User-provided values
   os_subnet_range: '10.0.0.0/16'
   os_flavor_master: 'my-bare-metal-flavor'
   os_flavor_worker: 'my-bare-metal-flavor'
   os_image_rhcos: 'rhcos'
   os_external_network: 'external'

   ...
   ```

   1. If you want to have bare-metal control plane machines, change this value to a bare metal flavor.

   2. Change this value to a bare metal flavor to use for compute machines.

   Use the updated `inventory.yaml` file to complete the installation process. Machines that are created during deployment use the flavor that you added to the file.

   **NOTE**

   The installer may time out while waiting for bare metal machines to boot.

   If the installer times out, restart and then complete the deployment by using the `wait-for` command of the installer. For example:

   ```bash
   ./openshift-install wait-for install-complete --log-level debug
   ```

17.5.9.6. Sample customized `install-config.yaml` file for RHOSP

This sample `install-config.yaml` demonstrates all of the possible Red Hat OpenStack Platform (RHOSP) customization options.

**IMPORTANT**

This sample file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program.

```yaml
apiVersion: v1
baseDomain: example.com
```
17.5.10. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

Procedure
1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ ssh-keygen -t ed25519 -N " -f <path>/<file_name>  
   ```

   Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the `x86_64` architecture, do not create a key that uses the `ed25519` algorithm. Instead, create a key that uses the `rsa` or `ecdsa` algorithm.

2. View the public SSH key:

   ```
   $ cat <path>/<file_name>.pub
   ```

   For example, run the following to view the `~/.ssh/id_rsa.pub` public key:

   ```
   $ cat ~/.ssh/id_rsa.pub
   ```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `.openshift-install gather` command.

   **NOTE**

   On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

   a. If the `ssh-agent` process is not already running for your local user, start it as a background task:

   ```
   $ eval "$(sshd-agent -s)"
   ```

   **Example output**

   ```
   Agent pid 31874
   ```

   **NOTE**

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the `ssh-agent`:

   ```
   $ ssh-add <path>/<file_name>  
   ```
Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

Example output

Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

17.5.11. Enabling access to the environment

At deployment, all OpenShift Container Platform machines are created in a Red Hat OpenStack Platform (RHOSP)-tenant network. Therefore, they are not accessible directly in most RHOSP deployments.

You can configure OpenShift Container Platform API and application access by using floating IP addresses (FIPs) during installation. You can also complete an installation without configuring FIPs, but the installer will not configure a way to reach the API or applications externally.

17.5.11.1. Enabling access with floating IP addresses

Create floating IP (FIP) addresses for external access to the OpenShift Container Platform API and cluster applications.

Procedure

1. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the API FIP:

   $ openstack floating ip create --description "API <cluster_name>.<base_domain>" <external_network>

2. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the apps, or Ingress, FIP:

   $ openstack floating ip create --description "Ingress <cluster_name>.<base_domain>" <external_network>

3. Add records that follow these patterns to your DNS server for the API and Ingress FIPs:

   api.<cluster_name>.<base_domain>. IN A <API_FIP>
   *.apps.<cluster_name>.<base_domain>. IN A <apps_FIP>

   **NOTE**
   If you do not control the DNS server, you can add the record to your /etc/hosts file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

4. Add the FIPs to the install-config.yaml file as the values of the following parameters:

   - platform.openstack.ingressFloatingIP
- `platform.openstack.apiFloatingIP`

If you use these values, you must also enter an external network as the value of the `platform.openstack.externalNetwork` parameter in the `install-config.yaml` file.

**TIP**

You can make OpenShift Container Platform resources available outside of the cluster by assigning a floating IP address and updating your firewall configuration.

### 17.5.11.2. Completing installation without floating IP addresses

You can install OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) without providing floating IP addresses.

In the file, do not define the following:

If you run the installer from a system that cannot reach the cluster API due to a lack of floating IP addresses or name resolution, installation fails. To prevent installation failure in these cases, you can use a proxy network or run the installer from a system that is on the same network as your machines.

**NOTE**

You can enable name resolution by creating DNS records for the API and Ingress ports. For example:

```
api.<cluster_name>.<base_domain>. IN A <api_port_IP>
*.apps.<cluster_name>.<base_domain>. IN A <ingress_port_IP>
```

If you do not control the DNS server, you can add the record to your `/etc/hosts` file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

### 17.5.12. Creating SR-IOV networks for compute machines

If your Red Hat OpenStack Platform (RHOSP) deployment supports single root I/O virtualization (SR-IOV), you can provision SR-IOV networks that compute machines run on.

**NOTE**

The following instructions entail creating an external flat network and an external, VLAN-based network that can be attached to a compute machine. Depending on your RHOSP deployment, other network types might be required.

**Prerequisites**

- Your cluster supports SR-IOV.

**NOTE**

If you are unsure about what your cluster supports, review the OpenShift Container Platform SR-IOV hardware networks documentation.
You created radio and uplink provider networks as part of your RHOSP deployment. The names `radio` and `uplink` are used in all example commands to represent these networks.

**Procedure**

1. On a command line, create a radio RHOSP network:
   
   ```bash
   $ openstack network create radio --provider-physical-network radio --provider-network-type flat --external
   ```

2. Create an uplink RHOSP network:
   
   ```bash
   $ openstack network create uplink --provider-physical-network uplink --provider-network-type vlan --external
   ```

3. Create a subnet for the radio network:
   
   ```bash
   $ openstack subnet create --network radio --subnet-range <radio_network_subnet_range> radio
   ```

4. Create a subnet for the uplink network:
   
   ```bash
   $ openstack subnet create --network uplink --subnet-range <uplink_network_subnet_range> uplink
   ```

**17.5.13. Deploying the cluster**

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

**Prerequisites**

- Configure an account with the cloud platform that hosts your cluster.
- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Change to the directory that contains the installation program and initialize the cluster deployment:
   
   ```bash
   $ ./openshift-install create cluster --dir <installation_directory> \  
   --log-level=info
   ```

   1. For `<installation_directory>`, specify the
   2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`. 

NOTE

If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.

When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the `kubeadmin` user, display in your terminal.

Example output

```
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-Wi5AL"
INFO Time elapsed: 36m22s
```

NOTE

The cluster access and credential information also outputs to `<installation_directory>/openshift_install.log` when an installation succeeds.

IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

IMPORTANT

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

17.5.14. Verifying cluster status

You can verify your OpenShift Container Platform cluster’s status during or after installation.

Procedure
1. In the cluster environment, export the administrator’s kubeconfig file:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server.

2. View the control plane and compute machines created after a deployment:

```
$ oc get nodes
```

3. View your cluster’s version:

```
$ oc get clusterversion
```

4. View your Operators’ status:

```
$ oc get clusteroperator
```

5. View all running pods in the cluster:

```
$ oc get pods -A
```

### 17.5.15. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

```
$ oc whoami
```
Example output

The cluster is operational. Before you can add OVS-DPDK compute machines though, you must perform additional tasks.

17.5.16. Enabling the RHOSP metadata service as a mountable drive

You can apply a machine config to your machine pool that makes the Red Hat OpenStack Platform (RHOSP) metadata service available as a mountable drive.

The following machine config enables the display of RHOSP network UUIDs from within the SR-IOV Network Operator. This configuration simplifies the association of SR-IOV resources to cluster SR-IOV resources.

Procedure

1. Create a machine config file from the following template:

   A mountable metadata service machine config file

   ```yaml
   kind: MachineConfig
   apiVersion: machineconfiguration.openshift.io/v1
   metadata:
     name: 20-mount-config
     labels:
       machineconfiguration.openshift.io/role: worker
   spec:
     config:
       ignition:
         version: 3.2.0
       systemd:
         units:
           - name: create-mountpoint-var-config.service
             enabled: true
             contents:
               [Unit]
               Description=Create mountpoint /var/config
               Before=kubelet.service
               [Service]
               ExecStart=/bin/mkdir -p /var/config
               [Install]
               WantedBy=var-config.mount
           - name: var-config.mount
             enabled: true
             contents:
               [Unit]
               Before=local-fs.target
               [Mount]
               Where=/var/config
   ```
1. You can substitute a name of your choice.

2. From a command line, apply the machine config:

   $ oc apply -f <machine_config_file_name>.yaml

### 17.5.17. Enabling the No-IOMMU feature for the RHOSP VFIO driver

You can apply a machine config to your machine pool that enables the No-IOMMU feature for the Red Hat OpenStack Platform (RHOSP) virtual function I/O (VFIO) driver. The RHOSP vfio-pci driver requires this feature.

**Procedure**

1. Create a machine config file from the following template:

   **A No-IOMMU VFIO machine config file**

   ```yaml
   kind: MachineConfig
   apiVersion: machineconfiguration.openshift.io/v1
   metadata:
     name: 99-vfio-noiommu
     labels:
       machineconfiguration.openshift.io/role: worker
   spec:
     config:
       ignition:
         version: 3.2.0
     storage:
       files:
         - path: /etc/modprobe.d/vfio-noiommu.conf
           mode: 0644
           contents:
             source: data:;base64,b3B0aW9ucyB2ZmlvIGVuYWJsZV91bnNhZmVfYmFsbG9yY29tb2RlPTEK
   
   $ oc apply -f <machine_config_file_name>.yaml
   ```

   You can substitute a name of your choice.

2. From a command line, apply the machine config:

   $ oc apply -f <machine_config_file_name>.yaml

### 17.5.18. Binding the vfio-pci kernel driver to NICs

Compute machines that connect to a virtual function I/O (VFIO) network require the `vfio-pci` kernel driver to be bound to the ports that are attached to a configured network. Create a machine set for workers that attach to this VFIO network.
Procedure

1. From a command line, retrieve VFIO network UUIDs:

   ```
   $ openstack network show <VFIO_network_name> -f value -c id
   ```

2. Create a machine set on your cluster from the following template:

   ```json
   apiVersion: machineconfiguration.openshift.io/v1
   kind: MachineConfig
   metadata:
     labels:
       machineconfiguration.openshift.io/role: worker
     name: 99-vhostuser-bind
   spec:
     config:
       ignition:
         version: 2.2.0
       systemd:
         units:
           - name: vhostuser-bind.service
             enabled: true
             contents:
               [Unit]
               Description=Vhostuser Interface vfio-pci Bind
               Wants=network-online.target
               After=network-online.target ignition-firstboot-complete.service
               [Service]
               Type=oneshot
               EnvironmentFile=/etc/vhostuser-bind.conf
               ExecStart=/usr/local/bin/vhostuser $ARG
               [Install]
               WantedBy=multi-user.target
   storage:
   files:
     - contents:
       inline: vfio-pci
     filesystem: root
     mode: 0644
     path: /etc/modules-load.d/vfio-pci.conf
   - contents:
     inline: |
     #!/bin/bash
     set -e
     if [[ "$#" -lt 1 ]]; then
       echo "Network ID not provided, nothing to do"
       exit
     fi
     source /etc/vhostuser-bind.conf
     NW_DATA="/var/config/openstack/latest/network_data.json"
     if [ ! -f $NW_DATA ]; then
       echo "Network data file not found, trying to download it from nova metadata"
       if ! curl http://169.254.169.254/openstack/latest/network_data.json > /tmp/network_data.json; then
   ```
function parseNetwork() {
    local nwid=$1
    local pcis=()
    echo "Network ID is $nwid"
    links=$(jq '.networks[] | select(.network_id == "$nwid") | .link' $NW_DATA)
    if [ ${#links} -gt 0 ]; then
        for link in $links; do
            echo "Link Name: $link"
            mac=$(jq -r '.links[] | select(.id == "$link") | .ethernet_mac_address' $NW_DATA)
            if [ -n $mac ]; then
                pci=$(bindDriver $mac)
                pci_ret=0
                if [[ "$pci_ret" -eq 0 ]]; then
                    echo "$pci bind succesful"
                fi
            fi
        done
    fi
}

function bindDriver() {
    local mac=$1
    for file in /sys/class/net/*; do
        dev_mac=$(cat $file/address)
        if [[ "$mac" == "$dev_mac" ]]; then
            name=${file##*/}
            bus_str=$(ethtool -i $name | grep bus)
            dev_t=${bus_str#*:}
            dev=${dev_t#[:space:]}$dev
            devlink="/sys/bus/pci/devices/$dev"
            syspath=$(realpath "$devlink")
            if [ ! -f "$syspath/driver/unbind" ]; then
                echo "File $syspath/driver/unbind not found"
                return 1
            fi
            if echo "$dev">"$syspath/driver/unbind"; then
                return 1
            fi
        fi
    fi
}

CHAPTER 17. INSTALLING ON OPENSTACK

2193
Replace this value with a comma-separated list of VFIO network UUIDs.

On boot for machines that are part of this set, the MAC addresses of ports are translated into PCI bus IDs. The \texttt{vfio-pci} module is bound to any port that is associated with a network that is identified by the RHOSP network ID.

**Verification**

1. On a compute node, from a command line, retrieve the name of the node by entering:

   ```
   $ oc get nodes
   ```

2. Create a shell to debug the node:

   ```
   $ oc debug node/<node_name>
   ```

3. Change the root directory for the current running process:

   ```
   $ chroot /host
   ```

4. Enter the following command to list the kernel drivers that are handling each device on your machine:

   ```
   $ lspci -k
   ```
VFIO ethernet controllers use the \texttt{vfio-pci} kernel driver.

17.5.19. Exposing the host-device interface to the pod

You can use the Container Network Interface (CNI) plug-in to expose an interface that is on the host to the pod. The plug-in moves the interface from the namespace of the host network to the namespace of the pod. The pod then has direct control of the interface.

**Procedure**

- Create an additional network attachment with the host-device CNI plug-in by using the following object as an example:

```
apiVersion: k8s.cni.cncf.io/v1
kind: NetworkAttachmentDefinition
metadata:
  name: vhostuser1
  namespace: default
spec:
  config: '{ "cniVersion": "0.3.1", "name": "hostonly", "type": "host-device", "pciBusId": "0000:00:04.0", "ipam": { } }'
```

**Verification**

- From a command line, run the following command to see if networks are created in the namespace:

  ```bash
  $ oc -n <your_cnf_namespace> get net-attach-def
  ```

**Additional resources**

- Creating an additional network attachment with the Cluster Network Operator

The cluster is installed and prepared for configuration. You must now perform the OVS-DPDK configuration tasks in Next steps.

17.5.20. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.10, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- See About remote health monitoring for more information about the Telemetry service
17.5.21. Additional resources

- See Performance Addon Operator for low latency nodes for information about configuring your deployment for real-time running and low latency.

17.5.22. Next steps

- To complete OVS-DPDK configuration for your cluster:
  - Install the Performance Addon Operator.
  - Configure the Performance Addon Operator with huge pages support.
- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- If you need to enable external access to node ports, configure ingress cluster traffic by using a node port.
- If you did not configure RHOSP to accept application traffic over floating IP addresses, configure RHOSP access with floating IP addresses.

17.6. INSTALLING A CLUSTER ON OPENSTACK ON YOUR OWN INFRASTRUCTURE

In OpenShift Container Platform version 4.10, you can install a cluster on Red Hat OpenStack Platform (RHOSP) that runs on user-provisioned infrastructure.

Using your own infrastructure allows you to integrate your cluster with existing infrastructure and modifications. The process requires more labor on your part than installer-provisioned installations, because you must create all RHOSP resources, like Nova servers, Neutron ports, and security groups. However, Red Hat provides Ansible playbooks to help you in the deployment process.

17.6.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You verified that OpenShift Container Platform 4.10 is compatible with your RHOSP version by using the Supported platforms for OpenShift clusters section. You can also compare platform support across different versions by viewing the OpenShift Container Platform on RHOSP support matrix.
- You have an RHOSP account where you want to install OpenShift Container Platform.
- On the machine from which you run the installation program, you have:
  - A single directory in which you can keep the files you create during the installation process
  - Python 3
17.6.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.10, you require access to the internet to obtain the images that are necessary to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- Access Quay.io to obtain the packages that are required to install your cluster.

- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

17.6.3. Resource guidelines for installing OpenShift Container Platform on RHOSP

To support an OpenShift Container Platform installation, your Red Hat OpenStack Platform (RHOSP) quota must meet the following requirements:

**Table 17.21. Recommended resources for a default OpenShift Container Platform cluster on RHOSP**

<table>
<thead>
<tr>
<th>Resource</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Floating IP addresses</td>
<td>3</td>
</tr>
<tr>
<td>Ports</td>
<td>15</td>
</tr>
<tr>
<td>Routers</td>
<td>1</td>
</tr>
<tr>
<td>Subnets</td>
<td>1</td>
</tr>
<tr>
<td>RAM</td>
<td>112 GB</td>
</tr>
<tr>
<td>vCPUs</td>
<td>28</td>
</tr>
<tr>
<td>Volume storage</td>
<td>275 GB</td>
</tr>
<tr>
<td>Instances</td>
<td>7</td>
</tr>
<tr>
<td>Security groups</td>
<td>3</td>
</tr>
</tbody>
</table>
A cluster might function with fewer than recommended resources, but its performance is not guaranteed.

**IMPORTANT**

If RHOSP object storage (Swift) is available and operated by a user account with the `swiftoperator` role, it is used as the default backend for the OpenShift Container Platform image registry. In this case, the volume storage requirement is 175 GB. Swift space requirements vary depending on the size of the image registry.

**NOTE**

By default, your security group and security group rule quotas might be low. If you encounter problems, run `openstack quota set --secgroups 3 --secgroup-rules 60 <project>` as an administrator to increase them.

An OpenShift Container Platform deployment comprises control plane machines, compute machines, and a bootstrap machine.

### 17.6.3.1. Control plane and compute machines

By default, the OpenShift Container Platform installation process stands up three control plane and three compute machines.

Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 25 GB storage space

**TIP**

Compute machines host the applications that you run on OpenShift Container Platform; aim to run as many as you can.

### 17.6.3.2. Bootstrap machine

During installation, a bootstrap machine is temporarily provisioned to stand up the control plane. After the production control plane is ready, the bootstrap machine is deprovisioned.

The bootstrap machine requires:
17.6.4. Downloading playbook dependencies

The Ansible playbooks that simplify the installation process on user-provisioned infrastructure require several Python modules. On the machine where you will run the installer, add the modules’ repositories and then download them.

NOTE

These instructions assume that you are using Red Hat Enterprise Linux (RHEL) 8.

Prerequisites

- Python 3 is installed on your machine.

Procedure

1. On a command line, add the repositories:
   a. Register with Red Hat Subscription Manager:
      
      ```
      $ sudo subscription-manager register # If not done already
      ```
   b. Pull the latest subscription data:
      
      ```
      $ sudo subscription-manager attach --pool=$YOUR_POOLID # If not done already
      ```
   c. Disable the current repositories:
      
      ```
      $ sudo subscription-manager repos --disable=* # If not done already
      ```
   d. Add the required repositories:
      
      ```
      $ sudo subscription-manager repos \
      --enable=rhel-8-for-x86_64-baseos-rpms \
      --enable=openstack-16-tools-for-rhel-8-x86_64-rpms \
      --enable=ansible-2.9-for-rhel-8-x86_64-rpms \
      --enable=rhel-8-for-x86_64-appstream-rpms
      ```

2. Install the modules:

   ```
   $ sudo yum install python3-openstackclient ansible python3-openstacksdk python3-netaddr
   ```

3. Ensure that the python command points to python3:

   ```
   $ sudo alternatives --set python /usr/bin/python3
   ```
17.6.5. Downloading the installation playbooks

Download Ansible playbooks that you can use to install OpenShift Container Platform on your own Red Hat OpenStack Platform (RHOSP) infrastructure.

Prerequisites

- The curl command-line tool is available on your machine.

Procedure

- To download the playbooks to your working directory, run the following script from a command line:

  ```
  $ xargs -n 1 curl -O <<< 
  https://raw.githubusercontent.com/openshift/installer/release-4.10/upi/openstack/bootstrap.yaml
  https://raw.githubusercontent.com/openshift/installer/release-4.10/upi/openstack/common.yaml
  https://raw.githubusercontent.com/openshift/installer/release-4.10/upi/openstack/compute-nodes.yaml
  https://raw.githubusercontent.com/openshift/installer/release-4.10/upi/openstack/control-plane.yaml
  https://raw.githubusercontent.com/openshift/installer/release-4.10/upi/openstack/inventory.yaml
  https://raw.githubusercontent.com/openshift/installer/release-4.10/upi/openstack/network.yaml
  https://raw.githubusercontent.com/openshift/installer/release-4.10/upi/openstack/security-groups.yaml
  https://raw.githubusercontent.com/openshift/installer/release-4.10/upi/openstack/download-control-plane.yaml
  https://raw.githubusercontent.com/openshift/installer/release-4.10/upi/openstack/download-security-groups.yaml
  https://raw.githubusercontent.com/openshift/installer/release-4.10/upi/openstack/download-containers.yaml"
  
  The playbooks are downloaded to your machine.

  IMPORTANT

  During the installation process, you can modify the playbooks to configure your deployment.

  Retain all playbooks for the life of your cluster. You must have the playbooks to remove your OpenShift Container Platform cluster from RHOSP.
You must match any edits you make in the `bootstrap.yaml`, `compute-nodes.yaml`, `control-plane.yaml`, `network.yaml`, and `security-groups.yaml` files to the corresponding playbooks that are prefixed with `down-`. For example, edits to the `bootstrap.yaml` file must be reflected in the `down-bootstrap.yaml` file, too. If you do not edit both files, the supported cluster removal process will fail.

### 17.6.6. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the mirror host.

**Prerequisites**

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space

**Procedure**

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

**IMPORTANT**

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ tar -xvf openshift-install-linux.tar.gz
   ```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 17.6.7. Generating a key pair for cluster node SSH access
During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The ./openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>  
   ```

   Specifying the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   ```
   $ cat <path>/<file_name>.pub
   ```

   For example, run the following to view the ~/.ssh/id_rsa.pub public key:

   ```
   $ cat ~/.ssh/id_rsa.pub
   ```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the ./openshift-install gather command.
NOTE

On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.

a. If the ssh-agent process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

Example output

```
Agent pid 31874
```

NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the ssh-agent:

```
$ ssh-add <path>/<file_name> ¹
```

1 Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

17.6.8. Creating the Red Hat Enterprise Linux CoreOS (RHCOS) image

The OpenShift Container Platform installation program requires that a Red Hat Enterprise Linux CoreOS (RHCOS) image be present in the Red Hat OpenStack Platform (RHOSP) cluster. Retrieve the latest RHCOS image, then upload it using the RHOSP CLI.

Prerequisites

- The RHOSP CLI is installed.

Procedure

2. Under Version, select the most recent release of OpenShift Container Platform 4.10 for Red Hat Enterprise Linux (RHEL) 8.
IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available.

3. Download the Red Hat Enterprise Linux CoreOS (RHCOS) - OpenStack Image (QCOW).

4. Decompress the image.

NOTE

You must decompress the RHOSP image before the cluster can use it. The name of the downloaded file might not contain a compression extension, like .gz or .tgz. To find out if or how the file is compressed, in a command line, enter:

```
$ file <name_of_downloaded_file>
```

5. From the image that you downloaded, create an image that is named rhcos in your cluster by using the RHOSP CLI:

```
$ openstack image create --container-format=bare --disk-format=qcow2 --file rhcos-${RHCOS_VERSION}-openstack.qcow2 rhcos
```

IMPORTANT

Depending on your RHOSP environment, you might be able to upload the image in either .raw or .qcow2 formats. If you use Ceph, you must use the .raw format.

WARNING

If the installation program finds multiple images with the same name, it chooses one of them at random. To avoid this behavior, create unique names for resources in RHOSP.

After you upload the image to RHOSP, it is usable in the installation process.

17.6.9. Verifying external network access

The OpenShift Container Platform installation process requires external network access. You must provide an external network value to it, or deployment fails. Before you begin the process, verify that a network with the external router type exists in Red Hat OpenStack Platform (RHOSP).

Prerequisites
Configure OpenStack’s networking service to have DHCP agents forward instances’ DNS queries

Procedure

1. Using the RHOSP CLI, verify the name and ID of the 'External' network:

   ```
   $ openstack network list --long -c ID -c Name -c "Router Type"
   +--------------------------------------+----------------+-------------+
   | ID                                   | Name           | Router Type |
   +--------------------------------------+----------------+-------------+
   | 148a8023-62a7-4672-b018-003462f8d7dc | public_network | External    |
   +--------------------------------------+----------------+-------------+
   ```

   A network with an external router type appears in the network list. If at least one does not, see Creating a default floating IP network and Creating a default provider network.

   **NOTE**

   If the Neutron trunk service plug-in is enabled, a trunk port is created by default. For more information, see Neutron trunk port.

17.6.10. Enabling access to the environment

At deployment, all OpenShift Container Platform machines are created in a Red Hat OpenStack Platform (RHOSP)-tenant network. Therefore, they are not accessible directly in most RHOSP deployments.

You can configure OpenShift Container Platform API and application access by using floating IP addresses (FIPs) during installation. You can also complete an installation without configuring FIPs, but the installer will not configure a way to reach the API or applications externally.

17.6.10.1. Enabling access with floating IP addresses

Create floating IP (FIP) addresses for external access to the OpenShift Container Platform API, cluster applications, and the bootstrap process.

Procedure

1. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the API FIP:

   ```
   $ openstack floating ip create --description "API <cluster_name>.<base_domain>" <external_network>
   ```

2. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the apps, or Ingress, FIP:

   ```
   $ openstack floating ip create --description "Ingress <cluster_name>.<base_domain>" <external_network>
   ```

3. By using the Red Hat OpenStack Platform (RHOSP) CLI, create the bootstrap FIP:
Add records that follow these patterns to your DNS server for the API and Ingress FIPs:

```bash
$ openstack floating ip create --description "bootstrap machine" <external_network>
```

4. Add records that follow these patterns to your DNS server for the API and Ingress FIPs:

```
api.<cluster_name>.<base_domain>. IN A <API_FIP>
*.apps.<cluster_name>.<base_domain>. IN A <apps_FIP>
```

**NOTE**

If you do not control the DNS server, you can add the record to your `/etc/hosts` file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

5. Add the FIPs to the `inventory.yaml` file as the values of the following variables:

- `os_api_fip`
- `os_bootstrap_fip`
- `os_ingress_fip`

If you use these values, you must also enter an external network as the value of the `os_external_network` variable in the `inventory.yaml` file.

**TIP**

You can make OpenShift Container Platform resources available outside of the cluster by assigning a floating IP address and updating your firewall configuration.

17.6.10.2. Completing installation without floating IP addresses

You can install OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) without providing floating IP addresses.

In the `inventory.yaml` file, do not define the following variables:

- `os_api_fip`
- `os_bootstrap_fip`
- `os_ingress_fip`

If you cannot provide an external network, you can also leave `os_external_network` blank. If you do not provide a value for `os_external_network`, a router is not created for you, and, without additional action, the installer will fail to retrieve an image from Glance. Later in the installation process, when you create network resources, you must configure external connectivity on your own.

If you run the installer with the `wait-for` command from a system that cannot reach the cluster API due to a lack of floating IP addresses or name resolution, installation fails. To prevent installation failure in these cases, you can use a proxy network or run the installer from a system that is on the same network as your machines.
NOTE
You can enable name resolution by creating DNS records for the API and Ingress ports. For example:

```
api.<cluster_name>..<base_domain>  IN  A  <api_port_IP>
*.apps.<cluster_name>..<base_domain>  IN  A  <ingress_port_IP>
```

If you do not control the DNS server, you can add the record to your `/etc/hosts` file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

17.6.11. Defining parameters for the installation program

The OpenShift Container Platform installation program relies on a file that is called `clouds.yaml`. The file describes Red Hat OpenStack Platform (RHOSP) configuration parameters, including the project name, log in information, and authorization service URLs.

Procedure

1. Create the `clouds.yaml` file:
   - If your RHOSP distribution includes the Horizon web UI, generate a `clouds.yaml` file in it.
     - **IMPORTANT**
       
       Remember to add a password to the `auth` field. You can also keep secrets in a separate file from `clouds.yaml`.
   - If your RHOSP distribution does not include the Horizon web UI, or you do not want to use Horizon, create the file yourself. For detailed information about `clouds.yaml`, see Config files in the RHOSP documentation.

   ```yaml
   clouds:
   shiftstack:
     auth:
       project_name: shiftstack
       username: shiftstack_user
       password: XXX
       user_domain_name: Default
       project_domain_name: Default
     dev-env:
       region_name: RegionOne
       auth:
         username: 'devuser'
         password: XXX
         project_name: 'devonly'
   ```

2. If your RHOSP installation uses self-signed certificate authority (CA) certificates for endpoint authentication:
   - Copy the certificate authority file to your machine.
b. Add the **cacerts** key to the **clouds.yaml** file. The value must be an absolute, non-root-accessible path to the CA certificate:

```yaml
clouds:
  shiftstack:
    ...
  cacert: "/etc/pki/ca-trust/source/anchors/ca.crt.pem"
```

**TIP**

After you run the installer with a custom CA certificate, you can update the certificate by editing the value of the **ca-cert.pem** key in the **cloud-provider-config** keymap. On a command line, run:

```bash
$ oc edit configmap -n openshift-config cloud-provider-config
```

3. Place the **clouds.yaml** file in one of the following locations:

   a. The value of the **OS_CLIENT_CONFIG_FILE** environment variable

   b. The current directory

   c. A Unix-specific user configuration directory, for example `~/.config/openstack/clouds.yaml`

   d. A Unix-specific site configuration directory, for example `/etc/openstack/clouds.yaml`

The installation program searches for **clouds.yaml** in that order.

### 17.6.12. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Red Hat OpenStack Platform (RHOSP).

**Prerequisites**

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster. For a restricted network installation, these files are on your mirror host.

- Have the **imageContentSources** values that were generated during mirror registry creation.

- Obtain the contents of the certificate for your mirror registry.

- Retrieve a Red Hat Enterprise Linux CoreOS (RHCOS) image and upload it to an accessible location.

- Obtain service principal permissions at the subscription level.

**Procedure**

1. Create the **install-config.yaml** file.

   a. Change to the directory that contains the installation program and run the following command:

   ```bash
   $ ./openshift-install create install-config --dir <installation_directory>
   ```
1 For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

**IMPORTANT**

Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

b. At the prompts, provide the configuration details for your cloud:

   i. Optional: Select an SSH key to use to access your cluster machines.

   **NOTE**

   For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

   ii. Select `openstack` as the platform to target.

   iii. Specify the Red Hat OpenStack Platform (RHOSP) external network name to use for installing the cluster.

   iv. Specify the floating IP address to use for external access to the OpenShift API.

   v. Specify a RHOSP flavor with at least 16 GB RAM to use for control plane and compute nodes.

   vi. Select the base domain to deploy the cluster to. All DNS records will be sub-domains of this base and will also include the cluster name.

   vii. Enter a name for your cluster. The name must be 14 or fewer characters long.

   viii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

2. In the `install-config.yaml` file, set the value of `platform.openstack.clusterOSImage` to the image location or name. For example:

   ```yaml
   platform:
     openstack:
       clusterOSImage: http://mirror.example.com/images/rhcos-43.81.201912131630.0-openstack.x86_64.qcow2.gz?
       sha256=ffeabbd68e8a112a245ca19522c16c86f67f9ac8e4e0c1a1812b068b16f7265d
   ```

3. Edit the `install-config.yaml` file to provide the additional information that is required for an installation in a restricted network.

   a. Update the `pullSecret` value to contain the authentication information for your registry:
For `<mirror_host_name>`, specify the registry domain name that you specified in the certificate for your mirror registry, and for `<credentials>`, specify the base64-encoded user name and password for your mirror registry.

b. Add the `additionalTrustBundle` parameter and value.

```
additionalTrustBundle: |
        -----BEGIN CERTIFICATE-----
ZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZ
-----END CERTIFICATE-----
```

The value must be the contents of the certificate file that you used for your mirror registry, which can be an existing, trusted certificate authority or the self-signed certificate that you generated for the mirror registry.

c. Add the image content resources, which look like this excerpt:

```
imageContentSources:
- mirrors:
  - `<mirror_host_name>:5000/<repo_name>/release`
    source: quay.example.com/openshift-release-dev/ocp-release
  - `<mirror_host_name>:5000/<repo_name>/release`
    source: registry.example.com/ocp/release
```

To complete these values, use the `imageContentSources` that you recorded during mirror registry creation.

4. Make any other modifications to the `install-config.yaml` file that you require. You can find more information about the available parameters in the `Installation configuration parameters` section.

5. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

**IMPORTANT**

The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

You now have the file `install-config.yaml` in the directory that you specified.

### 17.6.13. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide a customized `install-config.yaml` installation configuration file that describes the details for your environment.

**NOTE**

After installation, you cannot modify these parameters in the `install-config.yaml` file.
### 17.6.13.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>apiVersion</strong></td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is v1. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td><strong>baseDomain</strong></td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the <code>baseDomain</code> and <code>metadata.name</code> parameter values that uses the <code>&lt;metadata.name&gt;.&lt;baseDomain&gt;</code> format.</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
</tr>
<tr>
<td><strong>metadata</strong></td>
<td>Kubernetes resource <code>ObjectMeta</code>, from which only the <code>name</code> parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td><strong>metadata.name</strong></td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of <code>{{.metadata.name}}.{{.baseDomain}}</code>.</td>
<td>String of lowercase letters, hyphens (-), and periods (.), such as dev. The string must be 14 characters or fewer long.</td>
</tr>
<tr>
<td><strong>platform</strong></td>
<td>The configuration for the specific platform upon which to perform the installation: alibabacloud, aws, baremetal, azure, ibmcloud, openstack, ovirt, vsphere, or {}. For additional information about <code>platform.&lt;platform&gt;</code> parameters, consult the table for your specific platform that follows.</td>
<td>Object</td>
</tr>
</tbody>
</table>
### pullSecret

Get a **pull secret from the Red Hat OpenShift Cluster Manager** to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.

```json
{
    "auths": {
        "cloud.openshift.com": {
            "auth": "b3Blb=",
            "email": "you@example.com"
        },
        "quay.io": {
            "auth": "b3Blb=",
            "email": "you@example.com"
        }
    }
}
```

### 17.6.13.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

**Table 17.23. Network parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td></td>
<td>NOTE</td>
<td>You cannot modify parameters specified by the <strong>networking</strong> object after installation.</td>
</tr>
<tr>
<td>networking.networkType</td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either <strong>OpenShiftSDN</strong> or <strong>OVNKubernetes</strong>. The default value is <strong>OpenShiftSDN</strong>.</td>
</tr>
<tr>
<td>networking.clusterNetwork</td>
<td>The IP address blocks for pods.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td>networking.clusterNetwork.cidr</td>
<td>Required if you use <code>networking.clusterNetwork</code>. An IP address block. An IPv4 network.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td>networking.clusterNetwork.hostPrefix</td>
<td>The subnet prefix length to assign to each individual node. For example, if <code>hostPrefix</code> is set to 23 then each node is assigned a /23 subnet out of the given <code>cidr</code>. A <code>hostPrefix</code> value of 23 provides 510 (2^(32 - 23) - 2) pod IP addresses.</td>
<td>A subnet prefix. The default value is 23.</td>
</tr>
<tr>
<td>networking.serviceNetwork</td>
<td>The IP address block for services. The default value is 172.30.0.0/16. The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.</td>
<td>An array with an IP address block in CIDR format. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>networking:</code></td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>serviceNetwork:</code></td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>- 172.30.0.0/16</code></td>
</tr>
<tr>
<td>networking.machineNetwork</td>
<td>The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap. If you specify multiple IP kernel arguments, the <code>machineNetwork.cidr</code> value must be the CIDR of the primary network.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>networking:</code></td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>machineNetwork:</code></td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>- cidr: 10.0.0.0/16</code></td>
</tr>
<tr>
<td>networking.machineNetwork.cidr</td>
<td>Required if you use <code>networking.machineNetwork</code>. An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24.</td>
<td>An IP network block in CIDR notation. For example, 10.0.0.0/16.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>NOTE</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Set the <code>networking.machineNetwork</code> to match the CIDR that the preferred NIC resides in.</td>
</tr>
</tbody>
</table>

17.6.13.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

Table 17.24. Optional parameters
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes' trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>cgrouspV2</td>
<td>Enables Linux control groups version 2 (cgroups v2) on specific nodes in your cluster. The OpenShift Container Platform process for enabling cgroups v2 disables all cgroup version 1 controllers and hierarchies. The OpenShift Container Platform cgroups version 2 feature is in Developer Preview and is not supported by Red Hat at this time.</td>
<td>true</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of MachinePool objects.</td>
</tr>
<tr>
<td>compute.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are s390x (the default).</td>
<td>String</td>
</tr>
<tr>
<td>compute.hyperthreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td></td>
</tr>
<tr>
<td>compute.name</td>
<td>Required if you use compute. The name of the machine pool.</td>
<td>worker</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------</td>
</tr>
<tr>
<td>compute.platform</td>
<td>Required if you use <code>compute</code>. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <code>controlPlane.platform</code> parameter value.</td>
<td>alibaba, aws, azure, gcp, ibmcloud, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td>compute.replicas</td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td>controlPlane</td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of MachinePool objects.</td>
</tr>
<tr>
<td>controlPlane.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are s390x (the default).</td>
<td>String</td>
</tr>
<tr>
<td>controlPlane.hypertreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>controlPlane.name</td>
<td>Required if you use <code>controlPlane</code>. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------</td>
</tr>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use <code>controlPlane</code>. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the <code>compute.platform</code> parameter value.</td>
<td>alibaba, aws, azure, gcp, ibmcloud, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (“”).</td>
</tr>
</tbody>
</table>

**NOTE**

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Platform Operators reference content.
Enable or disable FIPS mode. The default is `false` (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>fips</code></td>
<td>Enable or disable FIPS mode. The default is <code>false</code> (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</td>
<td><code>false</code> or <code>true</code></td>
</tr>
<tr>
<td><code>imageContentSources</code></td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects. Includes a <code>source</code> and, optionally, <code>mirrors</code>, as described in the following rows of this table.</td>
</tr>
<tr>
<td><code>imageContentSources.source</code></td>
<td>Required if you use <code>imageContentSources</code>. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td><code>imageContentSources.mirrors</code></td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
</tbody>
</table>
How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.

**Internal** or **External**. The default value is **External**.

Setting this field to **Internal** is not supported on non-cloud platforms and IBM Cloud.

**IMPORTANT**

If the value of the field is set to **Internal**, the cluster will become non-functional. For more information, refer to [BZ#1953035](#).

The SSH key or keys to authenticate access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

One or more keys. For example:

```
sshKey:
  <key1>
  <key2>
  <key3>
```

### 17.6.13.4. Additional Red Hat OpenStack Platform (RHOSP) configuration parameters

Additional RHOSP configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>compute.platform.openstack.rootVolume.size</code></td>
<td>For compute machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.</td>
<td>Integer, for example <strong>30</strong>.</td>
</tr>
<tr>
<td><code>compute.platform.openstack.rootVolume.type</code></td>
<td>For compute machines, the root volume’s type.</td>
<td>String, for example <strong>performance</strong>.</td>
</tr>
</tbody>
</table>
### Parameter | Description | Values
--- | --- | ---
`controlPlane.platform.openstack.rootVolume.size` | For control plane machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage. | Integer, for example 30.

`controlPlane.platform.openstack.rootVolume.type` | For control plane machines, the root volume’s type. | String, for example `performance`.

`platform.openstack.cloud` | The name of the RHOSP cloud to use from the list of clouds in the `clouds.yaml` file. | String, for example `MyCloud`.

`platform.openstack.externalNetwork` | The RHOSP external network name to be used for installation. | String, for example `external`.

`platform.openstack.computeFlavor` | The RHOSP flavor to use for control plane and compute machines. This property is deprecated. To use a flavor as the default for all machine pools, add it as the value of the `type` key in the `platform.openstack.defaultMachinePlatform` property. You can also set a flavor value for each machine pool individually. | String, for example `m1.xlarge`.

#### 17.6.13.5. Optional RHOSP configuration parameters

Optional RHOSP configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>compute.platform.openstack.additionalNetworkIIDs</code></td>
<td>Additional networks that are associated with compute machines. Allowed address pairs are not created for additional networks.</td>
<td>A list of one or more UUIDs as strings. For example, <code>fa806b2f-ac49-4bce-b9db-124bc64209bf</code>.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------</td>
</tr>
<tr>
<td>compute.platform.openstack.additionalSecurityGroupIDs</td>
<td>Additional security groups that are associated with compute machines.</td>
<td>A list of one or more UUIDs as strings. For example, 7ee219f3-d2e9-48a1-96c2-e7429f1b0da7.</td>
</tr>
<tr>
<td>compute.platform.openstack.zones</td>
<td>RHOSP Compute (Nova) availability zones (AZs) to install machines on. If this parameter is not set, the installer relies on the default settings for Nova that the RHOSP administrator configured. On clusters that use Kuryr, RHOSP Octavia does not support availability zones. Load balancers and, if you are using the Amphora provider driver, OpenShift Container Platform services that rely on Amphora VMs, are not created according to the value of this property.</td>
<td>A list of strings. For example, [&quot;zone-1&quot;, &quot;zone-2&quot;].</td>
</tr>
<tr>
<td>compute.platform.openstack.rootVolume.zones</td>
<td>For compute machines, the availability zone to install root volumes on. If you do not set a value for this parameter, the installer selects the default availability zone.</td>
<td>A list of strings, for example [&quot;zone-1&quot;, &quot;zone-2&quot;].</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td><strong>compute.platform.openstack.serverGroupPolicy</strong></td>
<td>Server group policy to apply to the group that will contain the compute machines in the pool. You cannot change server group policies or affiliations after creation. Supported options include <strong>anti-affinity</strong>, <strong>soft-affinity</strong>, and <strong>soft-anti-affinity</strong>. The default value is <strong>soft-anti-affinity</strong>. An <strong>affinity</strong> policy prevents migrations and therefore affects RHOSP upgrades. The <strong>affinity</strong> policy is not supported. If you use a strict <strong>anti-affinity</strong> policy, an additional RHOSP host is required during instance migration.</td>
<td>A server group policy to apply to the machine pool. For example, <strong>soft-affinity</strong>.</td>
</tr>
<tr>
<td><strong>controlPlane.platform.openstack.additionalNetworkIDs</strong></td>
<td>Additional networks that are associated with control plane machines. Allowed address pairs are not created for additional networks.</td>
<td>A list of one or more UUIDs as strings. For example, <code>fa806b2f-ac49-4bce-b9db-124bc64209bf</code>.</td>
</tr>
<tr>
<td><strong>controlPlane.platform.openstack.additionalSecurityGroupIDs</strong></td>
<td>Additional security groups that are associated with control plane machines.</td>
<td>A list of one or more UUIDs as strings. For example, <code>7ee219f3-d2e9-48a1-96c2-e7429f1b0da7</code>.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td><code>controlPlane.platform.openstack.zones</code></td>
<td>RHOSP Compute (Nova) availability zones (AZs) to install machines on. If this parameter is not set, the installer relies on the default settings for Nova that the RHOSP administrator configured. On clusters that use Kuryr, RHOSP Octavia does not support availability zones. Load balancers and, if you are using the Amphora provider driver, OpenShift Container Platform services that rely on Amphora VMs, are not created according to the value of this property.</td>
<td>A list of strings. For example, [&quot;zone-1&quot;, &quot;zone-2&quot;].</td>
</tr>
<tr>
<td><code>controlPlane.platform.openstack.rootVolume.zones</code></td>
<td>For control plane machines, the availability zone to install root volumes on. If you do not set this value, the installer selects the default availability zone.</td>
<td>A list of strings, for example [&quot;zone-1&quot;, &quot;zone-2&quot;].</td>
</tr>
<tr>
<td><code>controlPlane.platform.openstack.serverGroupPolicy</code></td>
<td>Server group policy to apply to the group that will contain the control plane machines in the pool. You cannot change server group policies or affiliations after creation. Supported options include anti-affinity, soft-affinity, and soft-anti-affinity. The default value is soft-anti-affinity. An affinity policy prevents migrations, and therefore affects RHOSP upgrades. The affinity policy is not supported. If you use a strict anti-affinity policy, an additional RHOSP host is required during instance migration.</td>
<td>A server group policy to apply to the machine pool. For example, soft-affinity.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td><code>platform.openstack.clusterOSImage</code></td>
<td>The location from which the installer downloads the RH COS image. You must set this parameter to perform an installation in a restricted network.</td>
<td>An HTTP or HTTPS URL, optionally with an SHA-256 checksum. For example, <code>http://mirror.example.com/images/rhcos-43.81.201912131630.0-openstack.x86_64.qcow2.gz?sha256=ffebbd68e8a1f2a245ca19522c16c86f67f9ac8e4e0c1f0a812b068b16f7265d</code>. The value can also be the name of an existing Glance image, for example <code>my-rhcos</code>.</td>
</tr>
<tr>
<td><code>platform.openstack.clusterOSImageProperties</code></td>
<td>Properties to add to the installer-uploaded ClusterOSImage in Glance. This property is ignored if <code>platform.openstack.clusterOSImage</code> is set to an existing Glance image. You can use this property to exceed the default persistent volume (PV) limit for RHOSP of 26 PVs per node. To exceed the limit, set the <code>hw_scsi_model</code> property value to <code>virtio-scsi</code> and the <code>hw_disk_bus</code> value to <code>scsi</code>. You can also use this property to enable the QEMU guest agent by including the <code>hw_qemu_guest_agent</code> property with a value of <code>yes</code>.</td>
<td>A list of key-value string pairs. For example, `[&quot;hw_scsi_model&quot;: &quot;virtio-scsi&quot;, &quot;hw_disk_bus&quot;: &quot;scsi&quot;]').</td>
</tr>
<tr>
<td><code>platform.openstack.defaultMachinePlatform</code></td>
<td>The default machine pool platform configuration.</td>
<td><code>{ &quot;type&quot;: &quot;ml.large&quot;, &quot;rootVolume&quot;: { &quot;size&quot;: 30, &quot;type&quot;: &quot;performance&quot; } }</code></td>
</tr>
<tr>
<td><code>platform.openstack.ingressFloatingIP</code></td>
<td>An existing floating IP address to associate with the Ingress port. To use this property, you must also define the <code>platform.openstack.externalNetwork</code> property.</td>
<td>An IP address, for example <code>128.0.0.1</code>.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-----------------------------------------------------------------------------------------</td>

<tr>
<td>platform.openstack.externalDNS</td>
<td>IP addresses for external DNS servers that cluster instances use for DNS resolution.</td>
<td>A list of IP addresses as strings. For example, [&quot;8.8.8.8&quot;, &quot;192.168.1.12&quot;]</td>
</tr>
<tr>
<td>platform.openstack.machinesSubnet</td>
<td>The UUID of a RHOSP subnet that the cluster’s nodes use. Nodes and virtual IP (VIP) ports are created on this subnet. The first item in networking.machineNetwork must match the value of machinesSubnet. If you deploy to a custom subnet, you cannot specify an external DNS server to the OpenShift Container Platform installer. Instead, add DNS to the subnet in RHOSP.</td>
<td>A UUID as a string. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf.</td>
</tr>
</tbody>
</table>

### 17.6.13.6. Custom subnets in RHOSP deployments

Optionally, you can deploy a cluster on a Red Hat OpenStack Platform (RHOSP) subnet of your choice. The subnet’s GUID is passed as the value of platform.openstack.machinesSubnet in the install-config.yaml file.

This subnet is used as the cluster’s primary subnet. By default, nodes and ports are created on it. You can create nodes and ports on a different RHOSP subnet by setting the value of the platform.openstack.machinesSubnet property to the subnet’s UUID.

Before you run the OpenShift Container Platform installer with a custom subnet, verify that your configuration meets the following requirements:

- The subnet that is used by platform.openstack.machinesSubnet has DHCP enabled.
- The CIDR of platform.openstack.machinesSubnet matches the CIDR of networking.machineNetwork.
- The installation program user has permission to create ports on this network, including ports with fixed IP addresses.

Clusters that use custom subnets have the following limitations:
If you plan to install a cluster that uses floating IP addresses, the `platform.openstack.machinesSubnet` subnet must be attached to a router that is connected to the `externalNetwork` network.

If the `platform.openstack.machinesSubnet` value is set in the `install-config.yaml` file, the installation program does not create a private network or subnet for your RHOSP machines.

You cannot use the `platform.openstack.externalDNS` property at the same time as a custom subnet. To add DNS to a cluster that uses a custom subnet, configure DNS on the RHOSP network.

**NOTE**

By default, the API VIP takes x.x.x.5 and the Ingress VIP takes x.x.x.7 from your network’s CIDR block. To override these default values, set values for `platform.openstack.apiVIP` and `platform.openstack.ingressVIP` that are outside of the DHCP allocation pool.

### 17.6.13.7. Sample customized install-config.yaml file for RHOSP

This sample `install-config.yaml` demonstrates all of the possible Red Hat OpenStack Platform (RHOSP) customization options.

**IMPORTANT**

This sample file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program.

```yaml
apiVersion: v1
baseDomain: example.com
controlPlane:
  name: master
  platform: {}
  replicas: 3
compute:
  - name: worker
    platform:
      openstack:
        type: ml.large
        replicas: 3
    metadata:
      name: example
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
      hostPrefix: 23
  machineNetwork:
    - cidr: 10.0.0.0/16
  serviceNetwork:
    - 172.30.0.0/16
networkType: OpenShiftSDN
platform:
  openstack:
    cloud: mycloud
    externalNetwork: external
```
17.6.13.8. Setting a custom subnet for machines

The IP range that the installation program uses by default might not match the Neutron subnet that you create when you install OpenShift Container Platform. If necessary, update the CIDR value for new machines by editing the installation configuration file.

Prerequisites

- You have the `install-config.yaml` file that was generated by the OpenShift Container Platform installation program.

Procedure

1. On a command line, browse to the directory that contains `install-config.yaml`.

2. From that directory, either run a script to edit the `install-config.yaml` file or update the file manually:

   - To set the value by using a script, run:

     ```
     $ python -c 'import yaml; path = "install-config.yaml"; data = yaml.safe_load(open(path)); data["networking"]['machineNetwork'] = ["cidr": "192.168.0.0/18"]; open(path, "w").write(yaml.dump(data, default_flow_style=False))'
     ```

   - Insert a value that matches your intended Neutron subnet, e.g. `192.0.2.0/24`.

   - To set the value manually, open the file and set the value of `networking.machineCIDR` to something that matches your intended Neutron subnet.

17.6.13.9. Emptying compute machine pools

To proceed with an installation that uses your own infrastructure, set the number of compute machines in the installation configuration file to zero. Later, you create these machines manually.

Prerequisites

- You have the `install-config.yaml` file that was generated by the OpenShift Container Platform installation program.

Procedure

1. On a command line, browse to the directory that contains `install-config.yaml`.

```python
computeFlavor: m1.xlarge
apiFloatingIP: 128.0.0.1
fips: false
pullSecret: '{"auths": ...}’
sshKey: ssh-ed25519 AAAA...
```
2. From that directory, either run a script to edit the `install-config.yaml` file or update the file manually:

- To set the value by using a script, run:

  ```python
  $ python -c '
  import yaml;
  path = "install-config.yaml";
  data = yaml.safe_load(open(path));
  data["compute"][0]["replicas"] = 0;
  open(path, "w").write(yaml.dump(data, default_flow_style=False))'
  ```

- To set the value manually, open the file and set the value of `compute.<first entry>.replicas` to 0.

### 17.6.13.10. Cluster deployment on RHOSP provider networks

You can deploy your OpenShift Container Platform clusters on Red Hat OpenStack Platform (RHOSP) with a primary network interface on a provider network. Provider networks are commonly used to give projects direct access to a public network that can be used to reach the internet. You can also share provider networks among projects as part of the network creation process.

RHOSP provider networks map directly to an existing physical network in the data center. A RHOSP administrator must create them.

In the following example, OpenShift Container Platform workloads are connected to a data center by using a provider network:
OpenShift Container Platform clusters that are installed on provider networks do not require tenant networks or floating IP addresses. The installer does not create these resources during installation.

Example provider network types include flat (untagged) and VLAN (802.1Q tagged).

**NOTE**

A cluster can support as many provider network connections as the network type allows. For example, VLAN networks typically support up to 4096 connections.

You can learn more about provider and tenant networks in the RHOSP documentation.

### 17.6.13.10.1. RHOSP provider network requirements for cluster installation

Before you install an OpenShift Container Platform cluster, your Red Hat OpenStack Platform (RHOSP) deployment and provider network must meet a number of conditions:

- The RHOSP networking service (Neutron) is enabled and accessible through the RHOSP networking API.
- The RHOSP networking service has the port security and allowed address pairs extensions enabled.
The provider network can be shared with other tenants.

**TIP**

Use the `openstack network create` command with the `--share` flag to create a network that can be shared.

The RHOSP project that you use to install the cluster must own the provider network, as well as an appropriate subnet.

**TIP**

To create a network for a project that is named "openshift," enter the following command:

```bash
$ openstack network create --project openshift
```

To create a subnet for a project that is named "openshift," enter the following command:

```bash
$ openstack subnet create --project openshift
```

To learn more about creating networks on RHOSP, read the provider networks documentation.

If the cluster is owned by the `admin` user, you must run the installer as that user to create ports on the network.

**IMPORTANT**

Provider networks must be owned by the RHOSP project that is used to create the cluster. If they are not, the RHOSP Compute service (Nova) cannot request a port from that network.

Verify that the provider network can reach the RHOSP metadata service IP address, which is 169.254.169.254 by default. Depending on your RHOSP SDN and networking service configuration, you might need to provide the route when you create the subnet. For example:

```bash
$ openstack subnet create --dhcp --host-route
destination=169.254.169.254/32,gateway=192.0.2.2 ...
```

Optional: To secure the network, create role-based access control (RBAC) rules that limit network access to a single project.

### 17.6.13.10.2. Deploying a cluster that has a primary interface on a provider network

You can deploy an OpenShift Container Platform cluster that has its primary network interface on an Red Hat OpenStack Platform (RHOSP) provider network.

**Prerequisites**

- Your Red Hat OpenStack Platform (RHOSP) deployment is configured as described by "RHOSP provider network requirements for cluster installation".
1. In a text editor, open the `install-config.yaml` file.

2. Set the value of the `platform.openstack.apiVIP` property to the IP address for the API VIP.

3. Set the value of the `platform.openstack.ingressVIP` property to the IP address for the Ingress VIP.

4. Set the value of the `platform.openstack.machinesSubnet` property to the UUID of the provider network subnet.

5. Set the value of the `networking.machineNetwork.cidr` property to the CIDR block of the provider network subnet.

**IMPORTANT**

The `platform.openstack.apiVIP` and `platform.openstack.ingressVIP` properties must both be unassigned IP addresses from the `networking.machineNetwork.cidr` block.

Section of an installation configuration file for a cluster that relies on a RHOSP provider network

...  
platform:  
  openstack:  
    apiVIP: 192.0.2.13  
    ingressVIP: 192.0.2.23  
    machinesSubnet: fa806b2f-ac49-4bce-b9db-124bc64209bf  
    # ...  
  networking:  
    machineNetwork:  
    - cidr: 192.0.2.0/24

**WARNING**

You cannot set the `platform.openstack.externalNetwork` or `platform.openstack.externalDNS` parameters while using a provider network for the primary network interface.

When you deploy the cluster, the installer uses the `install-config.yaml` file to deploy the cluster on the provider network.

**TIP**

You can add additional networks, including provider networks, to the `platform.openstack.additionalNetworkIDs` list.

After you deploy your cluster, you can attach pods to additional networks. For more information, see Understanding multiple networks.
17.6.14. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

**IMPORTANT**

- The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

**NOTE**

The installation program that generates the manifest and Ignition files is architecture specific and can be obtained from the client image mirror. The Linux version of the installation program runs on s390x only. This installer program is also available as a Mac OS version.

**Prerequisites**

- You obtained the OpenShift Container Platform installation program. For a restricted network installation, these files are on your mirror host.

- You created the `install-config.yaml` installation configuration file.

**Procedure**

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

   ```
   $ ./openshift-install create manifests --dir <installation_directory>
   ```

   **Example output**

   ```
   INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
   INFO Consuming Install Config from target directory
   INFO Manifests created in: install_dir/manifests and install_dir/openshift
   ```

   **For `<installation_directory>`**, specify the installation directory that contains the `install-config.yaml` file you created.
2. Remove the Kubernetes manifest files that define the control plane machines and compute machine sets:

```bash
$ rm -f openshift/99_openshift-cluster-api_master-machines-*.*.yaml
```

Because you create and manage these resources yourself, you do not have to initialize them.

- You can preserve the machine set files to create compute machines by using the machine API, but you must update references to them to match your environment.

**WARNING**

If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.

**IMPORTANT**

When you configure control plane nodes from the default unschedulable to schedulable, additional subscriptions are required. This is because control plane nodes then become worker nodes.

3. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:

   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.
   
   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.
   
   c. Save and exit the file.

4. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

   ```bash
   $ ./openshift-install create ignition-configs --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The `kubeadmin-password` and `kubeconfig` files are created in the `./<installation_directory>/auth` directory:

```
├── auth
│   └── kubeadmin-password
│       └── kubeconfig
└── bootstrap.ign
```
5. Export the metadata file’s `infraID` key as an environment variable:

```
$ export INFRA_ID=$(jq -r .infraID metadata.json)
```

**TIP**

Extract the `infraID` key from `metadata.json` and use it as a prefix for all of the RHOSP resources that you create. By doing so, you avoid name conflicts when making multiple deployments in the same project.

### 17.6.15. Preparing the bootstrap Ignition files

The OpenShift Container Platform installation process relies on bootstrap machines that are created from a bootstrap Ignition configuration file.

Edit the file and upload it. Then, create a secondary bootstrap Ignition configuration file that Red Hat OpenStack Platform (RHOSP) uses to download the primary file.

**Prerequisites**

- You have the bootstrap Ignition file that the installer program generates, `bootstrap.ign`.
- The infrastructure ID from the installer’s metadata file is set as an environment variable (`$INFRA_ID`).
  - If the variable is not set, see *Creating the Kubernetes manifest and Ignition config files*.
- You have an HTTP(S)-accessible way to store the bootstrap Ignition file.
  - The documented procedure uses the RHOSP image service (Glance), but you can also use the RHOSP storage service (Swift), Amazon S3, an internal HTTP server, or an ad hoc Nova server.

**Procedure**

1. Run the following Python script. The script modifies the bootstrap Ignition file to set the hostname and, if available, CA certificate file when it runs:

```python
import base64
import json
import os

with open('bootstrap.ign', 'r') as f:
    ignition = json.load(f)

files = ignition['storage'].get('files', [])

infra_id = os.environ.get('INFRA_ID', 'openshift').encode()
hostname_b64 = base64.standard_b64encode(infra_id + b'-bootstrap\n').decode().strip()
files.append(
    {
        'uri': hostname_b64
    })

for file in files:
    file['uri'] = file['uri'] + '

with open('bootstrap.ign', 'w') as f:
    json.dump(ignition, f, sort_keys=True, indent=4)
```
Using the RHOSP CLI, create an image that uses the bootstrap Ignition file:

```
$ openstack image create --disk-format=raw --container-format=bare --file bootstrap.ign <image_name>
```

3. Get the image’s details:

```
$ openstack image show <image_name>
```

Make a note of the `file` value; it follows the pattern `v2/images/<image_ID>/file`.

**NOTE**

Verify that the image you created is active.

4. Retrieve the image service’s public address:

```
$ openstack catalog show image
```

5. Combine the public address with the image `file` value and save the result as the storage location. The location follows the pattern `<$image_service_public_URL>/v2/images/<image_ID>/file`.

6. Generate an auth token and save the token ID:

```
$ openstack token issue -c id -f value
```
7. Insert the following content into a file called $INFRA_ID-bootstrap-ignition.json and edit the placeholders to match your own values:

```json
{
  "ignition": {
    "config": {
      "merge": [{
        "source": "<storage_url>",
        "httpHeaders": [{
          "name": "X-Auth-Token",
          "value": "<token_ID>"
        }]
      }]
    },
    "security": {
      "tls": {
        "certificateAuthorities": [{
          "source": "data:text/plain;charset=utf-8;base64,<base64_encoded_certificate>"
        }]
      }
    },
    "version": "3.2.0"
  }
}
```

1. Replace the value of `ignition.config.merge.source` with the bootstrap Ignition file storage URL.
2. Set `name` in `httpHeaders` to "X-Auth-Token".
3. Set `value` in `httpHeaders` to your token’s ID.
4. If the bootstrap Ignition file server uses a self-signed certificate, include the base64-encoded certificate.

8. Save the secondary Ignition config file.

The bootstrap Ignition data will be passed to RHOSP during installation.

**WARNING**

The bootstrap Ignition file contains sensitive information, like `clouds.yaml` credentials. Ensure that you store it in a secure place, and delete it after you complete the installation process.

### 17.6.16. Creating control plane Ignition config files on RHOSP

Installing OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) on your own infrastructure requires control plane Ignition config files. You must create multiple config files.
NOTE

As with the bootstrap Ignition configuration, you must explicitly define a hostname for each control plane machine.

Prerequisites

- The infrastructure ID from the installation program’s metadata file is set as an environment variable ($INFRA_ID).
  - If the variable is not set, see "Creating the Kubernetes manifest and Ignition config files".

Procedure

- On a command line, run the following Python script:

```bash
$ for index in $(seq 0 2); do
    MASTER_HOSTNAME="$INFRA_ID-master-$index"
    python -c "import base64, json, sys;
    ignition = json.load(sys.stdin);
    storage = ignition.get('storage', {});
    files = storage.get('files', []);
    files.append({'path': '/etc/hostname', 'mode': 420, 'contents': {'source':
        'data:text/plain;charset=utf-8;base64,' +
        base64.standard_b64encode(b'$MASTER_HOSTNAME').decode().strip(), 'verification': {}},
        'filesystem': 'root'});
    storage['files'] = files;
    ignition['storage'] = storage
    json.dump(ignition, sys.stdout)" <master.ign >"$INFRA_ID-master-$index-ignition.json"
done
```

You now have three control plane Ignition files: <INFRA_ID>-master-0-ignition.json, <INFRA_ID>-master-1-ignition.json, and <INFRA_ID>-master-2-ignition.json.

17.6.17. Creating network resources on RHOSP

Create the network resources that an OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) installation on your own infrastructure requires. To save time, run supplied Ansible playbooks that generate security groups, networks, subnets, routers, and ports.

Prerequisites

- Python 3 is installed on your machine.
- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".

Procedure

1. Optional: Add an external network value to the inventory.yaml playbook:

   Example external network value in the inventory.yaml Ansible playbook

   ```yaml
   ...
   ```
# The public network providing connectivity to the cluster. If not provided, the cluster external connectivity must be provided in another way.

# Required for os_api_fip, os_ingress_fip, os_bootstrap_fip.

os_external_network: 'external'

... IMPORTANT

If you did not provide a value for os_external_network in the inventory.yaml file, you must ensure that VMs can access Glance and an external connection yourself.

2. Optional: Add external network and floating IP (FIP) address values to the inventory.yaml playbook:

Example FIP values in the inventory.yaml Ansible playbook

... # OpenShift API floating IP address. If this value is non-empty, the # corresponding floating IP will be attached to the Control Plane to # serve the OpenShift API. os_api_fip: '203.0.113.23'

# OpenShift Ingress floating IP address. If this value is non-empty, the # corresponding floating IP will be attached to the worker nodes to serve # the applications. os_ingress_fip: '203.0.113.19'

# If this value is non-empty, the corresponding floating IP will be # attached to the bootstrap machine. This is needed for collecting logs # in case of install failure. os_bootstrap_fip: '203.0.113.20'

... IMPORTANT

If you do not define values for os_api_fip and os_ingress_fip, you must perform post-installation network configuration.

If you do not define a value for os_bootstrap_fip, the installer cannot download debugging information from failed installations.

See "Enabling access to the environment" for more information.

3. On a command line, create security groups by running the security-groups.yaml playbook:

`$ ansible-playbook -i inventory.yaml security-groups.yaml`

4. On a command line, create a network, subnet, and router by running the network.yaml playbook:

`$ ansible-playbook -i inventory.yaml network.yaml`
5. Optional: If you want to control the default resolvers that Nova servers use, run the RHOSP CLI command:

```
$ openstack subnet set --dns-nameserver <server_1> --dns-nameserver <server_2> "$INFRA_ID-nodes"
```

Optionally, you can use the `inventory.yaml` file that you created to customize your installation. For example, you can deploy a cluster that uses bare metal machines.

### 17.6.17.1. Deploying a cluster with bare metal machines

If you want your cluster to use bare metal machines, modify the `inventory.yaml` file. Your cluster can have both control plane and compute machines running on bare metal, or just compute machines.

Bare-metal compute machines are not supported on clusters that use Kuryr.

**NOTE**

Be sure that your `install-config.yaml` file reflects whether the RHOSP network that you use for bare metal workers supports floating IP addresses or not.

**Prerequisites**

- The RHOSP Bare Metal service (Ironic) is enabled and accessible via the RHOSP Compute API.
- Bare metal is available as a RHOSP flavor.
- The RHOSP network supports both VM and bare metal server attachment.
- Your network configuration does not rely on a provider network. Provider networks are not supported.
- If you want to deploy the machines on a pre-existing network, a RHOSP subnet is provisioned.
- If you want to deploy the machines on an installer-provisioned network, the RHOSP Bare Metal service (Ironic) is able to listen for and interact with Preboot eXecution Environment (PXE) boot machines that run on tenant networks.
- You created an `inventory.yaml` file as part of the OpenShift Container Platform installation process.

**Procedure**

1. In the `inventory.yaml` file, edit the flavors for machines:
   a. If you want to use bare-metal control plane machines, change the value of `os_flavor_master` to a bare metal flavor.
   b. Change the value of `os_flavor_worker` to a bare metal flavor.

   **An example bare metal inventory.yaml file**

   ```yaml
   all:
     hosts:
       localhost:
   ```
If you want to have bare-metal control plane machines, change this value to a bare metal flavor.

Change this value to a bare metal flavor to use for compute machines.

Use the updated `inventory.yaml` file to complete the installation process. Machines that are created during deployment use the flavor that you added to the file.

**NOTE**

The installer may time out while waiting for bare metal machines to boot.

If the installer times out, restart and then complete the deployment by using the `wait-for` command of the installer. For example:

```
./openshift-install wait-for install-complete --log-level debug
```

17.6.18. Creating the bootstrap machine on RHOSP

Create a bootstrap machine and give it the network access it needs to run on Red Hat OpenStack Platform (RHOSP). Red Hat provides an Ansible playbook that you run to simplify this process.

**Prerequisites**

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The `inventory.yaml`, `common.yaml`, and `bootstrap.yaml` Ansible playbooks are in a common directory.
- The `metadata.json` file that the installation program created is in the same directory as the Ansible playbooks.

**Procedure**

1. On a command line, change the working directory to the location of the playbooks.

2. On a command line, run the `bootstrap.yaml` playbook:

   ```
   $ ansible-playbook -i inventory.yaml bootstrap.yaml
   ```
3. After the bootstrap server is active, view the logs to verify that the Ignition files were received:

   $ openstack console log show "$INFRA_ID-bootstrap"

17.6.19. Creating the control plane machines on RHOSP

Create three control plane machines by using the Ignition config files that you generated. Red Hat provides an Ansible playbook that you run to simplify this process.

Prerequisites

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The infrastructure ID from the installation program's metadata file is set as an environment variable ($INFRA_ID).
- The inventory.yaml, common.yaml, and control-plane.yaml Ansible playbooks are in a common directory.
- You have the three Ignition files that were created in "Creating control plane Ignition config files".

Procedure

1. On a command line, change the working directory to the location of the playbooks.

2. If the control plane Ignition config files aren't already in your working directory, copy them into it.

3. On a command line, run the control-plane.yaml playbook:

   $ ansible-playbook -i inventory.yaml control-plane.yaml

4. Run the following command to monitor the bootstrapping process:

   $ openshift-install wait-for bootstrap-complete

   You will see messages that confirm that the control plane machines are running and have joined the cluster:

   INFO API v1.23.0 up
   INFO Waiting up to 30m0s for bootstrapping to complete...
   ...
   INFO It is now safe to remove the bootstrap resources

17.6.20. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster kubeconfig file. The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.
Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

Procedure

1. Export the `kubeadmin` credentials:

   ```
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ``
   
   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```
   $ oc whoami
   ``
   
   Example output
   
   ```
   system:admin
   ```

17.6.21. Deleting bootstrap resources from RHOSP

Delete the bootstrap resources that you no longer need.

Prerequisites

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The `inventory.yaml`, `common.yaml`, and `down-bootstrap.yaml` Ansible playbooks are in a common directory.
- The control plane machines are running.
  - If you do not know the status of the machines, see "Verifying cluster status".

Procedure

1. On a command line, change the working directory to the location of the playbooks.

2. On a command line, run the `down-bootstrap.yaml` playbook:

   ```
   $ ansible-playbook -i inventory.yaml down-bootstrap.yaml
   ``
   
   The bootstrap port, server, and floating IP address are deleted.
WARNING
If you did not disable the bootstrap Ignition file URL earlier, do so now.

17.6.22. Creating compute machines on RHOSP

After standing up the control plane, create compute machines. Red Hat provides an Ansible playbook that you run to simplify this process.

Prerequisites

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The `inventory.yaml`, `common.yaml`, and `compute-nodes.yaml` Ansible playbooks are in a common directory.
- The `metadata.json` file that the installation program created is in the same directory as the Ansible playbooks.
- The control plane is active.

Procedure

1. On a command line, change the working directory to the location of the playbooks.

2. On a command line, run the playbook:
   ```
   $ ansible-playbook -i inventory.yaml compute-nodes.yaml
   ```

Next steps

- Approve the certificate signing requests for the machines.

17.6.23. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

Prerequisites

- You added machines to your cluster.

Procedure

1. Confirm that the cluster recognizes the machines:
   ```
   $ oc get nodes
   ```
The output lists all of the machines that you created.

NOTE
The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the Pending or Approved status for each machine that you added to the cluster:

   $ oc get csr

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-mddf5</td>
<td>20m</td>
<td>system:node:master-01.example.com</td>
<td>Approved,Issued</td>
</tr>
<tr>
<td>csr-z5rln</td>
<td>16m</td>
<td>system:node:worker-21.example.com</td>
<td>Approved,Issued</td>
</tr>
</tbody>
</table>

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in Pending status, approve the CSRs for your cluster machines:

NOTE
Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the machine-approver if the Kubelet requests a new certificate with identical parameters.

NOTE
For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the oc exec, oc rsh, and oc logs commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the node-bootstrapper service account in the system:node or system:admin groups, and confirm the identity of the node.
To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> ①
```

① `<csr_name>` is the name of a CSR from the list of current CSRs.

To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
```

**NOTE**

Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-c57lv</td>
<td>5m26s</td>
<td>system:node:ip-10-0-95-157.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> ①
```

① `<csr_name>` is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs oc adm certificate approve
```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

**Example output**
NOTE
It can take a few minutes after approval of the server CSRs for the machines to transition to the Ready status.

Additional information
- For more information on CSRs, see Certificate Signing Requests.

17.6.24. Verifying a successful installation
Verify that the OpenShift Container Platform installation is complete.

Prerequisites
- You have the installation program (openshift-install)

Procedure
- On a command line, enter:

```
$ openshift-install --log-level debug wait-for install-complete
```

The program outputs the console URL, as well as the administrator’s login information.

17.6.25. Telemetry access for OpenShift Container Platform
In OpenShift Container Platform 4.10, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources
- See About remote health monitoring for more information about the Telemetry service

17.6.26. Next steps
- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
If you need to enable external access to node ports, configure ingress cluster traffic by using a node port.

If you did not configure RHOSP to accept application traffic over floating IP addresses, configure RHOSP access with floating IP addresses.

17.7. INSTALLING A CLUSTER ON OPENSTACK WITH KURYR ON YOUR OWN INFRASTRUCTURE

In OpenShift Container Platform version 4.10, you can install a cluster on Red Hat OpenStack Platform (RHOSP) that runs on user-provisioned infrastructure.

Using your own infrastructure allows you to integrate your cluster with existing infrastructure and modifications. The process requires more labor on your part than installer-provisioned installations, because you must create all RHOSP resources, like Nova servers, Neutron ports, and security groups. However, Red Hat provides Ansible playbooks to help you in the deployment process.

17.7.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You verified that OpenShift Container Platform 4.10 is compatible with your RHOSP version by using the Supported platforms for OpenShift clusters section. You can also compare platform support across different versions by viewing the OpenShift Container Platform on RHOSP support matrix.
- You have an RHOSP account where you want to install OpenShift Container Platform.
- On the machine from which you run the installation program, you have:
  - A single directory in which you can keep the files you create during the installation process
  - Python 3

17.7.2. About Kuryr SDN

Kuryr is a container network interface (CNI) plug-in solution that uses the Neutron and Octavia Red Hat OpenStack Platform (RHOSP) services to provide networking for pods and Services.

Kuryr and OpenShift Container Platform integration is primarily designed for OpenShift Container Platform clusters running on RHOSP VMs. Kuryr improves the network performance by plugging OpenShift Container Platform pods into RHOSP SDN. In addition, it provides interconnectivity between pods and RHOSP virtual instances.

Kuryr components are installed as pods in OpenShift Container Platform using the openshift-kuryr namespace:

- kuryr-controller - a single service instance installed on a master node. This is modeled in OpenShift Container Platform as a Deployment object.
• **kuryr-cni** - a container installing and configuring Kuryr as a CNI driver on each OpenShift Container Platform node. This is modeled in OpenShift Container Platform as a **DaemonSet** object.

The Kuryr controller watches the OpenShift Container Platform API server for pod, service, and namespace create, update, and delete events. It maps the OpenShift Container Platform API calls to corresponding objects in Neutron and Octavia. This means that every network solution that implements the Neutron trunk port functionality can be used to back OpenShift Container Platform via Kuryr. This includes open source solutions such as Open vSwitch (OVS) and Open Virtual Network (OVN) as well as Neutron-compatible commercial SDNs.

Kuryr is recommended for OpenShift Container Platform deployments on encapsulated RHOSP tenant networks to avoid double encapsulation, such as running an encapsulated OpenShift Container Platform SDN over an RHOSP network.

If you use provider networks or tenant VLANs, you do not need to use Kuryr to avoid double encapsulation. The performance benefit is negligible. Depending on your configuration, though, using Kuryr to avoid having two overlays might still be beneficial.

Kuryr is not recommended in deployments where all of the following criteria are true:

- The RHOSP version is less than 16.
- The deployment uses UDP services, or a large number of TCP services on few hypervisors.

or

- The **ovn-octavia** Octavia driver is disabled.
- The deployment uses a large number of TCP services on few hypervisors.

### 17.7.3. Resource guidelines for installing OpenShift Container Platform on RHOSP with Kuryr

When using Kuryr SDN, the pods, services, namespaces, and network policies are using resources from the RHOSP quota; this increases the minimum requirements. Kuryr also has some additional requirements on top of what a default install requires.

Use the following quota to satisfy a default cluster’s minimum requirements:

**Table 17.27. Recommended resources for a default OpenShift Container Platform cluster on RHOSP with Kuryr**

<table>
<thead>
<tr>
<th>Resource</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Floating IP addresses</td>
<td>3 - plus the expected number of Services of LoadBalancer type</td>
</tr>
<tr>
<td>Ports</td>
<td>1500 - 1 needed per Pod</td>
</tr>
<tr>
<td>Routers</td>
<td>1</td>
</tr>
<tr>
<td>Subnets</td>
<td>250 - 1 needed per Namespace/Project</td>
</tr>
<tr>
<td>Resource</td>
<td>Value</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-----------------------------------------------------------------------</td>
</tr>
<tr>
<td>Networks</td>
<td>250 - 1 needed per Namespace/Project</td>
</tr>
<tr>
<td>RAM</td>
<td>112 GB</td>
</tr>
<tr>
<td>vCPUs</td>
<td>28</td>
</tr>
<tr>
<td>Volume storage</td>
<td>275 GB</td>
</tr>
<tr>
<td>Instances</td>
<td>7</td>
</tr>
<tr>
<td>Security groups</td>
<td>250 - 1 needed per Service and per NetworkPolicy</td>
</tr>
<tr>
<td>Security group rules</td>
<td>1000</td>
</tr>
<tr>
<td>Server groups</td>
<td>2 - plus 1 for each additional availability zone in each machine pool</td>
</tr>
<tr>
<td>Load balancers</td>
<td>100 - 1 needed per Service</td>
</tr>
<tr>
<td>Load balancer listeners</td>
<td>500 - 1 needed per Service-exposed port</td>
</tr>
<tr>
<td>Load balancer pools</td>
<td>500 - 1 needed per Service-exposed port</td>
</tr>
</tbody>
</table>

A cluster might function with fewer than recommended resources, but its performance is not guaranteed.

**IMPORTANT**

If RHOSP object storage (Swift) is available and operated by a user account with the `switoperator` role, it is used as the default backend for the OpenShift Container Platform image registry. In this case, the volume storage requirement is 175 GB. Swift space requirements vary depending on the size of the image registry.

**IMPORTANT**

If you are using Red Hat OpenStack Platform (RHOSP) version 16 with the Amphora driver rather than the OVN Octavia driver, security groups are associated with service accounts instead of user projects.

Take the following notes into consideration when setting resources:

- The number of ports that are required is larger than the number of pods. Kuryr uses ports pools to have pre-created ports ready to be used by pods and speed up the pods' booting time.

- Each network policy is mapped into an RHOSP security group, and depending on the `NetworkPolicy` spec, one or more rules are added to the security group.
Each service is mapped to an RHOSP load balancer. Consider this requirement when estimating the number of security groups required for the quota. If you are using RHOSP version 15 or earlier, or the ovn-octavia driver, each load balancer has a security group with the user project.

The quota does not account for load balancer resources (such as VM resources), but you must consider these resources when you decide the RHOSP deployment’s size. The default installation will have more than 50 load balancers; the clusters must be able to accommodate them. If you are using RHOSP version 16 with the OVN Octavia driver enabled, only one load balancer VM is generated; services are load balanced through OVN flows.

An OpenShift Container Platform deployment comprises control plane machines, compute machines, and a bootstrap machine.

To enable Kuryr SDN, your environment must meet the following requirements:

- Run RHOSP 13+.
- Have Overcloud with Octavia.
- Use Neutron Trunk ports extension.
- Use openvswitch firewall driver if ML2/OVS Neutron driver is used instead of ovs-hybrid.

### 17.7.3.1. Increasing quota

When using Kuryr SDN, you must increase quotas to satisfy the Red Hat OpenStack Platform (RHOSP) resources used by pods, services, namespaces, and network policies.

**Procedure**

- Increase the quotas for a project by running the following command:

  ```bash
  $ sudo openstack quota set --secgroups 250 --secgroup-rules 1000 --ports 1500 --subnets 250 --networks 250 <project>
  ```

### 17.7.3.2. Configuring Neutron

Kuryr CNI leverages the Neutron Trunks extension to plug containers into the Red Hat OpenStack Platform (RHOSP) SDN, so you must use the trunks extension for Kuryr to properly work.

In addition, if you leverage the default ML2/OVS Neutron driver, the firewall must be set to openvswitch instead of ovs_hybrid so that security groups are enforced on trunk subports and Kuryr can properly handle network policies.

### 17.7.3.3. Configuring Octavia

Kuryr SDN uses Red Hat OpenStack Platform (RHOSP)’s Octavia LBaaS to implement OpenShift Container Platform services. Thus, you must install and configure Octavia components in RHOSP to use Kuryr SDN.

To enable Octavia, you must include the Octavia service during the installation of the RHOSP Overcloud, or upgrade the Octavia service if the Overcloud already exists. The following steps for enabling Octavia apply to both a clean install of the Overcloud or an Overcloud update.
The following steps only capture the key pieces required during the deployment of RHOSP when dealing with Octavia. It is also important to note that registry methods vary.

This example uses the local registry method.

Procedure

1. If you are using the local registry, create a template to upload the images to the registry. For example:

   (undercloud) $ openstack overcloud container image prepare \
   -e /usr/share/openstack-tripleo-heat-templates/environments/services-docker/octavia.yaml \
   --namespace=registry.access.redhat.com/rhosp13 \
   --push-destination=<local-ip-from-undercloud.conf>:8787 \
   --prefix=openstack- \
   --tag-from-label {version}-{product-version} \
   --output-env-file=/home/stack/templates/overcloud_images.yaml \
   --output-images-file /home/stack/local_registry_images.yaml

2. Verify that the local_registry_images.yaml file contains the Octavia images. For example:

   ...
   - imagename: registry.access.redhat.com/rhosp13/openstack-octavia-api:13.0-43
     push_destination: <local-ip-from-undercloud.conf>:8787
   - imagename: registry.access.redhat.com/rhosp13/openstack-octavia-health-manager:13.0-45
     push_destination: <local-ip-from-undercloud.conf>:8787
   - imagename: registry.access.redhat.com/rhosp13/openstack-octavia-housekeeping:13.0-45
     push_destination: <local-ip-from-undercloud.conf>:8787
   - imagename: registry.access.redhat.com/rhosp13/openstack-octavia-worker:13.0-44
     push_destination: <local-ip-from-undercloud.conf>:8787

3. Pull the container images from registry.redhat.io to the Undercloud node:

   (undercloud) $ sudo openstack overcloud container image upload \
   --config-file /home/stack/local_registry_images.yaml \
   --verbose

   This may take some time depending on the speed of your network and Undercloud disk.

4. Since an Octavia load balancer is used to access the OpenShift Container Platform API, you must increase their listeners’ default timeouts for the connections. The default timeout is 50 seconds. Increase the timeout to 20 minutes by passing the following file to the Overcloud deploy command:

   (undercloud) $ cat octavia_timeouts.yaml
   parameter_defaults:
   
   NOTE
   The Octavia container versions vary depending upon the specific RHOSP release installed.
NOTE
This is not needed for RHOSP 13.0.13+.

5. Install or update your Overcloud environment with Octavia:

   `$ openstack overcloud deploy --templates \\
   -e /usr/share/openstack-tripleo-heat-templates/environments/services-docker/octavia.yaml \\
   -e octavia_timeouts.yaml`

NOTE
This command only includes the files associated with Octavia; it varies based on your specific installation of RHOSP. See the RHOSP documentation for further information. For more information on customizing your Octavia installation, see installation of Octavia using Director.

NOTE
When leveraging Kuryr SDN, the Overcloud installation requires the Neutron trunk extension. This is available by default on director deployments. Use the openvswitch firewall instead of the default ovs-hybrid when the Neutron backend is ML2/OVS. There is no need for modifications if the backend is ML2/OVN.

6. In RHOSP versions earlier than 13.0.13, add the project ID to the octavia.conf configuration file after you create the project.

   - To enforce network policies across services, like when traffic goes through the Octavia load balancer, you must ensure Octavia creates the Amphora VM security groups on the user project.
     This change ensures that required load balancer security groups belong to that project, and that they can be updated to enforce services isolation.

   NOTE
This task is unnecessary in RHOSP version 13.0.13 or later.

   Octavia implements a new ACL API that restricts access to the load balancers VIP.

   a. Get the project ID

   `$ openstack project show <project>`

   Example output

   +-------------------------------+-------+
   | Field       | Value |
   +-------------------------------+-------+
b. Add the project ID to `octavia.conf` for the controllers.

i. Source the `stackrc` file:

```bash
$ source stackrc  # Undercloud credentials
```

ii. List the Overcloud controllers:

```bash
$ openstack server list
```

**Example output**

```
+--------------------------------------+--------------+--------+-----------------------+-------+
| description |                                  |         |                       |       |
| domain_id   | default                          | True   |                       |       |
| enabled     | False                            |        |                       |       |
| id          | PROJECT_ID                       |        |                       |       |
| is_domain   | False                            |        |                       |       |
| name        | "<project>"*                     |        |                       |       |
| parent_id   | default                          |        |                       |       |
| tags        | []                               |        |                       |       |
```

iii. SSH into the controller(s).

```bash
$ ssh heat-admin@192.168.24.8
```

iv. Edit the `octavia.conf` file to add the project into the list of projects where Amphora security groups are on the user’s account.

```bash
# List of project IDs that are allowed to have Load balancer security groups # belonging to them.
amp_secgroup_allowed_projects = PROJECT_ID
```

c. Restart the Octavia worker so the new configuration loads.
Octavia supports multiple provider drivers through the Octavia API.

To see all available Octavia provider drivers, on a command line, enter:

```bash
$ openstack loadbalancer provider list
```

**Example output**

```
+---------+-------------------------------------------------+
| name    | description                                     |
+---------+-------------------------------------------------+
| amphora | The Octavia Amphora driver.                     |
| octavia | Deprecated alias of the Octavia Amphora driver. |
| ovn     | Octavia OVN driver.                             |
+---------+-------------------------------------------------+
```

Beginning with RHOSP version 16, the Octavia OVN provider driver (**ovn**) is supported on OpenShift Container Platform on RHOSP deployments.

**ovn** is an integration driver for the load balancing that Octavia and OVN provide. It supports basic load balancing capabilities, and is based on OpenFlow rules. The driver is automatically enabled in Octavia by Director on deployments that use OVN Neutron ML2.

The Amphora provider driver is the default driver. If **ovn** is enabled, however, Kuryr uses it.

If Kuryr uses **ovn** instead of Amphora, it offers the following benefits:

- Decreased resource requirements. Kuryr does not require a load balancer VM for each service.
- Reduced network latency.
- Increased service creation speed by using OpenFlow rules instead of a VM for each service.
- Distributed load balancing actions across all nodes instead of centralized on Amphora VMs.

### 17.7.3.4. Known limitations of installing with Kuryr

Using OpenShift Container Platform with Kuryr SDN has several known limitations.

**RHOSP general limitations**

Using OpenShift Container Platform with Kuryr SDN has several limitations that apply to all versions and environments:

- Service objects with the **NodePort** type are not supported.
- Clusters that use the OVN Octavia provider driver support **Service** objects for which the
  `.spec.selector` property is unspecified only if the `.subsets.addresses` property of the
  **Endpoints** object includes the subnet of the nodes or pods.

- If the subnet on which machines are created is not connected to a router, or if the subnet is
  connected, but the router has no external gateway set, Kuryr cannot create floating IPs for
  **Service** objects with type **LoadBalancer**.

- Configuring the `sessionAffinity=ClientIP` property on **Service** objects does not have an effect.
  Kuryr does not support this setting.

**RHOSP version limitations**

Using OpenShift Container Platform with Kuryr SDN has several limitations that depend on the RHOSP
version.

- RHOSP versions before 16 use the default Octavia load balancer driver (Amphora). This driver
  requires that one Amphora load balancer VM is deployed per OpenShift Container Platform
  service. Creating too many services can cause you to run out of resources.
  Deployments of later versions of RHOSP that have the OVN Octavia driver disabled also use
  the Amphora driver. They are subject to the same resource concerns as earlier versions of
  RHOSP.

- Octavia RHOSP versions before 13.0.13 do not support UDP listeners. Therefore, OpenShift
  Container Platform UDP services are not supported.

- Octavia RHOSP versions before 13.0.13 cannot listen to multiple protocols on the same port.
  Services that expose the same port to different protocols, like TCP and UDP, are not
  supported.

- Kuryr SDN does not support automatic unidling by a service.

**RHOSP environment limitations**

There are limitations when using Kuryr SDN that depend on your deployment environment.

Because of Octavia’s lack of support for the UDP protocol and multiple listeners, if the RHOSP version
is earlier than 13.0.13, Kuryr forces pods to use TCP for DNS resolution.

In Go versions 1.12 and earlier, applications that are compiled with CGO support disabled use UDP only.
In this case, the native Go resolver does not recognize the `use-vc` option in `resolv.conf`, which controls
whether TCP is forced for DNS resolution. As a result, UDP is still used for DNS resolution, which fails.

To ensure that TCP forcing is allowed, compile applications either with the environment variable
**CGO_ENABLED** set to 1, i.e. **CGO_ENABLED=1** or ensure that the variable is absent.

In Go versions 1.13 and later, TCP is used automatically if DNS resolution using UDP fails.

**NOTE**

musl-based containers, including Alpine-based containers, do not support the `use-vc` option.

**RHOSP upgrade limitations**

As a result of the RHOSP upgrade process, the Octavia API might be changed, and upgrades to the
Amphora images that are used for load balancers might be required.

You can address API changes on an individual basis.
If the Amphora image is upgraded, the RHOSP operator can handle existing load balancer VMs in two ways:

- Upgrade each VM by triggering a load balancer failover.
- Leave responsibility for upgrading the VMs to users.

If the operator takes the first option, there might be short downtimes during failovers.

If the operator takes the second option, the existing load balancers will not support upgraded Octavia API features, like UDP listeners. In this case, users must recreate their Services to use these features.

**IMPORTANT**

If OpenShift Container Platform detects a new Octavia version that supports UDP load balancing, it recreates the DNS service automatically. The service recreation ensures that the service default supports UDP load balancing.

The recreation causes the DNS service approximately one minute of downtime.

### 17.7.3.5. Control plane and compute machines

By default, the OpenShift Container Platform installation process stands up three control plane and three compute machines.

Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 25 GB storage space

**TIP**

Compute machines host the applications that you run on OpenShift Container Platform; aim to run as many as you can.

### 17.7.3.6. Bootstrap machine

During installation, a bootstrap machine is temporarily provisioned to stand up the control plane. After the production control plane is ready, the bootstrap machine is deprovisioned.

The bootstrap machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 25 GB storage space

### 17.7.4. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.10, you require access to the internet to obtain the images that are necessary to install your cluster.
You must have internet access to:

- Access **OpenShift Cluster Manager** to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- Access **Quay.io** to obtain the packages that are required to install your cluster.

- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

17.7.5. Downloading playbook dependencies

The Ansible playbooks that simplify the installation process on user-provisioned infrastructure require several Python modules. On the machine where you will run the installer, add the modules' repositories and then download them.

**NOTE**

These instructions assume that you are using Red Hat Enterprise Linux (RHEL) 8.

**Prerequisites**

- Python 3 is installed on your machine.

**Procedure**

1. On a command line, add the repositories:
   a. Register with Red Hat Subscription Manager:

   ```bash
   $ sudo subscription-manager register # If not done already
   
   b. Pull the latest subscription data:

   ```bash
   $ sudo subscription-manager attach --pool=$YOUR_POOLID # If not done already
   ```

   c. Disable the current repositories:

   ```bash
   $ sudo subscription-manager repos --disable=* # If not done already
   ```

   d. Add the required repositories:

   ```bash
   $ sudo subscription-manager repos \
   --enable=rhel-8-for-x86_64-baseos-rpms \
   --enable=openstack-16-tools-for-rhel-8-x86_64-rpms \
   ```
2. Install the modules:
   
   ```
   $ sudo yum install python3-openstackclient ansible python3-openstacksdk python3-netaddr
   ```

3. Ensure that the `python` command points to `python3`:
   
   ```
   $ sudo alternatives --set python /usr/bin/python3
   ```

### 17.7.6. Downloading the installation playbooks

Download Ansible playbooks that you can use to install OpenShift Container Platform on your own Red Hat OpenStack Platform (RHOSP) infrastructure.

**Prerequisites**

- The curl command-line tool is available on your machine.

**Procedure**

- To download the playbooks to your working directory, run the following script from a command line:

   ```
   $ xargs -n 1 curl -O <<< "
   https://raw.githubusercontent.com/openshift/installer/release-4.10/upi/openstack/bootstrap.yaml
   https://raw.githubusercontent.com/openshift/installer/release-4.10/upi/openstack/common.yaml
   https://raw.githubusercontent.com/openshift/installer/release-4.10/upi/openstack/compute-nodes.yaml
   https://raw.githubusercontent.com/openshift/installer/release-4.10/upi/openstack/control-plane.yaml
   https://raw.githubusercontent.com/openshift/installer/release-4.10/upi/openstack/inventory.yaml
   https://raw.githubusercontent.com/openshift/installer/release-4.10/upi/openstack/network.yaml
   https://raw.githubusercontent.com/openshift/installer/release-4.10/upi/openstack/security-groups.yaml
   "
   ```
The playbooks are downloaded to your machine.

**IMPORTANT**

During the installation process, you can modify the playbooks to configure your deployment.

Retain all playbooks for the life of your cluster. You must have the playbooks to remove your OpenShift Container Platform cluster from RHOSP.

**IMPORTANT**

You must match any edits you make in the `bootstrap.yaml`, `compute-nodes.yaml`, `control-plane.yaml`, `network.yaml`, and `security-groups.yaml` files to the corresponding playbooks that are prefixed with `down-`. For example, edits to the `bootstrap.yaml` file must be reflected in the `down-bootstrap.yaml` file, too. If you do not edit both files, the supported cluster removal process will fail.

17.7.7. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the mirror host.

**Prerequisites**

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space

**Procedure**

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

**IMPORTANT**

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:
1. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

17.7.8. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The ./openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>

   Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   NOTE

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   $ cat <path>/<file_name>.pub

   For example, run the following to view the ~/.ssh/id_rsa.pub public key:
3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

   **NOTE**
   
   On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

   a. If the `ssh-agent` process is not already running for your local user, start it as a background task:

   ```
   $ eval "$(ssh-agent -s)"
   
   Example output
   
   Agent pid 31874
   ```

   **NOTE**
   
   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the `ssh-agent`:

   ```
   $ ssh-add <path>/<file_name>
   ```

   Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

   **Example output**

   ```
   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
   ```

   **Next steps**
   
   - When you install OpenShift Container Platform, provide the SSH public key to the installation program.

**17.7.9. Creating the Red Hat Enterprise Linux CoreOS (RHCOS) image**

The OpenShift Container Platform installation program requires that a Red Hat Enterprise Linux CoreOS (RHCOS) image be present in the Red Hat OpenStack Platform (RHOSP) cluster. Retrieve the latest RHCOS image, then upload it using the RHOSP CLI.

**Prerequisites**

- The RHOSP CLI is installed.
Procedure

2. Under Version, select the most recent release of OpenShift Container Platform 4.10 for Red Hat Enterprise Linux (RHEL) 8.

   IMPORTANT

   The RH COS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available.

3. Download the Red Hat Enterprise Linux CoreOS (RH COS) - OpenStack Image (QCOW).

4. Decompress the image.

   NOTE

   You must decompress the RHOSP image before the cluster can use it. The name of the downloaded file might not contain a compression extension, like .gz or .tgz. To find out if or how the file is compressed, in a command line, enter:

   ```
   $ file <name_of_downloaded_file>
   ```

5. From the image that you downloaded, create an image that is named rhcos in your cluster by using the RHOSP CLI:

   ```
   $ openstack image create --container-format=bare --disk-format=qcow2 --file rhcos-$(RHCOS_VERSION)-openstack.qcow2 rhcos
   ```

   IMPORTANT

   Depending on your RHOSP environment, you might be able to upload the image in either .raw or .qcow2 formats. If you use Ceph, you must use the .raw format.

   WARNING

   If the installation program finds multiple images with the same name, it chooses one of them at random. To avoid this behavior, create unique names for resources in RHOSP.

   After you upload the image to RHOSP, it is usable in the installation process.

17.7.10. Verifying external network access
The OpenShift Container Platform installation process requires external network access. You must provide an external network value to it, or deployment fails. Before you begin the process, verify that a network with the external router type exists in Red Hat OpenStack Platform (RHOSP).

**Prerequisites**

- Configure OpenStack’s networking service to have DHCP agents forward instances' DNS queries

**Procedure**

1. Using the RHOSP CLI, verify the name and ID of the 'External' network:

   ```
   $ openstack network list --long -c ID -c Name -c "Router Type"
   +--------------------------------------+----------------+-------------+
   | ID                                   | Name           | Router Type |
   +--------------------------------------+----------------+-------------+
   | 148a8023-62a7-4672-b018-003462f8d7dc | public_network | External    |
   +--------------------------------------+----------------+-------------+
   ```

   Example output

   A network with an external router type appears in the network list. If at least one does not, see [Creating a default floating IP network](#) and [Creating a default provider network](#).

   **NOTE**
   If the Neutron trunk service plug-in is enabled, a trunk port is created by default. For more information, see [Neutron trunk port](#).

17.7.11. Enabling access to the environment

At deployment, all OpenShift Container Platform machines are created in a Red Hat OpenStack Platform (RHOSP)-tenant network. Therefore, they are not accessible directly in most RHOSP deployments.

You can configure OpenShift Container Platform API and application access by using floating IP addresses (FIPs) during installation. You can also complete an installation without configuring FIPs, but the installer will not configure a way to reach the API or applications externally.

17.7.11.1. Enabling access with floating IP addresses

Create floating IP (FIP) addresses for external access to the OpenShift Container Platform API, cluster applications, and the bootstrap process.

**Procedure**

1. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the API FIP:

   ```
   $ openstack floating ip create --description "API <cluster_name>.<base_domain>" <external_network>
   ```
2. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the apps, or Ingress, FIP:

   ```
   $ openstack floating ip create --description "Ingress <cluster_name>.<base_domain>" <external_network>
   ```

3. By using the Red Hat OpenStack Platform (RHOSP) CLI, create the bootstrap FIP:

   ```
   $ openstack floating ip create --description "bootstrap machine" <external_network>
   ```

4. Add records that follow these patterns to your DNS server for the API and Ingress FIPs:

   ```
   api.<cluster_name>.<base_domain>. IN A <API_FIP>
   *.apps.<cluster_name>.<base_domain>. IN A <apps_FIP>
   ```

   **NOTE**

   If you do not control the DNS server, you can add the record to your `/etc/hosts` file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

5. Add the FIPs to the `inventory.yaml` file as the values of the following variables:

   - `os_api_fip`
   - `os_bootstrap_fip`
   - `os_ingress_fip`

   If you use these values, you must also enter an external network as the value of the `os_external_network` variable in the `inventory.yaml` file.

   **TIP**

   You can make OpenShift Container Platform resources available outside of the cluster by assigning a floating IP address and updating your firewall configuration.

### 17.7.11.2. Completing installation without floating IP addresses

You can install OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) without providing floating IP addresses.

In the `inventory.yaml` file, do not define the following variables:

   - `os_api_fip`
   - `os_bootstrap_fip`
   - `os_ingress_fip`

   If you cannot provide an external network, you can also leave `os_external_network` blank. If you do not provide a value for `os_external_network`, a router is not created for you, and, without additional action, the installer will fail to retrieve an image from Glance. Later in the installation process, when you create network resources, you must configure external connectivity on your own.
If you run the installer with the `wait-for` command from a system that cannot reach the cluster API due to a lack of floating IP addresses or name resolution, installation fails. To prevent installation failure in these cases, you can use a proxy network or run the installer from a system that is on the same network as your machines.

**NOTE**

You can enable name resolution by creating DNS records for the API and Ingress ports. For example:

```
api.<cluster_name>.<base_domain>. IN A <api_port_IP>
*.apps.<cluster_name>.<base_domain>. IN A <ingress_port_IP>
```

If you do not control the DNS server, you can add the record to your `/etc/hosts` file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

### 17.7.12. Defining parameters for the installation program

The OpenShift Container Platform installation program relies on a file that is called `clouds.yaml`. The file describes Red Hat OpenStack Platform (RHOSP) configuration parameters, including the project name, log in information, and authorization service URLs.

**Procedure**

1. Create the `clouds.yaml` file:

   - If your RHOSP distribution includes the Horizon web UI, generate a `clouds.yaml` file in it.

     **IMPORTANT**

     Remember to add a password to the `auth` field. You can also keep secrets in a separate file from `clouds.yaml`.

   - If your RHOSP distribution does not include the Horizon web UI, or you do not want to use Horizon, create the file yourself. For detailed information about `clouds.yaml`, see Config files in the RHOSP documentation.

```yaml
clouds:
  shiftstack:
    auth:
      project_name: shiftstack
      username: shiftstack_user
      password: XXX
      user_domain_name: Default
      project_domain_name: Default
    dev-env:
      region_name: RegionOne
      auth:
        username: 'devuser'
        password: XXX
        project_name: 'devonly'
```
2. If your RHOSP installation uses self-signed certificate authority (CA) certificates for endpoint authentication:

   a. Copy the certificate authority file to your machine.

   b. Add the **cacerts** key to the **clouds.yaml** file. The value must be an absolute, non-root-accessible path to the CA certificate:

   ```yaml
   clouds:
     shiftstack:
       ...
     cacert: "/etc/pki/ca-trust/source/anchors/ca.crt.pem"
   ```

   **TIP**

   After you run the installer with a custom CA certificate, you can update the certificate by editing the value of the **ca-cert.pem** key in the **cloud-provider-config** keymap. On a command line, run:

   ```bash
   $ oc edit configmap -n openshift-config cloud-provider-config
   ```

3. Place the **clouds.yaml** file in one of the following locations:

   a. The value of the **OS_CLIENT_CONFIG_FILE** environment variable

   b. The current directory

   c. A Unix-specific user configuration directory, for example `~/.config/openstack/clouds.yaml`

   d. A Unix-specific site configuration directory, for example `/etc/openstack/clouds.yaml`

   The installation program searches for **clouds.yaml** in that order.

### 17.7.13. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Red Hat OpenStack Platform (RHOSP).

**Prerequisites**

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster. For a restricted network installation, these files are on your mirror host.

- Have the **imageContentSources** values that were generated during mirror registry creation.

- Obtain the contents of the certificate for your mirror registry.

- Retrieve a Red Hat Enterprise Linux CoreOS (RHCOS) image and upload it to an accessible location.

- Obtain service principal permissions at the subscription level.

**Procedure**

1. Create the **install-config.yaml** file.
a. Change to the directory that contains the installation program and run the following command:

```
$ ./openshift-install create install-config --dir <installation_directory> 1
```

For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

**IMPORTANT**

Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

b. At the prompts, provide the configuration details for your cloud:

i. Optional: Select an SSH key to use to access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

ii. Select `openstack` as the platform to target.

iii. Specify the Red Hat OpenStack Platform (RHOSP) external network name to use for installing the cluster.

iv. Specify the floating IP address to use for external access to the OpenShift API.

v. Specify a RHOSP flavor with at least 16 GB RAM to use for control plane and compute nodes.

vi. Select the base domain to deploy the cluster to. All DNS records will be sub-domains of this base and will also include the cluster name.

vii. Enter a name for your cluster. The name must be 14 or fewer characters long.

viii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

2. In the `install-config.yaml` file, set the value of `platform.openstack.clusterOSImage` to the image location or name. For example:

```yaml
platform:
  openstack:
    clusterOSImage: http://mirror.example.com/images/rhcos-43.81.201912131630.0-openstack.x86_64.qcow2.gz?
    sha256=ffe8d68e8a1f2a245ca19522c16c856f67f9ac8e4e0c1f0a812b068b16f7265d
```
3. Edit the `install-config.yaml` file to provide the additional information that is required for an installation in a restricted network.

   a. Update the `pullSecret` value to contain the authentication information for your registry:

   ```yaml
   pullSecret: {
     "auths": {
       "<mirror_host_name>:5000": {
         "auth": "<credentials>",
         "email": "you@example.com"
       }
     }
   }
   
   For `<mirror_host_name>`, specify the registry domain name that you specified in the certificate for your mirror registry, and for `<credentials>`, specify the base64-encoded user name and password for your mirror registry.

   b. Add the `additionalTrustBundle` parameter and value.

   ```yaml
   additionalTrustBundle: |
   -----BEGIN CERTIFICATE-----
   ZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZ
   -----END CERTIFICATE-----
   
   The value must be the contents of the certificate file that you used for your mirror registry, which can be an existing, trusted certificate authority or the self-signed certificate that you generated for the mirror registry.

   c. Add the image content resources, which look like this excerpt:

   ```yaml
   imageContentSources:
   - mirrors:
     - <mirror_host_name>:5000/<repo_name>/release
       source: quay.example.com/openshift-release-dev/ocp-release
     - mirrors:
       - <mirror_host_name>:5000/<repo_name>/release
         source: registry.example.com/ocp/release
   
   To complete these values, use the `imageContentSources` that you recorded during mirror registry creation.

4. Make any other modifications to the `install-config.yaml` file that you require. You can find more information about the available parameters in the `Installation configuration parameters` section.

5. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

   **IMPORTANT**

   The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

You now have the file `install-config.yaml` in the directory that you specified.

### 17.7.14. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide a customized `install-config.yaml` installation configuration file that describes the details for your environment.
### 17.7.14.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is <code>v1</code>. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the <code>baseDomain</code> and <code>metadata.name</code> parameter values that uses the <code>&lt;metadata.name&gt;.-&lt;baseDomain&gt;</code> format.</td>
<td>A fully-qualified domain or subdomain name, such as <code>example.com</code>.</td>
</tr>
<tr>
<td>metadata</td>
<td>Kubernetes resource <code>ObjectMeta</code>, from which only the <code>name</code> parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of <code>{.metadata.name}.-{.baseDomain}</code>.</td>
<td>String of lowercase letters, hyphens (<code>-</code>), and periods (<code>.</code>), such as <code>dev</code>. The string must be 14 characters or fewer long.</td>
</tr>
</tbody>
</table>
### 17.7.14.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

**Table 17.29. Network parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>platform</td>
<td>The configuration for the specific platform upon which to perform the installation: <strong>alibabacloud, aws, baremetal, azure, ibmcloud, openstack, ovirt, vsphere</strong>, or {}. For additional information about platform.&lt;platform&gt; parameters, consult the table for your specific platform that follows.</td>
<td>Object</td>
</tr>
<tr>
<td>pullSecret</td>
<td>Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.</td>
<td><code>{  &quot;auths&quot;:{  &quot;cloud.openshift.com&quot;:{  &quot;auth&quot;:&quot;b3Blb=&quot;,  &quot;email&quot;:&quot;you@example.com&quot;  },  &quot;quay.io&quot;:{  &quot;auth&quot;:&quot;b3Blb=&quot;,  &quot;email&quot;:&quot;you@example.com&quot;  }  }  }</code></td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>----------------------------------------------</td>
<td>------------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------</td>
</tr>
<tr>
<td>networking</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong></td>
<td>You cannot modify parameters specified by the <code>networking</code> object after installation.</td>
</tr>
<tr>
<td>networking.network Type</td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either <code>OpenShiftSDN</code> or <code>OVNKubernetes</code>. The default value is <code>OpenShiftSDN</code>.</td>
</tr>
<tr>
<td>networking.clusterNetwork</td>
<td>The IP address blocks for pods.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td>The default value is <code>10.128.0.0/14</code> with a host prefix of <code>/23</code>.</td>
<td><code>networking:</code></td>
</tr>
<tr>
<td></td>
<td>If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td><code>clusterNetwork:</code>,</td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>- cidr: 10.128.0.0/14</code></td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>hostPrefix: 23</code></td>
</tr>
<tr>
<td>networking.clusterNetwork.cidr</td>
<td>Required if you use <code>networking.clusterNetwork</code>. An IP address block.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td></td>
<td>An IPv4 network.</td>
<td></td>
</tr>
<tr>
<td>networking.clusterNetwork.hostPrefix</td>
<td>The subnet prefix length to assign to each individual node. For example, if <code>hostPrefix</code> is set to 23 then each node is assigned a /23 subnet out of the given <code>cidr</code>. A <code>hostPrefix</code> value of 23 provides 510 (2^{(32 - 23)} - 2) pod IP addresses.</td>
<td>A subnet prefix.</td>
</tr>
<tr>
<td></td>
<td>The default value is 23.</td>
<td>The default value is 23.</td>
</tr>
<tr>
<td>networking.serviceNetwork</td>
<td>The IP address block for services. The default value is <code>172.30.0.0/16</code>.</td>
<td>An array with an IP address block in CIDR format. For example:</td>
</tr>
<tr>
<td></td>
<td>The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.</td>
<td><code>networking:</code>,</td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>serviceNetwork:</code>,</td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>- 172.30.0.0/16</code></td>
</tr>
</tbody>
</table>
networking.machine
Network | The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap. If you specify multiple IP kernel arguments, the machineNetwork.cidr value must be the CIDR of the primary network.

An array of objects. For example:

```yaml
networking:
machineNetwork:
  - cidr: 10.0.0.0/16
```

networking.machine
Network.cidr | Required if you use networking.machineNetwork. An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24.

An IP network block in CIDR notation. For example, 10.0.0.0/16.

**NOTE**

Set the networking.machineNetwork to match the CIDR that the preferred NIC resides in.

17.7.14.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

**Table 17.30. Optional parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>--------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>----------------------</td>
</tr>
<tr>
<td>cgroupsV2</td>
<td>Enables Linux control groups version 2 (cgroups v2) on specific nodes in your cluster. The OpenShift Container Platform process for enabling cgroups v2 disables all cgroup version 1 controllers and hierarchies. The OpenShift Container Platform cgroups version 2 feature is in Developer Preview and is not supported by Red Hat at this time.</td>
<td>true</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of MachinePool objects.</td>
</tr>
<tr>
<td>compute.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are s390x (the default).</td>
<td>String</td>
</tr>
<tr>
<td>compute.hyperthreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>IMPORTANT</td>
<td>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td></td>
</tr>
<tr>
<td>compute.name</td>
<td>Required if you use compute. The name of the machine pool.</td>
<td>worker</td>
</tr>
<tr>
<td>compute.platform</td>
<td>Required if you use compute. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the controlPlane.platform parameter value.</td>
<td>alibaba, aws, azure, gcp, ibmcloud, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-------------------</td>
<td>------------------------------------------------------------------------------</td>
<td>-----------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>compute.replicas</td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td>controlPlane</td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of MachinePool objects.</td>
</tr>
<tr>
<td>controlPlane.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are s390x (the default).</td>
<td>String</td>
</tr>
<tr>
<td>controlPlane.hypertreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>controlPlane.name</td>
<td>Required if you use controlPlane. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use controlPlane. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the compute.platform parameter value.</td>
<td>alibaba, aws, azure, gcp, ibmcloud, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------------------------------------------</td>
</tr>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (&quot;&quot;).</td>
</tr>
<tr>
<td>fips</td>
<td>Enable or disable FIPS mode. The default is false (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</td>
<td>false or true</td>
</tr>
</tbody>
</table>

**NOTE**
Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Platform Operators reference content.

**IMPORTANT**
The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

**NOTE**
If you are using Azure File storage, you cannot enable FIPS mode.
### Parameter Description Values

### 17.7.14.4. Additional Red Hat OpenStack Platform (RHOSP) configuration parameters

Additional RHOSP configuration parameters are described in the following table:

Table 17.31. Additional RHOSP parameters
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>compute.platform.openstack.rootVolume.size</td>
<td>For compute machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.</td>
<td>Integer, for example 30.</td>
</tr>
<tr>
<td>compute.platform.openstack.rootVolume.type</td>
<td>For compute machines, the root volume’s type.</td>
<td>String, for example performance.</td>
</tr>
<tr>
<td>controlPlane.platform.openstack.rootVolume.size</td>
<td>For control plane machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.</td>
<td>Integer, for example 30.</td>
</tr>
<tr>
<td>controlPlane.platform.openstack.rootVolume.type</td>
<td>For control plane machines, the root volume’s type.</td>
<td>String, for example performance.</td>
</tr>
<tr>
<td>platform.openstack.cloud</td>
<td>The name of the RHOSP cloud to use from the list of clouds in the clouds.yaml file.</td>
<td>String, for example MyCloud.</td>
</tr>
<tr>
<td>platform.openstack.externalNetwork</td>
<td>The RHOSP external network name to be used for installation.</td>
<td>String, for example external.</td>
</tr>
<tr>
<td>platform.openstack.computeFlavor</td>
<td>The RHOSP flavor to use for control plane and compute machines.</td>
<td>String, for example m1.xlarge.</td>
</tr>
<tr>
<td></td>
<td>This property is deprecated. To use a flavor as the default for all machine pools, add it as the value of the type key in the platform.openstack.defaultMachinePlatform property. You can also set a flavor value for each machine pool individually.</td>
<td></td>
</tr>
</tbody>
</table>

17.7.14.5. Optional RHOSP configuration parameters

Optional RHOSP configuration parameters are described in the following table:

Table 17.32. Optional RHOSP parameters
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>compute.platform.openstack.additionalNetworkIDs</code></td>
<td>Additional networks that are associated with compute machines. Allowed address pairs are not created for additional networks.</td>
<td>A list of one or more UUIDs as strings. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf.</td>
</tr>
<tr>
<td><code>compute.platform.openstack.additionalSecurityGroupIDs</code></td>
<td>Additional security groups that are associated with compute machines.</td>
<td>A list of one or more UUIDs as strings. For example, 7ee219f3-d2e9-48a1-96c2-e7429f1b0da7.</td>
</tr>
<tr>
<td><code>compute.platform.openstack.zones</code></td>
<td>RHOSP Compute (Nova) availability zones (AZs) to install machines on. If this parameter is not set, the installer relies on the default settings for Nova that the RHOSP administrator configured. On clusters that use Kuryr, RHOSP Octavia does not support availability zones. Load balancers and, if you are using the Amphora provider driver, OpenShift Container Platform services that rely on Amphora VMs, are not created according to the value of this property.</td>
<td>A list of strings. For example, [&quot;zone-1&quot;, &quot;zone-2&quot;].</td>
</tr>
<tr>
<td><code>compute.platform.openstack.rootVolume.zones</code></td>
<td>For compute machines, the availability zone to install root volumes on. If you do not set a value for this parameter, the installer selects the default availability zone.</td>
<td>A list of strings, for example [&quot;zone-1&quot;, &quot;zone-2&quot;].</td>
</tr>
<tr>

</tr>
<tr>
<td><code>platform.openstack.machinesSubnet</code></td>
<td>The UUID of a RHOSP subnet that the cluster’s nodes use. Nodes and virtual IP (VIP) ports are created on this subnet.</td>
<td>A UUID as a string. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf.</td>
</tr>
</tbody>
</table>

#### 17.7.14.6. Custom subnets in RHOSP deployments

Optionally, you can deploy a cluster on a Red Hat OpenStack Platform (RHOSP) subnet of your choice. The subnet’s GUID is passed as the value of `platform.openstack.machinesSubnet` in the `install-config.yaml` file.

This subnet is used as the cluster’s primary subnet. By default, nodes and ports are created on it. You can create nodes and ports on a different RHOSP subnet by setting the value of the `platform.openstack.machinesSubnet` property to the subnet’s UUID.

Before you run the OpenShift Container Platform installer with a custom subnet, verify that your configuration meets the following requirements:

- The subnet that is used by `platform.openstack.machinesSubnet` has DHCP enabled.
The CIDR of `platform.openstack.machinesSubnet` matches the CIDR of `networking.machineNetwork`.

The installation program user has permission to create ports on this network, including ports with fixed IP addresses.

Clusters that use custom subnets have the following limitations:

- If you plan to install a cluster that uses floating IP addresses, the `platform.openstack.machinesSubnet` subnet must be attached to a router that is connected to the `externalNetwork` network.

- If the `platform.openstack.machinesSubnet` value is set in the `install-config.yaml` file, the installation program does not create a private network or subnet for your RHOSP machines.

- You cannot use the `platform.openstack.externalDNS` property at the same time as a custom subnet. To add DNS to a cluster that uses a custom subnet, configure DNS on the RHOSP network.

**NOTE**

By default, the API VIP takes x.x.x.5 and the Ingress VIP takes x.x.x.7 from your network’s CIDR block. To override these default values, set values for `platform.openstack.apiVIP` and `platform.openstack.ingressVIP` that are outside of the DHCP allocation pool.

17.7.14.7. Sample customized install-config.yaml file for RHOSP with Kuryr

To deploy with Kuryr SDN instead of the default OpenShift SDN, you must modify the `install-config.yaml` file to include `Kuryr` as the desired `networking.networkType` and proceed with the default OpenShift Container Platform SDN installation steps. This sample `install-config.yaml` demonstrates all of the possible Red Hat OpenStack Platform (RHOSP) customization options.

**IMPORTANT**

This sample file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program.

```
apiVersion: v1
baseDomain: example.com
controlPlane:
  name: master
  platform: {}
  replicas: 3
compute:
- name: worker
  platform:
    openstack:
      type: ml.large
      replicas: 3
metadata:
  name: example
networking:
  clusterNetwork:
  - cidr: 10.128.0.0/14
  hostPrefix: 23
```
The Amphora Octavia driver creates two ports per load balancer. As a result, the service subnet that the installer creates is twice the size of the CIDR that is specified as the value of the `serviceNetwork` property. The larger range is required to prevent IP address conflicts.

Both `trunkSupport` and `octaviaSupport` are automatically discovered by the installer, so there is no need to set them. But if your environment does not meet both requirements, Kuryr SDN will not properly work. Trunks are needed to connect the pods to the RHOSP network and Octavia is required to create the OpenShift Container Platform services.

17.7.14.8. Cluster deployment on RHOSP provider networks

You can deploy your OpenShift Container Platform clusters on Red Hat OpenStack Platform (RHOSP) with a primary network interface on a provider network. Provider networks are commonly used to give projects direct access to a public network that can be used to reach the internet. You can also share provider networks among projects as part of the network creation process.

RHOSP provider networks map directly to an existing physical network in the data center. A RHOSP administrator must create them.

In the following example, OpenShift Container Platform workloads are connected to a data center by using a provider network:

```
machineNetwork:  
- cidr: 10.0.0.0/16  

serviceNetwork:  
- 172.30.0.0/16  

networkType: Kuryr  

platform:  
openstack:  
cloud: mycloud  
externalNetwork: external  
computeFlavor: m1.xlarge  
apiFloatingIP: 128.0.0.1  
trunkSupport: true  
octaviaSupport: true  
pullSecret: '{"auths": ...}'  
sshKey: ssh-ed25519 AAAA...
```
OpenShift Container Platform clusters that are installed on provider networks do not require tenant networks or floating IP addresses. The installer does not create these resources during installation.

Example provider network types include flat (untagged) and VLAN (802.1Q tagged).

**NOTE**

A cluster can support as many provider network connections as the network type allows. For example, VLAN networks typically support up to 4096 connections.

You can learn more about provider and tenant networks in the RHOSP documentation.

### 17.7.14.8.1. RHOSP provider network requirements for cluster installation

Before you install an OpenShift Container Platform cluster, your Red Hat OpenStack Platform (RHOSP) deployment and provider network must meet a number of conditions:

- The RHOSP networking service (Neutron) is enabled and accessible through the RHOSP networking API.
- The RHOSP networking service has the port security and allowed address pairs extensions enabled.
The provider network can be shared with other tenants.

TIP

Use the `openstack network create` command with the `--share` flag to create a network that can be shared.

The RHOSP project that you use to install the cluster must own the provider network, as well as an appropriate subnet.

TIP

To create a network for a project that is named "openshift," enter the following command

```
$ openstack network create --project openshift
```

To create a subnet for a project that is named "openshift," enter the following command

```
$ openstack subnet create --project openshift
```

To learn more about creating networks on RHOSP, read the provider networks documentation.

If the cluster is owned by the `admin` user, you must run the installer as that user to create ports on the network.

**IMPORTANT**

Provider networks must be owned by the RHOSP project that is used to create the cluster. If they are not, the RHOSP Compute service (Nova) cannot request a port from that network.

Verify that the provider network can reach the RHOSP metadata service IP address, which is `169.254.169.254` by default.

Depending on your RHOSP SDN and networking service configuration, you might need to provide the route when you create the subnet. For example:

```
$ openstack subnet create --dhcp --host-route destination=169.254.169.254/32,gateway=192.0.2.2 ...
```

Optional: To secure the network, create role-based access control (RBAC) rules that limit network access to a single project.

### 17.7.14.8.2. Deploying a cluster that has a primary interface on a provider network

You can deploy an OpenShift Container Platform cluster that has its primary network interface on an Red Hat OpenStack Platform (RHOSP) provider network.

**Prerequisites**

- Your Red Hat OpenStack Platform (RHOSP) deployment is configured as described by "RHOSP provider network requirements for cluster installation".
1. In a text editor, open the `install-config.yaml` file.

2. Set the value of the `platform.openstack.apiVIP` property to the IP address for the API VIP.

3. Set the value of the `platform.openstack.ingressVIP` property to the IP address for the Ingress VIP.

4. Set the value of the `platform.openstack.machinesSubnet` property to the UUID of the provider network subnet.

5. Set the value of the `networking.machineNetwork.cidr` property to the CIDR block of the provider network subnet.

**IMPORTANT**

The `platform.openstack.apiVIP` and `platform.openstack.ingressVIP` properties must both be unassigned IP addresses from the `networking.machineNetwork.cidr` block.

**Section of an installation configuration file for a cluster that relies on a RHOSP provider network**

```yaml
...  
platform:  
  openstack:  
    apiVIP: 192.0.2.13  
    ingressVIP: 192.0.2.23  
    machinesSubnet: fa806b2f-ac49-4bce-b9db-124bc64209bf
  # ...
networking:  
  machineNetwork:  
    - cidr: 192.0.2.0/24
```

**WARNING**

You cannot set the `platform.openstack.externalNetwork` or `platform.openstack.externalDNS` parameters while using a provider network for the primary network interface.

When you deploy the cluster, the installer uses the `install-config.yaml` file to deploy the cluster on the provider network.

**TIP**

You can add additional networks, including provider networks, to the `platform.openstack.additionNetworkIDs` list.

After you deploy your cluster, you can attach pods to additional networks. For more information, see [Understanding multiple networks](#).
17.7.14.9. Kuryr ports pools

A Kuryr ports pool maintains a number of ports on standby for pod creation.

Keeping ports on standby minimizes pod creation time. Without ports pools, Kuryr must explicitly request port creation or deletion whenever a pod is created or deleted.

The Neutron ports that Kuryr uses are created in subnets that are tied to namespaces. These pod ports are also added as subports to the primary port of OpenShift Container Platform cluster nodes.

Because Kuryr keeps each namespace in a separate subnet, a separate ports pool is maintained for each namespace-worker pair.

Prior to installing a cluster, you can set the following parameters in the `cluster-network-03-config.yml` manifest file to configure ports pool behavior:

- The `enablePortPoolsPrepopulation` parameter controls pool prepopulation, which forces Kuryr to add Neutron ports to the pools when the first pod that is configured to use the dedicated network for pods is created in a namespace. The default value is `false`.

- The `poolMinPorts` parameter is the minimum number of free ports that are kept in the pool. The default value is `1`.

- The `poolMaxPorts` parameter is the maximum number of free ports that are kept in the pool. A value of `0` disables that upper bound. This is the default setting. If your OpenStack port quota is low, or you have a limited number of IP addresses on the pod network, consider setting this option to ensure that unneeded ports are deleted.

- The `poolBatchPorts` parameter defines the maximum number of Neutron ports that can be created at once. The default value is `3`.

17.7.14.10. Adjusting Kuryr ports pools during installation

During installation, you can configure how Kuryr manages Red Hat OpenStack Platform (RHOSP) Neutron ports to control the speed and efficiency of pod creation.

Prerequisites

- Create and modify the `install-config.yaml` file.

Procedure

1. From a command line, create the manifest files:

   ```
   $ ./openshift-install create manifests --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the name of the directory that contains the `install-config.yaml` file for your cluster.

2. Create a file that is named `cluster-network-03-config.yml` in the `<installation_directory>/manifests/` directory:

   ```
   $ touch <installation_directory>/manifests/cluster-network-03-config.yml
   ```
1. For `<installation_directory>`, specify the directory name that contains the `manifests/` directory for your cluster.

After creating the file, several network configuration files are in the `manifests/` directory, as shown:

```
$ ls <installation_directory>/manifests/cluster-network-*
```

**Example output**

- cluster-network-01-crd.yml
- cluster-network-02-config.yml
- cluster-network-03-config.yml

3. Open the `cluster-network-03-config.yml` file in an editor, and enter a custom resource (CR) that describes the Cluster Network Operator configuration that you want:

```
$ oc edit networks.operator.openshift.io cluster
```

4. Edit the settings to meet your requirements. The following file is provided as an example:

```yaml
apiVersion: operator.openshift.io/v1
class: Network
metadata:
  name: cluster
spec:
  clusterNetwork:
    - cidr: 10.128.0.0/14
      hostPrefix: 23
  serviceNetwork:
    - 172.30.0.0/16
  defaultNetwork:
    type: Kuryr
    kuryrConfig:
      enablePortPoolsPrepopulation: false
      poolMinPorts: 1
      poolBatchPorts: 3
      poolMaxPorts: 5
      openstackServiceNetwork: 172.30.0.0/15
```

1. Set `enablePortPoolsPrepopulation` to `true` to make Kuryr create new Neutron ports when the first pod on the network for pods is created in a namespace. This setting raises the Neutron ports quota but can reduce the time that is required to spawn pods. The default value is `false`.

2. Kuryr creates new ports for a pool if the number of free ports in that pool is lower than the value of `poolMinPorts`. The default value is 1.

3. `poolBatchPorts` controls the number of new ports that are created if the number of free ports is lower than the value of `poolMinPorts`. The default value is 3.
If the number of free ports in a pool is higher than the value of `poolMaxPorts`, Kuryr deletes them until the number matches that value. Setting this value to 0 disables this.

The `openStackServiceNetwork` parameter defines the CIDR range of the network from which IP addresses are allocated to RHOSP Octavia’s LoadBalancers.

If this parameter is used with the Amphora driver, Octavia takes two IP addresses from this network for each load balancer: one for OpenShift and the other for VRRP connections. Because these IP addresses are managed by OpenShift Container Platform and Neutron respectively, they must come from different pools. Therefore, the value of `openStackServiceNetwork` must be at least twice the size of the value of `serviceNetwork`, and the value of `serviceNetwork` must overlap entirely with the range that is defined by `openStackServiceNetwork`.

The CNO verifies that VRRP IP addresses that are taken from the range that is defined by this parameter do not overlap with the range that is defined by the `serviceNetwork` parameter.

If this parameter is not set, the CNO uses an expanded value of `serviceNetwork` that is determined by decrementing the prefix size by 1.

5. Save the `cluster-network-03-config.yml` file, and exit the text editor.

6. Optional: Back up the `manifests/cluster-network-03-config.yml` file. The installation program deletes the `manifests/` directory while creating the cluster.

17.7.14.11. Setting a custom subnet for machines

The IP range that the installation program uses by default might not match the Neutron subnet that you create when you install OpenShift Container Platform. If necessary, update the CIDR value for new machines by editing the installation configuration file.

Prerequisites

- You have the `install-config.yaml` file that was generated by the OpenShift Container Platform installation program.

Procedure

1. On a command line, browse to the directory that contains `install-config.yaml`.

2. From that directory, either run a script to edit the `install-config.yaml` file or update the file manually:

   - To set the value by using a script, run:

     ```
     $ python -c '
     import yaml;
     path = "install-config.yaml";
     data = yaml.safe_load(open(path));
     data["networking"]['machineNetwork'] = '{{"cidr": "192.168.0.0/18"}};
     open(path, "w").write(yaml.dump(data, default_flow_style=False))'
     ```

   Insert a value that matches your intended Neutron subnet, e.g. `192.0.2.0/24`. 
To set the value manually, open the file and set the value of `networking.machineCIDR` to something that matches your intended Neutron subnet.

### 17.7.14.12. Emptying compute machine pools

To proceed with an installation that uses your own infrastructure, set the number of compute machines in the installation configuration file to zero. Later, you create these machines manually.

**Prerequisites**

- You have the `install-config.yaml` file that was generated by the OpenShift Container Platform installation program.

**Procedure**

1. On a command line, browse to the directory that contains `install-config.yaml`.
2. From that directory, either run a script to edit the `install-config.yaml` file or update the file manually:
   - To set the value by using a script, run:
     ```python
     $ python -c '
     import yaml;
     path = "install-config.yaml";
     data = yaml.safe_load(open(path));
     data["compute"]""""0""""["replicas"] = 0;
     open(path, "w").write(yaml.dump(data, default_flow_style=False));'
     ```
   - To set the value manually, open the file and set the value of `compute.<first entry>.replicas` to `0`.

### 17.7.14.13. Modifying the network type

By default, the installation program selects the `OpenShiftSDN` network type. To use Kuryr instead, change the value in the installation configuration file that the program generated.

**Prerequisites**

- You have the file `install-config.yaml` that was generated by the OpenShift Container Platform installation program.

**Procedure**

1. In a command prompt, browse to the directory that contains `install-config.yaml`.
2. From that directory, either run a script to edit the `install-config.yaml` file or update the file manually:
   - To set the value by using a script, run:
     ```python
     $ python -c '
     import yaml;
     path = "install-config.yaml";
     data = yaml.safe_load(open(path));
     open(path, "w").write(yaml.dump(data, default_flow_style=False));'
     ```
To set the value manually, open the file and set `networking.networkType` to "Kuryr".

### 17.7.15. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

**IMPORTANT**

- The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

**NOTE**

The installation program that generates the manifest and Ignition files is architecture specific and can be obtained from the client image mirror. The Linux version of the installation program runs on s390x only. This installer program is also available as a Mac OS version.

**Prerequisites**

- You obtained the OpenShift Container Platform installation program. For a restricted network installation, these files are on your mirror host.

- You created the `install-config.yaml` installation configuration file.

**Procedure**

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

   ```bash
   $ ./openshift-install create manifests --dir <installation_directory>
   ```

   **Example output**
1. For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.

2. Remove the Kubernetes manifest files that define the control plane machines and compute machine sets:

   ```
   $ rm -f openshift/99_openshift-cluster-api_master-machines-*_.yaml openshift/99_openshift-cluster-api_worker-machineset-*_.yaml
   ```

   Because you create and manage these resources yourself, you do not have to initialize them.

   - You can preserve the machine set files to create compute machines by using the machine API, but you must update references to them to match your environment.

   **WARNING**

   If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.

   **IMPORTANT**

   When you configure control plane nodes from the default unschedulable to schedulable, additional subscriptions are required. This is because control plane nodes then become worker nodes.

3. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:

   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.

   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.

   c. Save and exit the file.

4. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

   ```
   $ ./openshift-install create ignition-configs --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the same installation directory.
Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The `kubeadmin-password` and `kubeconfig` files are created in the ./<installation_directory>/auth directory:

```
├── auth
│   ├── kubeadmin-password
│   └── kubeconfig
└── bootstrap.ign
```

5. Export the metadata file’s `infraID` key as an environment variable:

```
$ export INFRA_ID=$(jq -r .infraID metadata.json)
```

**TIP**

Extract the `infraID` key from `metadata.json` and use it as a prefix for all of the RHOSP resources that you create. By doing so, you avoid name conflicts when making multiple deployments in the same project.

### 17.7.16. Preparing the bootstrap Ignition files

The OpenShift Container Platform installation process relies on bootstrap machines that are created from a bootstrap Ignition configuration file.

Edit the file and upload it. Then, create a secondary bootstrap Ignition configuration file that Red Hat OpenStack Platform (RHOSP) uses to download the primary file.

**Prerequisites**

- You have the bootstrap Ignition file that the installer program generates, `bootstrap.ign`.
- The infrastructure ID from the installer’s metadata file is set as an environment variable (`$INFRA_ID`).
  - If the variable is not set, see Creating the Kubernetes manifest and Ignition config files
- You have an HTTP(S)-accessible way to store the bootstrap Ignition file.
  - The documented procedure uses the RHOSP image service (Glance), but you can also use the RHOSP storage service (Swift), Amazon S3, an internal HTTP server, or an ad hoc Nova server.

**Procedure**

1. Run the following Python script. The script modifies the bootstrap Ignition file to set the hostname and, if available, CA certificate file when it runs:

```
import base64
import json
import os
```
with open('bootstrap.ign', 'r') as f:
    ignition = json.load(f)

files = ignition['storage'].get('files', [])

infra_id = os.environ.get('INFRA_ID', 'openshift').encode()
hostname_b64 = base64.standard_b64encode(infra_id + b'-bootstrap').decode().strip()
files.append(
    {'path': '/etc/hostname',
     'mode': 420,
     'contents': {
         'source': 'data:text/plain;charset=utf-8;base64,\n' + hostname_b64
     }
    }
)

ca_cert_path = os.environ.get('OS_CACERT', '')
if ca_cert_path:
    with open(ca_cert_path, 'r') as f:
        ca_cert = f.read().encode()
    ca_cert_b64 = base64.standard_b64encode(ca_cert).decode().strip()

files.append(
    {'path': '/opt/openshift/tls/cloud-ca-cert.pem',
     'mode': 420,
     'contents': {
         'source': 'data:text/plain;charset=utf-8;base64,\n' + ca_cert_b64
     }
    }
)

ignition['storage']['files'] = files;

with open('bootstrap.ign', 'w') as f:
    json.dump(ignition, f)

2. Using the RHOSP CLI, create an image that uses the bootstrap Ignition file:

   $ openstack image create --disk-format=raw --container-format=bare --file bootstrap.ign <image_name>

3. Get the image’s details:

   $ openstack image show <image_name>

   Make a note of the file value; it follows the pattern v2/images/<image_ID>/file.

   NOTE

   Verify that the image you created is active.

4. Retrieve the image service’s public address:
5. Combine the public address with the image file value and save the result as the storage location. The location follows the pattern

6. Generate an auth token and save the token ID:
   ```bash
   $ openstack token issue -c id -f value
   ```

7. Insert the following content into a file called `$INFRA_ID-bootstrap-ignition.json` and edit the placeholders to match your own values:

   ```json
   {
     "ignition": {
       "config": {
         "merge": [{
           "source": "<storage_url>",
           "httpHeaders": [{
             "name": "X-Auth-Token",
             "value": "<token_ID>
           }]
         }],
         "security": {
           "tls": {
             "certificateAuthorities": [{
               "source": "data:text/plain;charset=utf-8;base64,<base64_encoded_certificate>",
           }]
         }
       },
       "version": "3.2.0"
     }
   }
   ```

   1. Replace the value of `ignition.config.merge.source` with the bootstrap Ignition file storage URL.
   2. Set `name` in `httpHeaders` to "X-Auth-Token".
   3. Set `value` in `httpHeaders` to your token’s ID.
   4. If the bootstrap Ignition file server uses a self-signed certificate, include the base64-encoded certificate.

8. Save the secondary Ignition config file.

The bootstrap Ignition data will be passed to RHOSP during installation.
WARNING

The bootstrap Ignition file contains sensitive information, like `clouds.yaml` credentials. Ensure that you store it in a secure place, and delete it after you complete the installation process.

---

### 17.7.17. Creating control plane Ignition config files on RHOSP

Installing OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) on your own infrastructure requires control plane Ignition config files. You must create multiple config files.

---

**NOTE**

As with the bootstrap Ignition configuration, you must explicitly define a hostname for each control plane machine.

---

**Prerequisites**

- The infrastructure ID from the installation program’s metadata file is set as an environment variable (`$INFRA_ID`).
  - If the variable is not set, see "Creating the Kubernetes manifest and Ignition config files".

---

**Procedure**

- On a command line, run the following Python script:

```bash
$ for index in $(seq 0 2); do
  MASTER_HOSTNAME="$INFRA_ID-master-$index"
  python -c "import base64, json, sys;
    ignition = json.load(sys.stdin);
    storage = ignition.get('storage', {});
    files = storage.get('files', []);
    files.append({'path': '/etc/hostname', 'mode': 420, 'contents': {'source':
        'data:text/plain;charset=utf-8;base64,' + base64.standard_b64encode(b'$MASTER_HOSTNAME').decode().strip(), 'verification': {}},
        'filesystem': 'root'});
    storage['files'] = files;
    json.dump(ignition, sys.stdout)" <master.ign >"$INFRA_ID-master-$index-ignition.json"
done
```

You now have three control plane Ignition files: `<INFRA_ID>-master-0-ignition.json`, `<INFRA_ID>-master-1-ignition.json`, and `<INFRA_ID>-master-2-ignition.json`.

---

### 17.7.18. Creating network resources on RHOSP

Create the network resources that an OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) installation on your own infrastructure requires. To save time, run supplied Ansible playbooks that generate security groups, networks, subnets, routers, and ports.
Prerequisites

- Python 3 is installed on your machine.
- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".

Procedure

1. Optional: Add an external network value to the `inventory.yml` playbook:

   **Example external network value in the inventory.yml Ansible playbook**

   ```yaml
   ...
   # The public network providing connectivity to the cluster. If not
   # provided, the cluster external connectivity must be provided in another
   # way.
   
   # Required for os_api_fip, os_ingress_fip, os_bootstrap_fip.
   os_external_network: 'external'
   ...
   ```

   **IMPORTANT**

   If you did not provide a value for `os_external_network` in the `inventory.yml` file, you must ensure that VMs can access Glance and an external connection yourself.

2. Optional: Add external network and floating IP (FIP) address values to the `inventory.yml` playbook:

   **Example FIP values in the inventory.yml Ansible playbook**

   ```yaml
   ...
   # OpenShift API floating IP address. If this value is non-empty, the
   # corresponding floating IP will be attached to the Control Plane to
   # serve the OpenShift API.
   os_api_fip: '203.0.113.23'
   
   # OpenShift Ingress floating IP address. If this value is non-empty, the
   # corresponding floating IP will be attached to the worker nodes to serve
   # the applications.
   os_ingress_fip: '203.0.113.19'
   
   # If this value is non-empty, the corresponding floating IP will be
   # attached to the bootstrap machine. This is needed for collecting logs
   # in case of install failure.
   os_bootstrap_fip: '203.0.113.20'
   ```
**IMPORTANT**

If you do not define values for `os_api_fip` and `os_ingress_fip`, you must perform post-installation network configuration.

If you do not define a value for `os_bootstrap_fip`, the installer cannot download debugging information from failed installations.

See "Enabling access to the environment" for more information.

3. On a command line, create security groups by running the `security-groups.yaml` playbook:

   ```bash
   $ ansible-playbook -i inventory.yaml security-groups.yaml
   ```

4. On a command line, create a network, subnet, and router by running the `network.yaml` playbook:

   ```bash
   $ ansible-playbook -i inventory.yaml network.yaml
   ```

5. Optional: If you want to control the default resolvers that Nova servers use, run the RHOSP CLI command:

   ```bash
   $ openstack subnet set --dns-nameserver <server_1> --dns-nameserver <server_2> "$INFRA_ID-nodes"
   ```

### 17.7.19. Creating the bootstrap machine on RHOSP

Create a bootstrap machine and give it the network access it needs to run on Red Hat OpenStack Platform (RHOSP). Red Hat provides an Ansible playbook that you run to simplify this process.

**Prerequisites**

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The `inventory.yaml`, `common.yaml`, and `bootstrap.yaml` Ansible playbooks are in a common directory.
- The `metadata.json` file that the installation program created is in the same directory as the Ansible playbooks.

**Procedure**

1. On a command line, change the working directory to the location of the playbooks.

2. On a command line, run the `bootstrap.yaml` playbook:

   ```bash
   $ ansible-playbook -i inventory.yaml bootstrap.yaml
   ```

3. After the bootstrap server is active, view the logs to verify that the Ignition files were received:

   ```bash
   $ openstack console log show "$INFRA_ID-bootstrap"
   ```
17.7.20. Creating the control plane machines on RHOSP

Create three control plane machines by using the Ignition config files that you generated. Red Hat provides an Ansible playbook that you run to simplify this process.

Prerequisites

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The infrastructure ID from the installation program’s metadata file is set as an environment variable (\$INFRA_ID).
- The inventory.yaml, common.yaml, and control-plane.yaml Ansible playbooks are in a common directory.
- You have the three Ignition files that were created in "Creating control plane Ignition config files".

Procedure

1. On a command line, change the working directory to the location of the playbooks.
2. If the control plane Ignition config files aren’t already in your working directory, copy them into it.
3. On a command line, run the control-plane.yaml playbook:
   
   ```bash
   $ ansible-playbook -i inventory.yaml control-plane.yaml
   ```
4. Run the following command to monitor the bootstrapping process:
   
   ```bash
   $ openshift-install wait-for bootstrap-complete
   ```

   You will see messages that confirm that the control plane machines are running and have joined the cluster:

   ```
   INFO API v1.23.0 up
   INFO Waiting up to 30m0s for bootstrapping to complete...
   ... INFO It is now safe to remove the bootstrap resources
   ```

17.7.21. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster kubeconfig file. The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
• You installed the `oc` CLI.

Procedure

1. Export the `kubeadmin` credentials:

   ```
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```
   $ oc whoami
   ```

   Example output

   ```
   system:admin
   ```

17.7.22. Deleting bootstrap resources from RHOSP

Delete the bootstrap resources that you no longer need.

Prerequisites

• You downloaded the modules in “Downloading playbook dependencies”.

• You downloaded the playbooks in "Downloading the installation playbooks".

• The `inventory.yaml`, `common.yaml`, and `down-bootstrap.yaml` Ansible playbooks are in a common directory.

• The control plane machines are running.
  • If you do not know the status of the machines, see “Verifying cluster status”.

Procedure

1. On a command line, change the working directory to the location of the playbooks.

2. On a command line, run the `down-bootstrap.yaml` playbook:

   ```
   $ ansible-playbook -i inventory.yaml down-bootstrap.yaml
   ```

   The bootstrap port, server, and floating IP address are deleted.
17.7.23. Creating compute machines on RHOSP

After standing up the control plane, create compute machines. Red Hat provides an Ansible playbook that you run to simplify this process.

**Prerequisites**

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The `inventory.yaml`, `common.yaml`, and `compute-nodes.yaml` Ansible playbooks are in a common directory.
- The `metadata.json` file that the installation program created is in the same directory as the Ansible playbooks.
- The control plane is active.

**Procedure**

1. On a command line, change the working directory to the location of the playbooks.
2. On a command line, run the playbook:

   ```
   $ ansible-playbook -i inventory.yaml compute-nodes.yaml
   ```

**Next steps**

- Approve the certificate signing requests for the machines.

17.7.24. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

**Prerequisites**

- You added machines to your cluster.

**Procedure**

1. Confirm that the cluster recognizes the machines:

   ```
   $ oc get nodes
   ```
Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.23.0</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.23.0</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>64m</td>
<td>v1.23.0</td>
</tr>
</tbody>
</table>

The output lists all of the machines that you created.

**NOTE**

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

   $ oc get csr

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-mddf 5</td>
<td>20m</td>
<td>system:node:master-01.example.com</td>
<td>Approved,Issued</td>
</tr>
<tr>
<td>csr-z5rln</td>
<td>16m</td>
<td>system:node:worker-21.example.com</td>
<td>Approved,Issued</td>
</tr>
</tbody>
</table>

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

**NOTE**

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

**NOTE**

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the oc exec, oc rsh, and oc logs commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrapper** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.
To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name>  
```

<csr_name> is the name of a CSR from the list of current CSRs.

To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" {{end}}{{end}} | xargs --no-run-if-empty oc adm certificate approve
```

**NOTE**

Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-c57lv</td>
<td>5m26s</td>
<td>system:node:ip-10-0-95-157.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
</tbody>
</table>

5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name>  
```

<csr_name> is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" {{end}}{{end}} | xargs oc adm certificate approve
```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

**Example output**
It can take a few minutes after approval of the server CSRs for the machines to transition to the `Ready` status.

Additional information

- For more information on CSRs, see Certificate Signing Requests.

### 17.7.25. Verifying a successful installation

Verify that the OpenShift Container Platform installation is complete.

**Prerequisites**

- You have the installation program (`openshift-install`)

**Procedure**

- On a command line, enter:

  ```
  $ openshift-install --log-level debug wait-for install-complete
  ```

  The program outputs the console URL, as well as the administrator’s login information.

### 17.7.26. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.10, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use `subscription watch` to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- See About remote health monitoring for more information about the Telemetry service

### 17.7.27. Next steps

- Customize your cluster.

  - If necessary, you can opt out of remote health reporting.
If you need to enable external access to node ports, configure ingress cluster traffic by using a node port.

If you did not configure RHOSP to accept application traffic over floating IP addresses, configure RHOSP access with floating IP addresses.

17.8. INSTALLING A CLUSTER ON OPENSTACK ON YOUR OWN SR-IOV INFRASTRUCTURE

In OpenShift Container Platform 4.10, you can install a cluster on Red Hat OpenStack Platform (RHOSP) that runs on user-provisioned infrastructure and uses single-root input/output virtualization (SR-IOV) networks to run compute machines.

Using your own infrastructure allows you to integrate your cluster with existing infrastructure and modifications. The process requires more labor on your part than installer-provisioned installations, because you must create all RHOSP resources, such as Nova servers, Neutron ports, and security groups. However, Red Hat provides Ansible playbooks to help you in the deployment process.

17.8.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You verified that OpenShift Container Platform 4.10 is compatible with your RHOSP version by using the Supported platforms for OpenShift clusters section. You can also compare platform support across different versions by viewing the OpenShift Container Platform on RHOSP support matrix.
- Your network configuration does not rely on a provider network. Provider networks are not supported.
- You have an RHOSP account where you want to install OpenShift Container Platform.
- On the machine where you run the installation program, you have:
  - A single directory in which you can keep the files you create during the installation process
  - Python 3

17.8.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.10, you require access to the internet to obtain the images that are necessary to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.
IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

17.8.3. Resource guidelines for installing OpenShift Container Platform on RHOSP

To support an OpenShift Container Platform installation, your Red Hat OpenStack Platform (RHOSP) quota must meet the following requirements:

Table 17.33. Recommended resources for a default OpenShift Container Platform cluster on RHOSP

<table>
<thead>
<tr>
<th>Resource</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Floating IP addresses</td>
<td>3</td>
</tr>
<tr>
<td>Ports</td>
<td>15</td>
</tr>
<tr>
<td>Routers</td>
<td>1</td>
</tr>
<tr>
<td>Subnets</td>
<td>1</td>
</tr>
<tr>
<td>RAM</td>
<td>112 GB</td>
</tr>
<tr>
<td>vCPUs</td>
<td>28</td>
</tr>
<tr>
<td>Volume storage</td>
<td>275 GB</td>
</tr>
<tr>
<td>Instances</td>
<td>7</td>
</tr>
<tr>
<td>Security groups</td>
<td>3</td>
</tr>
<tr>
<td>Security group rules</td>
<td>60</td>
</tr>
<tr>
<td>Server groups</td>
<td>2 - plus 1 for each additional availability zone in each machine pool</td>
</tr>
</tbody>
</table>

A cluster might function with fewer than recommended resources, but its performance is not guaranteed.
IMPORTANT

If RHOSP object storage (Swift) is available and operated by a user account with the `swift-operator` role, it is used as the default backend for the OpenShift Container Platform image registry. In this case, the volume storage requirement is 175 GB. Swift space requirements vary depending on the size of the image registry.

NOTE

By default, your security group and security group rule quotas might be low. If you encounter problems, run `openstack quota set --secgroups 3 --secgroup-rules 60 <project>` as an administrator to increase them.

An OpenShift Container Platform deployment comprises control plane machines, compute machines, and a bootstrap machine.

17.8.3.1. Control plane and compute machines

By default, the OpenShift Container Platform installation process stands up three control plane and three compute machines.

Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 25 GB storage space

TIP

Compute machines host the applications that you run on OpenShift Container Platform; aim to run as many as you can.

Additionally, for clusters that use single-root input/output virtualization (SR-IOV), RHOSP compute nodes require a flavor that supports huge pages.

IMPORTANT

SR-IOV deployments often employ performance optimizations, such as dedicated or isolated CPUs. For maximum performance, configure your underlying RHOSP deployment to use these optimizations, and then run OpenShift Container Platform compute machines on the optimized infrastructure.

Additional resources

- For more information about configuring performant RHOSP compute nodes, see Configuring Compute nodes for performance.

17.8.3.2. Bootstrap machine

During installation, a bootstrap machine is temporarily provisioned to stand up the control plane. After the production control plane is ready, the bootstrap machine is deprovisioned.
The bootstrap machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 25 GB storage space

17.8.4. Downloading playbook dependencies

The Ansible playbooks that simplify the installation process on user-provisioned infrastructure require several Python modules. On the machine where you will run the installer, add the modules’ repositories and then download them.

**NOTE**

These instructions assume that you are using Red Hat Enterprise Linux (RHEL) 8.

**Prerequisites**

- Python 3 is installed on your machine.

**Procedure**

1. On a command line, add the repositories:
   
   a. Register with Red Hat Subscription Manager:

      ```
      $ sudo subscription-manager register # If not done already
      ```

   b. Pull the latest subscription data:

      ```
      $ sudo subscription-manager attach --pool=$YOUR_POOLID # If not done already
      ```

   c. Disable the current repositories:

      ```
      $ sudo subscription-manager repos --disable=* # If not done already
      ```

   d. Add the required repositories:

      ```
      $ sudo subscription-manager repos \
      --enable=rhel-8-for-x86_64-baseos-rpms \
      --enable=openstack-16-tools-for-rhel-8-x86_64-rpms \
      --enable=ansible-2.9-for-rhel-8-x86_64-rpms \
      --enable=rhel-8-for-x86_64-appstream-rpms
      ```

2. Install the modules:

   ```
   $ sudo yum install python3-openstackclient ansible python3-openstacksdk python3-netaddr
   ```

3. Ensure that the `python` command points to `python3`:

   ```
   $ sudo alternatives --set python /usr/bin/python3
   ```
17.8.5. Downloading the installation playbooks

Download Ansible playbooks that you can use to install OpenShift Container Platform on your own Red Hat OpenStack Platform (RHOSP) infrastructure.

Prerequisites

- The curl command-line tool is available on your machine.

Procedure

- To download the playbooks to your working directory, run the following script from a command line:

  ```bash
  $ xargs -n 1 curl -O <<< 'https://raw.githubusercontent.com/openshift/installer/release-4.10/upi/openstack/bootstrap.yaml
  https://raw.githubusercontent.com/openshift/installer/release-4.10/upi/openstack/common.yaml
  https://raw.githubusercontent.com/openshift/installer/release-4.10/upi/openstack/compute-nodes.yaml
  https://raw.githubusercontent.com/openshift/installer/release-4.10/upi/openstack/control-plane.yaml
  https://raw.githubusercontent.com/openshift/installer/release-4.10/upi/openstack/inventory.yaml
  https://raw.githubusercontent.com/openshift/installer/release-4.10/upi/openstack/network.yaml
  https://raw.githubusercontent.com/openshift/installer/release-4.10/upi/openstack/security-groups.yaml
  https://raw.githubusercontent.com/openshift/installer/release-4.10/upi/openstack/downbootstrap.yaml
  https://raw.githubusercontent.com/openshift/installer/release-4.10/upi/openstack/downcompute-nodes.yaml
  https://raw.githubusercontent.com/openshift/installer/release-4.10/upi/openstack/downcontrol-plane.yaml
  https://raw.githubusercontent.com/openshift/installer/release-4.10/upi/openstack/donload-balancers.yaml
  https://raw.githubusercontent.com/openshift/installer/release-4.10/upi/openstack/donnetwork.yaml
  https://raw.githubusercontent.com/openshift/installer/release-4.10/upi/openstack/donsecurity-groups.yaml
  https://raw.githubusercontent.com/openshift/installer/release-4.10/upi/openstack/doncontainers.yaml'
  
  The playbooks are downloaded to your machine.

  **IMPORTANT**

  During the installation process, you can modify the playbooks to configure your deployment.

  Retain all playbooks for the life of your cluster. You must have the playbooks to remove your OpenShift Container Platform cluster from RHOSP.
17.8.6. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the mirror host.

Prerequisites

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

   IMPORTANT

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   IMPORTANT

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   $ tar -xvf openshift-install-linux.tar.gz

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

17.8.7. Generating a key pair for cluster node SSH access
During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The ./openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>  
   ```

   Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   ```
   $ cat <path>/<file_name>.pub
   ```

   For example, run the following to view the ~/.ssh/id_rsa.pub public key:

   ```
   $ cat ~/.ssh/id_rsa.pub
   ```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the ./openshift-install gather command.
NOTE

On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.

a. If the ssh-agent process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

Example output

```
Agent pid 31874
```

NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the ssh-agent:

```
$ ssh-add <path>/<file_name>
```

   Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

17.8.8. Creating the Red Hat Enterprise Linux CoreOS (RHCOS) image

The OpenShift Container Platform installation program requires that a Red Hat Enterprise Linux CoreOS (RHCOS) image be present in the Red Hat OpenStack Platform (RHOSP) cluster. Retrieve the latest RHCOS image, then upload it using the RHOSP CLI.

Prerequisites

- The RHOSP CLI is installed.

Procedure

2. Under Version, select the most recent release of OpenShift Container Platform 4.10 for Red Hat Enterprise Linux (RHEL) 8.
IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available.

3. Download the Red Hat Enterprise Linux CoreOS (RHCOS) - OpenStack Image (QCOW).

4. Decompress the image.

NOTE

You must decompress the RHOSP image before the cluster can use it. The name of the downloaded file might not contain a compression extension, like .gz or .tgz. To find out if or how the file is compressed, in a command line, enter:

```
$ file <name_of_downloaded_file>
```

5. From the image that you downloaded, create an image that is named rhcos in your cluster by using the RHOSP CLI:

```
$ openstack image create --container-format=bare --disk-format=qcow2 --file rhcos-$(RHCOS_VERSION)-openstack.qcow2 rhcos
```

IMPORTANT

Depending on your RHOSP environment, you might be able to upload the image in either .raw or .qcow2 formats. If you use Ceph, you must use the .raw format.

WARNING

If the installation program finds multiple images with the same name, it chooses one of them at random. To avoid this behavior, create unique names for resources in RHOSP.

After you upload the image to RHOSP, it is usable in the installation process.

17.8.9. Verifying external network access

The OpenShift Container Platform installation process requires external network access. You must provide an external network value to it, or deployment fails. Before you begin the process, verify that a network with the external router type exists in Red Hat OpenStack Platform (RHOSP).

Prerequisites
Configure OpenStack’s networking service to have DHCP agents forward instances’ DNS queries

**Procedure**

1. Using the RHOSP CLI, verify the name and ID of the ‘External’ network:

   ```
   $ openstack network list --long -c ID -c Name -c "Router Type"
   ```

   **Example output**

   ```
   +--------------------------------------+----------------+-------------+
<table>
<thead>
<tr>
<th>ID</th>
<th>Name</th>
<th>Router Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>148a8023-62a7-4672-b018-003462f8d7dc</td>
<td>public_network</td>
<td>External</td>
</tr>
</tbody>
</table>
   +---------------------------------------+----------------+-------------+
   ```

   A network with an external router type appears in the network list. If at least one does not, see Creating a default floating IP network and Creating a default provider network.

   **NOTE**

   If the Neutron trunk service plug-in is enabled, a trunk port is created by default. For more information, see Neutron trunk port.

17.8.10. Enabling access to the environment

At deployment, all OpenShift Container Platform machines are created in a Red Hat OpenStack Platform (RHOSP)-tenant network. Therefore, they are not accessible directly in most RHOSP deployments.

You can configure OpenShift Container Platform API and application access by using floating IP addresses (FIPs) during installation. You can also complete an installation without configuring FIPs, but the installer will not configure a way to reach the API or applications externally.

17.8.10.1. Enabling access with floating IP addresses

Create floating IP (FIP) addresses for external access to the OpenShift Container Platform API, cluster applications, and the bootstrap process.

**Procedure**

1. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the API FIP:

   ```
   $ openstack floating ip create --description "API <cluster_name>.<base_domain>" <external_network>
   ```

2. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the apps, or Ingress, FIP:

   ```
   $ openstack floating ip create --description "Ingress <cluster_name>.<base_domain>" <external_network>
   ```

3. By using the Red Hat OpenStack Platform (RHOSP) CLI, create the bootstrap FIP:
4. Add records that follow these patterns to your DNS server for the API and Ingress FIPs:

```
$ openstack floating ip create --description "bootstrap machine" <external_network>
```

```
api.<cluster_name>.<base_domain>. IN A <API_FIP>
*.apps.<cluster_name>.<base_domain>. IN A <apps_FIP>
```

**NOTE**

If you do not control the DNS server, you can add the record to your `/etc/hosts` file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

5. Add the FIPs to the `inventory.yaml` file as the values of the following variables:

- `os_api_fip`
- `os_bootstrap_fip`
- `os_ingress_fip`

If you use these values, you must also enter an external network as the value of the `os_external_network` variable in the `inventory.yaml` file.

**TIP**

You can make OpenShift Container Platform resources available outside of the cluster by assigning a floating IP address and updating your firewall configuration.

### 17.8.10.2. Completing installation without floating IP addresses

You can install OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) without providing floating IP addresses.

In the `inventory.yaml` file, do not define the following variables:

- `os_api_fip`
- `os_bootstrap_fip`
- `os_ingress_fip`

If you cannot provide an external network, you can also leave `os_external_network` blank. If you do not provide a value for `os_external_network`, a router is not created for you, and, without additional action, the installer will fail to retrieve an image from Glance. Later in the installation process, when you create network resources, you must configure external connectivity on your own.

If you run the installer with the `wait-for` command from a system that cannot reach the cluster API due to a lack of floating IP addresses or name resolution, installation fails. To prevent installation failure in these cases, you can use a proxy network or run the installer from a system that is on the same network as your machines.
NOTE

You can enable name resolution by creating DNS records for the API and Ingress ports. For example:

```plaintext
api.<cluster_name>.<base_domain>. IN A <api_port_IP>
*.apps.<cluster_name>.<base_domain>. IN A <ingress_port_IP>
```

If you do not control the DNS server, you can add the record to your `/etc/hosts` file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

### 17.8.11. Defining parameters for the installation program

The OpenShift Container Platform installation program relies on a file that is called `clouds.yaml`. The file describes Red Hat OpenStack Platform (RHOSP) configuration parameters, including the project name, log in information, and authorization service URLs.

#### Procedure

1. Create the `clouds.yaml` file:
   - If your RHOSP distribution includes the Horizon web UI, generate a `clouds.yaml` file in it.

   IMPORTANT

   Remember to add a password to the `auth` field. You can also keep secrets in a separate file from `clouds.yaml`.

   - If your RHOSP distribution does not include the Horizon web UI, or you do not want to use Horizon, create the file yourself. For detailed information about `clouds.yaml`, see Config files in the RHOSP documentation.

```yaml
clouds:
  shiftstack:
    auth:
      project_name: shiftstack
      username: shiftstack_user
      password: XXX
      user_domain_name: Default
      project_domain_name: Default
  dev-env:
    region_name: RegionOne
    auth:
      username: 'devuser'
      password: XXX
      project_name: 'devonly'
```

2. If your RHOSP installation uses self-signed certificate authority (CA) certificates for endpoint authentication:
   - Copy the certificate authority file to your machine.
b. Add the `cacerts` key to the `clouds.yaml` file. The value must be an absolute, non-root-accessible path to the CA certificate:

```yaml
clouds:
    shiftstack:
    ...
    cacert: "/etc/pki/ca-trust/source/anchors/ca.crt.pem"
```

**TIP**

After you run the installer with a custom CA certificate, you can update the certificate by editing the value of the `ca-cert.pem` key in the `cloud-provider-config` keymap. On a command line, run:

```
$ oc edit configmap -n openshift-config cloud-provider-config
```

3. Place the `clouds.yaml` file in one of the following locations:
   a. The value of the `OS_CLIENT_CONFIG_FILE` environment variable
   b. The current directory
   c. A Unix-specific user configuration directory, for example `~/.config/openstack/clouds.yaml`
   d. A Unix-specific site configuration directory, for example `/etc/openstack/clouds.yaml`

The installation program searches for `clouds.yaml` in that order.

### 17.8.12. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Red Hat OpenStack Platform (RHOSP).

**Prerequisites**

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster. For a restricted network installation, these files are on your mirror host.
- Have the `imageContentSources` values that were generated during mirror registry creation.
- Obtain the contents of the certificate for your mirror registry.
-Retrieve a Red Hat Enterprise Linux CoreOS (RHCOS) image and upload it to an accessible location.
- Obtain service principal permissions at the subscription level.

**Procedure**

1. Create the `install-config.yaml` file.
   a. Change to the directory that contains the installation program and run the following command:

```
$ ./openshift-install create install-config --dir <installation_directory>
```
For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

**IMPORTANT**

Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

b. At the prompts, provide the configuration details for your cloud:

i. Optional: Select an SSH key to use to access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

ii. Select `openstack` as the platform to target.

iii. Specify the Red Hat OpenStack Platform (RHOSP) external network name to use for installing the cluster.

iv. Specify the floating IP address to use for external access to the OpenShift API.

v. Specify a RHOSP flavor with at least 16 GB RAM to use for control plane and compute nodes.

vi. Select the base domain to deploy the cluster to. All DNS records will be sub-domains of this base and will also include the cluster name.

vii. Enter a name for your cluster. The name must be 14 or fewer characters long.

viii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

2. In the `install-config.yaml` file, set the value of `platform.openstack.clusterOSImage` to the image location or name. For example:

```yaml
platform:
    openstack:
        clusterOSImage: http://mirror.example.com/images/rhcos-43.81.201912131630.0-openstack.x86_64.qcow2.gz?
        sha256=ffe6b6d88a1f2a245ca19522c16c86f67f9ac8e4e0c1f0a81282b068b16f7265d
```

3. Edit the `install-config.yaml` file to provide the additional information that is required for an installation in a restricted network.

a. Update the `pullSecret` value to contain the authentication information for your registry:
pullSecret: {"auths":{"<mirror_host_name>:5000": {"auth": "<credentials>"}},"email": "you@example.com"}}

For `<mirror_host_name>`, specify the registry domain name that you specified in the certificate for your mirror registry, and for `<credentials>`, specify the base64-encoded user name and password for your mirror registry.

b. Add the `additionalTrustBundle` parameter and value.

```
additionalTrustBundle: |
    -----BEGIN CERTIFICATE-----
    ZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZ
    -----END CERTIFICATE-----
```

The value must be the contents of the certificate file that you used for your mirror registry, which can be an existing, trusted certificate authority or the self-signed certificate that you generated for the mirror registry.

c. Add the image content resources, which look like this excerpt:

```
imageContentSources:
  - mirrors:
    - `<mirror_host_name>:5000/<repo_name>/release`
      source: quay.example.com/openshift-release-dev/ocp-release
    - mirrors:
      - `<mirror_host_name>:5000/<repo_name>/release`
        source: registry.example.com/ocp/release
```

To complete these values, use the `imageContentSources` that you recorded during mirror registry creation.

4. Make any other modifications to the `install-config.yaml` file that you require. You can find more information about the available parameters in the **Installation configuration parameters** section.

5. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

**IMPORTANT**

The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

You now have the file `install-config.yaml` in the directory that you specified.

17.8.13. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide a customized `install-config.yaml` installation configuration file that describes the details for your environment.

**NOTE**

After installation, you cannot modify these parameters in the `install-config.yaml` file.
17.8.13.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

Table 17.34. Required parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the install-config.yaml content. The current version is v1. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the baseDomain and metadata.name parameter values that uses the &lt;metadata.name&gt;.&lt;baseDomain&gt; format.</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
</tr>
<tr>
<td>metadata</td>
<td>Kubernetes resource ObjectMeta, from which only the name parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of {{.metadata.name}}. {{.baseDomain}}.</td>
<td>String of lowercase letters, hyphens (-), and periods (.), such as dev. The string must be 14 characters or fewer long.</td>
</tr>
<tr>
<td>platform</td>
<td>The configuration for the specific platform upon which to perform the installation: alibabacloud, aws, baremetal, azure, ibmcloud, openstack, ovirt, vsphere, or {}. For additional information about platform.&lt;platform&gt; parameters, consult the table for your specific platform that follows.</td>
<td>Object</td>
</tr>
</tbody>
</table>
17.8.13.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

Table 17.35. Network parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>NOTE</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>You cannot modify parameters specified by the <code>networking</code> object after installation.</td>
</tr>
<tr>
<td>networking.networkType</td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either <strong>OpenShiftSDN</strong> or <strong>OVNKubernetes</strong>. The default value is <strong>OpenShiftSDN</strong>.</td>
</tr>
<tr>
<td>networking.clusterNetwork</td>
<td>The IP address blocks for pods.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td>The default value is <strong>10.128.0.0/14</strong> with a host prefix of <strong>/23</strong>.</td>
<td>networking:</td>
</tr>
<tr>
<td></td>
<td>If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td>clusterNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- cidr: <strong>10.128.0.0/14</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- hostPrefix: <strong>23</strong></td>
</tr>
</tbody>
</table>

Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.

```
{
  "auths":{
    "cloud.openshift.com":{
      "auth":"b3Blb",
      "email"":"you@example.com"
    },
    "quay.io":{
      "auth":"b3Blb",
      "email"":"you@example.com"
    }
  }
}
```
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking.clusterNetwork.cidr</td>
<td>Required if you use networking.clusterNetwork. An IP address block. An IPv4 network.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td>networking.clusterNetwork.hostPrefix</td>
<td>The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given cidr. A hostPrefix value of 23 provides 510 (2^(32 - 23) - 2) pod IP addresses.</td>
<td>A subnet prefix. The default value is 23.</td>
</tr>
<tr>
<td>networking.serviceNetwork</td>
<td>The IP address block for services. The default value is 172.30.0.0/16. The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.</td>
<td>An array with an IP address block in CIDR format. For example:</td>
</tr>
<tr>
<td>networking.machineNetwork</td>
<td>The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap. If you specify multiple IP kernel arguments, the machineNetwork.cidr value must be the CIDR of the primary network.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td>networking.machineNetwork.cidr</td>
<td>Required if you use networking.machineNetwork. An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24.</td>
<td>An IP network block in CIDR notation. For example, 10.0.0.0/16.</td>
</tr>
</tbody>
</table>

### 17.8.13.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>cgroupsV2</td>
<td>Enables Linux control groups version 2 (cgroups v2) on specific nodes in your cluster. The OpenShift Container Platform process for enabling cgroups v2 disables all cgroup version 1 controllers and hierarchies. The OpenShift Container Platform cgroups version 2 feature is in Developer Preview and is not supported by Red Hat at this time.</td>
<td>true</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of MachinePool objects.</td>
</tr>
<tr>
<td>compute.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are s390x (the default).</td>
<td>String</td>
</tr>
<tr>
<td>compute.hyperthreading</td>
<td>Whether to enable or disable simultaneous multithreading, or <strong>hyperthreading</strong>, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>compute.name</td>
<td>Required if you use <code>compute</code>. The name of the machine pool.</td>
<td>worker</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>---------------------------</td>
<td>------------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------</td>
</tr>
<tr>
<td>compute.platform</td>
<td>Required if you use <code>compute</code>. Use this parameter to specify the cloud</td>
<td>alibaba, aws, azure, gcp,</td>
</tr>
<tr>
<td></td>
<td>provider to host the worker machines. This parameter value must match the</td>
<td>ibmcloud, openstack, ovirt,</td>
</tr>
<tr>
<td></td>
<td><code>controlPlane.platform</code> parameter value.</td>
<td>vsphere, or {}</td>
</tr>
<tr>
<td>compute.replicas</td>
<td>The number of compute machines, which are also known as worker machines,</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td></td>
<td>to provision.</td>
<td></td>
</tr>
<tr>
<td>controlPlane</td>
<td>The configuration for the machines</td>
<td>Array of <code>MachinePool</code> objects.</td>
</tr>
<tr>
<td></td>
<td>that comprise the control plane.</td>
<td></td>
</tr>
<tr>
<td>controlPlane.architecture</td>
<td>Determines the instruction set</td>
<td>String</td>
</tr>
<tr>
<td></td>
<td>architecture of the machines in the</td>
<td></td>
</tr>
<tr>
<td></td>
<td>pool. Currently, heterogeneous clusters are not supported, so all pools</td>
<td></td>
</tr>
<tr>
<td></td>
<td>must specify the same architecture. Valid values are s390x (the default).</td>
<td></td>
</tr>
<tr>
<td>controlPlane.hypert</td>
<td>Whether to enable or disable</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td></td>
<td>simultaneous multithreading, or</td>
<td></td>
</tr>
<tr>
<td></td>
<td>hyperthreading, on control plane</td>
<td></td>
</tr>
<tr>
<td></td>
<td>machines. By default, simultaneous multithreading is enabled to increase</td>
<td></td>
</tr>
<tr>
<td></td>
<td>the performance of your machines’</td>
<td></td>
</tr>
<tr>
<td></td>
<td>cores.</td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you disable simultaneous multithreading, ensure that your capacity</td>
<td></td>
</tr>
<tr>
<td></td>
<td>planning accounts for the dramatically decreased machine</td>
<td></td>
</tr>
<tr>
<td></td>
<td>performance.</td>
<td></td>
</tr>
<tr>
<td>controlPlane.name</td>
<td>Required if you use <code>controlPlane</code>. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use <code>controlPlane</code>. Use this parameter to specify the cloud</td>
<td>alibaba, aws, azure, gcp,</td>
</tr>
<tr>
<td></td>
<td>provider that hosts the control plane machines. This parameter value must</td>
<td>ibmcloud, openstack, ovirt,</td>
</tr>
<tr>
<td></td>
<td>match the <code>compute.platform</code> parameter value.</td>
<td>vsphere, or {}</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>--------------------</td>
<td>------------------------------------------------------------------------------</td>
<td>--------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO</td>
<td>Mint, Passthrough, Manual, or an empty string (&quot;&quot;&quot;).</td>
</tr>
<tr>
<td></td>
<td>dynamically tries to determine the capabilities of the provided credentials,</td>
<td></td>
</tr>
<tr>
<td></td>
<td>with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td></td>
</tr>
</tbody>
</table>

**NOTE**

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Platform Operators reference content.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>fips</strong></td>
<td>Enable or disable FIPS mode. The default is false (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</td>
<td>false or true</td>
</tr>
</tbody>
</table>

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.

<table>
<thead>
<tr>
<th><strong>imageContentSources</strong></th>
<th>Sources and repositories for the release-image content.</th>
<th>Array of objects. Includes a <code>source</code> and, optionally, <code>mirrors</code>, as described in the following rows of this table.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>imageContentSources.source</strong></td>
<td>Required if you use <code>imageContentSources</code>. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td><strong>imageContentSources.mirrors</strong></td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
</tbody>
</table>
How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.

**Internal** or **External**. The default value is **External**.

Setting this field to **Internal** is not supported on non-cloud platforms and IBM Cloud.

**IMPORTANT**

If the value of the field is set to **Internal**, the cluster will become non-functional. For more information, refer to BZ#1953035.

The SSH key or keys to authenticate access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

One or more keys. For example:

```
sshKey:
  <key1>
  <key2>
  <key3>
```

### 17.8.13.4. Additional Red Hat OpenStack Platform (RHOSP) configuration parameters

Additional RHOSP configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>compute.platform.openstack.rootVolume.size</strong></td>
<td>For compute machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.</td>
<td>Integer, for example <strong>30</strong>.</td>
</tr>
<tr>
<td><strong>compute.platform.openstack.rootVolume.type</strong></td>
<td>For compute machines, the root volume’s type.</td>
<td>String, for example <strong>performance</strong>.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>---------------------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>controlPlane.platform.openstack.rootVolume.size</code></td>
<td>For control plane machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.</td>
<td>Integer, for example 30.</td>
</tr>
<tr>
<td><code>controlPlane.platform.openstack.rootVolume.type</code></td>
<td>For control plane machines, the root volume’s type.</td>
<td>String, for example performance.</td>
</tr>
<tr>
<td><code>platform.openstack.cloud</code></td>
<td>The name of the RHOSP cloud to use from the list of clouds in the <code>clouds.yaml</code> file.</td>
<td>String, for example MyCloud.</td>
</tr>
<tr>
<td><code>platform.openstack.externalNetwork</code></td>
<td>The RHOSP external network name to be used for installation.</td>
<td>String, for example external.</td>
</tr>
<tr>
<td><code>platform.openstack.computeFlavor</code></td>
<td>The RHOSP flavor to use for control plane and compute machines.</td>
<td>String, for example m1.xlarge.</td>
</tr>
<tr>
<td></td>
<td>This property is deprecated. To use a flavor as the default for all machine pools, add it as the value of the <code>type</code> key in the <code>platform.openstack.defaultMachinePlatform</code> property. You can also set a flavor value for each machine pool individually.</td>
<td></td>
</tr>
</tbody>
</table>

### 17.8.13.5. Optional RHOSP configuration parameters

Optional RHOSP configuration parameters are described in the following table:

Table 17.38. Optional RHOSP parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>compute.platform.openstack.additionalNetworkIDs</code></td>
<td>Additional networks that are associated with compute machines. Allowed address pairs are not created for additional networks.</td>
<td>A list of one or more UUIDs as strings. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>compute.platform.openstack.additionalSecurityGroupIDs</code></td>
<td>Additional security groups that are associated with compute machines.</td>
<td>A list of one or more UUIDs as strings. For example, 7ee219f3-d2e9-48a1-96c2-e7429f1b0da7.</td>
</tr>
<tr>
<td><code>compute.platform.openstack.zones</code></td>
<td>RHOSP Compute (Nova) availability zones (AZs) to install machines on. If this parameter is not set, the installer relies on the default settings for Nova that the RHOSP administrator configured.</td>
<td>A list of strings. For example, [&quot;zone-1&quot;, &quot;zone-2&quot;].</td>
</tr>
<tr>
<td></td>
<td>On clusters that use Kuryr, RHOSP Octavia does not support availability zones. Load balancers and, if you are using the Amphora provider driver, OpenShift Container Platform services that rely on Amphora VMs, are not created according to the value of this property.</td>
<td></td>
</tr>
<tr>
<td><code>compute.platform.openstack.rootVolume.zones</code></td>
<td>For compute machines, the availability zone to install root volumes on. If you do not set a value for this parameter, the installer selects the default availability zone.</td>
<td>A list of strings, for example [&quot;zone-1&quot;, &quot;zone-2&quot;].</td>
</tr>
<tr>

<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td><strong>controlPlane.platform.openstack.zones</strong></td>
<td>RHOSP Compute (Nova) availability zones (AZs) to install machines on. If this parameter is not set, the installer relies on the default settings for Nova that the RHOSP administrator configured. On clusters that use Kuryr, RHOSP Octavia does not support availability zones. Load balancers and, if you are using the Amphora provider driver, OpenShift Container Platform services that rely on Amphora VMs, are not created according to the value of this property.</td>
<td>A list of strings. For example, [&quot;zone-1&quot;, &quot;zone-2&quot;].</td>
</tr>
<tr>
<td><strong>controlPlane.platform.openstack.rootVolume.zones</strong></td>
<td>For control plane machines, the availability zone to install root volumes on. If you do not set this value, the installer selects the default availability zone.</td>
<td>A list of strings, for example [&quot;zone-1&quot;, &quot;zone-2&quot;].</td>
</tr>
<tr>
<td><strong>controlPlane.platform.openstack.serverGroupPolicy</strong></td>
<td>Server group policy to apply to the group that will contain the control plane machines in the pool. You cannot change server group policies or affiliations after creation. Supported options include <strong>anti-affinity</strong>, <strong>soft-affinity</strong>, and <strong>soft-anti-affinity</strong>. The default value is <strong>soft-anti-affinity</strong>. An <strong>affinity</strong> policy prevents migrations, and therefore affects RHOSP upgrades. The <strong>affinity</strong> policy is not supported. If you use a strict <strong>anti-affinity</strong> policy, an additional RHOSP host is required during instance migration.</td>
<td>A server group policy to apply to the machine pool. For example, <strong>soft-affinity</strong>.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>platform.openstack.clusterOSImage</strong></td>
<td>The location from which the installer downloads the RH COS image. You must set this parameter to perform an installation in a restricted network.</td>
<td>An HTTP or HTTPS URL, optionally with an SHA-256 checksum. For example, <a href="http://mirror.example.com/images/rhcos-43.81.201912131630.0-openstack.x86_64.qcow2.gz?sha256=ffe86888a1f2a245ca19522c16c86f671f9ac8e4e0c1f0a81b09a8f">http://mirror.example.com/images/rhcos-43.81.201912131630.0-openstack.x86_64.qcow2.gz?sha256=ffe86888a1f2a245ca19522c16c86f671f9ac8e4e0c1f0a81b09a8f</a>. The value can also be the name of an existing Glance image, for example my-rhcos.</td>
</tr>
<tr>
<td><strong>platform.openstack.clusterOSImageProperties</strong></td>
<td>Properties to add to the installer-uploaded ClusterOSImage in Glance. This property is ignored if platform.openstack.clusterOSImage is set to an existing Glance image. You can use this property to exceed the default persistent volume (PV) limit for RHOSP of 26 PVs per node. To exceed the limit, set the hw_scsi_model property value to virtio-scsi and the hw_disk_bus value to scsi. You can also use this property to enable the QEMU guest agent by including the hw_qemu_guest_agent property with a value of yes.</td>
<td>A list of key-value string pairs. For example, [&quot;hw_scsi_model&quot;: &quot;virtio-scsi&quot;, &quot;hw_disk_bus&quot;: &quot;scsi&quot;].</td>
</tr>
</tbody>
</table>
| **platform.openstack.defaultMachinePlatform** | The default machine pool platform configuration.                                                                                                                                                            | {  
|                                             |                                                                                             |   "type": "ml.large",  
|                                             |                                                                                             |   "rootVolume": {  
|                                             |                                                                                             |     "size": 30,   
|                                             |                                                                                             |     "type": "performance"  
<p>|                                             |                                                                                             | }  |
| <strong>platform.openstack.ingressFloatingIP</strong> | An existing floating IP address to associate with the Ingress port. To use this property, you must also define the platform.openstack.externalNetwork property.                                                 | An IP address, for example 128.0.0.1. |</p>
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>platform.openstack.apiFloatingIP</strong></td>
<td>An existing floating IP address to associate with the API load balancer. To use this property, you must also define the <code>platform.openstack.externalNetwork</code> property.</td>
<td>An IP address, for example <code>128.0.0.1</code>.</td>
</tr>
<tr>
<td><strong>platform.openstack.externalDNS</strong></td>
<td>IP addresses for external DNS servers that cluster instances use for DNS resolution.</td>
<td>A list of IP addresses as strings. For example, <code>[&quot;8.8.8.8&quot;, &quot;192.168.1.12&quot;]</code>.</td>
</tr>
<tr>
<td><strong>platform.openstack.machinesSubnet</strong></td>
<td>The UUID of a RHOSP subnet that the cluster’s nodes use. Nodes and virtual IP (VIP) ports are created on this subnet. The first item in <code>networking.machineNetwork</code> must match the value of <code>machinesSubnet</code>. If you deploy to a custom subnet, you cannot specify an external DNS server to the OpenShift Container Platform installer. Instead, add DNS to the subnet in RHOSP.</td>
<td>A UUID as a string. For example, <code>fa806b2f-ac49-4bce-b9db-124bc64209bf</code>.</td>
</tr>
</tbody>
</table>

17.8.13.6. Sample customized `install-config.yaml` file for RHOSP

This sample `install-config.yaml` demonstrates all of the possible Red Hat OpenStack Platform (RHOSP) customization options.

**IMPORTANT**

This sample file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program.

```yaml
apiVersion: v1
baseDomain: example.com
controlPlane:
  name: master
  platform: {}
  replicas: 3
compute:
  - name: worker
    platform:
      openstack:
        type: ml.large
```
Optionally, you can deploy a cluster on a Red Hat OpenStack Platform (RHOSP) subnet of your choice. The subnet’s GUID is passed as the value of `platform.openstack.machinesSubnet` in the `install-config.yaml` file.

This subnet is used as the cluster’s primary subnet. By default, nodes and ports are created on it. You can create nodes and ports on a different RHOSP subnet by setting the value of the `platform.openstack.machinesSubnet` property to the subnet’s UUID.

Before you run the OpenShift Container Platform installer with a custom subnet, verify that your configuration meets the following requirements:

- The subnet that is used by `platform.openstack.machinesSubnet` has DHCP enabled.
- The CIDR of `platform.openstack.machinesSubnet` matches the CIDR of `networking.machineNetwork`.
- The installation program user has permission to create ports on this network, including ports with fixed IP addresses.

Clusters that use custom subnets have the following limitations:

- If you plan to install a cluster that uses floating IP addresses, the `platform.openstack.machinesSubnet` subnet must be attached to a router that is connected to the `externalNetwork` network.
- If the `platform.openstack.machinesSubnet` value is set in the `install-config.yaml` file, the installation program does not create a private network or subnet for your RHOSP machines.
- You cannot use the `platform.openstack.externalDNS` property at the same time as a custom subnet. To add DNS to a cluster that uses a custom subnet, configure DNS on the RHOSP network.
NOTE

By default, the API VIP takes x.x.x.5 and the Ingress VIP takes x.x.x.7 from your network’s CIDR block. To override these default values, set values for platform.openstack.apiVIP and platform.openstack.ingressVIP that are outside of the DHCP allocation pool.

17.8.13.8. Setting a custom subnet for machines

The IP range that the installation program uses by default might not match the Neutron subnet that you create when you install OpenShift Container Platform. If necessary, update the CIDR value for new machines by editing the installation configuration file.

Prerequisites

- You have the install-config.yaml file that was generated by the OpenShift Container Platform installation program.

Procedure

1. On a command line, browse to the directory that contains install-config.yaml.

2. From that directory, either run a script to edit the install-config.yaml file or update the file manually:
   - To set the value by using a script, run:
     ```
     $ python -c '
     import yaml;
     path = "install-config.yaml";
     data = yaml.safe_load(open(path));
     data["networking"]="machineNetwork" = [{"cidr": "192.168.0.0/18"}];
     open(path, "w").write(yaml.dump(data, default_flow_style=False))'
     ```
     Insert a value that matches your intended Neutron subnet, e.g. 192.0.2.0/24.
   - To set the value manually, open the file and set the value of networking.machineCIDR to something that matches your intended Neutron subnet.

17.8.13.9. Emptying compute machine pools

To proceed with an installation that uses your own infrastructure, set the number of compute machines in the installation configuration file to zero. Later, you create these machines manually.

Prerequisites

- You have the install-config.yaml file that was generated by the OpenShift Container Platform installation program.

Procedure

1. On a command line, browse to the directory that contains install-config.yaml.

2. From that directory, either run a script to edit the install-config.yaml file or update the file manually:
To set the value by using a script, run:

```bash
$ python -c '
import yaml;
path = "install-config.yaml";
data = yaml.safe_load(open(path));
data["compute"][0]["replicas"] = 0;
open(path, "w").write(yaml.dump(data, default_flow_style=False))'
```

To set the value manually, open the file and set the value of `compute.<first entry>.replicas` to 0.

17.8.14. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

**IMPORTANT**

- The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

**NOTE**

The installation program that generates the manifest and Ignition files is architecture specific and can be obtained from the client image mirror. The Linux version of the installation program runs on s390x only. This installer program is also available as a Mac OS version.

**Prerequisites**

- You obtained the OpenShift Container Platform installation program. For a restricted network installation, these files are on your mirror host.

- You created the `install-config.yaml` installation configuration file.

**Procedure**
1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

   ```
   $ ./openshift-install create manifests --dir <installation_directory>  
   ```

   **Example output**

   ```
   INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
   INFO Consuming Install Config from target directory
   INFO Manifests created in: install_dir/manifests and install_dir/openshift
   ```

   For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.

2. Remove the Kubernetes manifest files that define the control plane machines and compute machine sets:

   ```
   $ rm -f openshift/99_openshift-cluster-api_master-machines-*.yaml openshift/99_openshift-cluster-api_worker-machineset-*.yaml
   ```

   Because you create and manage these resources yourself, you do not have to initialize them.

   - You can preserve the machine set files to create compute machines by using the machine API, but you must update references to them to match your environment.

   **WARNING**

   If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.

   **IMPORTANT**

   When you configure control plane nodes from the default unschedulable to schedulable, additional subscriptions are required. This is because control plane nodes then become worker nodes.

3. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:

   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.

   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.

   c. Save and exit the file.

4. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

   ```
   $ rm -f openshift/99_openshift-cluster-api_master-machines-*.yaml openshift/99_openshift-cluster-api_worker-machineset-*.yaml
   ```
For `<installation_directory>`, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The `kubadmin-password` and `kubeconfig` files are created in the `./<installation_directory>/auth` directory:

```
├── auth
│   ├── kubadmin-password
│   └── kubeconfig
└── └── bootstrap.ign
      ├── master.ign
      ├── metadata.json
      └── worker.ign
```

5. Export the metadata file's `infraID` key as an environment variable:

```
$ export INFRA_ID=$(jq -r .infraID metadata.json)
```

**TIP**

Extract the `infraID` key from `metadata.json` and use it as a prefix for all of the RHOSP resources that you create. By doing so, you avoid name conflicts when making multiple deployments in the same project.

### 17.8.15. Preparing the bootstrap Ignition files

The OpenShift Container Platform installation process relies on bootstrap machines that are created from a bootstrap Ignition configuration file.

Edit the file and upload it. Then, create a secondary bootstrap Ignition configuration file that Red Hat OpenStack Platform (RHOSP) uses to download the primary file.

**Prerequisites**

- You have the bootstrap Ignition file that the installer program generates, `bootstrap.ign`.

- The infrastructure ID from the installer’s metadata file is set as an environment variable (`$INFRA_ID`).
  - If the variable is not set, see Creating the Kubernetes manifest and Ignition config files

- You have an HTTP(S)-accessible way to store the bootstrap Ignition file.
  - The documented procedure uses the RHOSP image service (Glance), but you can also use the RHOSP storage service (Swift), Amazon S3, an internal HTTP server, or an ad hoc Nova server.

**Procedure**

```
$ ./openshift-install create ignition-configs --dir <installation_directory>
```

1. Run the following Python script. The script modifies the bootstrap Ignition file to set the hostname and, if available, CA certificate file when it runs:

```python
import base64
import json
import os

with open('bootstrap.ign', 'r') as f:
    ignition = json.load(f)

files = ignition['storage'].get('files', [])

infra_id = os.environ.get('INFRA_ID', 'openshift').encode()
hostname_b64 = base64.standard_b64encode(infra_id + b'-bootstrap
').decode().strip()
files.append(
    {'path': '/etc/hostname',
     'mode': 420,
     'contents': {'source': 'data:text/plain;charset=utf-8;base64,' + hostname_b64}
})

ca_cert_path = os.environ.get('OS_CACERT', '')
if ca_cert_path:
    with open(ca_cert_path, 'r') as f:
        ca_cert = f.read().encode()
    ca_cert_b64 = base64.standard_b64encode(ca_cert).decode().strip()
    files.append(
        {'path': '/opt/openshift/tls/cloud-ca-cert.pem',
         'mode': 420,
         'contents': {'source': 'data:text/plain;charset=utf-8;base64,' + ca_cert_b64}
    )

ignition['storage']['files'] = files;

with open('bootstrap.ign', 'w') as f:
    json.dump(ignition, f)
```

2. Using the RHOSP CLI, create an image that uses the bootstrap Ignition file:

```
$ openstack image create --disk-format=raw --container-format=bare --file bootstrap.ign <image_name>
```

3. Get the image’s details:

```
$ openstack image show <image_name>
```

Make a note of the `file` value; it follows the pattern `v2/images/<image_ID>/file`.

CHAPTER 17. INSTALLING ON OPENSTACK

2339
NOTE
Verify that the image you created is active.

4. Retrieve the image service's public address:

```bash
$ openstack catalog show image
```

5. Combine the public address with the image file value and save the result as the storage location. The location follows the pattern `<image_service_public_URL>/v2/images/<image_ID>/file`.

6. Generate an auth token and save the token ID:

```bash
$ openstack token issue -c id -f value
```

7. Insert the following content into a file called `$INFRA_ID-bootstrap-ignition.json` and edit the placeholders to match your own values:

```json
{
  "ignition": {
    "config": {
      "merge": [{
        "source": `<storage_url>`,
        "httpHeaders": [{
          "name": "X-Auth-Token",
          "value": `<token_ID>`
        }]
      }]
    },
    "security": {
      "tls": {
        "certificateAuthorities": [{
          "source": "data:text/plain;charset=utf-8;base64,<base64_encoded_certificate>`
        }]
      }
    },
    "version": "3.2.0"
  }
}
```

1. Replace the value of `ignition.config.merge.source` with the bootstrap Ignition file storage URL.

2. Set `name` in `httpHeaders` to "X-Auth-Token".

3. Set `value` in `httpHeaders` to your token’s ID.

4. If the bootstrap Ignition file server uses a self-signed certificate, include the base64-encoded certificate.

8. Save the secondary Ignition config file.

The bootstrap Ignition data will be passed to RHOSP during installation.
WARNING
The bootstrap Ignition file contains sensitive information, like clouds.yaml credentials. Ensure that you store it in a secure place, and delete it after you complete the installation process.

17.8.16. Creating control plane Ignition config files on RHOSP

Installing OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) on your own infrastructure requires control plane Ignition config files. You must create multiple config files.

NOTE
As with the bootstrap Ignition configuration, you must explicitly define a hostname for each control plane machine.

Prerequisites
- The infrastructure ID from the installation program’s metadata file is set as an environment variable ($INFRA_ID).
  - If the variable is not set, see "Creating the Kubernetes manifest and Ignition config files".

Procedure
- On a command line, run the following Python script:

```bash
$ for index in $(seq 0 2); do
    MASTER_HOSTNAME="$INFRA_ID-master-$index"
    python -c "import base64, json, sys;
    ignition = json.load(sys.stdin);
    storage = ignition.get('storage', {});
    files = storage.get('files', []);
    files.append({'path': '/etc/hostname', 'mode': 420, 'contents': {'source':
        'data:text/plain;charset=utf-8;base64,' + base64.standard_b64encode(b'$MASTER_HOSTNAME').decode().strip(), 'verification': {}},
        'filesystem': 'root'});
    storage['files'] = files;
    json.dump(ignition, sys.stdout)"
      <master.ign >"$INFRA_ID-master-$index-ignition.json"
done
```

You now have three control plane Ignition files: `<INFRA_ID>-master-0-ignition.json`, `<INFRA_ID>-master-1-ignition.json`, and `<INFRA_ID>-master-2-ignition.json`.

17.8.17. Creating network resources on RHOSP

Create the network resources that an OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) installation on your own infrastructure requires. To save time, run supplied Ansible playbooks that generate security groups, networks, subnets, routers, and ports.
Prerequisites

- Python 3 is installed on your machine.
- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".

Procedure

1. Optional: Add an external network value to the `inventory.yaml` playbook:

   **Example external network value in the inventory.yaml Ansible playbook**

   ```yaml
   ... 
   # The public network providing connectivity to the cluster. If not
   # provided, the cluster external connectivity must be provided in another
   # way.
   
   # Required for os_api_fip, os_ingress_fip, os_bootstrap_fip.
   os_external_network: 'external'
   ...
   ```

   **IMPORTANT**

   If you did not provide a value for `os_external_network` in the `inventory.yaml` file, you must ensure that VMs can access Glance and an external connection yourself.

2. Optional: Add external network and floating IP (FIP) address values to the `inventory.yaml` playbook:

   **Example FIP values in the inventory.yaml Ansible playbook**

   ```yaml
   ...
   # OpenShift API floating IP address. If this value is non-empty, the
   # corresponding floating IP will be attached to the Control Plane to
   # serve the OpenShift API.
   os_api_fip: '203.0.113.23'

   # OpenShift Ingress floating IP address. If this value is non-empty, the
   # corresponding floating IP will be attached to the worker nodes to serve
   # the applications.
   os_ingress_fip: '203.0.113.19'

   # If this value is non-empty, the corresponding floating IP will be
   # attached to the bootstrap machine. This is needed for collecting logs
   # in case of install failure.
   os_bootstrap_fip: '203.0.113.20'
   ```
IMPORTANT

If you do not define values for `os_api_fip` and `os_ingress_fip`, you must perform post-installation network configuration.

If you do not define a value for `os_bootstrap_fip`, the installer cannot download debugging information from failed installations.

See "Enabling access to the environment" for more information.

3. On a command line, create security groups by running the `security-groups.yaml` playbook:

   $ ansible-playbook -i inventory.yaml security-groups.yaml

4. On a command line, create a network, subnet, and router by running the `network.yaml` playbook:

   $ ansible-playbook -i inventory.yaml network.yaml

5. Optional: If you want to control the default resolvers that Nova servers use, run the RHOSP CLI command:

   $ openstack subnet set --dns-nameserver <server_1> --dns-nameserver <server_2> "$INFRA_ID-nodes"

Optionally, you can use the `inventory.yaml` file that you created to customize your installation. For example, you can deploy a cluster that uses bare metal machines.

17.8.17.1. Deploying a cluster with bare metal machines

If you want your cluster to use bare metal machines, modify the `inventory.yaml` file. Your cluster can have both control plane and compute machines running on bare metal, or just compute machines.

Bare-metal compute machines are not supported on clusters that use Kuryr.

**NOTE**

Be sure that your `install-config.yaml` file reflects whether the RHOSP network that you use for bare metal workers supports floating IP addresses or not.

**Prerequisites**

- The RHOSP Bare Metal service (Ironic) is enabled and accessible via the RHOSP Compute API.
- Bare metal is available as a RHOSP flavor.
- The RHOSP network supports both VM and bare metal server attachment.
- Your network configuration does not rely on a provider network. Provider networks are not supported.
- If you want to deploy the machines on a pre-existing network, a RHOSP subnet is provisioned.
If you want to deploy the machines on an installer-provisioned network, the RHOSP Bare Metal service (Ironic) is able to listen for and interact with Preboot eXecution Environment (PXE) boot machines that run on tenant networks.

- You created an inventory.yaml file as part of the OpenShift Container Platform installation process.

**Procedure**

1. In the inventory.yaml file, edit the flavors for machines:
   a. If you want to use bare-metal control plane machines, change the value of `os_flavor_master` to a bare metal flavor.
   b. Change the value of `os_flavor_worker` to a bare metal flavor.

   **An example bare metal inventory.yaml file**

   ```yaml
   all:
   hosts:
   localhost:
      ansible_connection: local
      ansible_python_interpreter: "{{ansible_playbook_python}}"

      # User-provided values
      os_subnet_range: '10.0.0.0/16'
      os_flavor_master: 'my-bare-metal-flavor'  # 1
      os_flavor_worker: 'my-bare-metal-flavor'  # 2
      os_image_rhcos: 'rhcos'
      os_external_network: 'external'

   ...  
   ```

   1. If you want to have bare-metal control plane machines, change this value to a bare metal flavor.
   2. Change this value to a bare metal flavor to use for compute machines.

   Use the updated inventory.yaml file to complete the installation process. Machines that are created during deployment use the flavor that you added to the file.

   **NOTE**

   The installer may time out while waiting for bare metal machines to boot.

   If the installer times out, restart and then complete the deployment by using the `wait-for` command of the installer. For example:

   ```bash
   ./openshift-install wait-for install-complete --log-level debug
   ```

   **17.8.18. Creating the bootstrap machine on RHOSP**

   Create a bootstrap machine and give it the network access it needs to run on Red Hat OpenStack Platform (RHOSP). Red Hat provides an Ansible playbook that you run to simplify this process.
Prerequisites

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The `inventory.yaml`, `common.yaml`, and `bootstrap.yaml` Ansible playbooks are in a common directory.
- The `metadata.json` file that the installation program created is in the same directory as the Ansible playbooks.

Procedure

1. On a command line, change the working directory to the location of the playbooks.
2. On a command line, run the `bootstrap.yaml` playbook:
   
   ```
   $ ansible-playbook -i inventory.yaml bootstrap.yaml
   ```
3. After the bootstrap server is active, view the logs to verify that the Ignition files were received:
   
   ```
   $ openstack console log show "$INFRA_ID-bootstrap"
   ```

17.8.19. Creating the control plane machines on RHOSP

Create three control plane machines by using the Ignition config files that you generated. Red Hat provides an Ansible playbook that you run to simplify this process.

Prerequisites

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The infrastructure ID from the installation program’s metadata file is set as an environment variable (`$INFRA_ID`).
- The `inventory.yaml`, `common.yaml`, and `control-plane.yaml` Ansible playbooks are in a common directory.
- You have the three Ignition files that were created in "Creating control plane Ignition config files".

Procedure

1. On a command line, change the working directory to the location of the playbooks.
2. If the control plane Ignition config files aren’t already in your working directory, copy them into it.
3. On a command line, run the `control-plane.yaml` playbook:
   
   ```
   $ ansible-playbook -i inventory.yaml control-plane.yaml
   ```
4. Run the following command to monitor the bootstrapping process:

```
$ openshift-install wait-for bootstrap-complete
```

You will see messages that confirm that the control plane machines are running and have joined the cluster:

```
INFO API v1.23.0 up
INFO Waiting up to 30m0s for bootstrapping to complete...
... INFO It is now safe to remove the bootstrap resources
```

17.8.20. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig
```

   1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

```
$ oc whoami
```

**Example output**

```
system:admin
```

17.8.21. Deleting bootstrap resources from RHOSP

Delete the bootstrap resources that you no longer need.

**Prerequisites**

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
• The `inventory.yaml`, `common.yaml`, and `down-bootstrap.yaml` Ansible playbooks are in a common directory.

• The control plane machines are running.
  - If you do not know the status of the machines, see "Verifying cluster status".

**Procedure**

1. On a command line, change the working directory to the location of the playbooks.

2. On a command line, run the `down-bootstrap.yaml` playbook:

   ```bash
   $ ansible-playbook -i inventory.yaml down-bootstrap.yaml
   ```

   The bootstrap port, server, and floating IP address are deleted.

**WARNING**

If you did not disable the bootstrap Ignition file URL earlier, do so now.

---

### 17.8.22. Creating SR-IOV networks for compute machines

If your Red Hat OpenStack Platform (RHOSP) deployment supports *single root I/O virtualization (SR-IOV)*, you can provision SR-IOV networks that compute machines run on.

**NOTE**

The following instructions entail creating an external flat network and an external, VLAN-based network that can be attached to a compute machine. Depending on your RHOSP deployment, other network types might be required.

**Prerequisites**

• Your cluster supports SR-IOV.

**NOTE**

If you are unsure about what your cluster supports, review the OpenShift Container Platform SR-IOV hardware networks documentation.

• You created radio and uplink provider networks as part of your RHOSP deployment. The names `radio` and `uplink` are used in all example commands to represent these networks.

**Procedure**

1. On a command line, create a radio RHOSP network:
Create an uplink RHOSP network:

```bash
$ openstack network create uplink --provider-physical-network uplink --provider-network-type vlan --external
```

Create a subnet for the radio network:

```bash
$ openstack subnet create --network radio --subnet-range <radio_network_subnet_range> radio
```

Create a subnet for the uplink network:

```bash
$ openstack subnet create --network uplink --subnet-range <uplink_network_subnet_range> uplink
```

17.8.23. Creating compute machines that run on SR-IOV networks

After standing up the control plane, create compute machines that run on the SR-IOV networks that you created in "Creating SR-IOV networks for compute machines".

**Prerequisites**

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The `metadata.yaml` file that the installation program created is in the same directory as the Ansible playbooks.
- The control plane is active.
- You created radio and uplink SR-IOV networks as described in "Creating SR-IOV networks for compute machines".

**Procedure**

1. On a command line, change the working directory to the location of the `inventory.yaml` and `common.yaml` files.

2. Add the radio and uplink networks to the end of the `inventory.yaml` file by using the `additionalNetworks` parameter:

```yaml
....
# If this value is non-empty, the corresponding floating IP will be
# attached to the bootstrap machine. This is needed for collecting logs
# in case of install failure.
  os_bootstrap_fip: '203.0.113.20'

  additionalNetworks:
    - id: radio
      count: 4
```
The `count` parameter defines the number of SR-IOV virtual functions (VFs) to attach to each worker node. In this case, each network has four VFs.

3. Replace the content of the `compute-nodes.yaml` file with the following text:

Example 17.1. `compute-nodes.yaml`

```yaml
- import_playbook: common.yaml
- hosts: all
gather_facts: no

vars:
  worker_list: []
  port_name_list: []
  nic_list: []

tasks:
  # Create the SDN/primary port for each worker node
  - name: 'Create the Compute ports'
    os_port:
      name: "{{ item.1 }}-{{ item.0 }}"
      network: "{{ os_network }}"
      security_groups:
      - "{{ os_sg_worker }}"
      allowed_address_pairs:
      - ip_address: "{{ os_ingressVIP }}"
    with_indexed_items: "{{ [os_port_worker] * os_compute_nodes_number }}"
    register: ports

  # Tag each SDN/primary port with cluster name
  - name: 'Set Compute ports tag'
    command:
      cmd: "openstack port set --tag {{ cluster_id_tag }} {{ item.1 }}-{{ item.0 }}"
    with_indexed_items: "{{ [os_port_worker] * os_compute_nodes_number }}"

  - name: 'List the Compute Trunks'
    command:
      cmd: "openstack network trunk list"
    when: os_networking_type == "Kuryr"
    register: compute_trunks

  - name: 'Create the Compute trunks'
    command:
      cmd: "openstack network trunk create --parent-port {{ item.1.id }} {{ os_compute_trunk_name }}-{{ item.0 }}"
    with_indexed_items: "{{ ports.results }}"
    when: 
```
- os_networking_type == "Kuryr"
  "os_compute_trunk_name|string not in compute_trunks.stdout"

- name: ‘Call additional-port processing’
  include_tasks: additional-ports.yaml

# Create additional ports in OpenStack
- name: ‘Create additionalNetworks ports’
s_port:
  name: "{{ item.0 }}-{{ item.1.name }}"
  vnic_type: "{{ item.1.type }}"
  network: "{{ item.1.uuid }}"
  port_security_enabled: "{{ item.1.port_security_enabled|default(omit) }}"
  no_security_groups: "{{ 'true' if item.1.security_groups is not defined else omit }}"
  security_groups: "{{ item.1.security_groups | default(omit) }}"
  with_nested:
    - "{{ worker_list }}"
    - "{{ port_name_list }}"

# Tag the ports with the cluster info
- name: ‘Set additionalNetworks ports tag’
  command:
    cmd: "openstack port set --tag {{ cluster_id_tag }} {{ item.0 }}-{{ item.1.name }}"
  with_nested:
    - "{{ worker_list }}"
    - "{{ port_name_list }}"

# Build the nic list to use for server create
- name: Build nic list
  set_fact:
    nic_list: "{{ nic_list | default([]) + [ item.name ] }}"
    with_items:
      - "{{ port_name_list }}"

# Create the servers
- name: ‘Create the Compute servers’
vats:
  worker_nics: "{{ [ item.1 ] | product(nic_list) | map('join','-') | map('regex_replace', '(.*)', 'port-name=\1') | list }}"
  os_server:
    name: "{{ item.1 }}"
    image: "{{ os_image_rhcos }}"
    flavor: "{{ os_flavor_worker }}"
    auto_ip: no
    userdata: "{{ lookup('file', 'worker.ign') | string }}"
    security_groups: []
    nics: "{{ [ 'port-name=' + os_port_worker + '-' + item.0|string ] + worker_nics }}"
    config_drive: yes
    with_indexed_items: "{{ worker_list }}"

4. Insert the following content into a local file that is called additional-ports.yaml:

   Example 17.2. additional-ports.yaml

   # Build a list of worker nodes with indexes
   - name: ‘Build worker list’
On a command line, run the `compute-nodes.yaml` playbook:

```
$ ansible-playbook -i inventory.yaml compute-nodes.yaml
```

### 17.8.24. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

#### Prerequisites
- You added machines to your cluster.

#### Procedure
1. Confirm that the cluster recognizes the machines:

```
$ oc get nodes
```

5. On a command line, run the `compute-nodes.yaml` playbook:
Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.23.0</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.23.0</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>64m</td>
<td>v1.23.0</td>
</tr>
</tbody>
</table>

The output lists all of the machines that you created.

NOTE

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```
$ oc get csr
```

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-mddf5</td>
<td>20m</td>
<td>system:node:master-01.example.com</td>
<td>Approved, Issued</td>
</tr>
<tr>
<td>csr-z5rln</td>
<td>16m</td>
<td>system:node:worker-21.example.com</td>
<td>Approved, Issued</td>
</tr>
</tbody>
</table>

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

NOTE

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine approver** if the Kubelet requests a new certificate with identical parameters.

NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrapper** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.
To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name>
```

<csr_name> is the name of a CSR from the list of current CSRs.

To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
```

**NOTE**

Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

**Example output**

| NAME     | AGE      | REQUESTOR                                                      | CONDITION      |
|----------|----------|----------------------------------------------------------------|
| csr-bfd72| 5m26s    | system:node:ip-10-0-50-126.us-east-2.compute.internal         | Pending        |
| csr-c57lv| 5m26s    | system:node:ip-10-0-95-157.us-east-2.compute.internal         | Pending        |

5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name>
```

<csr_name> is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs oc adm certificate approve
```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

**Example output**
It can take a few minutes after approval of the server CSRs for the machines to transition to the `Ready` status.

Additional information

- For more information on CSRs, see [Certificate Signing Requests](#).

### 17.8.25. Verifying a successful installation

Verify that the OpenShift Container Platform installation is complete.

**Prerequisites**

- You have the installation program (`openshift-install`)

**Procedure**

- On a command line, enter:

  ```
  $ openshift-install --log-level debug wait-for install-complete
  ```

The program outputs the console URL, as well as the administrator’s login information.

The cluster is operational. Before you can configure it for SR-IOV networks though, you must perform additional tasks.

### 17.8.26. Preparing a cluster that runs on RHOSP for SR-IOV

Before you use single root I/O virtualization (SR-IOV) on a cluster that runs on Red Hat OpenStack Platform (RHOSP), make the RHOSP metadata service mountable as a drive and enable the No-IOMMU Operator for the virtual function I/O (VFIO) driver.

#### 17.8.26.1. Enabling the RHOSP metadata service as a mountable drive

You can apply a machine config to your machine pool that makes the Red Hat OpenStack Platform (RHOSP) metadata service available as a mountable drive.

The following machine config enables the display of RHOSP network UUIDs from within the SR-IOV Network Operator. This configuration simplifies the association of SR-IOV resources to cluster SR-IOV resources.

**Procedure**

1. Create a machine config file from the following template:
A mountable metadata service machine config file

```yaml
kind: MachineConfig
apiVersion: machineconfiguration.openshift.io/v1
metadata:
  name: 20-mount-config
labels:
  machineconfiguration.openshift.io/role: worker
spec:
  config:
    ignition:
      version: 3.2.0
    systemd:
      units:
      - name: create-mountpoint-var-config.service
        enabled: true
        contents: |
        [Unit]
        Description=Create mountpoint /var/config
        Before=kubelet.service

        [Service]
        ExecStart=/bin/mkdir -p /var/config

        [Install]
        WantedBy=var-config.mount

      - name: var-config.mount
        enabled: true
        contents: |
        [Unit]
        Before=local-fs.target
        [Mount]
        Where=/var/config
        What=/dev/disk/by-label/config-2

        [Install]
        WantedBy=local-fs.target
```

1. You can substitute a name of your choice.

2. From a command line, apply the machine config:

   ```bash
   $ oc apply -f <machine_config_file_name>.yaml
   ```

17.8.26.2. Enabling the No-IOMMU feature for the RHOSP VFIO driver

You can apply a machine config to your machine pool that enables the No-IOMMU feature for the Red Hat OpenStack Platform (RHOSP) virtual function I/O (VFIO) driver. The RHOSP vfio-pci driver requires this feature.

**Procedure**

1. Create a machine config file from the following template:
A No-IOMMU VFIO machine config file

```yaml
kind: MachineConfig
apiVersion: machineconfiguration.openshift.io/v1
metadata:
  name: 99-vfio-noiommu
labels:
  machineconfiguration.openshift.io/role: worker
spec:
  config:
    ignition:
      version: 3.2.0
    storage:
      files:
      - path: /etc/modprobe.d/vfio-noiommu.conf
        mode: 0644
        contents:
          source: data;base64,b3B0aW9ucyB2ZmlvIGVuYWJsZV91bnNhZmVfsm9pb21tdV9tb2RIPTEK
```

You can substitute a name of your choice.

2. From a command line, apply the machine config:

   ```bash
   $ oc apply -f <machine_config_file_name>.yaml
   ```

   **NOTE**

   After you apply the machine config to the machine pool, you can watch the machine config pool status to see when the machines are available.

The cluster is installed and prepared for SR-IOV configuration. You must now perform the SR-IOV configuration tasks in "Next steps".

### 17.8.27. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.10, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- See [About remote health monitoring](https://example.com) for more information about the Telemetry service

### 17.8.28. Additional resources

- See Performance Addon Operator for low latency nodes for information about configuring your deployment for real-time running and low latency.
17.8.29. Next steps

- To complete SR-IOV configuration for your cluster:
  - Install the Performance Addon Operator.
  - Configure the Performance Addon Operator with huge pages support.
  - Install the SR-IOV Operator.
  - Configure your SR-IOV network device.
- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- If you need to enable external access to node ports, configure ingress cluster traffic by using a node port.
- If you did not configure RHOSP to accept application traffic over floating IP addresses, configure RHOSP access with floating IP addresses.

17.9. INSTALLING A CLUSTER ON OPENSTACK IN A RESTRICTED NETWORK

In OpenShift Container Platform 4.10, you can install a cluster on Red Hat OpenStack Platform (RHOSP) in a restricted network by creating an internal mirror of the installation release content.

17.9.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You verified that OpenShift Container Platform 4.10 is compatible with your RHOSP version by using the Supported platforms for OpenShift clusters section. You can also compare platform support across different versions by viewing the OpenShift Container Platform on RHOSP support matrix.
- You created a registry on your mirror host and obtained the imageContentSources data for your version of OpenShift Container Platform.

**IMPORTANT**

Because the installation media is on the mirror host, you can use that computer to complete all installation steps.

- You have the metadata service enabled in RHOSP.

17.9.2. About installations in restricted networks

In OpenShift Container Platform 4.10, you can perform an installation that does not require an active connection to the internet to obtain software components. Restricted network installations can be
completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on
the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to
its cloud APIs. Some cloud functions, like Amazon Web Service’s IAM service, require internet access, so
you might still require internet access. Depending on your network, you might require less internet
access for an installation on bare metal hardware or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the
OpenShift Container Platform registry and contains the installation media. You can create this registry
on a mirror host, which can access both the internet and your closed network, or by using other methods
that meet your restrictions.

17.9.2.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The ClusterVersion status includes an Unable to retrieve available updates error.
- By default, you cannot use the contents of the Developer Catalog because you cannot access
  the required image stream tags.

17.9.3. Resource guidelines for installing OpenShift Container Platform on RHOSP

To support an OpenShift Container Platform installation, your Red Hat OpenStack Platform (RHOSP)
quota must meet the following requirements:

Table 17.39. Recommended resources for a default OpenShift Container Platform cluster on
RHOSP

<table>
<thead>
<tr>
<th>Resource</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Floating IP addresses</td>
<td>3</td>
</tr>
<tr>
<td>Ports</td>
<td>15</td>
</tr>
<tr>
<td>Routers</td>
<td>1</td>
</tr>
<tr>
<td>Subnets</td>
<td>1</td>
</tr>
<tr>
<td>RAM</td>
<td>112 GB</td>
</tr>
<tr>
<td>vCPUs</td>
<td>28</td>
</tr>
<tr>
<td>Volume storage</td>
<td>275 GB</td>
</tr>
<tr>
<td>Instances</td>
<td>7</td>
</tr>
<tr>
<td>Security groups</td>
<td>3</td>
</tr>
<tr>
<td>Security group rules</td>
<td>60</td>
</tr>
</tbody>
</table>
A cluster might function with fewer than recommended resources, but its performance is not guaranteed.

**IMPORTANT**

If RHOSP object storage (Swift) is available and operated by a user account with the `swiftoperator` role, it is used as the default backend for the OpenShift Container Platform image registry. In this case, the volume storage requirement is 175 GB. Swift space requirements vary depending on the size of the image registry.

**NOTE**

By default, your security group and security group rule quotas might be low. If you encounter problems, run `openstack quota set --secgroups 3 --secgroup-rules 60 <project>` as an administrator to increase them.

An OpenShift Container Platform deployment comprises control plane machines, compute machines, and a bootstrap machine.

### 17.9.3.1. Control plane and compute machines

By default, the OpenShift Container Platform installation process stands up three control plane and three compute machines.

Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory, 4 vCPUs, and 25 GB storage space

**TIP**

Compute machines host the applications that you run on OpenShift Container Platform; aim to run as many as you can.

### 17.9.3.2. Bootstrap machine

During installation, a bootstrap machine is temporarily provisioned to stand up the control plane. After the production control plane is ready, the bootstrap machine is deprovisioned.

The bootstrap machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
A flavor with at least 16 GB memory, 4 vCPUs, and 25 GB storage space

17.9.4. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.10, you require access to the internet to obtain the images that are necessary to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- Access Quay.io to obtain the packages that are required to install your cluster.

- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

17.9.5. Enabling Swift on RHOSP

Swift is operated by a user account with the `swiftoperator` role. Add the role to an account before you run the installation program.

**IMPORTANT**

If the Red Hat OpenStack Platform (RHOSP) object storage service, commonly known as Swift, is available, OpenShift Container Platform uses it as the image registry storage. If it is unavailable, the installation program relies on the RHOSP block storage service, commonly known as Cinder.

If Swift is present and you want to use it, you must enable access to it. If it is not present, or if you do not want to use it, skip this section.

**Prerequisites**

- You have a RHOSP administrator account on the target environment.

- The Swift service is installed.

- On Ceph RGW, the `account in url` option is enabled.

**Procedure**

To enable Swift on RHOSP:

1. As an administrator in the RHOSP CLI, add the `swiftoperator` role to the account that will access Swift:
Your RHOSP deployment can now use Swift for the image registry.

17.9.6. Defining parameters for the installation program

The OpenShift Container Platform installation program relies on a file that is called `clouds.yaml`. The file describes Red Hat OpenStack Platform (RHOSP) configuration parameters, including the project name, log in information, and authorization service URLs.

Procedure

1. Create the `clouds.yaml` file:
   - If your RHOSP distribution includes the Horizon web UI, generate a `clouds.yaml` file in it.

     **IMPORTANT**
     
     Remember to add a password to the `auth` field. You can also keep secrets in a separate file from `clouds.yaml`.

   - If your RHOSP distribution does not include the Horizon web UI, or you do not want to use Horizon, create the file yourself. For detailed information about `clouds.yaml`, see Config files in the RHOSP documentation.

     ```yaml
     clouds:
     shiftstack:
     auth:
     project_name: shiftstack
     username: shiftstack_user
     password: XXX
     user_domain_name: Default
     project_domain_name: Default
     dev-env:
     region_name: RegionOne
     auth:
     username: 'devuser'
     password: XXX
     project_name: 'devonly'
     ```

2. If your RHOSP installation uses self-signed certificate authority (CA) certificates for endpoint authentication:
   a. Copy the certificate authority file to your machine.
   b. Add the `cacerts` key to the `clouds.yaml` file. The value must be an absolute, non-root-accessible path to the CA certificate:

     ```yaml
     clouds:
     shiftstack:
     ...
     cacert: "/etc/pki/ca-trust/source/anchors/ca.crt.pem"
     ```
After you run the installer with a custom CA certificate, you can update the certificate by editing the value of the `ca-cert.pem` key in the `cloud-provider-config` keymap. On a command line, run:

```
$ oc edit configmap -n openshift-config cloud-provider-config
```

3. Place the `clouds.yaml` file in one of the following locations:
   a. The value of the `OS_CLIENT_CONFIG_FILE` environment variable
   b. The current directory
   c. A Unix-specific user configuration directory, for example `~/.config/openstack/clouds.yaml`
   d. A Unix-specific site configuration directory, for example `/etc/openstack/clouds.yaml`
   The installation program searches for `clouds.yaml` in that order.

### 17.9.7. Setting cloud provider options

Optionally, you can edit the cloud provider configuration for your cluster. The cloud provider configuration controls how OpenShift Container Platform interacts with Red Hat OpenStack Platform (RHOSP).

For a complete list of cloud provider configuration parameters, see [the cloud.conf specification](#).

**Procedure**

1. If you have not already generated manifest files for your cluster, generate them by running the following command:

   ```
   $ openshift-install --dir <destination_directory> create manifests
   ```

2. In a text editor, open the cloud-provider configuration manifest file. For example:

   ```
   $ vi openshift/manifests/cloud-provider-config.yaml
   ```

3. Modify the options based on [the cloud.conf specification](#).
   Configuring Octavia for load balancing is a common case. For example:

   ```yaml
   #...
   [LoadBalancer]
   use-octavia=true 1
   lb-provider = "amphora" 2
   floating-network-id="d3deb660-4190-40a3-91f1-37326fe6ec4a" 3
   #...
   ```

   1. This property enables Octavia integration.
   2. This property sets the Octavia provider that your load balancer uses. It accepts "ovn" or "amphora" as values. If you choose to use OVN, you must also set `lb-method` to `SOURCE_IP_PORT`.  
   3. This property enables Octavia integration.
This property is required if you want to use multiple external networks with your cluster. The cloud provider creates floating IP addresses on the network that is specified here.

**IMPORTANT**

Prior to saving your changes, verify that the file is structured correctly. Clusters might fail if properties are not placed in the appropriate section.

4. Save the changes to the file and proceed with installation.

**TIP**

You can update your cloud provider configuration after you run the installer. On a command line, run:

```
$ oc edit configmap -n openshift-config cloud-provider-config
```

After you save your changes, your cluster will take some time to reconfigure itself. The process is complete if none of your nodes have a `SchedulingDisabled` status.

### 17.9.8. Creating the RHCOS image for restricted network installations

Download the Red Hat Enterprise Linux CoreOS (RHCOS) image to install OpenShift Container Platform on a restricted network Red Hat OpenStack Platform (RHOSP) environment.

**Prerequisites**

- Obtain the OpenShift Container Platform installation program. For a restricted network installation, the program is on your mirror registry host.

**Procedure**

2. Under **Version**, select the most recent release of OpenShift Container Platform 4.10 for RHEL 8.

**IMPORTANT**

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available.

3. Download the Red Hat Enterprise Linux CoreOS (RHCOS) - OpenStack Image (QCOW) image.

4. Decompress the image.
NOTE
You must decompress the image before the cluster can use it. The name of the downloaded file might not contain a compression extension, like .gz or .tgz. To find out if or how the file is compressed, in a command line, enter:

```
$ file <name_of_downloaded_file>
```

5. Upload the image that you decompressed to a location that is accessible from the bastion server, like Glance. For example:

```
$ openstack image create --file rhcos-44.81.202003110027-0-openstack.x86_64.qcow2 --disk-format qcow2 rhcos-$\{RHCOS\_VERSION\}
```

IMPORTANT
Depending on your RHOSP environment, you might be able to upload the image in either .raw or .qcow2 formats. If you use Ceph, you must use the .raw format.

WARNING
If the installation program finds multiple images with the same name, it chooses one of them at random. To avoid this behavior, create unique names for resources in RHOSP.

The image is now available for a restricted installation. Note the image name or location for use in OpenShift Container Platform deployment.

17.9.9. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Red Hat OpenStack Platform (RHOSP).

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster. For a restricted network installation, these files are on your mirror host.

- Have the imageContentSources values that were generated during mirror registry creation.

- Obtain the contents of the certificate for your mirror registry.

- Retrieve a Red Hat Enterprise Linux CoreOS (RHCOS) image and upload it to an accessible location.

- Obtain service principal permissions at the subscription level.

Procedure
1. Create the `install-config.yaml` file.

   a. Change to the directory that contains the installation program and run the following command:

   ```
   $ ./openshift-install create install-config --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

   **IMPORTANT**

   Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

   b. At the prompts, provide the configuration details for your cloud:

      i. Optional: Select an SSH key to use to access your cluster machines.

      **NOTE**

      For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

      ii. Select `openstack` as the platform to target.

      iii. Specify the Red Hat OpenStack Platform (RHOSP) external network name to use for installing the cluster.

      iv. Specify the floating IP address to use for external access to the OpenShift API.

      v. Specify a RHOSP flavor with at least 16 GB RAM to use for control plane and compute nodes.

      vi. Select the base domain to deploy the cluster to. All DNS records will be sub-domains of this base and will also include the cluster name.

      vii. Enter a name for your cluster. The name must be 14 or fewer characters long.

      viii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

2. In the `install-config.yaml` file, set the value of `platform.openstack.clusterOSImage` to the image location or name. For example:

   ```yaml
   platform:
     openstack:
       clusterOSImage: http://mirror.example.com/images/rhcos-43.81.201912131630.0-
   ```
3. Edit the `install-config.yaml` file to provide the additional information that is required for an installation in a restricted network.

a. Update the `pullSecret` value to contain the authentication information for your registry:

   ```yaml
   pullSecret: {
     "auths": {
       "<mirror_host_name>:5000": {
         "auth": "<credentials>",
         "email": "you@example.com"
       }
     }
   }
   ```

   For `<mirror_host_name>`, specify the registry domain name that you specified in the certificate for your mirror registry, and for `<credentials>`, specify the base64-encoded user name and password for your mirror registry.

b. Add the `additionalTrustBundle` parameter and value.

   ```yaml
   additionalTrustBundle: |
   -----BEGIN CERTIFICATE-----
   ZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZ
   -----END CERTIFICATE-----
   ```

   The value must be the contents of the certificate file that you used for your mirror registry, which can be an existing, trusted certificate authority or the self-signed certificate that you generated for the mirror registry.

c. Add the image content resources, which look like this excerpt:

   ```yaml
   imageContentSources:
     - mirrors:
       - <mirror_host_name>:5000/<repo_name>/release
         source: quay.example.com/openshift-release-dev/ocp-release
     - mirrors:
       - <mirror_host_name>:5000/<repo_name>/release
         source: registry.example.com/ocp/release
   ```

   To complete these values, use the `imageContentSources` that you recorded during mirror registry creation.

4. Make any other modifications to the `install-config.yaml` file that you require. You can find more information about the available parameters in the `Installation configuration parameters` section.

5. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

   IMPORTANT

   The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

17.9.9.1. Configuring the cluster-wide proxy during installation
Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**NOTE**

Kuryr installations default to HTTP proxies.

**Prerequisites**

- For Kuryr installations on restricted networks that use the `Proxy` object, the proxy must be able to reply to the router that the cluster uses. To add a static route for the proxy configuration, from a command line as the root user, enter:

  ```
  $ ip route add <cluster_network_cidr> via <installer_subnet_gateway>
  ```

- The restricted subnet must have a gateway that is defined and available to be linked to the `Router` resource that Kuryr creates.

- You have an existing `install-config.yaml` file.

- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

**Procedure**

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
     httpProxy: http://<username>:<pswd>@<ip>:<port>
     httpsProxy: https://<username>:<pswd>@<ip>:<port>
     noProxy: example.com
   additionalTrustBundle: |
   -----BEGIN CERTIFICATE-----
   <MY_TRUSTED_CA_CERT>
   -----END CERTIFICATE-----
   ```
1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.

2. A proxy URL to use for creating HTTPS connections outside the cluster.

3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.

4. If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the trustedCA field of the Proxy object. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

NOTE

The installation program does not support the proxy readinessEndpoints field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

NOTE

Only the Proxy object named cluster is supported, and no additional proxies can be created.

17.9.9.2. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide a customized install-config.yaml installation configuration file that describes the details for your environment.

NOTE

After installation, you cannot modify these parameters in the install-config.yaml file.

17.9.9.2.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

Table 17.40. Required parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is <code>v1</code>. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the <code>baseDomain</code> and <code>metadata.name</code> parameter values that uses the <code>&lt;metadata.name&gt;</code>. <code>&lt;baseDomain&gt;</code> format.</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
</tr>
<tr>
<td>metadata</td>
<td>Kubernetes resource <code>ObjectMeta</code>, from which only the <code>name</code> parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of <code>{metadata.name}.{baseDomain}</code>.</td>
<td>String of lowercase letters, hyphens (-), and periods (.), such as dev. The string must be 14 characters or fewer long.</td>
</tr>
<tr>
<td>platform</td>
<td>The configuration for the specific platform upon which to perform the installation: alibabacloud, aws, baremetal, azure, ibmcloud, openstack, ovirt, vsphere, or {}. For additional information about platform. <code>&lt;platform&gt;</code> parameters, consult the table for your specific platform that follows.</td>
<td>Object</td>
</tr>
</tbody>
</table>
Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.

```json
{
  "auths":{
    "cloud.openshift.com":{
      "auth":"b3Blb=",
      "email":"you@example.com"
    },
    "quay.io":{
      "auth":"b3Blb=",
      "email":"you@example.com"
    }
  }
}
```

### 17.9.9.2.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

#### Table 17.41. Network parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>networking</strong></td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td><strong>networking.network.Type</strong></td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN.</td>
</tr>
<tr>
<td><strong>networking.clusterNetwork</strong></td>
<td>The IP address blocks for pods. The default value is 10.128.0.0/14 with a host prefix of /23. If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td>An array of objects. For example: networking: clusterNetwork: - cidr: 10.128.0.0/14 hostPrefix: 23</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td>networking.clusterNetwork.cidr</td>
<td>Required if you use <code>networking.clusterNetwork</code>. An IP address block.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td>networking.clusterNetwork.hostPrefix</td>
<td>The subnet prefix length to assign to each individual node. For example, if <code>hostPrefix</code> is set to 23 then each node is assigned a /23 subnet out of the given <code>cidr</code>. A <code>hostPrefix</code> value of 23 provides 510 ((2^{32} - 23) - 2) pod IP addresses.</td>
<td>A subnet prefix. The default value is 23.</td>
</tr>
<tr>
<td>networking.serviceNetwork</td>
<td>The IP address block for services. The default value is <code>172.30.0.0/16</code>.</td>
<td>An array with an IP address block in CIDR format. For example:</td>
</tr>
</tbody>
</table>
| | The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network. | `networking:`
| | `serviceNetwork:`
| | `- 172.30.0.0/16` |
| networking.machineNetwork | The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap. If you specify multiple IP kernel arguments, the `machineNetwork.cidr` value must be the CIDR of the primary network. | An array of objects. For example: |
| | | `networking:`
| | `machineNetwork:`
| | `- cidr: 10.0.0.0/16` |
| networking.machineNetwork.cidr | Required if you use `networking.machineNetwork`. An IP address block. The default value is `10.0.0.0/16` for all platforms other than libvirt. For libvirt, the default value is `192.168.126.0/24`. | An IP network block in CIDR notation. For example, `10.0.0.0/16`. **NOTE** Set the `networking.machineNetwork` to match the CIDR that the preferred NIC resides in. |

17.9.9.2.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>cgroupsV2</td>
<td>Enables Linux control groups version 2 (cgroups v2) on specific nodes in your cluster. The OpenShift Container Platform process for enabling cgroups v2 disables all cgroup version 1 controllers and hierarchies. The OpenShift Container Platform cgroups version 2 feature is in Developer Preview and is not supported by Red Hat at this time.</td>
<td>true</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of MachinePool objects.</td>
</tr>
<tr>
<td>compute.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are s390x (the default).</td>
<td>String</td>
</tr>
<tr>
<td>compute.hyperthreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td></td>
</tr>
<tr>
<td>compute.name</td>
<td>Required if you use compute. The name of the machine pool.</td>
<td>worker</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>compute.platform</td>
<td>Required if you use <code>compute</code>. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <code>controlPlane.platform</code> parameter value.</td>
<td>alibaba, aws, azure, gcp, ibmcloud, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td>compute.replicas</td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td>controlPlane</td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of <code>MachinePool</code> objects.</td>
</tr>
<tr>
<td>controlPlane.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>s390x</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td>controlPlane.hypertreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>controlPlane.name</td>
<td>Required if you use <code>controlPlane</code>. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use <code>controlPlane</code>. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the <code>compute.platform</code> parameter value.</td>
<td>alibaba, aws, azure, gcp, ibmcloud, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-------------------</td>
<td>----------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO</td>
<td>Mint, Passthrough, Manual, or an empty string (&quot;&quot;).</td>
</tr>
<tr>
<td></td>
<td>dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td></td>
</tr>
</tbody>
</table>

**NOTE**

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Platform Operators reference content.
Enable or disable FIPS mode. The default is `false` (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>fips</td>
<td>Sources and repositories for the release-image content.</td>
<td><code>false</code> or <code>true</code></td>
</tr>
<tr>
<td>imageContentSources.source</td>
<td>Required if you use <code>imageContentSources</code>. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td>imageContentSources.mirrors</td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
</tbody>
</table>
### publish

How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.

**Internal** or **External**. The default value is **External**.

Setting this field to **Internal** is not supported on non-cloud platforms and IBM Cloud.

**IMPORTANT**

If the value of the field is set to **Internal**, the cluster will become non-functional. For more information, refer to [BZ#1953035](#).

### sshKey

The SSH key or keys to authenticate access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

One or more keys. For example:

```
sshKey:
  - <key1>
  - <key2>
  - <key3>
```

---

### 17.9.9.2.4. Additional Red Hat OpenStack Platform (RHOSP) configuration parameters

Additional RHOSP configuration parameters are described in the following table:

**Table 17.43. Additional RHOSP parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>compute.platform.openstack. rootVolume.size</code></td>
<td>For compute machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.</td>
<td>Integer, for example 30.</td>
</tr>
<tr>
<td><code>compute.platform.openstack. rootVolume.type</code></td>
<td>For compute machines, the root volume’s type.</td>
<td>String, for example performance.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td>controlPlane.platform.openstack.rootVolume.size</td>
<td>For control plane machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.</td>
<td>Integer, for example 30.</td>
</tr>
<tr>
<td>controlPlane.platform.openstack.rootVolume.type</td>
<td>For control plane machines, the root volume’s type.</td>
<td>String, for example performance.</td>
</tr>
<tr>
<td>platform.openstack.cloud</td>
<td>The name of the RHOSP cloud to use from the list of clouds in the clouds.yaml file.</td>
<td>String, for example MyCloud.</td>
</tr>
<tr>
<td>platform.openstack.externalNetwork</td>
<td>The RHOSP external network name to be used for installation.</td>
<td>String, for example external.</td>
</tr>
<tr>
<td>platform.openstack.computeFlavor</td>
<td>The RHOSP flavor to use for control plane and compute machines. This property is deprecated. To use a flavor as the default for all machine pools, add it as the value of the type key in the platform.openstack.defaultMachinePlatform property. You can also set a flavor value for each machine pool individually.</td>
<td>String, for example m1.xlarge.</td>
</tr>
</tbody>
</table>

### 17.9.9.2.5. Optional RHOSP configuration parameters

Optional RHOSP configuration parameters are described in the following table:

#### Table 17.44. Optional RHOSP parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>compute.platform.openstack.additionalNetworkIDs</td>
<td>Additional networks that are associated with compute machines. Allowed address pairs are not created for additional networks.</td>
<td>A list of one or more UUIDs as strings. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td><code>compute.platform.openstack.additionalSecurityGroupIDs</code></td>
<td>Additional security groups that are associated with compute machines.</td>
<td>A list of one or more UUIDs as strings. For example, 7ee219f3-d2e9-48a1-96c2-e7429f1b0da7.</td>
</tr>
<tr>
<td><code>compute.platform.openstack.zones</code></td>
<td>RHOSP Compute (Nova) availability zones (AZs) to install machines on. If this parameter is not set, the installer relies on the default settings for Nova that the RHOSP administrator configured. On clusters that use Kuryr, RHOSP Octavia does not support availability zones. Load balancers and, if you are using the Amphora provider driver, OpenShift Container Platform services that rely on Amphora VMs, are not created according to the value of this property.</td>
<td>A list of strings. For example, [&quot;zone-1&quot;, &quot;zone-2&quot;].</td>
</tr>
<tr>
<td><code>compute.platform.openstack.rootVolume.zones</code></td>
<td>For compute machines, the availability zone to install root volumes on. If you do not set a value for this parameter, the installer selects the default availability zone.</td>
<td>A list of strings, for example [&quot;zone-1&quot;, &quot;zone-2&quot;].</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td><code>compute.platform.openstack.serverGroupPolicy</code></td>
<td>Server group policy to apply to the group that will contain the compute machines in the pool. You cannot change server group policies or affiliations after creation. Supported options include <code>anti-affinity</code>, <code>soft-affinity</code>, and <code>soft-anti-affinity</code>. The default value is <code>soft-anti-affinity</code>. An <strong>affinity</strong> policy prevents migrations and therefore affects RHOSP upgrades. The <strong>affinity</strong> policy is not supported. If you use a strict <strong>anti-affinity</strong> policy, an additional RHOSP host is required during instance migration.</td>
<td>A server group policy to apply to the machine pool. For example, <strong>soft-affinity</strong>.</td>
</tr>
<tr>
<td><code>controlPlane.platform.openstack.additionalNetworkIDs</code></td>
<td>Additional networks that are associated with control plane machines. Allowed address pairs are not created for additional networks.</td>
<td>A list of one or more UUIDs as strings. For example, <code>fa806b2f-ac49-4bce-b9db-124bc64209bf</code>.</td>
</tr>
<tr>
<td><code>controlPlane.platform.openstack.additionSecurityGroupIDs</code></td>
<td>Additional security groups that are associated with control plane machines.</td>
<td>A list of one or more UUIDs as strings. For example, <code>7ee219f3-d2e9-48a1-96c2-e7429f1b0da7</code>.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td>controlPlane.platform.openstack.zones</td>
<td>RHOSP Compute (Nova) availability zones (AZs) to install machines on. If this parameter is not set, the installer relies on the default settings for Nova that the RHOSP administrator configured. On clusters that use Kuryr, RHOSP Octavia does not support availability zones. Load balancers and, if you are using the Amphora provider driver, OpenShift Container Platform services that rely on Amphora VMs, are not created according to the value of this property.</td>
<td>A list of strings. For example, [&quot;zone-1&quot;, &quot;zone-2&quot;].</td>
</tr>
<tr>
<td>controlPlane.platform.openstack.rootVolume.zones</td>
<td>For control plane machines, the availability zone to install root volumes on. If you do not set this value, the installer selects the default availability zone.</td>
<td>A list of strings, for example [&quot;zone-1&quot;, &quot;zone-2&quot;].</td>
</tr>
<tr>
<td>controlPlane.platform.openstack.serverGroupPolicy</td>
<td>Server group policy to apply to the group that will contain the control plane machines in the pool. You cannot change server group policies or affiliations after creation. Supported options include anti-affinity, soft-affinity, and soft-anti-affinity. The default value is soft-anti-affinity. An affinity policy prevents migrations, and therefore affects RHOSP upgrades. The affinity policy is not supported. If you use a strict anti-affinity policy, an additional RHOSP host is required during instance migration.</td>
<td>A server group policy to apply to the machine pool. For example, soft-affinity.</td>
</tr>
<tr>

<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>platform.openstack.clusterOSImage</code></td>
<td>The location from which the installer downloads the RHCOS image.</td>
<td>An HTTP or HTTPS URL, optionally with an SHA-256 checksum.</td>
</tr>
<tr>
<td></td>
<td>You must set this parameter to perform an installation in a restricted network.</td>
<td>For example, <a href="http://mirror.example.com/images/rhcos-43.81.201912131630.0-openstack.x86_64.qcow2.gz?sha256=ffebebd68e812a245ca19522c16c86f67f9ac8e4e0c1f0a812b068b16f7265d">http://mirror.example.com/images/rhcos-43.81.201912131630.0-openstack.x86_64.qcow2.gz?sha256=ffebebd68e812a245ca19522c16c86f67f9ac8e4e0c1f0a812b068b16f7265d</a>. The value can also be the name of an existing Glance image, for example my-rhcos.</td>
</tr>
<tr>
<td><code>platform.openstack.clusterOSImageProperties</code></td>
<td>Properties to add to the installer-uploaded ClusterOSImage in Glance.</td>
<td>A list of key-value string pairs. For example, [&quot;hw_scsi_model&quot;: &quot;virtio-scsii&quot;, &quot;hw_disk_bus&quot;: &quot;scsii&quot;].</td>
</tr>
<tr>
<td></td>
<td>This property is ignored if <code>platform.openstack.clusterOSImage</code> is set to an existing Glance image.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>You can use this property to exceed the default persistent volume (PV) limit for RHOSP of 26 PVs per node. To exceed the limit, set the <code>hw_scsi_model</code> property value to <code>virtio-scsii</code> and the <code>hw_disk_bus</code> value to <code>scsii</code>.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>You can also use this property to enable the QEMU guest agent by including the <code>hw_qemu_guest_agent</code> property with a value of <code>yes</code>.</td>
<td></td>
</tr>
<tr>
<td><code>platform.openstack.defaultMachinePlatform</code></td>
<td>The default machine pool platform configuration.</td>
<td>{</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;type&quot;: &quot;ml.large&quot;,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;rootVolume&quot;: {</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;size&quot;: 30,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;type&quot;: &quot;performance&quot;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>}</td>
</tr>
<tr>
<td><code>platform.openstack.ingressFloatingIP</code></td>
<td>An existing floating IP address to associate with the Ingress port.</td>
<td>An IP address, for example 128.0.0.1.</td>
</tr>
</tbody>
</table>
### 17.9.9.3. Sample customized install-config.yaml file for restricted OpenStack installations

This sample install-config.yaml demonstrates all of the possible Red Hat OpenStack Platform (RHOSP) customization options.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>platform.openstack.apiFloatingIP</td>
<td>An existing floating IP address to associate with the API load balancer. To use this property, you must also define the platform.openstack.externalNetwork property.</td>
<td>An IP address, for example <strong>128.0.0.1</strong>.</td>
</tr>
<tr>
<td>platform.openstack.externalDNS</td>
<td>IP addresses for external DNS servers that cluster instances use for DNS resolution.</td>
<td>A list of IP addresses as strings. For example, [&quot;8.8.8.8&quot;, &quot;192.168.1.12&quot;].</td>
</tr>
<tr>
<td>platform.openstack.machinesSubnet</td>
<td>The UUID of a RHOSP subnet that the cluster’s nodes use. Nodes and virtual IP (VIP) ports are created on this subnet.</td>
<td>A UUID as a string. For example, <strong>fa806b2f-ac49-4bce-b9db-124bc64209bf</strong>.</td>
</tr>
</tbody>
</table>

The first item in networking.machineNetwork must match the value of machinesSubnet.

If you deploy to a custom subnet, you cannot specify an external DNS server to the OpenShift Container Platform installer. Instead, add DNS to the subnet in RHOSP.

**IMPORTANT**

This sample file is provided for reference only. You must obtain your install-config.yaml file by using the installation program.

```yaml
apiVersion: v1
baseDomain: example.com
controlPlane:
  name: master
  platform: {}
  replicas: 3
compute:

    openstack:
      type: ml.large
```
17.9.10. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.
IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>
   ```

   Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   ```bash
   $ cat <path>/<file_name>.pub
   ```

   For example, run the following to view the `~/.ssh/id_rsa.pub` public key:

   ```bash
   $ cat ~/.ssh/id_rsa.pub
   ```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

   **NOTE**

   On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

   a. If the ssh-agent process is not already running for your local user, start it as a background task:

   ```bash
   $ eval "$(ssh-agent -s)"
   ```

   **Example output**

   ```bash
   Agent pid 31874
   ```
NOTE
If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the ssh-agent:

```
$ ssh-add <path>/<file_name>
```

Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

17.9.11. Enabling access to the environment

At deployment, all OpenShift Container Platform machines are created in a Red Hat OpenStack Platform (RHOSP)-tenant network. Therefore, they are not accessible directly in most RHOSP deployments.

You can configure OpenShift Container Platform API and application access by using floating IP addresses (FIPs) during installation. You can also complete an installation without configuring FIPs, but the installer will not configure a way to reach the API or applications externally.

17.9.11.1. Enabling access with floating IP addresses

Create floating IP (FIP) addresses for external access to the OpenShift Container Platform API and cluster applications.

Procedure

1. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the API FIP:

```
$ openstack floating ip create --description "API <cluster_name>.<base_domain>" <external_network>
```

2. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the apps, or Ingress, FIP:

```
$ openstack floating ip create --description "Ingress <cluster_name>.<base_domain>" <external_network>
```

3. Add records that follow these patterns to your DNS server for the API and Ingress FIPs:

```
api.<cluster_name>.<base_domain>. IN A <API_FIP>
*.apps.<cluster_name>.<base_domain>. IN A <apps_FIP>
```
4. Add the FIPs to the `install-config.yaml` file as the values of the following parameters:

- `platform.openstack.ingressFloatingIP`
- `platform.openstack.apiFloatingIP`

If you use these values, you must also enter an external network as the value of the `platform.openstack.externalNetwork` parameter in the `install-config.yaml` file.

**TIP**

You can make OpenShift Container Platform resources available outside of the cluster by assigning a floating IP address and updating your firewall configuration.

### 17.9.11.2. Completing installation without floating IP addresses

You can install OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) without providing floating IP addresses.

In the `install-config.yaml` file, do not define the following parameters:

- `platform.openstack.ingressFloatingIP`
- `platform.openstack.apiFloatingIP`

If you cannot provide an external network, you can also leave `platform.openstack.externalNetwork` blank. If you do not provide a value for `platform.openstack.externalNetwork`, a router is not created for you, and, without additional action, the installer will fail to retrieve an image from Glance. You must configure external connectivity on your own.

If you run the installer from a system that cannot reach the cluster API due to a lack of floating IP addresses or name resolution, installation fails. To prevent installation failure in these cases, you can use a proxy network or run the installer from a system that is on the same network as your machines.

**NOTE**

You can enable name resolution by creating DNS records for the API and Ingress ports. For example:

```
api.<cluster_name>.<base_domain>. IN A <api_port_IP>
*.apps.<cluster_name>.<base_domain>. IN A <ingress_port_IP>
```

If you do not control the DNS server, you can add the record to your `/etc/hosts` file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

### 17.9.12. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.
IMPORTANT

You can run the `create cluster` command of the installation program only once, during initial installation.

Prerequisites

- Configure an account with the cloud platform that hosts your cluster.
- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Change to the directory that contains the installation program and initialize the cluster deployment:

   $ ./openshift-install create cluster --dir <installation_directory> --log-level=info

   1 For `<installation_directory>`, specify the
   2 To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

   **NOTE**

   If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.

   When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the `kubeadmin` user, display in your terminal.

Example output

   ...
   INFO Install complete!
   INFO To access the cluster as the system:admin user when using `oc`, run `export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig`
   INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
   INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-Wt5AL"
   INFO Time elapsed: 36m22s

   **NOTE**

   The cluster access and credential information also outputs to `<installation_directory>/openshift_install.log` when an installation succeeds.
IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

IMPORTANT

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

17.9.13. Verifying cluster status

You can verify your OpenShift Container Platform cluster’s status during or after installation.

Procedure

1. In the cluster environment, export the administrator’s kubeconfig file:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server.

2. View the control plane and compute machines created after a deployment:

   ```bash
   $ oc get nodes
   ```

3. View your cluster’s version:

   ```bash
   $ oc get clusterversion
   ```

4. View your Operators’ status:

   ```bash
   $ oc get clusteroperator
   ```

5. View all running pods in the cluster:

   ```bash
   $ oc get pods -A
   ```
17.9.14. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

Procedure

1. Export the `kubeadmin` credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ``

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   system:admin
   ```

Additional resources

- See Accessing the web console for more details about accessing and understanding the OpenShift Container Platform web console.

17.9.15. Disabling the default OperatorHub sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

Procedure

- Disable the sources for the default catalogs by adding `disableAllDefaultSources: true` to the `OperatorHub` object:

  ```bash
  $ oc patch OperatorHub cluster --type json \n  -p '[{"op": "add", "path": "/spec/disableAllDefaultSources", "value": true}]'
  ```
TIP

Alternatively, you can use the web console to manage catalog sources. From the Administration → Cluster Settings → Configuration → OperatorHub page, click the Sources tab, where you can create, delete, disable, and enable individual sources.

17.9.16. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.10, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service.

17.9.17. Next steps

- Customize your cluster.
  - If the mirror registry that you used to install your cluster has a trusted CA, add it to the cluster by configuring additional trust stores.
  - If necessary, you can opt out of remote health reporting.
- Configure image streams for the Cluster Samples Operator and the must-gather tool.
- Learn how to use Operator Lifecycle Manager (OLM) on restricted networks.
- If you did not configure RHOSP to accept application traffic over floating IP addresses, configure RHOSP access with floating IP addresses.

17.10. UNINSTALLING A CLUSTER ON OPENSTACK

You can remove a cluster that you deployed to Red Hat OpenStack Platform (RHOSP).

17.10.1. Removing a cluster that uses installer-provisioned infrastructure

You can remove a cluster that uses installer-provisioned infrastructure from your cloud.

NOTE

After uninstallation, check your cloud provider for any resources not removed properly, especially with User Provisioned Infrastructure (UPI) clusters. There might be resources that the installer did not create or that the installer is unable to access.

Prerequisites

- Have a copy of the installation program that you used to deploy the cluster.
• Have the files that the installation program generated when you created your cluster.

Procedure

1. From the directory that contains the installation program on the computer that you used to install the cluster, run the following command:

```
$ ./openshift-install destroy cluster \n--dir <installation_directory> --log-level info
```

   1 For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   2 To view different details, specify `warn`, `debug`, or `error` instead of `info`.

   **NOTE**

   You must specify the directory that contains the cluster definition files for your cluster. The installation program requires the `metadata.json` file in this directory to delete the cluster.

1. Optional: Delete the `<installation_directory>` directory and the OpenShift Container Platform installation program.

17.11. UNINSTALLING A CLUSTER ON RHOSP FROM YOUR OWN INFRASTRUCTURE

You can remove a cluster that you deployed to Red Hat OpenStack Platform (RHOSP) on user-provisioned infrastructure.

17.11.1. Downloading playbook dependencies

The Ansible playbooks that simplify the removal process on user-provisioned infrastructure require several Python modules. On the machine where you will run the process, add the modules' repositories and then download them.

   **NOTE**

   These instructions assume that you are using Red Hat Enterprise Linux (RHEL) 8.

Prerequisites

• Python 3 is installed on your machine.

Procedure

1. On a command line, add the repositories:

   a. Register with Red Hat Subscription Manager:

```
$ sudo subscription-manager register # If not done already
```
b. Pull the latest subscription data:

$ sudo subscription-manager attach --pool=$YOUR_POOLID # If not done already

c. Disable the current repositories:

$ sudo subscription-manager repos --disable=* # If not done already

d. Add the required repositories:

$ sudo subscription-manager repos \
   --enable=rhel-8-for-x86_64-baseos-rpms \
   --enable=openstack-16-tools-for-rhel-8-x86_64-rpms \
   --enable=ansible-2.9-for-rhel-8-x86_64-rpms \
   --enable=rhel-8-for-x86_64-appstream-rpms

2. Install the modules:

$ sudo yum install python3-openstackclient ansible python3-openstacksdk

3. Ensure that the python command points to python3:

$ sudo alternatives --set python /usr/bin/python3

17.11.2. Removing a cluster from RHOSP that uses your own infrastructure

You can remove an OpenShift Container Platform cluster on Red Hat OpenStack Platform (RHOSP) that uses your own infrastructure. To complete the removal process quickly, run several Ansible playbooks.

Prerequisites

- Python 3 is installed on your machine.
- You downloaded the modules in "Downloading playbook dependencies."
- You have the playbooks that you used to install the cluster.
- You modified the playbooks that are prefixed with down- to reflect any changes that you made to their corresponding installation playbooks. For example, changes to the bootstrap.yaml file are reflected in the down-bootstrap.yaml file.
- All of the playbooks are in a common directory.

Procedure

1. On a command line, run the playbooks that you downloaded:

   $ ansible-playbook -i inventory.yaml \
   down-bootstrap.yaml \
   down-control-plane.yaml \
   down-compute-nodes.yaml \
   OpenShift Container Platform 4.10 Installing 2392
2. Remove any DNS record changes you made for the OpenShift Container Platform installation.

OpenShift Container Platform is removed from your infrastructure.
CHAPTER 18. INSTALLING ON RHV

18.1. PREPARING TO INSTALL ON RED HAT VIRTUALIZATION (RHV)

18.1.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.

- You have a supported combination of versions in the Support Matrix for OpenShift Container Platform on Red Hat Virtualization (RHV).

- You read the documentation on selecting a cluster installation method and preparing it for users.

18.1.2. Choosing a method to install OpenShift Container Platform on RHV

You can install OpenShift Container Platform on installer-provisioned or user-provisioned infrastructure. The default installation type uses installer-provisioned infrastructure, where the installation program provisions the underlying infrastructure for the cluster. You can also install OpenShift Container Platform on infrastructure that you provision. If you do not use infrastructure that the installation program provisions, you must manage and maintain the cluster resources yourself.

See Installation process for more information about installer-provisioned and user-provisioned installation processes.

18.1.2.1. Installing a cluster on installer-provisioned infrastructure

You can install a cluster on Red Hat Virtualization (RHV) virtual machines that are provisioned by the OpenShift Container Platform installation program, by using one of the following methods:

- Installing a cluster quickly on RHV You can quickly install OpenShift Container Platform on RHV virtual machines that the OpenShift Container Platform installation program provisions.

- Installing a cluster on RHV with customizations You can install a customized OpenShift Container Platform cluster on installer-provisioned guests on RHV. The installation program allows for some customization to be applied at the installation stage. Many other customization options are available post-installation.

18.1.2.2. Installing a cluster on user-provisioned infrastructure

You can install a cluster on RHV virtual machines that you provision, by using one of the following methods:

- Installing a cluster on RHV with user-provisioned infrastructure You can install OpenShift Container Platform on RHV virtual machines that you provision. You can use the provided Ansible playbooks to assist with the installation.

- Installing a cluster on RHV in a restricted network You can install OpenShift Container Platform on RHV in a restricted or disconnected network by creating an internal mirror of the installation release content. You can use this method to install a user-provisioned cluster that does not require an active internet connection to obtain the software components. You can also use this installation method to ensure that your clusters only use container images that satisfy your organizational controls on external content.
18.2. INSTALLING A CLUSTER QUICKLY ON RHV

You can quickly install a default, non-customized, OpenShift Container Platform cluster on a Red Hat Virtualization (RHV) cluster, similar to the one shown in the following diagram.

The installation program uses installer-provisioned infrastructure to automate creating and deploying the cluster.

To install a default cluster, you prepare the environment, run the installation program and answer its prompts. Then, the installation program creates the OpenShift Container Platform cluster.

For an alternative to installing a default cluster, see Installing a cluster with customizations.

NOTE

This installation program is available for Linux and macOS only.

18.2.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.

- You have a supported combination of versions in the Support Matrix for OpenShift Container Platform on Red Hat Virtualization (RHV).

- You read the documentation on selecting a cluster installation method and preparing it for users.
If you use a firewall, you configured it to allow the sites that your cluster requires access to.

18.2.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.10, you require access to the internet to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

18.2.3. Requirements for the RHV environment

To install and run an OpenShift Container Platform version 4.10 cluster, the RHV environment must meet the following requirements.

Not meeting these requirements can cause the installation or process to fail. Additionally, not meeting these requirements can cause the OpenShift Container Platform cluster to fail days or weeks after installation.

The following requirements for CPU, memory, and storage resources are based on default values multiplied by the default number of virtual machines the installation program creates. These resources must be available in addition to what the RHV environment uses for non-OpenShift Container Platform operations.

By default, the installation program creates seven virtual machines during the installation process. First, it creates a bootstrap virtual machine to provide temporary services and a control plane while it creates the rest of the OpenShift Container Platform cluster. When the installation program finishes creating the cluster, deleting the bootstrap machine frees up its resources.

If you increase the number of virtual machines in the RHV environment, you must increase the resources accordingly.

**Requirements**

- The RHV version is 4.4.
- The RHV environment has one data center whose state is **Up**.
- The RHV data center contains an RHV cluster.
The RHV cluster has the following resources exclusively for the OpenShift Container Platform cluster:

- Minimum 28 vCPUs: four for each of the seven virtual machines created during installation.
- 112 GiB RAM or more, including:
  - 16 GiB or more for the bootstrap machine, which provides the temporary control plane.
  - 16 GiB or more for each of the three control plane machines which provide the control plane.
  - 16 GiB or more for each of the three compute machines, which run the application workloads.

The RHV storage domain must meet these etcd backend performance requirements.

For affinity group support: Three or more hosts in the RHV cluster. If necessary, you can disable affinity groups. For details, see Example: Removing all affinity groups for a non-production lab setup in Installing a cluster on RHV with customizations.

In production environments, each virtual machine must have 120 GiB or more. Therefore, the storage domain must provide 840 GiB or more for the default OpenShift Container Platform cluster. In resource-constrained or non-production environments, each virtual machine must have 32 GiB or more, so the storage domain must have 230 GiB or more for the default OpenShift Container Platform cluster.

To download images from the Red Hat Ecosystem Catalog during installation and update procedures, the RHV cluster must have access to an internet connection. The Telemetry service also needs an internet connection to simplify the subscription and entitlement process.

The RHV cluster must have a virtual network with access to the REST API on the RHV Manager. Ensure that DHCP is enabled on this network, because the VMs that the installer creates obtain their IP address by using DHCP.

A user account and group with the following least privileges for installing and managing an OpenShift Container Platform cluster on the target RHV cluster:

- DiskOperator
- DiskCreator
- UserTemplateBasedVm
- TemplateOwner
- TemplateCreator
- ClusterAdmin on the target cluster
WARNING
Apply the principle of least privilege: Avoid using an administrator account with SuperUser privileges on RHV during the installation process. The installation program saves the credentials you provide to a temporary ovirt-config.yaml file that might be compromised.

Additional resources
- Example: Removing all affinity groups for a non-production lab setup.

18.2.4. Verifying the requirements for the RHV environment
Verify that the RHV environment meets the requirements to install and run an OpenShift Container Platform cluster. Not meeting these requirements can cause failures.

IMPORTANT
These requirements are based on the default resources the installation program uses to create control plane and compute machines. These resources include vCPUs, memory, and storage. If you change these resources or increase the number of OpenShift Container Platform machines, adjust these requirements accordingly.

Procedure
1. Check that the RHV version supports installation of OpenShift Container Platform version 4.10.
   a. In the RHV Administration Portal, click the ? help icon in the upper-right corner and select About.
   b. In the window that opens, make a note of the RHV Software Version.
   c. Confirm that the RHV version is 4.4. For more information about supported version combinations, see Support Matrix for OpenShift Container Platform on RHV.
2. Inspect the data center, cluster, and storage.
   a. In the RHV Administration Portal, click Compute → Data Centers.
   b. Confirm that the data center where you plan to install OpenShift Container Platform is accessible.
   c. Click the name of that data center.
   d. In the data center details, on the Storage tab, confirm the storage domain where you plan to install OpenShift Container Platform is Active.
   e. Record the Domain Name for use later on.
   f. Confirm Free Space has at least 230 GiB.
g. Confirm that the storage domain meets **these etcd backend performance requirements**, which you can measure by using the **fio performance benchmarking tool**.

h. In the data center details, click the **Clusters** tab.

i. Find the RHV cluster where you plan to install OpenShift Container Platform. Record the cluster name for use later on.

3. Inspect the RHV host resources.
   a. In the RHV Administration Portal, click **Compute > Clusters**.
   b. Click the cluster where you plan to install OpenShift Container Platform.
   c. In the cluster details, click the **Hosts** tab.
   d. Inspect the hosts and confirm they have a combined total of at least **28 Logical CPU Cores** available **exclusively** for the OpenShift Container Platform cluster.
   e. Record the number of available **Logical CPU Cores** for use later on.
   f. Confirm that these CPU cores are distributed so that each of the seven virtual machines created during installation can have four cores.
   g. Confirm that, all together, the hosts have **112 GiB of Max free Memory for scheduling new virtual machines** distributed to meet the requirements for each of the following OpenShift Container Platform machines:
      - 16 GiB required for the bootstrap machine
      - 16 GiB required for each of the three control plane machines
      - 16 GiB for each of the three compute machines
   h. Record the amount of **Max free Memory for scheduling new virtual machines** for use later on.

4. Verify that the virtual network for installing OpenShift Container Platform has access to the RHV Manager’s REST API. From a virtual machine on this network, use curl to reach the RHV Manager’s REST API:

```
$ curl -k -u <username>@<profile>:<password> \
    https://<engine-fqdn>/ovirt-engine/api  
```

1. For **<username>**, specify the user name of an RHV account with privileges to create and manage an OpenShift Container Platform cluster on RHV. For **<profile>**, specify the login profile, which you can get by going to the RHV Administration Portal login page and reviewing the **Profile** dropdown list. For **<password>**, specify the password for that user name.

2. For **<engine-fqdn>**, specify the fully qualified domain name of the RHV environment.

For example:

```
$ curl -k -u ocpadmin@internal:pw123 \
    https://rhv-env.virtlab.example.com/ovirt-engine/api
```
18.2.5. Preparing the network environment on RHV

Configure two static IP addresses for the OpenShift Container Platform cluster and create DNS entries using these addresses.

Procedure

1. Reserve two static IP addresses
   a. On the network where you plan to install OpenShift Container Platform, identify two static IP addresses that are outside the DHCP lease pool.
   b. Connect to a host on this network and verify that each of the IP addresses is not in use. For example, use Address Resolution Protocol (ARP) to check that none of the IP addresses have entries:

   ```bash
   $ arp 10.35.1.19
   ```

   **Example output**

   ```text
   10.35.1.19 (10.35.1.19) -- no entry
   ```

   c. Reserve two static IP addresses following the standard practices for your network environment.
   d. Record these IP addresses for future reference.

2. Create DNS entries for the OpenShift Container Platform REST API and apps domain names using this format:

   ```text
   api.<cluster-name>.<base-domain> <ip-address>  
   *.apps.<cluster-name>.<base-domain> <ip-address>
   ```

   1 For `<cluster-name>`, `<base-domain>`, and `<ip-address>`, specify the cluster name, base domain, and static IP address of your OpenShift Container Platform API.

   2 Specify the cluster name, base domain, and static IP address of your OpenShift Container Platform apps for Ingress and the load balancer.

   For example:

   ```text
   api.my-cluster.virtlab.example.com 10.35.1.19  
   *.apps.my-cluster.virtlab.example.com 10.35.1.20
   ```

18.2.6. Installing OpenShift Container Platform on RHV in insecure mode

By default, the installer creates a CA certificate, prompts you for confirmation, and stores the certificate to use during installation. You do not need to create or install one manually.

Although it is not recommended, you can override this functionality and install OpenShift Container Platform without verifying a certificate by installing OpenShift Container Platform on RHV in **insecure** mode.
WARNING

Installing in insecure mode is not recommended, because it enables a potential attacker to perform a Man-in-the-Middle attack and capture sensitive credentials on the network.

Procedure

1. Create a file named ~/.ovirt/ovirt-config.yaml.

2. Add the following content to ovirt-config.yaml:

```yaml
ovirt_url: https://ovirt.example.com/ovirt-engine/api
ovirt_fqdn: ovirt.example.com
ovirt_pem_url: ""
ovirt_username: ocpadmin@internal
ovirt_password: super-secret-password
ovirt_insecure: true
```

1. Specify the hostname or address of your oVirt engine.
2. Specify the fully qualified domain name of your oVirt engine.
3. Specify the admin password for your oVirt engine.

3. Run the installer.

18.2.7. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The ./openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

Procedure
1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N " -f <path>/<file_name>
```

Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

**NOTE**

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the `x86_64` architecture, do not create a key that uses the `ed25519` algorithm. Instead, create a key that uses the `rsa` or `ecdsa` algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_rsa.pub` public key:

```
$ cat ~/.ssh/id_rsa.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `/openshift-install gather` command.

**NOTE**

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

a. If the `ssh-agent` process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

**Example output**

```
Agent pid 31874
```

**NOTE**

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the `ssh-agent`:

```
$ ssh-add <path>/<file_name>
```
Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

Example output

Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

18.2.8. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on your provisioning machine.

Prerequisites

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

   IMPORTANT

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   IMPORTANT

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   $ tar -xvf openshift-install-linux.tar.gz

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull
secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

18.2.9. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

Prerequisites

- Open the `ovirt-imageio` port to the Manager from the machine running the installer. By default, the port is 54322.

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Change to the directory that contains the installation program and initialize the cluster deployment:

   ```bash
   $ ./openshift-install create cluster --dir <installation_directory> \ 
   --log-level=info
   ```

   1. For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

   2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

   **IMPORTANT**

   Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

   Respond to the installation program prompts.

   a. Optional: For SSH Public Key, select a password-less public key, such as `~/.ssh/id_rsa.pub`. This key authenticates connections with the new OpenShift Container Platform cluster.
NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, select an SSH key that your ssh-agent process uses.

b. For **Platform**, select ovirt.

c. For **Engine FQDN[:PORT]**, enter the fully qualified domain name (FQDN) of the RHV environment.
   For example:
   
   rhv-env.virtlab.example.com:443

d. The installer automatically generates a CA certificate. For **Would you like to use the above certificate to connect to the Manager?**, answer **y** or **N**. If you answer **N**, you must install OpenShift Container Platform in insecure mode.

e. For **Engine username**, enter the user name and profile of the RHV administrator using this format:

   `<username>@<profile>`

   For **<username>**, specify the user name of an RHV administrator. For **<profile>**, specify the login profile, which you can get by going to the RHV Administration Portal login page and reviewing the **Profile** dropdown list. For example: **admin@internal**.

f. For **Engine password**, enter the RHV admin password.

g. For **Cluster**, select the RHV cluster for installing OpenShift Container Platform.

h. For **Storage domain**, select the storage domain for installing OpenShift Container Platform.

i. For **Network**, select a virtual network that has access to the RHV Manager REST API.

j. For **Internal API Virtual IP**, enter the static IP address you set aside for the cluster’s REST API.

k. For **Ingress virtual IP**, enter the static IP address you reserved for the wildcard apps domain.

l. For **Base Domain**, enter the base domain of the OpenShift Container Platform cluster. If this cluster is exposed to the outside world, this must be a valid domain recognized by DNS infrastructure. For example, enter: **virtlab.example.com**

m. For **Cluster Name**, enter the name of the cluster. For example, **my-cluster**. Use cluster name from the externally registered/resolvable DNS entries you created for the OpenShift Container Platform REST API and apps domain names. The installation program also gives this name to the cluster in the RHV environment.

n. For **Pull Secret**, copy the pull secret from the **pull-secret.txt** file you downloaded earlier and paste it here. You can also get a copy of the same pull secret from the Red Hat OpenShift Cluster Manager.
NOTE

If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.

When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the `kubeadmin` user, display in your terminal.

Example output

```
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-W15AL"
INFO Time elapsed: 36m22s
```

NOTE

The cluster access and credential information also outputs to `<installation_directory>/openshift_install.log` when an installation succeeds.

IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

IMPORTANT

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

IMPORTANT

You have completed the steps required to install the cluster. The remaining steps show you how to verify the cluster and troubleshoot the installation.
18.2.10. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.10. Download and install the new version of oc.

Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

**Procedure**

2. Select the appropriate version in the Version drop-down menu.
3. Click Download Now next to the OpenShift v4.10 Linux Client entry and save the file.
4. Unpack the archive:
   
   ```
   $ tar xvzf <file>
   ```
5. Place the oc binary in a directory that is on your PATH.
   
   To check your PATH, execute the following command:

   ```
   $ echo $PATH
   ```

After you install the OpenShift CLI, it is available using the oc command:

```
$ oc <command>
```

Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version in the Version drop-down menu.
3. Click Download Now next to the OpenShift v4.10 Windows Client entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the oc binary to a directory that is on your PATH.
   
   To check your PATH, open the command prompt and execute the following command:

   ```
   C:\> path
   ```
After you install the OpenShift CLI, it is available using the `oc` command:

```bash
C:> oc <command>
```

**Installing the OpenShift CLI on macOS**

You can install the OpenShift CLI (`oc`) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.10 MacOSX Client entry and save the file.

4. Unpack and unzip the archive.

5. Move the `oc` binary to a directory on your PATH. To check your `PATH`, open a terminal and execute the following command:

```bash
$ echo $PATH
```

After you install the OpenShift CLI, it is available using the `oc` command:

```bash
$ oc <command>
```

To learn more, see Getting started with the OpenShift CLI.

**18.2.11. Logging in to the cluster by using the CLI**

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   **1** For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:
### 18.2.12. Verifying cluster status

You can verify your OpenShift Container Platform cluster’s status during or after installation.

#### Procedure

1. In the cluster environment, export the administrator’s kubeconfig file:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```
   
   _1_ For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server.

2. View the control plane and compute machines created after a deployment:

   ```bash
   $ oc get nodes
   ```

3. View your cluster’s version:

   ```bash
   $ oc get clusterversion
   ```

4. View your Operators’ status:

   ```bash
   $ oc get clusteroperator
   ```

5. View all running pods in the cluster:

   ```bash
   $ oc get pods -A
   ```

#### Troubleshooting

If the installation fails, the installation program times out and displays an error message. To learn more, see [Troubleshooting installation issues](#).

### 18.2.13. Accessing the OpenShift Container Platform web console on RHV

- $ oc whoami

  _Example output_

  `system:admin`

**Additional resources**

- See [Accessing the web console](#) for more details about accessing and understanding the OpenShift Container Platform web console.
After the OpenShift Container Platform cluster initializes, you can log in to the OpenShift Container Platform web console.

Procedure

2. Verify that the installation program creates the virtual machines.

3. Return to the command line where the installation program is running. When the installation program finishes, it displays the user name and temporary password for logging into the OpenShift Container Platform web console.

4. In a browser, open the URL of the OpenShift Container Platform web console. The URL uses this format:

   console-openshift-console.apps.<clusternamem>.<basedomain>  

   For `<clusternamem>.<basedomain>`, specify the cluster name and base domain.

   For example:

   console-openshift-console.apps.my-cluster.virtlab.example.com

18.2.14. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.10, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use `subscription watch` to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service

18.2.15. Troubleshooting common issues with installing on Red Hat Virtualization (RHV)

Here are some common issues you might encounter, along with proposed causes and solutions.

18.2.15.1. CPU load increases and nodes go into a Not Ready state

- **Symptom**: CPU load increases significantly and nodes start going into a Not Ready state.

- **Cause**: The storage domain latency might be too high, especially for control plane nodes.

- **Solution**: Make the nodes ready again by restarting the kubelet service:

  $ systemctl restart kubelet
Inspect the OpenShift Container Platform metrics service, which automatically gathers and reports on some valuable data such as the etcd disk sync duration. If the cluster is operational, use this data to help determine whether storage latency or throughput is the root issue. If so, consider using a storage resource that has lower latency and higher throughput.

To get raw metrics, enter the following command as kubeadmin or user with cluster-admin privileges:

```
```

To learn more, see Exploring Application Endpoints for the purposes of Debugging with OpenShift 4.x

### 18.2.15.2. Trouble connecting the OpenShift Container Platform cluster API

- **Symptom:** The installation program completes but the OpenShift Container Platform cluster API is not available. The bootstrap virtual machine remains up after the bootstrap process is complete. When you enter the following command, the response will time out.

  ```
  $ oc login -u kubeadmin -p *** <apiurl>
  ```

- **Cause:** The bootstrap VM was not deleted by the installation program and has not released the cluster’s API IP address.

- **Solution:** Use the `wait-for` subcommand to be notified when the bootstrap process is complete:

  ```
  $ ./openshift-install wait-for bootstrap-complete
  ```

  When the bootstrap process is complete, delete the bootstrap virtual machine:

  ```
  $ ./openshift-install destroy bootstrap
  ```

### 18.2.16. Post-installation tasks

After the OpenShift Container Platform cluster initializes, you can perform the following tasks.

- **Optional:** After deployment, add or replace SSH keys using the Machine Config Operator (MCO) in OpenShift Container Platform.

- **Optional:** Remove the `kubeadmin` user. Instead, use the authentication provider to create a user with cluster-admin privileges.

### 18.3. INSTALLING A CLUSTER ON RHV WITH CUSTOMIZATIONS

You can customize and install an OpenShift Container Platform cluster on Red Hat Virtualization (RHV), similar to the one shown in the following diagram.
The installation program uses installer-provisioned infrastructure to automate creating and deploying the cluster.

To install a customized cluster, you prepare the environment and perform the following steps:

1. Create an installation configuration file, the `install-config.yaml` file, by running the installation program and answering its prompts.

2. Inspect and modify parameters in the `install-config.yaml` file.

3. Make a working copy of the `install-config.yaml` file.

4. Run the installation program with a copy of the `install-config.yaml` file.

Then, the installation program creates the OpenShift Container Platform cluster.

For an alternative to installing a customized cluster, see Installing a default cluster.

**NOTE**

This installation program is available for Linux and macOS only.

18.3.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
You have a supported combination of versions in the Support Matrix for OpenShift Container Platform on Red Hat Virtualization (RHV).

You read the documentation on selecting a cluster installation method and preparing it for users.

If you use a firewall, you configured it to allow the sites that your cluster requires access to.

18.3.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.10, you require access to the internet to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- Access Quay.io to obtain the packages that are required to install your cluster.

- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

18.3.3. Requirements for the RHV environment

To install and run an OpenShift Container Platform version 4.10 cluster, the RHV environment must meet the following requirements.

Not meeting these requirements can cause the installation or process to fail. Additionally, not meeting these requirements can cause the OpenShift Container Platform cluster to fail days or weeks after installation.

The following requirements for CPU, memory, and storage resources are based on default values multiplied by the default number of virtual machines the installation program creates. These resources must be available in addition to what the RHV environment uses for non-OpenShift Container Platform operations.

By default, the installation program creates seven virtual machines during the installation process. First, it creates a bootstrap virtual machine to provide temporary services and a control plane while it creates the rest of the OpenShift Container Platform cluster. When the installation program finishes creating the cluster, deleting the bootstrap machine frees up its resources.

If you increase the number of virtual machines in the RHV environment, you must increase the resources accordingly.

**Requirements**

- The RHV version is 4.4.
The RHV environment has one data center whose state is **Up**.

The RHV data center contains an RHV cluster.

The RHV cluster has the following resources exclusively for the OpenShift Container Platform cluster:

- Minimum 28 vCPUs: four for each of the seven virtual machines created during installation.
- 112 GiB RAM or more, including:
  - 16 GiB or more for the bootstrap machine, which provides the temporary control plane.
  - 16 GiB or more for each of the three control plane machines which provide the control plane.
  - 16 GiB or more for each of the three compute machines, which run the application workloads.

The RHV storage domain must meet these etcd backend performance requirements.

For affinity group support:
One physical machine per worker or control plane. Workers and control planes can be on the same physical machine. For example, if you have three workers and three control planes, you need three physical machines. If you have four workers and three control planes, you need four physical machines.

- For hard anti-affinity (default): A minimum of three physical machines. For more than three worker nodes, one physical machine per worker or control plane. Workers and control planes can be on the same physical machine.
- For custom affinity groups: Ensure that the resources are appropriate for the affinity group rules that you define.

In production environments, each virtual machine must have 120 GiB or more. Therefore, the storage domain must provide 840 GiB or more for the default OpenShift Container Platform cluster. In resource-constrained or non-production environments, each virtual machine must have 32 GiB or more, so the storage domain must have 230 GiB or more for the default OpenShift Container Platform cluster.

To download images from the Red Hat Ecosystem Catalog during installation and update procedures, the RHV cluster must have access to an internet connection. The Telemetry service also needs an internet connection to simplify the subscription and entitlement process.

The RHV cluster must have a virtual network with access to the REST API on the RHV Manager. Ensure that DHCP is enabled on this network, because the VMs that the installer creates obtain their IP address by using DHCP.

A user account and group with the following least privileges for installing and managing an OpenShift Container Platform cluster on the target RHV cluster:

- **DiskOperator**
- **DiskCreator**
- **UserTemplateBasedVm**
- **TemplateOwner**
18.3.4. Verifying the requirements for the RHV environment

Verify that the RHV environment meets the requirements to install and run an OpenShift Container Platform cluster. Not meeting these requirements can cause failures.

**IMPORTANT**

These requirements are based on the default resources the installation program uses to create control plane and compute machines. These resources include vCPUs, memory, and storage. If you change these resources or increase the number of OpenShift Container Platform machines, adjust these requirements accordingly.

**Procedure**

1. Check that the RHV version supports installation of OpenShift Container Platform version 4.10.
   a. In the RHV Administration Portal, click the ? help icon in the upper-right corner and select About.
   b. In the window that opens, make a note of the RHV Software Version.
   c. Confirm that the RHV version is 4.4. For more information about supported version combinations, see Support Matrix for OpenShift Container Platform on RHV.

2. Inspect the data center, cluster, and storage.
   a. In the RHV Administration Portal, click Compute → Data Centers.
   b. Confirm that the data center where you plan to install OpenShift Container Platform is accessible.
   c. Click the name of that data center.
   d. In the data center details, on the Storage tab, confirm the storage domain where you plan to install OpenShift Container Platform is Active.
   e. Record the Domain Name for use later on.
   f. Confirm Free Space has at least 230 GiB.
g. Confirm that the storage domain meets **these etcd backend performance requirements**, which you **can measure by using the fio performance benchmarking tool**.

h. In the data center details, click the **Clusters** tab.

i. Find the RHV cluster where you plan to install OpenShift Container Platform. Record the cluster name for use later on.

3. **Inspect the RHV host resources.**

   a. In the RHV Administration Portal, click **Compute > Clusters**.

   b. Click the cluster where you plan to install OpenShift Container Platform.

   c. In the cluster details, click the **Hosts** tab.

   d. Inspect the hosts and confirm they have a combined total of at least 28 **Logical CPU Cores available exclusively** for the OpenShift Container Platform cluster.

   e. Record the number of available **Logical CPU Cores** for use later on.

   f. Confirm that these CPU cores are distributed so that each of the seven virtual machines created during installation can have four cores.

   g. Confirm that, all together, the hosts have 112 GiB of **Max free Memory for scheduling new virtual machines** distributed to meet the requirements for each of the following OpenShift Container Platform machines:

      - 16 GiB required for the bootstrap machine
      - 16 GiB required for each of the three control plane machines
      - 16 GiB for each of the three compute machines

   h. Record the amount of **Max free Memory for scheduling new virtual machines** for use later on.

4. **Verify that the virtual network for installing OpenShift Container Platform has access to the RHV Manager’s REST API.** From a virtual machine on this network, use curl to reach the RHV Manager’s REST API:

   ```bash
   $ curl -k -u <username>@<profile>:<password> \\
   https://<engine-fqdn>/ovirt-engine/api
   ``

   **1** For `<username>`, specify the user name of an RHV account with privileges to create and manage an OpenShift Container Platform cluster on RHV. For `<profile>`, specify the login profile, which you can get by going to the RHV Administration Portal login page and reviewing the **Profile** dropdown list. For `<password>`, specify the password for that user name.

   **2** For `<engine-fqdn>`, specify the fully qualified domain name of the RHV environment.

   For example:

   ```bash
   $ curl -k -u ocpadmin@internal:pw123 \\
   https://rhv-env.virtlab.example.com/ovirt-engine/api
   ```
18.3.5. Preparing the network environment on RHV

Configure two static IP addresses for the OpenShift Container Platform cluster and create DNS entries using these addresses.

**Procedure**

1. Reserve two static IP addresses
   a. On the network where you plan to install OpenShift Container Platform, identify two static IP addresses that are outside the DHCP lease pool.
   b. Connect to a host on this network and verify that each of the IP addresses is not in use. For example, use Address Resolution Protocol (ARP) to check that none of the IP addresses have entries:

   ```
   $ arp 10.35.1.19
   ```

   **Example output**

   ```
   10.35.1.19 (10.35.1.19) -- no entry
   ```

c. Reserve two static IP addresses following the standard practices for your network environment.

d. Record these IP addresses for future reference.

2. Create DNS entries for the OpenShift Container Platform REST API and apps domain names using this format:

   ```
   api.<cluster-name>.<base-domain>   <ip-address>  
   *.apps.<cluster-name>.<base-domain>   <ip-address>  
   ```

   1 For `<cluster-name>`, `<base-domain>`, and `<ip-address>`, specify the cluster name, base domain, and static IP address of your OpenShift Container Platform API.

   2 Specify the cluster name, base domain, and static IP address of your OpenShift Container Platform apps for Ingress and the load balancer.

   For example:

   ```
   api.my-cluster.virtlab.example.com 10.35.1.19
   *.apps.my-cluster.virtlab.example.com 10.35.1.20
   ```

18.3.6. Installing OpenShift Container Platform on RHV in insecure mode

By default, the installer creates a CA certificate, prompts you for confirmation, and stores the certificate to use during installation. You do not need to create or install one manually.

Although it is not recommended, you can override this functionality and install OpenShift Container Platform without verifying a certificate by installing OpenShift Container Platform on RHV in **insecure** mode.
WARNING
Installing in insecure mode is not recommended, because it enables a potential attacker to perform a Man-in-the-Middle attack and capture sensitive credentials on the network.

Procedure

1. Create a file named ~/.ovirt/ovirt-config.yaml.

2. Add the following content to ovirt-config.yaml:

```yaml
ovirt_url: https://ovirt.example.com/ovirt-engine/api
ovirt_fqdn: ovirt.example.com
ovirt_pem_url: ""
ovirt_username: ocpadmin@internal
ovirt_password: super-secret-password
ovirt_insecure: true
```

   1 Specify the hostname or address of your oVirt engine.
   2 Specify the fully qualified domain name of your oVirt engine.
   3 Specify the admin password for your oVirt engine.

3. Run the installer.

18.3.7. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The ./openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

IMPORTANT
Do not skip this procedure in production environments, where disaster recovery and debugging is required.

Procedure
1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>
```

Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

**NOTE**

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the `x86_64` architecture, do not create a key that uses the `ed25519` algorithm. Instead, create a key that uses the `rsa` or `ecdsa` algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_rsa.pub` public key:

```
$ cat ~/.ssh/id_rsa.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `/openshift-install gather` command.

**NOTE**

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

a. If the `ssh-agent` process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

**Example output**

```
Agent pid 31874
```

**NOTE**

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the `ssh-agent`:

```
$ ssh-add <path>/<file_name>
```
Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

**Example output**

```bash
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

### 18.3.8. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on your provisioning machine.

**Prerequisites**

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space

**Procedure**

1. Access the **Infrastructure Provider** page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

   **IMPORTANT**

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   **IMPORTANT**

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ tar -xvf openshift-install-linux.tar.gz
   ```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull
secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

18.3.9. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Red Hat Virtualization (RHV).

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.
- Obtain service principal permissions at the subscription level.

Procedure

1. Create the install-config.yaml file.
   a. Change to the directory that contains the installation program and run the following command:

   ```
   $ ./openshift-install create install-config --dir <installation_directory>
   ```

   IMPORTANT

   Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

   b. Respond to the installation program prompts.
      i. For **SSH Public Key**, select a password-less public key, such as `~/.ssh/id_rsa.pub`. This key authenticates connections with the new OpenShift Container Platform cluster.

      NOTE

      For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, select an SSH key that your `ssh-agent` process uses.

      ii. For **Platform**, select **ovirt**.

      iii. For **Enter oVirt’s API endpoint URL**, enter the URL of the RHV API using this format:
For `<engine-fqdn>`, specify the fully qualified domain name of the RHV environment.

For example:

```bash
$ curl -k -u ocpadmin@internal:pw123 https://rhv-env.virtlab.example.com/ovirt-engine/api
```

iv. For Is the oVirt CA trusted locally?, enter Yes, because you have already set up a CA certificate. Otherwise, enter No.

v. For oVirt’s CA bundle, if you entered Yes for the preceding question, copy the certificate content from `/etc/pki/ca-trust/source/anchors/ca.pem` and paste it here. Then, press Enter twice. Otherwise, if you entered No for the preceding question, this question does not appear.

vi. For oVirt engine username, enter the user name and profile of the RHV administrator using this format:

`<username>@<profile>`

For `<username>`, specify the user name of an RHV administrator. For `<profile>`, specify the login profile, which you can get by going to the RHV Administration Portal login page and reviewing the Profile dropdown list. Together, the user name and profile should look similar to this example:

```bash
ocpadmin@internal
```

vii. For oVirt engine password, enter the RHV admin password.

viii. For oVirt cluster, select the cluster for installing OpenShift Container Platform.

ix. For oVirt storage domain, select the storage domain for installing OpenShift Container Platform.

x. For oVirt network, select a virtual network that has access to the RHV Manager REST API.

xi. For Internal API Virtual IP, enter the static IP address you set aside for the cluster’s REST API.

xii. For Ingress virtual IP, enter the static IP address you reserved for the wildcard apps domain.

xiii. For Base Domain, enter the base domain of the OpenShift Container Platform cluster. If this cluster is exposed to the outside world, this must be a valid domain recognized by DNS infrastructure. For example, enter: virtlab.example.com

xiv. For Cluster Name, enter the name of the cluster. For example, my-cluster. Use cluster name from the externally registered/resolvable DNS entries you created for the OpenShift Container Platform REST API and apps domain names. The installation
program also gives this name to the cluster in the RHV environment.

xv. For Pull Secret, copy the pull secret from the pull-secret.txt file you downloaded earlier and paste it here. You can also get a copy of the same pull secret from the Red Hat OpenShift Cluster Manager.

2. Modify the install-config.yaml file. You can find more information about the available parameters in the "Installation configuration parameters" section.

NOTE

If you have any intermediate CA certificates on the Manager, verify that the certificates appear in the ovirt-config.yaml file and the install-config.yaml file. If they do not appear, add them as follows:

1. In the ~/.ovirt/ovirt-config.yaml file:

[ovirt_ca_bundle]: |
-----BEGIN CERTIFICATE-----
<MY_TRUSTED_CA>
-----END CERTIFICATE-----

2. In the install-config.yaml file:

[additionalTrustBundle]: |
-----BEGIN CERTIFICATE-----
<MY_TRUSTED_CA>
-----END CERTIFICATE-----

3. Back up the install-config.yaml file so that you can use it to install multiple clusters.

IMPORTANT

The install-config.yaml file is consumed during the installation process. If you want to reuse the file, you must back it up now.

18.3.9.1. Example install-config.yaml files for Red Hat Virtualization (RHV)

You can customize the OpenShift Container Platform cluster the installation program creates by changing the parameters and parameter values in the install-config.yaml file.

The following examples are specific to installing OpenShift Container Platform on RHV.

install-config.yaml is located in <installation_directory>, which you specified when you ran the following command.

$ ./openshift-install create install-config --dir <installation_directory>
NOTE

- These example files are provided for reference only. You must obtain your `install-config.yaml` file by using the installation program.

- Changing the `install-config.yaml` file can increase the resources your cluster requires. Verify that your RHV environment has those additional resources. Otherwise, the installation or cluster will fail.

Example default `install-config.yaml` file

```yaml
apiVersion: v1
baseDomain: example.com
compute:
  - architecture: amd64
    hyperthreading: Enabled
    name: worker
    platform: {}
    replicas: 3
controlPlane:
  architecture: amd64
  hyperthreading: Enabled
  name: master
  platform: {}
  replicas: 3
metadata:
  creationTimestamp: null
  name: my-cluster
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
      hostPrefix: 23
  machineNetwork:
    - cidr: 10.0.0.0/16
  networkType: OpenShiftSDN
  serviceNetwork:
    - 172.30.0.0/16
platform:
ovirt:
  api_vip: 10.46.8.230
  ingress_vip: 192.168.1.5
  ovirt_cluster_id: 68833f9f-e89c-4891-b768-e2ba0815b76b
  ovirt_storage_domain_id: ed7b0f4e-0e96-492a-8ff-279213ee1468
  ovirt_network_name: ovirtmgmt
  vnicProfileID: 3fa86930-0be5-4052-b667-b79f0a729692
  publish: External
  pullSecret: '{"auths": ...}'
  sshKey: ssh-ed12345 AAAA...
```

Example minimal `install-config.yaml` file

```yaml
apiVersion: v1
baseDomain: example.com
metadata:
  name: test-cluster
```
Example Custom machine pools in an install-config.yaml file

apiVersion: v1
baseDomain: example.com
controlPlane:
  name: master
  platform:
    ovirt:
      cpu:
        cores: 4
        sockets: 2
      memoryMB: 65536
      osDisk:
        sizeGB: 100
        vmType: server
      replicas: 3
  compute:
    - name: worker
      platform:
        ovirt:
          cpu:
            cores: 4
            sockets: 4
          memoryMB: 65536
          osDisk:
            sizeGB: 200
            vmType: server
          replicas: 5
  metadata:

        api_vip: 10.46.8.230
        ingress_vip: 10.46.8.232
        ovirt_cluster_id: 68833f9f-e89c-4891-b768-e2ba0815b76b
        ovirt_storage_domain_id: ed7b0f4e-0e96-492a-8ff-279213ee1468
        ovirt_network_name: ovirtmgmt
        vnicProfileID: 3fa86930-0be5-4052-b667-b79f0a729692
        pullSecret: '{"auths": ...}"
        sshKey: ssh-ed12345 AAAA...

Example non-enforcing affinity group
It is recommended to add a non-enforcing affinity group to distribute the control plane and workers, if possible, to use as much of the cluster as possible.
Example removing all affinity groups for a non-production lab setup

For non-production lab setups, you must remove all affinity groups to concentrate the OpenShift Container Platform cluster on the few hosts you have.

```
platform:
  ovirt:
    affinityGroups:
      - description: AffinityGroup to place each compute machine on a separate host
        enforcing: true
        name: compute
        priority: 3
      - description: AffinityGroup to place each control plane machine on a separate host
        enforcing: true
        name: controlplane
        priority: 5
      - description: AffinityGroup to place worker nodes and control plane nodes on separate hosts
        enforcing: false
        name: openshift
        priority: 5

compute:
  - architecture: amd64
    hyperthreading: Enabled
    name: worker
    platform:
      ovirt:
        affinityGroupsNames:
          - compute
          - openshift
        replicas: 3

controlPlane:
  architecture: amd64
  hyperthreading: Enabled
  name: master
  platform:
    ovirt:
      affinityGroupsNames:
        - controlplane
        - openshift
      replicas: 3
```

---

platform:
  ovirt:
    affinityGroups: []
compute:
  - architecture: amd64
    hyperthreading: Enabled
    name: worker
    platform:
      ovirt:
        affinityGroupsNames: []
        replicas: 3

controlPlane:
  architecture: amd64
  hyperthreading: Enabled
  name: master
  platform:
18.3.9.2. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide a customized `install-config.yaml` installation configuration file that describes the details for your environment.

**NOTE**

After installation, you cannot modify these parameters in the `install-config.yaml` file.

18.3.9.2.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

**Table 18.1. Required parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is <strong>v1</strong>. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the <code>baseDomain</code> and <code>metadata.name</code> parameter values that uses the <code>&lt;metadata.name&gt;.&lt;baseDomain&gt;</code> format.</td>
<td>A fully-qualified domain or subdomain name, such as <code>example.com</code>.</td>
</tr>
<tr>
<td>metadata</td>
<td>Kubernetes resource <code>ObjectMeta</code>, from which only the <code>name</code> parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of <code>{{.metadata.name}}.{{.baseDomain}}</code>.</td>
<td>String of lowercase letters, hyphens (-), and periods (.), such as <code>dev</code>.</td>
</tr>
</tbody>
</table>
### platform

The configuration for the specific platform upon which to perform the installation: alibabacloud, aws, baremetal, azure, ibmcloud, openstack, ovirt, vsphere, or {}. For additional information about platform.<platform> parameters, consult the table for your specific platform that follows.

### pullSecret

Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.

```json
{
    "auths":{
        "cloud.openshift.com":{
            "auth":"b3Blb=",
            "email":"you@example.com"
        },
        "quay.io":{
            "auth":"b3Blb=",
            "email":"you@example.com"
        }
    }
}
```

### 18.3.9.2.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

#### Table 18.2. Network parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
</tbody>
</table>

**NOTE**

You cannot modify parameters specified by the networking object after installation.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking.network Type</td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN.</td>
</tr>
<tr>
<td>networking.clusterNetwork</td>
<td>The IP address blocks for pods.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td>The default value is 10.128.0.0/14 with a host prefix of /23.</td>
<td>networking:</td>
</tr>
<tr>
<td></td>
<td>If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- cidr: 10.128.0.0/14</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- hostPrefix: 23</td>
</tr>
<tr>
<td>networking.clusterNetwork.cidr</td>
<td>Required if you use networking.clusterNetwork. An IP address block.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td>networking.clusterNetwork.hostPrefix</td>
<td>The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given cidr. A hostPrefix value of 23 provides 510 (2^(32 - 23) - 2) pod IP addresses.</td>
<td>A subnet prefix.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The default value is 23.</td>
</tr>
<tr>
<td>networking.serviceNetwork</td>
<td>The IP address block for services. The default value is 172.30.0.0/16.</td>
<td>An array with an IP address block in CIDR format. For example:</td>
</tr>
<tr>
<td></td>
<td>The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.</td>
<td>networking:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- 172.30.0.0/16</td>
</tr>
<tr>
<td>networking.machineNetwork</td>
<td>The IP address blocks for machines.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td>If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td>networking:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you specify multiple IP kernel arguments, the machineNetwork.cidr value must be the CIDR of the primary network.</td>
<td>- cidr: 10.0.0.0/16</td>
</tr>
</tbody>
</table>
### Networking.machineNetwork

Required if you use `networking.machineNetwork`. An IP address block. The default value is `10.0.0.0/16` for all platforms other than libvirt. For libvirt, the default value is `192.168.126.0/24`.

**NOTE**

Set the `networking.machineNetwork` to match the CIDR that the preferred NIC resides in.

### 18.3.9.2.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

**Table 18.3. Optional parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>cgroupsV2</td>
<td>Enables Linux control groups version 2 (cgroups v2) on specific nodes in your cluster. The OpenShift Container Platform process for enabling cgroups v2 disables all cgroup version 1 controllers and hierarchies. The OpenShift Container Platform cgroups version 2 feature is in Developer Preview and is not supported by Red Hat at this time.</td>
<td>true</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of MachinePool objects. For details, see the “Additional RHV parameters for machine pools” table.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------</td>
</tr>
<tr>
<td>compute.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>s390x</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td>compute.hyperthreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td></td>
</tr>
<tr>
<td>compute.name</td>
<td>Required if you use <code>compute</code>. The name of the machine pool.</td>
<td>worker</td>
</tr>
<tr>
<td>compute.platform</td>
<td>Required if you use <code>compute</code>. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <code>controlPlane.platform</code> parameter value.</td>
<td>alibaba, aws, azure, gcp, ibmcloud, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td>compute.replicas</td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td>controlPlane</td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of <code>MachinePool</code> objects. For details, see the &quot;Additional RHV parameters for machine pools&quot; table.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------</td>
</tr>
<tr>
<td><code>controlPlane.architecture</code></td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>s390x</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td><code>controlPlane.hypertreading</code></td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td><code>Enabled</code> or <code>Disabled</code></td>
</tr>
<tr>
<td><strong>IMPORTANT</strong></td>
<td>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td></td>
</tr>
<tr>
<td><code>controlPlane.name</code></td>
<td>Required if you use <code>controlPlane</code>. The name of the machine pool.</td>
<td><code>master</code></td>
</tr>
<tr>
<td><code>controlPlane.platform</code></td>
<td>Required if you use <code>controlPlane</code>. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the <code>compute.platform</code> parameter value.</td>
<td><code>alibaba, aws, azure, gcp, ibmcloud, openstack, ovirt, vsphere, or {}</code></td>
</tr>
<tr>
<td><code>controlPlane.replicas</code></td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is <code>3</code>, which is the default value.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------------------</td>
</tr>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (&quot;&quot;&quot;).</td>
</tr>
<tr>
<td>fips</td>
<td>Enable or disable FIPS mode. The default is false (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</td>
<td>false or true</td>
</tr>
</tbody>
</table>

**NOTE**

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Platform Operators reference content.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>imageContentSources</td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects. Includes a <code>source</code> and, optionally, <code>mirrors</code>, as described in the following rows of this table.</td>
</tr>
<tr>
<td>imageContentSources.source</td>
<td>Required if you use <code>imageContentSources</code>. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td>imageContentSources.mirrors</td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
<tr>
<td>publish</td>
<td>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</td>
<td><code>Internal</code> or <code>External</code>. The default value is <code>External</code>. Setting this field to <code>Internal</code> is not supported on non-cloud platforms and IBM Cloud. <strong>IMPORTANT</strong> If the value of the field is set to <code>Internal</code>, the cluster will become non-functional. For more information, refer to BZ#1953035.</td>
</tr>
<tr>
<td>sshKey</td>
<td>The SSH key or keys to authenticate access your cluster machines.</td>
<td>One or more keys. For example: <code>sshKey: &lt;key1&gt; &lt;key2&gt; &lt;key3&gt;</code></td>
</tr>
</tbody>
</table>

**18.3.9.2.4. Additional Red Hat Virtualization (RHV) configuration parameters**

Additional RHV configuration parameters are described in the following table:
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>platform.ovirt.ovirt_cluster_id</code></td>
<td>Required. The Cluster where the VMs will be created.</td>
<td>String. For example: <code>68833f9f-e89c-4891-b768-e2ba0815b76b</code></td>
</tr>
<tr>
<td><code>platform.ovirt.ovirt_storage_domain_id</code></td>
<td>Required. The Storage Domain ID where the VM disks will be created.</td>
<td>String. For example: <code>ed7b0f4e-0e96-492a-8fff-279213ee1468</code></td>
</tr>
<tr>
<td><code>platform.ovirt.ovirt_network_name</code></td>
<td>Required. The network name where the VM nics will be created.</td>
<td>String. For example: <code>ocpcluster</code></td>
</tr>
<tr>
<td><code>platform.ovirt.vnicProfileID</code></td>
<td>Required. The vNIC profile ID of the VM network interfaces. This can be inferred if the cluster network has a single profile.</td>
<td>String. For example: <code>3fa86930-0be5-4052-b667-b79f0a729692</code></td>
</tr>
<tr>
<td><code>platform.ovirt.api_vip</code></td>
<td>Required. An IP address on the machine network that will be assigned to the API virtual IP (VIP). You can access the OpenShift API at this endpoint.</td>
<td>String. Example: <code>10.46.8.230</code></td>
</tr>
<tr>
<td><code>platform.ovirt.ingress_vip</code></td>
<td>Required. An IP address on the machine network that will be assigned to the Ingress virtual IP (VIP).</td>
<td>String. Example: <code>10.46.8.232</code></td>
</tr>
<tr>
<td><code>platform.ovirt.affinityGroups</code></td>
<td>Optional. A list of affinity groups to create during the installation process.</td>
<td>List of objects.</td>
</tr>
<tr>
<td><code>platform.ovirt.affinityGroups.description</code></td>
<td>Required if you include <code>platform.ovirt.affinityGroups</code>. A description of the affinity group.</td>
<td>String. Example: <code>AffinityGroup for spreading each compute machine to a different host</code></td>
</tr>
<tr>
<td><code>platform.ovirt.affinityGroups.enforcing</code></td>
<td>Required if you include <code>platform.ovirt.affinityGroups</code>. When set to <code>true</code>, RHV does not provision any machines if not enough hardware nodes are available. When set to <code>false</code>, RHV does provision machines even if not enough hardware nodes are available, resulting in multiple virtual machines being hosted on the same physical machine.</td>
<td>String. Example: <code>true</code></td>
</tr>
<tr>
<td><code>platform.ovirt.affinityGroups.name</code></td>
<td>Required if you include <code>platform.ovirt.affinityGroups</code>. The name of the affinity group.</td>
<td>String. Example: <code>compute</code></td>
</tr>
</tbody>
</table>
platform.ovirt.affinityGroups.priority

Required if you include platform.ovirt.affinityGroups. The priority given to an affinity group when platform.ovirt.affinityGroups.enforcing = false. RHV applies affinity groups in the order of priority, where a greater number takes precedence over a lesser one. If multiple affinity groups have the same priority, the order in which they are applied is not guaranteed.

Integer. Example: 3

18.3.9.2.5. Additional RHV parameters for machine pools

Additional RHV configuration parameters for machine pools are described in the following table:

Table 18.5. Additional RHV parameters for machine pools

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;machine-pool&gt;.platform.ovirt.cpu</td>
<td>Optional. Defines the CPU of the VM.</td>
<td>Object</td>
</tr>
<tr>
<td>&lt;machine-pool&gt;.platform.ovirt.cpu.cores</td>
<td>Required if you use &lt;machine-pool&gt;.platform.ovirt.cpu. The number of cores. Total virtual CPUs (vCPUs) is cores * sockets.</td>
<td>Integer</td>
</tr>
<tr>
<td>&lt;machine-pool&gt;.platform.ovirt.cpusockets</td>
<td>Required if you use &lt;machine-pool&gt;.platform.ovirt.cpu. The number of sockets per core. Total virtual CPUs (vCPUs) is cores * sockets.</td>
<td>Integer</td>
</tr>
<tr>
<td>&lt;machine-pool&gt;.platform.ovirt.memoryMB</td>
<td>Optional. Memory of the VM in MiB.</td>
<td>Integer</td>
</tr>
<tr>
<td>&lt;machine-pool&gt;.platform.ovirt.instanceTypeID</td>
<td>Optional. An instance type UUID, such as 00000000-0000-0000-0000-0000000000f1, which you can get from the https://&lt;engine-fqdn&gt;/ovirt-engine/api/instancetypes endpoint.</td>
<td>String of UUID</td>
</tr>

When the field is omitted, the default is <code>none</code>. Supported values: <code>none</code>, <code>resize_and_pin</code>. For more information, see Setting NUMA Nodes in the Virtual Machine Management Guide.</td>
<td>String</td>
</tr>
<tr>
<td><code>&lt;machine-pool&gt;.platform.ovirt.hugepages</code></td>
<td>Optional. Hugepages is the size in KiB for defining hugepages in a VM. Supported values: <code>2048</code> or <code>1048576</code>. For more information, see Configuring Huge Pages in the Virtual Machine Management Guide.</td>
<td>Integer</td>
</tr>
</tbody>
</table>

**NOTE**

You can replace `<machine-pool>` with `controlPlane` or `compute`. 
18.3.10. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

**Prerequisites**

- Open the `ovirt-imageio` port to the Manager from the machine running the installer. By default, the port is **54322**.

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Change to the directory that contains the installation program and initialize the cluster deployment:

   ```bash
   $ ./openshift-install create cluster --dir <installation_directory> \  
   --log-level=info
   
   For `<installation_directory>`, specify the location of your customized `./install-config.yaml` file.

   To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

   **NOTE**

   If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.

   When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the `kubeadmin` user, display in your terminal.

   **Example output**

   ```text
   ...  
   INFO Install complete!  
   INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'  
   INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com  
   INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-Wt5AL"  
   INFO Time elapsed: 36m22s
   ```
The cluster access and credential information also outputs to `<installation_directory>/openshift_install.log` when an installation succeeds.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

**IMPORTANT**

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

**IMPORTANT**

You have completed the steps required to install the cluster. The remaining steps show you how to verify the cluster and troubleshoot the installation.

### 18.3.11. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (`oc`) to interact with OpenShift Container Platform from a command-line interface. You can install `oc` on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of `oc`, you cannot use it to complete all of the commands in OpenShift Container Platform 4.10. Download and install the new version of `oc`.

**Installing the OpenShift CLI on Linux**

You can install the OpenShift CLI (`oc`) binary on Linux by using the following procedure.

**Procedure**

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.10 Linux Client entry and save the file.
4. Unpack the archive:

    $ tar xzvf <file>

5. Place the **oc** binary in a directory that is on your **PATH**.
   To check your **PATH**, execute the following command:

    $ echo $PATH

After you install the OpenShift CLI, it is available using the **oc** command:

    $ oc <command>

### Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.

3. Click **Download Now** next to the **OpenShift v4.10 Windows Client** entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the **oc** binary to a directory that is on your **PATH**.
   To check your **PATH**, open the command prompt and execute the following command:

    C:\> path

After you install the OpenShift CLI, it is available using the **oc** command:

    C:\> oc <command>

### Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.

3. Click **Download Now** next to the **OpenShift v4.10 MacOSX Client** entry and save the file.

4. Unpack and unzip the archive.

5. Move the **oc** binary to a directory on your **PATH**.
   To check your **PATH**, open a terminal and execute the following command:
After you install the OpenShift CLI, it is available using the oc command:

$ oc <command>

18.3.12. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster kubeconfig file. The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the oc CLI.

Procedure

1. Export the kubeadmin credentials:

   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig

   For <installation_directory>, specify the path to the directory that you stored the installation files in.

2. Verify you can run oc commands successfully using the exported configuration:

   $ oc whoami

   Example output

   system:admin

To learn more, see Getting started with the OpenShift CLI.

18.3.13. Verifying cluster status

You can verify your OpenShift Container Platform cluster’s status during or after installation.

Procedure

1. In the cluster environment, export the administrator’s kubeconfig file:

   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig

   For <installation_directory>, specify the path to the directory that you stored the installation files in.
The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server.

2. View the control plane and compute machines created after a deployment:

   ```
   $ oc get nodes
   ```

3. View your cluster’s version:

   ```
   $ oc get clusterversion
   ```

4. View your Operators' status:

   ```
   $ oc get clusteroperator
   ```

5. View all running pods in the cluster:

   ```
   $ oc get pods -A
   ```

**Troubleshooting**

If the installation fails, the installation program times out and displays an error message. To learn more, see [Troubleshooting installation issues](#).

### 18.3.14. Accessing the OpenShift Container Platform web console on RHV

After the OpenShift Container Platform cluster initializes, you can log in to the OpenShift Container Platform web console.

**Procedure**

1. Optional: In the Red Hat Virtualization (RHV) Administration Portal, open **Compute → Cluster**.

2. Verify that the installation program creates the virtual machines.

3. Return to the command line where the installation program is running. When the installation program finishes, it displays the user name and temporary password for logging into the OpenShift Container Platform web console.

4. In a browser, open the URL of the OpenShift Container Platform web console. The URL uses this format:

   ```
   console-openshift-console.apps.<clusternames>.<basedomain>  
   ```

   For `<clusternames>.<basedomain>`, specify the cluster name and base domain.

   For example:

   ```
   console-openshift-console.apps.my-cluster.virtlab.example.com
   ```

### 18.3.15. Telemetry access for OpenShift Container Platform
In OpenShift Container Platform 4.10, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service

18.3.16. Troubleshooting common issues with installing on Red Hat Virtualization (RHV)

Here are some common issues you might encounter, along with proposed causes and solutions.

18.3.16.1. CPU load increases and nodes go into a Not Ready state

- **Symptom:** CPU load increases significantly and nodes start going into a **Not Ready** state.
- **Cause:** The storage domain latency might be too high, especially for control plane nodes.
- **Solution:**
  Make the nodes ready again by restarting the kubelet service:

  ```
  $ systemctl restart kubelet
  ```

  Inspect the OpenShift Container Platform metrics service, which automatically gathers and reports on some valuable data such as the etcd disk sync duration. If the cluster is operational, use this data to help determine whether storage latency or throughput is the root issue. If so, consider using a storage resource that has lower latency and higher throughput.

  To get raw metrics, enter the following command as kubeadm or user with cluster-admin privileges:

  ```
  ```

  To learn more, see Exploring Application Endpoints for the purposes of Debugging with OpenShift 4.x

18.3.16.2. Trouble connecting the OpenShift Container Platform cluster API

- **Symptom:** The installation program completes but the OpenShift Container Platform cluster API is not available. The bootstrap virtual machine remains up after the bootstrap process is complete. When you enter the following command, the response will time out.

  ```
  $ oc login -u kubeadmin -p *** <apiurl>
  ```

- **Cause:** The bootstrap VM was not deleted by the installation program and has not released the cluster’s API IP address.

- **Solution:** Use the **wait-for** subcommand to be notified when the bootstrap process is complete:
When the bootstrap process is complete, delete the bootstrap virtual machine:

```
$ ./openshift-install destroy bootstrap
```

### 18.3.17. Post-installation tasks

After the OpenShift Container Platform cluster initializes, you can perform the following tasks.

- Optional: After deployment, add or replace SSH keys using the Machine Config Operator (MCO) in OpenShift Container Platform.

- Optional: Remove the `kubeadmin` user. Instead, use the authentication provider to create a user with cluster-admin privileges.

### 18.3.18. Next steps

- Customize your cluster.

- If necessary, you can opt out of remote health reporting.

### 18.4. INSTALLING A CLUSTER ON RHV WITH USER-PROVISIONED INFRASTRUCTURE

In OpenShift Container Platform version 4.10, you can install a customized OpenShift Container Platform cluster on Red Hat Virtualization (RHV) and other infrastructure that you provide. The OpenShift Container Platform documentation uses the term *user-provisioned infrastructure* to refer to this infrastructure type.

The following diagram shows an example of a potential OpenShift Container Platform cluster running on a RHV cluster.
The RHV hosts run virtual machines that contain both control plane and compute pods. One of the
hosts also runs a Manager virtual machine and a bootstrap virtual machine that contains a temporary
control plane pod.]

18.4.1. Prerequisites

The following items are required to install an OpenShift Container Platform cluster on a RHV
environment.

- You reviewed details about the OpenShift Container Platform installation and update
  processes.
- You read the documentation on selecting a cluster installation method and preparing it for
  users.
- You have a supported combination of versions in the Support Matrix for OpenShift Container
  Platform on Red Hat Virtualization (RHV).

18.4.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.10, you require access to the internet to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform
  subscription management. If the cluster has internet access and you do not disable Telemetry,
  that service automatically entitles your cluster.
Access [Quay.io](https://quay.io) to obtain the packages that are required to install your cluster.

Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 18.4.3. Requirements for the RHV environment

To install and run an OpenShift Container Platform version 4.10 cluster, the RHV environment must meet the following requirements.

Not meeting these requirements can cause the installation or process to fail. Additionally, not meeting these requirements can cause the OpenShift Container Platform cluster to fail days or weeks after installation.

The following requirements for CPU, memory, and storage resources are based on default values multiplied by the default number of virtual machines the installation program creates. These resources must be available in addition to what the RHV environment uses for non-OpenShift Container Platform operations.

By default, the installation program creates seven virtual machines during the installation process. First, it creates a bootstrap virtual machine to provide temporary services and a control plane while it creates the rest of the OpenShift Container Platform cluster. When the installation program finishes creating the cluster, deleting the bootstrap machine frees up its resources.

If you increase the number of virtual machines in the RHV environment, you must increase the resources accordingly.

**Requirements**

- The RHV version is 4.4.
- The RHV environment has one data center whose state is **Up**.
- The RHV data center contains an RHV cluster.
- The RHV cluster has the following resources exclusively for the OpenShift Container Platform cluster:
  - Minimum 28 vCPUs: four for each of the seven virtual machines created during installation.
  - 112 GiB RAM or more, including:
    - 16 GiB or more for the bootstrap machine, which provides the temporary control plane.
    - 16 GiB or more for each of the three control plane machines which provide the control plane.
- 16 GiB or more for each of the three compute machines, which run the application workloads.

- The RHV storage domain must meet these etcd backend performance requirements.

- In production environments, each virtual machine must have 120 GiB or more. Therefore, the storage domain must provide 840 GiB or more for the default OpenShift Container Platform cluster. In resource-constrained or non-production environments, each virtual machine must have 32 GiB or more, so the storage domain must have 230 GiB or more for the default OpenShift Container Platform cluster.

- To download images from the Red Hat Ecosystem Catalog during installation and update procedures, the RHV cluster must have access to an internet connection. The Telemetry service also needs an internet connection to simplify the subscription and entitlement process.

- The RHV cluster must have a virtual network with access to the REST API on the RHV Manager. Ensure that DHCP is enabled on this network, because the VMs that the installer creates obtain their IP address by using DHCP.

- A user account and group with the following least privileges for installing and managing an OpenShift Container Platform cluster on the target RHV cluster:
  - DiskOperator
  - DiskCreator
  - UserTemplateBasedVm
  - TemplateOwner
  - TemplateCreator
  - ClusterAdmin on the target cluster

**WARNING**

Apply the principle of least privilege: Avoid using an administrator account with **SuperUser** privileges on RHV during the installation process. The installation program saves the credentials you provide to a temporary **ovirt-config.yaml** file that might be compromised.

### 18.4.4. Verifying the requirements for the RHV environment

Verify that the RHV environment meets the requirements to install and run an OpenShift Container Platform cluster. Not meeting these requirements can cause failures.

**IMPORTANT**

These requirements are based on the default resources the installation program uses to create control plane and compute machines. These resources include vCPUs, memory, and storage. If you change these resources or increase the number of OpenShift Container Platform machines, adjust these requirements accordingly.
Procedure

1. Check that the RHV version supports installation of OpenShift Container Platform version 4.10.
   a. In the RHV Administration Portal, click the help icon in the upper-right corner and select About.
   b. In the window that opens, make a note of the RHV Software Version.
   c. Confirm that the RHV version is 4.4. For more information about supported version combinations, see Support Matrix for OpenShift Container Platform on RHV.

2. Inspect the data center, cluster, and storage.
   a. In the RHV Administration Portal, click Compute → Data Centers.
   b. Confirm that the data center where you plan to install OpenShift Container Platform is accessible.
   c. Click the name of that data center.
   d. In the data center details, on the Storage tab, confirm the storage domain where you plan to install OpenShift Container Platform is Active.
   e. Record the Domain Name for use later on.
   f. Confirm Free Space has at least 230 GiB.
   g. Confirm that the storage domain meets these etcd backend performance requirements, which you can measure by using the fio performance benchmarking tool.
   h. In the data center details, click the Clusters tab.
   i. Find the RHV cluster where you plan to install OpenShift Container Platform. Record the cluster name for use later on.

3. Inspect the RHV host resources.
   a. In the RHV Administration Portal, click Compute > Clusters.
   b. Click the cluster where you plan to install OpenShift Container Platform.
   c. In the cluster details, click the Hosts tab.
   d. Inspect the hosts and confirm they have a combined total of at least 28 Logical CPU Cores available exclusively for the OpenShift Container Platform cluster.
   e. Record the number of available Logical CPU Cores for use later on.
   f. Confirm that these CPU cores are distributed so that each of the seven virtual machines created during installation can have four cores.
   g. Confirm that, all together, the hosts have 112 GiB of Max free Memory for scheduling new virtual machines distributed to meet the requirements for each of the following OpenShift Container Platform machines:
      - 16 GiB required for the bootstrap machine
      - 16 GiB required for each of the three control plane machines
16 GiB for each of the three compute machines

h. Record the amount of **Max free Memory for scheduling new virtual machines** for use later on.

4. Verify that the virtual network for installing OpenShift Container Platform has access to the RHV Manager’s REST API. From a virtual machine on this network, use curl to reach the RHV Manager’s REST API:

```bash
$ curl -k -u <username>@<profile>:<password> \ 
  https://<engine-fqdn>/ovirt-engine/api
```

1. For `<username>`, specify the user name of an RHV account with privileges to create and manage an OpenShift Container Platform cluster on RHV. For `<profile>`, specify the login profile, which you can get by going to the RHV Administration Portal login page and reviewing the Profile dropdown list. For `<password>`, specify the password for that user name.

2. For `<engine-fqdn>`, specify the fully qualified domain name of the RHV environment.

For example:

```bash
$ curl -k -u ocpadmin@internal:pw123 \ 
  https://rhv-env.virtlab.example.com/ovirt-engine/api
```

### 18.4.5. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in **initramfs** during boot to fetch their Ignition config files.

During the initial boot, the machines require an HTTP or HTTPS server to establish a network connection to download their Ignition config files.

The machines are configured with static IP addresses. No DHCP server is required. Ensure that the machines have persistent IP addresses and hostnames.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

**Firewall**

Configure your firewall so your cluster has access to required sites.

See also:

- Red Hat Virtualization Manager firewall requirements
- Host firewall requirements

**Load balancers**

Configure one or preferably two layer-4 load balancers:
• Provide load balancing for ports 6443 and 22623 on the control plane and bootstrap machines. Port 6443 provides access to the Kubernetes API server and must be reachable both internally and externally. Port 22623 must be accessible to nodes within the cluster.

• Provide load balancing for port 443 and 80 for machines that run the Ingress router, which are usually compute nodes in the default configuration. Both ports must be accessible from within and outside the cluster.

DNS
Configure infrastructure-provided DNS to allow the correct resolution of the main components and services. If you use only one load balancer, these DNS records can point to the same IP address.

• Create DNS records for api.<cluster_name>.<base_domain> (internal and external resolution) and api-int.<cluster_name>.<base_domain> (internal resolution) that point to the load balancer for the control plane machines.

• Create a DNS record for *.apps.<cluster_name>.<base_domain> that points to the load balancer for the Ingress router. For example, ports 443 and 80 of the compute machines.

18.4.5.1. Network connectivity requirements
You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

**IMPORTANT**
In connected OpenShift Container Platform environments, all nodes are required to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

Table 18.6. Ports used for all-machine to all-machine communications

<table>
<thead>
<tr>

NTP configuration for user-provisioned infrastructure

OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for Configuring chrony time service.

18.4.6. Setting up the installation machine

To run the binary openshift-install installation program and Ansible scripts, set up the RHV Manager or an Red Hat Enterprise Linux (RHEL) computer with network access to the RHV environment and the REST API on the Manager.

Procedure

1. Update or install Python3 and Ansible. For example:

   ```
   # dnf update python3 ansible
   ```

2. Install the python3-ovirt-engine-sdk4 package to get the Python Software Development Kit.

3. Install the ovirt.image-template Ansible role. On the RHV Manager and other Red Hat Enterprise Linux (RHEL) machines, this role is distributed as the ovirt-ansible-image-template package. For example, enter:

   ```
   # dnf install ovirt-ansible-image-template
   ```

4. Install the ovirt.vm-infra Ansible role. On the RHV Manager and other RHEL machines, this role is distributed as the ovirt-ansible-vm-infra package.

   ```
   # dnf install ovirt-ansible-vm-infra
   ```
5. Create an environment variable and assign an absolute or relative path to it. For example, enter:

```
$ export ASSETS_DIR=./wrk
```

**NOTE**

The installation program uses this variable to create a directory where it saves important installation-related files. Later, the installation process reuses this variable to locate those asset files. Avoid deleting this assets directory; it is required for uninstalling the cluster.

### 18.4.7. Installing OpenShift Container Platform on RHV in insecure mode

By default, the installer creates a CA certificate, prompts you for confirmation, and stores the certificate to use during installation. You do not need to create or install one manually.

Although it is not recommended, you can override this functionality and install OpenShift Container Platform without verifying a certificate by installing OpenShift Container Platform on RHV in **insecure** mode.

**WARNING**

Installing in **insecure** mode is not recommended, because it enables a potential attacker to perform a Man-in-the-Middle attack and capture sensitive credentials on the network.

**Procedure**

1. Create a file named `~/.ovirt/ovirt-config.yaml`.

2. Add the following content to `ovirt-config.yaml`:

   ```yaml
   ovirt_url: https://ovirt.example.com/ovirt-engine/api
   ovirt_fqdn: ovirt.example.com
   ovirt_pem_url: ""
   ovirt_username: ocpadmin@internal
   ovirt_password: super-secret-password
   ovirt_insecure: true
   ```

   - Specify the hostname or address of your oVirt engine.
   - Specify the fully qualified domain name of your oVirt engine.
   - Specify the admin password for your oVirt engine.

3. Run the installer.
18.4.8. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH into the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH into your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The ./openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> 1
```

   Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the ~/.ssh/id_rsa.pub public key:

```
$ cat ~/.ssh/id_rsa.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the ./openshift-install gather command.
NOTE
On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.

a. If the ssh-agent process is not already running for your local user, start it as a background task:

```bash
$ eval "$(ssh-agent -s)"
```

Example output

```
Agent pid 31874
```

NOTE
If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the ssh-agent:

```bash
$ ssh-add <path>/<file_name>
```

Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

18.4.9. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on your provisioning machine.

Prerequisites

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.
3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

**IMPORTANT**

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

18.4.10. Downloading the Ansible playbooks

Download the Ansible playbooks for installing OpenShift Container Platform version 4.10 on RHV.

**Procedure**

- On your installation machine, run the following commands:

```
$ mkdir playbooks
$ cd playbooks
$ curl -s -L -X GET https://api.github.com/repos/openshift/installer/contents/upi/ovirt?ref=release-4.10 | grep 'download_url.*\.yml' | awk '{ print $2 }' | sed -r s/("\)/\)/g' | xargs -n 1 curl -O
```

**Next steps**

- After you download these Ansible playbooks, you must also create the environment variable for the assets directory and customize the `inventory.yml` file before you create an installation configuration file by running the installation program.
18.4.11. The inventory.yml file

You use the **inventory.yml** file to define and create elements of the OpenShift Container Platform cluster you are installing. This includes elements such as the Red Hat Enterprise Linux CoreOS (RHCOS) image, virtual machine templates, bootstrap machine, control plane nodes, and worker nodes. You also use **inventory.yml** to destroy the cluster.

The following **inventory.yml** example shows you the parameters and their default values. The quantities and numbers in these default values meet the requirements for running a production OpenShift Container Platform cluster in a RHV environment.

Example inventory.yml file

```yaml
---
all:
  vars:
    ovirt_cluster: "Default"
    ocp:
      assets_dir: "{{ lookup('env', 'ASSETS_DIR') }}"
      ovirt_config_path: "{{ lookup('env', 'HOME') }}/ovirt/ovirt-config.yaml"

# ---
# {op-system} section
# ---
rhcos:
  local_cmp_image_path: "/tmp/rhcos.qcow2.gz"
  local_image_path: "/tmp/rhcos.qcow2"

# ---
# Profiles section
# ---
control Plane:
  cluster: "{{ ovirt_cluster }}"
  memory: 16GiB
  sockets: 4
  cores: 1
  template: rhcos_tpl
  operating_system: "rhcos_x64"
  type: high_performance
  graphical_console:
    headless_mode: false
    protocol:
      - spice
      - vnc
  disks:
    - size: 120GiB
      name: os
      interface: virtio_scsi
      storage_domain: depot_nvme
      nics:
        - name: nic1
          network: lab
          profile: lab
```
compute:
  cluster: "{{ ovirt_cluster }}"
memory: 16GiB
sockets: 4
cores: 1
template: worker_rhcos_tpl
operating_system: "rhcos_x64"
type: high_performance

    network: lab
    profile: lab

# ---
# Virtual machines section
# ---
vms:
- name: "{{ metadata.infraID }}-bootstrap"
  ocp_type: bootstrap
  profile: "{{ control_plane }}"
  type: server
- name: "{{ metadata.infraID }}-master0"
  ocp_type: master
  profile: "{{ control_plane }}"
- name: "{{ metadata.infraID }}-master1"
  ocp_type: master
  profile: "{{ control_plane }}"
- name: "{{ metadata.infraID }}-master2"
  ocp_type: master
  profile: "{{ control_plane }}"
- name: "{{ metadata.infraID }}-worker0"
  ocp_type: worker
  profile: "{{ compute }}"
- name: "{{ metadata.infraID }}-worker1"
  ocp_type: worker
  profile: "{{ compute }}"
- name: "{{ metadata.infraID }}-worker2"
  ocp_type: worker
  profile: "{{ compute }}"

IMPORTANT
Enter values for parameters whose descriptions begin with "Enter." Otherwise, you can use the default value or replace it with a new value.
General section

- **ovirt_cluster**: Enter the name of an existing RHV cluster in which to install the OpenShift Container Platform cluster.

- **ocp.assets_dir**: The path of a directory the `openshift-install` installation program creates to store the files that it generates.

- **ocp.ovirt_config_path**: The path of the `ovirt-config.yaml` file the installation program generates, for example, `./wrk/install-config.yaml`. This file contains the credentials required to interact with the REST API of the Manager.

Red Hat Enterprise Linux CoreOS (RHCOS) section

- **image_url**: Enter the URL of the RHCOS image you specified for download.

- **local_cmp_image_path**: The path of a local download directory for the compressed RHCOS image.

- **local_image_path**: The path of a local directory for the extracted RHCOS image.

Profiles section

This section consists of two profiles:

- **control_plane**: The profile of the bootstrap and control plane nodes.

- **compute**: The profile of workers nodes in the compute plane.

These profiles have the following parameters. The default values of the parameters meet the minimum requirements for running a production cluster. You can increase or customize these values to meet your workload requirements.

- **cluster**: The value gets the cluster name from `ovirt_cluster` in the General Section.

- **memory**: The amount of memory, in GB, for the virtual machine.

- **sockets**: The number of sockets for the virtual machine.

- **cores**: The number of cores for the virtual machine.

- **template**: The name of the virtual machine template. If plan to install multiple clusters, and these clusters use templates that contain different specifications, prepend the template name with the ID of the cluster.

- **operating_system**: The type of guest operating system in the virtual machine. With oVirt/RHV version 4.4, this value must be `rhcos_x64` so the value of Ignition script can be passed to the VM.

- **type**: Enter `server` as the type of the virtual machine.

**IMPORTANT**

You must change the value of the `type` parameter from `high_performance` to `server`. 
- disks: The disk specifications. The control_plane and compute nodes can have different storage domains.

- size: The minimum disk size.

- name: Enter the name of a disk connected to the target cluster in RHV.

- interface: Enter the interface type of the disk you specified.

- storage_domain: Enter the storage domain of the disk you specified.

- nics: Enter the name and network the virtual machines use. You can also specify the virtual network interface profile. By default, NICs obtain their MAC addresses from the oVirt/RHV MAC pool.

Virtual machines section

This final section, vms, defines the virtual machines you plan to create and deploy in the cluster. By default, it provides the minimum number of control plane and worker nodes for a production environment.

vms contains three required elements:

- name: The name of the virtual machine. In this case, metadata.infraID prepends the virtual machine name with the infrastructure ID from the metadata.yml file.

- ocp_type: The role of the virtual machine in the OpenShift Container Platform cluster. Possible values are bootstrap, master, worker.

- profile: The name of the profile from which each virtual machine inherits specifications. Possible values in this example are control_plane or compute.

You can override the value a virtual machine inherits from its profile. To do this, you add the name of the profile attribute to the virtual machine in inventory.yml and assign it an overriding value. To see an example of this, examine the name: "{{ metadata.infraID }}-bootstrap" virtual machine in the preceding inventory.yml example: It has a type attribute whose value, server, overrides the value of the type attribute this virtual machine would otherwise inherit from the control_plane profile.

Metadata variables

For virtual machines, metadata.infraID prepends the name of the virtual machine with the infrastructure ID from the metadata.json file you create when you build the Ignition files.

The playbooks use the following code to read infraID from the specific file located in the ocp.assets_dir.

```yaml
---
- name: include metadata.json vars
  include_vars:
    file: "{{ ocp.assets_dir }}/metadata.json"
  name: metadata
...
```

18.4.12. Specifying the RHCOS image settings

Update the Red Hat Enterprise Linux CoreOS (RHCOS) image settings of the inventory.yml file. Later,
when you run this file one of the playbooks, it downloads a compressed Red Hat Enterprise Linux CoreOS (RHCOS) image from the `image_url` URL to the `local_cmp_image_path` directory. The playbook then uncompresses the image to the `local_image_path` directory and uses it to create oVirt/RHV templates.

Procedure

1. Locate the RHCOS image download page for the version of OpenShift Container Platform you are installing, such as [Index of /pub/openshift-v4/dependencies/rhcos/latest/latest](https://mirror.openshift.com/pub/openshift-v4/dependencies/rhcos/4.10/latest/rhcos-openstack.x86_64.qcow2.gz).

2. From that download page, copy the URL of an OpenStack `qcow2` image, such as `https://mirror.openshift.com/pub/openshift-v4/dependencies/rhcos/4.10/latest/rhcos-openstack.x86_64.qcow2.gz`.

3. Edit the `inventory.yml` playbook you downloaded earlier. In it, paste the URL as the value for `image_url`. For example:

   ```
   rhcos:
   "https://mirror.openshift.com/pub/openshift-v4/dependencies/rhcos/4.10/latest/rhcos-openstack.x86_64.qcow2.gz"
   ```

18.4.13. Creating the install config file

You create an installation configuration file by running the installation program, `openshift-install`, and responding to its prompts with information you specified or gathered earlier.

When you finish responding to the prompts, the installation program creates an initial version of the `install-config.yaml` file in the assets directory you specified earlier, for example, `./wrk/install-config.yaml`

The installation program also creates a file, `$HOME/.ovirt/ovirt-config.yaml`, that contains all the connection parameters that are required to reach the Manager and use its REST API.

**NOTE:** The installation process does not use values you supply for some parameters, such as `Internal API virtual IP` and `Ingress virtual IP`, because you have already configured them in your infrastructure DNS.

It also uses the values you supply for parameters in `inventory.yml`, like the ones for `oVirt cluster`, `oVirt storage`, and `oVirt network`. And uses a script to remove or replace these same values from `install-config.yaml` with the previously mentioned `virtual IPs`.

Procedure

1. Run the installation program:

   ```
   $ openshift-install create install-config --dir $ASSETS_DIR
   ```

2. Respond to the installation program’s prompts with information about your system.

**Example output**

```
? SSH Public Key /home/user/.ssh/id_dsa.pub
? Platform <ovirt>
? Enter ovirt-engine username <ocpadmin@internal>
```
For Internal API virtual IP and Ingress virtual IP, supply the IP addresses you specified when you configured the DNS service.

Together, the values you enter for the oVirt cluster and Base Domain prompts form the FQDN portion of URLs for the REST API and any applications you create, such as https://api.ocp4.example.org:6443/ and https://console-openshift-console.apps.ocp4.example.org.

You can get the pull secret from the Red Hat OpenShift Cluster Manager.

18.4.14. Customizing install-config.yaml

Here, you use three Python scripts to override some of the installation program’s default behaviors:

- By default, the installation program uses the machine API to create nodes. To override this default behavior, you set the number of compute nodes to zero replicas. Later, you use Ansible playbooks to create the compute nodes.

- By default, the installation program sets the IP range of the machine network for nodes. To override this default behavior, you set the IP range to match your infrastructure.

- By default, the installation program sets the platform to ovirt. However, installing a cluster on user-provisioned infrastructure is more similar to installing a cluster on bare metal. Therefore, you delete the ovirt platform section from install-config.yaml and change the platform to none. Instead, you use inventory.yml to specify all of the required settings.

NOTE

These snippets work with Python 3 and Python 2.
1. Set the number of compute nodes to zero replicas:

```bash
$ python3 -c 'import os, yaml
path = "%s/install-config.yaml" % os.environ["ASSETS_DIR"]
conf = yaml.safe_load(open(path))
conf["compute"][0]["replicas"] = 0
open(path, "w").write(yaml.dump(conf, default_flow_style=False))'
```

2. Set the IP range of the machine network. For example, to set the range to **172.16.0.0/16**, enter:

```bash
$ python3 -c 'import os, yaml
path = "%s/install-config.yaml" % os.environ["ASSETS_DIR"]
conf = yaml.safe_load(open(path))
conf["networking"]["machineNetwork"][0]["cidr"] = "172.16.0.0/16"
open(path, "w").write(yaml.dump(conf, default_flow_style=False))'
```

3. Remove the **ovirt** section and change the platform to **none**:

```bash
$ python3 -c 'import os, yaml
path = "%s/install-config.yaml" % os.environ["ASSETS_DIR"]
conf = yaml.safe_load(open(path))
platform = conf["platform"]
del platform["ovirt"]
platform["none"] = {}
open(path, "w").write(yaml.dump(conf, default_flow_style=False))'
```

**WARNING**

Red Hat Virtualization does not currently support installation with user-provisioned infrastructure on the oVirt platform. Therefore, you must set the platform to **none**, allowing OpenShift Container Platform to identify each node as a bare-metal node and the cluster as a bare-metal cluster. This is the same as installing a cluster on any platform, and has the following limitations:

1. There will be no cluster provider so you must manually add each machine and there will be no node scaling capabilities.

2. The oVirt CSI driver will not be installed and there will be no CSI capabilities.

### 18.4.15. Generate manifest files

Use the installation program to generate a set of manifest files in the assets directory.

The command to generate the manifest files displays a warning message before it consumes the **install-config.yaml** file.

If you plan to reuse the **install-config.yaml** file, create a backup copy of it before you back it up before you generate the manifest files.
Procedure

1. Optional: Create a backup copy of the `install-config.yaml` file:

   ```
   $ cp install-config.yaml install-config.yaml.backup
   ```

2. Generate a set of manifests in your assets directory:

   ```
   $ openshift-install create manifests --dir $ASSETS_DIR
   ```

   This command displays the following messages.

   **Example output**

   ```
   INFO Consuming Install Config from target directory
   WARNING Making control-plane schedulable by setting MastersSchedulable to true for Scheduler cluster settings
   ```

   The command generates the following manifest files:

   **Example output**

   ```
   $ tree
   .
   ├── wrk
   │   └── manifests
   │       ├── 04-openshift-machine-config-operator.yaml
   │       ├── cluster-config.yaml

   │            └── kube-system-configmap-root-ca.yaml
   │                   └── machine-config-server-tls-secret.yaml
   │                           └── openshift-config-secret-pull-secret.yaml
   │
   ├── openshift
   │   └── 99_kubeadmin-password-secret.yaml
   │
   └── 99_openshift-cluster-api_master-user-data-secret.yaml
   ```
Next steps

- Make control plane nodes non-schedulable.

18.4.16. Making control-plane nodes non-schedulable

Because you are manually creating and deploying the control plane machines, you must configure a manifest file to make the control plane nodes non-schedulable.

Procedure

1. To make the control plane nodes non-schedulable, enter:

```
$ python3 -c 'import os, yaml
path = "%s/manifests/cluster-scheduler-02-config.yml" % os.environ["ASSETS_DIR"]
data = yaml.safe_load(open(path))
data["spec"]["mastersSchedulable"] = False
open(path, "w").write(yaml.dump(data, default_flow_style=False))'
```

18.4.17. Building the Ignition files

To build the Ignition files from the manifest files you just generated and modified, you run the installation program. This action creates a Red Hat Enterprise Linux CoreOS (RHCOS) machine, initramfs, which fetches the Ignition files and performs the configurations needed to create a node.

In addition to the Ignition files, the installation program generates the following:

- An auth directory that contains the admin credentials for connecting to the cluster with the oc and kubectl utilities.

- A metadata.json file that contains information such as the OpenShift Container Platform cluster name, cluster ID, and infrastructure ID for the current installation.

The Ansible playbooks for this installation process use the value of infraID as a prefix for the virtual machines they create. This prevents naming conflicts when there are multiple installations in the same oVirt/RHV cluster.

NOTE

Certificates in Ignition configuration files expire after 24 hours. Complete the cluster installation and keep the cluster running in a non-degraded state for 24 hours so that the first certificate rotation can finish.

Procedure

1. To build the Ignition files, enter:

```
$ openshift-install create ignition-configs --dir $ASSETS_DIR
```
18.4.18. Creating templates and virtual machines

After confirming the variables in the inventory.yml, you run the first Ansible provisioning playbook, create-templates-and-vms.yml.

This playbook uses the connection parameters for the RHV Manager from $HOME/.ovirt/ovirt-config.yaml and reads metadata.json in the assets directory.

If a local Red Hat Enterprise Linux CoreOS (RHCOS) image is not already present, the playbook downloads one from the URL you specified for image_url in inventory.yml. It extracts the image and uploads it to RHV to create templates.

The playbook creates a template based on the control_plane and compute profiles in the inventory.yml file. If these profiles have different names, it creates two templates.

When the playbook finishes, the virtual machines it creates are stopped. You can get information from them to help configure other infrastructure elements. For example, you can get the virtual machines’ MAC addresses to configure DHCP to assign permanent IP addresses to the virtual machines.

Procedure

1. In inventory.yml, under the control_plane and compute variables, change both instances of type: high_performance to type: server.

2. Optional: If you plan to perform multiple installations to the same cluster, create different templates for each OpenShift Container Platform installation. In the inventory.yml file, prepend the value of template with infraID. For example:

   ```yaml
   control_plane:
     cluster: "{{ ovirt_cluster }}"
     memory: 16GiB
     sockets: 4
     cores: 1
     template: "{{ metadata.infraID }}-rhcos_tpl"
     operating_system: "rhcos_x64"
   ...
   ```

3. Create the templates and virtual machines:

   ```bash
   $ ansible-playbook -i inventory.yml create-templates-and-vms.yml
   ```
18.4.19. Creating the bootstrap machine

You create a bootstrap machine by running the `bootstrap.yml` playbook. This playbook starts the bootstrap virtual machine, and passes it the `bootstrap.ign` ignition file from the assets directory. The bootstrap node configures itself so it can serve Ignition files to the control plane nodes.

To monitor the bootstrap process, you use the console in the RHV Administration Portal or connect to the virtual machine by using SSH.

**Procedure**

1. Create the bootstrap machine:

   ```
   $ ansible-playbook -i inventory.yml bootstrap.yml
   ```

2. Connect to the bootstrap machine using a console in the Administration Portal or SSH. Replace `<bootstrap_ip>` with the bootstrap node IP address. To use SSH, enter:

   ```
   $ ssh core@<bootstrap.ip>
   ```

3. Collect `bootkube.service` journald unit logs for the release image service from the bootstrap node:

   ```
   [core@ocp4-lk6b4-bootstrap ~]$ journalctl -b -f -u release-image.service -u bootkube.service
   ```

   **NOTE**

   The `bootkube.service` log on the bootstrap node outputs etcd connection refused errors, indicating that the bootstrap server is unable to connect to etcd on control plane nodes. After etcd has started on each control plane node and the nodes have joined the cluster, the errors should stop.

18.4.20. Creating the control plane nodes

You create the control plane nodes by running the `masters.yml` playbook. This playbook passes the `master.ign` Ignition file to each of the virtual machines. The Ignition file contains a directive for the control plane node to get the Ignition from a URL such as `https://api-int.ocp4.example.org:22623/config/master`. The port number in this URL is managed by the load balancer, and is accessible only inside the cluster.

**Procedure**

1. Create the control plane nodes:

   ```
   $ ansible-playbook -i inventory.yml masters.yml
   ```

2. While the playbook creates your control plane, monitor the bootstrapping process:

   ```
   $ openshift-install wait-for bootstrap-complete --dir $ASSETS_DIR
   ```

   **Example output**
When all the pods on the control plane nodes and etcd are up and running, the installation program displays the following output.

**Example output**

```
INFO API v1.23.0 up
INFO Waiting up to 40m0s for bootstrapping to complete...
```

18.4.21. Verifying cluster status

You can verify your OpenShift Container Platform cluster’s status during or after installation.

**Procedure**

1. In the cluster environment, export the administrator’s kubeconfig file:

```
$ export KUBECONFIG=$ASSETS_DIR/auth/kubeconfig
```

The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server.

2. View the control plane and compute machines created after a deployment:

```
$ oc get nodes
```

3. View your cluster’s version:

```
$ oc get clusterversion
```

4. View your Operators’ status:

```
$ oc get clusteroperator
```

5. View all running pods in the cluster:

```
$ oc get pods -A
```

18.4.22. Removing the bootstrap machine

After the *wait-for* command shows that the bootstrap process is complete, you must remove the bootstrap virtual machine to free up compute, memory, and storage resources. Also, remove settings for the bootstrap machine from the load balancer directives.

**Procedure**

1. To remove the bootstrap machine from the cluster, enter:

```
$ ansible-playbook -i inventory.yml retire-bootstrap.yml
```
2. Remove settings for the bootstrap machine from the load balancer directives.

18.4.23. Creating the worker nodes and completing the installation

Creating worker nodes is similar to creating control plane nodes. However, worker nodes do not automatically join the cluster. To add them to the cluster, you review and approve the workers’ pending CSRs (Certificate Signing Requests).

After approving the first requests, you continue approving CSR until all of the worker nodes are approved. When you complete this process, the worker nodes become Ready and can have pods scheduled to run on them.

Finally, monitor the command line to see when the installation process completes.

Procedure

1. Create the worker nodes:

   $ ansible-playbook -i inventory.yml workers.yml

2. To list all of the CSRs, enter:

   $ oc get csr -A

   Eventually, this command displays one CSR per node. For example:

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>SIGNERNAME</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-2lndx</td>
<td>63m</td>
<td>kubernetes.io/kubelet-serving</td>
<td>system:node:ocp4-lk6b4-master0.ocp4.example.org</td>
<td>Approved,Issued</td>
</tr>
<tr>
<td>csr-hff4q</td>
<td>64m</td>
<td>kubernetes.io/kube-apiserver-client-kubelet</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Approved,Issued</td>
</tr>
<tr>
<td>csr-hsn96</td>
<td>60m</td>
<td>kubernetes.io/kubelet-serving</td>
<td>system:node:ocp4-lk6b4-master2.ocp4.example.org</td>
<td>Approved,Issued</td>
</tr>
<tr>
<td>csr-m724n</td>
<td>6m2s</td>
<td>kubernetes.io/kube-apiserver-client-kubelet</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-p4dz2</td>
<td>60m</td>
<td>kubernetes.io/kube-apiserver-client-kubelet</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Approved,Issued</td>
</tr>
<tr>
<td>csr-t9vfj</td>
<td>60m</td>
<td>kubernetes.io/kubelet-serving</td>
<td>system:node:ocp4-lk6b4-master1.ocp4.example.org</td>
<td>Approved,Issued</td>
</tr>
<tr>
<td>csr-tggtr</td>
<td>61m</td>
<td>kubernetes.io/kube-apiserver-client-kubelet</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Approved,Issued</td>
</tr>
<tr>
<td>csr-wcbrf</td>
<td>7m6s</td>
<td>kubernetes.io/kube-apiserver-client-kubelet</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Pending</td>
</tr>
</tbody>
</table>

3. To filter the list and see only pending CSRs, enter:

   $ watch "oc get csr -A | grep pending -i"
This command refreshes the output every two seconds and displays only pending CSRs. For example:

**Example output**

Every 2.0s: oc get csr -A | grep pending -i

csr-m724n 10m kubernetes.io/kube-apiserver-client-kubelet system:serviceaccount:openshift-machine-config-operator:node-bootstrapper Pending
csr-wcbrf 11m kubernetes.io/kube-apiserver-client-kubelet system:serviceaccount:openshift-machine-config-operator:node-bootstrapper Pending

4. Inspect each pending request. For example:

**Example output**

$ oc describe csr csr-m724n

**Example output**

Name: csr-m724n
Labels: <none>
Annotations: <none>
CreationTimestamp: Sun, 19 Jul 2020 15:59:37 +0200
Signer: kubernetes.io/kube-apiserver-client-kubelet
Status: Pending
Subject:
  Common Name: system:node:ocp4-lk6b4-worker1.ocp4.example.org
  Serial Number: 
  Organization: system:nodes
Events: <none>

5. If the CSR information is correct, approve the request:

$ oc adm certificate approve csr-m724n

6. Wait for the installation process to finish:

$ openshift-install wait-for install-complete --dir $ASSETS_DIR --log-level debug

When the installation completes, the command line displays the URL of the OpenShift Container Platform web console and the administrator user name and password.

**18.4.24. Telemetry access for OpenShift Container Platform**

In OpenShift Container Platform 4.10, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](https://openshift.redhat.com).
After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- See About remote health monitoring for more information about the Telemetry service

### 18.5. INSTALLING A CLUSTER ON RHV IN A RESTRICTED NETWORK

In OpenShift Container Platform version 4.10, you can install a customized OpenShift Container Platform cluster on Red Hat Virtualization (RHV) in a restricted network by creating an internal mirror of the installation release content.

#### 18.5.1. Prerequisites

The following items are required to install an OpenShift Container Platform cluster on a RHV environment.

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You have a supported combination of versions in the Support Matrix for OpenShift Container Platform on RHV.
- You created a registry on your mirror host and obtained the `imageContentSources` data for your version of OpenShift Container Platform.

**IMPORTANT**

Because the installation media is on the mirror host, you can use that computer to complete all installation steps.

- You provisioned persistent storage for your cluster. To deploy a private image registry, your storage must provide ReadWriteMany access modes.
- If you use a firewall and plan to use the Telemetry service, you configured the firewall to allow the sites that your cluster requires access to.

**NOTE**

Be sure to also review this site list if you are configuring a proxy.

#### 18.5.2. About installations in restricted networks

In OpenShift Container Platform 4.10, you can perform an installation that does not require an active connection to the internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to
its cloud APIs. Some cloud functions, like Amazon Web Service’s IAM service, require internet access, so you might still require internet access. Depending on your network, you might require less internet access for an installation on bare metal hardware or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift Container Platform registry and contains the installation media. You can create this registry on a mirror host, which can access both the internet and your closed network, or by using other methods that meet your restrictions.

18.5.2.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The **ClusterVersion** status includes an *Unable to retrieve available updates* error.
- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

18.5.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.10, you require access to the internet to obtain the images that are necessary to install your cluster.

You must have internet access to:

- Access **OpenShift Cluster Manager** to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access **Quay.io** to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

18.5.4. Requirements for the RHV environment

To install and run an OpenShift Container Platform version 4.10 cluster, the RHV environment must meet the following requirements.

Not meeting these requirements can cause the installation or process to fail. Additionally, not meeting these requirements can cause the OpenShift Container Platform cluster to fail days or weeks after installation.

The following requirements for CPU, memory, and storage resources are based on **default** values multiplied by the default number of virtual machines the installation program creates. These resources must be available **in addition to** what the RHV environment uses for non-OpenShift Container Platform operations.
By default, the installation program creates seven virtual machines during the installation process. First, it creates a bootstrap virtual machine to provide temporary services and a control plane while it creates the rest of the OpenShift Container Platform cluster. When the installation program finishes creating the cluster, deleting the bootstrap machine frees up its resources.

If you increase the number of virtual machines in the RHV environment, you must increase the resources accordingly.

**Requirements**

- The RHV version is 4.4.
- The RHV environment has one data center whose state is **Up**.
- The RHV data center contains an RHV cluster.
- The RHV cluster has the following resources exclusively for the OpenShift Container Platform cluster:
  - Minimum 28 vCPUs: four for each of the seven virtual machines created during installation.
  - 112 GiB RAM or more, including:
    - 16 GiB or more for the bootstrap machine, which provides the temporary control plane.
    - 16 GiB or more for each of the three control plane machines which provide the control plane.
    - 16 GiB or more for each of the three compute machines, which run the application workloads.
- The RHV storage domain must meet these etcd backend performance requirements.
- In production environments, each virtual machine must have 120 GiB or more. Therefore, the storage domain must provide 840 GiB or more for the default OpenShift Container Platform cluster. In resource-constrained or non-production environments, each virtual machine must have 32 GiB or more, so the storage domain must have 230 GiB or more for the default OpenShift Container Platform cluster.
- To download images from the Red Hat Ecosystem Catalog during installation and update procedures, the RHV cluster must have access to an internet connection. The Telemetry service also needs an internet connection to simplify the subscription and entitlement process.
- The RHV cluster must have a virtual network with access to the REST API on the RHV Manager. Ensure that DHCP is enabled on this network, because the VMs that the installer creates obtain their IP address by using DHCP.
- A user account and group with the following least privileges for installing and managing an OpenShift Container Platform cluster on the target RHV cluster:
  - **DiskOperator**
  - **DiskCreator**
  - **UserTemplateBasedVm**
  - **TemplateOwner**
TemplateCreator

ClusterAdmin on the target cluster

WARNING

Apply the principle of least privilege: Avoid using an administrator account with SuperUser privileges on RHV during the installation process. The installation program saves the credentials you provide to a temporary ovirt-config.yaml file that might be compromised.

18.5.5. Verifying the requirements for the RHV environment

Verify that the RHV environment meets the requirements to install and run an OpenShift Container Platform cluster. Not meeting these requirements can cause failures.

IMPORTANT

These requirements are based on the default resources the installation program uses to create control plane and compute machines. These resources include vCPUs, memory, and storage. If you change these resources or increase the number of OpenShift Container Platform machines, adjust these requirements accordingly.

Procedure

1. Check that the RHV version supports installation of OpenShift Container Platform version 4.10.
   a. In the RHV Administration Portal, click the ? help icon in the upper-right corner and select About.
   b. In the window that opens, make a note of the RHV Software Version.
   c. Confirm that the RHV version is 4.4. For more information about supported version combinations, see Support Matrix for OpenShift Container Platform on RHV.

2. Inspect the data center, cluster, and storage.
   a. In the RHV Administration Portal, click Compute → Data Centers.
   b. Confirm that the data center where you plan to install OpenShift Container Platform is accessible.
   c. Click the name of that data center.
   d. In the data center details, on the Storage tab, confirm the storage domain where you plan to install OpenShift Container Platform is Active.
   e. Record the Domain Name for use later on.
   f. Confirm Free Space has at least 230 GiB.
g. Confirm that the storage domain meets these etcd backend performance requirements, which you can measure by using the fio performance benchmarking tool.

h. In the data center details, click the Clusters tab.

i. Find the RHV cluster where you plan to install OpenShift Container Platform. Record the cluster name for use later on.

3. Inspect the RHV host resources.

   a. In the RHV Administration Portal, click Compute > Clusters.

   b. Click the cluster where you plan to install OpenShift Container Platform.

   c. In the cluster details, click the Hosts tab.

   d. Inspect the hosts and confirm they have a combined total of at least 28 Logical CPU Cores available exclusively for the OpenShift Container Platform cluster.

   e. Record the number of available Logical CPU Cores for use later on.

   f. Confirm that these CPU cores are distributed so that each of the seven virtual machines created during installation can have four cores.

   g. Confirm that, all together, the hosts have 112 GiB of Max free Memory for scheduling new virtual machines distributed to meet the requirements for each of the following OpenShift Container Platform machines:

      - 16 GiB required for the bootstrap machine
      - 16 GiB required for each of the three control plane machines
      - 16 GiB for each of the three compute machines

   h. Record the amount of Max free Memory for scheduling new virtual machines for use later on.

4. Verify that the virtual network for installing OpenShift Container Platform has access to the RHV Manager’s REST API. From a virtual machine on this network, use curl to reach the RHV Manager’s REST API:

   $ curl -k -u <username>@<profile>:<password> \ 1
   https://<engine-fqdn>/ovirt-engine/api 2

   For <username>, specify the user name of an RHV account with privileges to create and manage an OpenShift Container Platform cluster on RHV. For <profile>, specify the login profile, which you can get by going to the RHV Administration Portal login page and reviewing the Profile dropdown list. For <password>, specify the password for that user name.

   1 For <engine-fqdn>, specify the fully qualified domain name of the RHV environment.

   2 For example:

   $ curl -k -u ocpadmin@internal:pw123 \  
   https://rhv-env.virtlab.example.com/ovirt-engine/api
18.5.6. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in **initramfs** during boot to fetch their Ignition config files.

During the initial boot, the machines require an HTTP or HTTPS server to establish a network connection to download their Ignition config files.

The machines are configured with static IP addresses. No DHCP server is required. Ensure that the machines have persistent IP addresses and hostnames.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

**Firewall**

Configure your firewall so your cluster has access to required sites.

See also:

- Red Hat Virtualization Manager firewall requirements
- Host firewall requirements

**DNS**

Configure infrastructure-provided DNS to allow the correct resolution of the main components and services. If you use only one load balancer, these DNS records can point to the same IP address.

- Create DNS records for `api.<cluster_name>.<base_domain>` (internal and external resolution) and `api-int.<cluster_name>.<base_domain>` (internal resolution) that point to the load balancer for the control plane machines.
- Create a DNS record for `*.apps.<cluster_name>.<base_domain>` that points to the load balancer for the Ingress router. For example, ports 443 and 80 of the compute machines.

18.5.6.1. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

**IMPORTANT**

In connected OpenShift Container Platform environments, all nodes are required to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

Table 18.9. Ports used for all-machine to all-machine communications
<table>
<thead>

**NTP configuration for user-provisioned infrastructure**

OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for Configuring chrony time service.

**18.5.7. User-provisioned DNS requirements**

In OpenShift Container Platform deployments, DNS name resolution is required for the following components:

- The Kubernetes API
- The OpenShift Container Platform application wildcard
The bootstrap, control plane, and compute machines

Reverse DNS resolution is also required for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the hostnames for all the nodes, unless the hostnames are provided by DHCP. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

The following DNS records are required for a user-provisioned OpenShift Container Platform cluster and they must be in place before installation. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>`.

### Table 18.12. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes API</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the API load balancer. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td></td>
<td>api-int.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to internally identify the API load balancer. These records must be resolvable from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Routes</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A wildcard DNS A/AAAA or CNAME record that refers to the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster. For example, <code>console-openshift-console.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;</code> is used as a wildcard route to the OpenShift Container Platform console.</td>
</tr>
<tr>
<td>Bootstrap machine</td>
<td>bootstrap.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

The API server must be able to resolve the worker nodes by the hostnames that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.
Component | Record | Description
--- | --- | ---
Control plane machines | `<master><n>.<cluster_name>.<base_domain>`. | DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes. These records must be resolvable by the nodes within the cluster.

Computer machines | `<worker><n>.<cluster_name>.<base_domain>`. | DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.

NOTE

In OpenShift Container Platform 4.4 and later, you do not need to specify etcd host and SRV records in your DNS configuration.

TIP

You can use the **dig** command to verify name and reverse name resolution. See the section on *Validating DNS resolution for user-provisioned infrastructure* for detailed validation steps.

18.5.7.1. Example DNS configuration for user-provisioned clusters

This section provides A and PTR record configuration samples that meet the DNS requirements for deploying OpenShift Container Platform on user-provisioned infrastructure. The samples are not meant to provide advice for choosing one DNS solution over another.

In the examples, the cluster name is **ocp4** and the base domain is **example.com**.

Example DNS A record configuration for a user-provisioned cluster

The following example is a BIND zone file that shows sample A records for name resolution in a user-provisioned cluster.

```
$TTL 1W
@ IN SOA ns1.example.com. root (
  2019070700 ; serial
  3H ; refresh (3 hours)
  30M ; retry (30 minutes)
  2W ; expiry (2 weeks)
  1W ) ; minimum (1 week)
IN NS ns1.example.com.
IN MX 10 smtp.example.com.
; ;
ns1.example.com. IN A 192.168.1.5
smtp.example.com. IN A 192.168.1.5
; ;
helper.example.com. IN A 192.168.1.5
```
Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer.

Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer and is used for internal cluster communications.

Provides name resolution for the wildcard routes. The record refers to the IP address of the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

NOTE

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

Provides name resolution for the bootstrap machine.

Provides name resolution for the control plane machines.

Provides name resolution for the compute machines.

Example DNS PTR record configuration for a user-provisioned cluster

The following example BIND zone file shows sample PTR records for reverse name resolution in a user-provisioned cluster.

Example 18.2. Sample DNS zone database for reverse records

```
$TTL 1W
@ IN SOA ns1.example.com. root ( 2019070700 ; serial
```
Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer.

Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer and is used for internal cluster communications.

Provides reverse DNS resolution for the bootstrap machine.

Provides reverse DNS resolution for the control plane machines.

Provides reverse DNS resolution for the compute machines.

NOTE

A PTR record is not required for the OpenShift Container Platform application wildcard.

18.5.7.2. Load balancing requirements for user-provisioned infrastructure

Before you install OpenShift Container Platform, you must provision the API and application ingress load balancing infrastructure. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

The load balancing infrastructure must meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.
   - A stateless load balancing algorithm. The options vary based on the load balancer implementation.
Configure the following ports on both the front and back of the load balancers:

**Table 18.13. API load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the <code>/readyz</code> endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>

**NOTE**

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the `/readyz` endpoint to the removal of the API server instance from the pool. Within the time frame after `/readyz` returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application ingress load balancer**: Provides an ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

**TIP**

If the true IP address of the client can be seen by the application ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

Configure the following ports on both the front and back of the load balancers:

**Table 18.14. Application ingress load balancer**
<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
<tr>
<td>1936</td>
<td>The worker nodes that run the Ingress Controller pods, by default. You must configure the /healthz/ready endpoint for the ingress health check probe.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>

**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

**NOTE**

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

### 18.5.7.2.1. Example load balancer configuration for user-provisioned clusters

This section provides an example API and application ingress load balancer configuration that meets the load balancing requirements for user-provisioned clusters. The sample is an `/etc/haproxy/haproxy.cfg` configuration for an HAProxy load balancer. The example is not meant to provide advice for choosing one load balancing solution over another.

**NOTE**

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

### Example 18.3. Sample API and application ingress load balancer configuration

```
# Example 18.3. Sample API and application ingress load balancer configuration

global
  log 127.0.0.1 local2
  pidfile /var/run/haproxy.pid
  maxconn 4000
  daemon
  defaults
    mode http
```
In the example, the cluster name is `ocp4`.

Port **6443** handles the Kubernetes API traffic and points to the control plane machines.

---

1. In the example, the cluster name is **ocp4**.

2. Port **6443** handles the Kubernetes API traffic and points to the control plane machines.
The bootstrap entries must be in place before the OpenShift Container Platform cluster installation and they must be removed after the bootstrap process is complete.

Port 22623 handles the machine config server traffic and points to the control plane machines.

Port 443 handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

Port 80 handles the HTTP traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

**TIP**

If you are using HAProxy as a load balancer, you can check that the `haproxy` process is listening on ports 6443, 22623, 443, and 80 by running `netstat -ntlp` on the HAProxy node.

**NOTE**

If you are using HAProxy as a load balancer and SELinux is set to enforcing, you must ensure that the HAProxy service can bind to the configured TCP port by running `setsebool -P haproxy_connect_any=1`.

18.5.8. Setting up the installation machine

To run the binary `openshift-install` installation program and Ansible scripts, set up the RHV Manager or an Red Hat Enterprise Linux (RHEL) computer with network access to the RHV environment and the REST API on the Manager.

**Procedure**

1. Update or install Python3 and Ansible. For example:

```
# dnf update python3 ansible
```

2. Install the `python3-ovirt-engine-sdk4` package to get the Python Software Development Kit.

3. Install the `ovirt.image-template` Ansible role. On the RHV Manager and other Red Hat Enterprise Linux (RHEL) machines, this role is distributed as the `ovirt-ansible-image-template` package. For example, enter:

```
# dnf install ovirt-ansible-image-template
```

4. Install the `ovirt.vm-infra` Ansible role. On the RHV Manager and other RHEL machines, this role is distributed as the `ovirt-ansible-vm-infra` package.
5. Create an environment variable and assign an absolute or relative path to it. For example, enter:

```sh
$ export ASSETS_DIR=./wrk
```

NOTE

The installation program uses this variable to create a directory where it saves important installation-related files. Later, the installation process reuses this variable to locate those asset files. Avoid deleting this assets directory; it is required for uninstalling the cluster.

18.5.9. Setting up the CA certificate for RHV

Download the CA certificate from the Red Hat Virtualization (RHV) Manager and set it up on the installation machine.

You can download the certificate from a webpage on the RHV Manager or by using a `curl` command. Later, you provide the certificate to the installation program.

Procedure

1. Use either of these two methods to download the CA certificate:
   - Go to the Manager’s webpage, `https://<engine-fqdn>/ovirt-engine/`. Then, under Downloads, click the CA Certificate link.
   - Run the following command:

     ```sh
     ```

     For `<engine-fqdn>`, specify the fully qualified domain name of the RHV Manager, such as `rhv-env.virtlab.example.com`.

2. Configure the CA file to grant rootless user access to the Manager. Set the CA file permissions to have an octal value of 0644 (symbolic value: `-rw-r--r--`):

   ```sh
   $ sudo chmod 0644 /tmp/ca.pem
   ```

3. For Linux, copy the CA certificate to the directory for server certificates. Use `-p` to preserve the permissions:

   ```sh
   $ sudo cp -p /tmp/ca.pem /etc/pki/ca-trust/source/anchors/ca.pem
   ```

4. Add the certificate to the certificate manager for your operating system:
   - For macOS, double-click the certificate file and use the Keychain Access utility to add the file to the System keychain.
   - For Linux, update the CA trust:

     ```sh
     # dnf install ovirt-ansible-vm-infra
     ```
NOTE

If you use your own certificate authority, make sure the system trusts it.

Additional resources

- To learn more, see Authentication and Security in the RHV documentation.

18.5.10. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH into the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH into your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>
   ```

   Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   NOTE

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   ```
   $ cat <path>/<file_name>.pub
   ```
For example, run the following to view the ~/.ssh/id_rsa.pub public key:

$ cat ~/.ssh/id_rsa.pub

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the ./openshift-install gather command.

NOTE

On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.

a. If the ssh-agent process is not already running for your local user, start it as a background task:

$ eval "$(ssh-agent -s)"

Example output

Agent pid 31874

NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the ssh-agent:

$ ssh-add <path>/<file_name> 1

Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

Example output

Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

18.5.11. Downloading the Ansible playbooks

Download the Ansible playbooks for installing OpenShift Container Platform version 4.10 on RHV.

Procedure

- On your installation machine, run the following commands:
$ mkdir playbooks

$ cd playbooks

grep 'download_url.*\.yml' |
awk '{ print $2 }' | sed -r 's/"|,//g' |
xargs -n 1 curl -O

Next steps

- After you download these Ansible playbooks, you must also create the environment variable for the assets directory and customize the `inventory.yml` file before you create an installation configuration file by running the installation program.

18.5.12. The inventory.yml file

You use the `inventory.yml` file to define and create elements of the OpenShift Container Platform cluster you are installing. This includes elements such as the Red Hat Enterprise Linux CoreOS (RHCOS) image, virtual machine templates, bootstrap machine, control plane nodes, and worker nodes. You also use `inventory.yml` to destroy the cluster.

The following `inventory.yml` example shows you the parameters and their default values. The quantities and numbers in these default values meet the requirements for running a production OpenShift Container Platform cluster in a RHV environment.

Example inventory.yml file

```yaml
---
all:
  vars:

  ovirt_cluster: "Default"
  ocp:
    assets_dir: "{{ lookup('env', 'ASSETS_DIR') }}"
    ovirt_config_path: "{{ lookup('env', 'HOME') }}/ovirt-config.yaml"

# ---
# {op-system} section
# ---

rhcos:
  local_cmp_image_path: "/tmp/rhcos.qcow2.gz"
  local_image_path:="/tmp/rhcos.qcow2"

# ---
# Profiles section
# ---

control_plane:
  cluster: "{{ ovirt_cluster }}"
  memory: 16GiB
  sockets: 4
```
cores: 1
template: rhcos_tpl
operating_system: "rhcos_x64"
type: high_performance
graphical_console:
  headless_mode: false
protocol:
  - spice
  - vnc
disks:
  - size: 120GiB
    name: os
    interface: virtio_scsi
    storage_domain: depot_nvme
nics:
  - name: nic1
    network: lab
    profile: lab

compute:
  cluster: "{{ ovirt_cluster }}"
memory: 16GiB
sockets: 4
cores: 1
template: worker_rhcos_tpl
operating_system: "rhcos_x64"
type: high_performance
graphical_console:
  headless_mode: false
protocol:
  - spice
  - vnc
disks:
  - size: 120GiB
    name: os
    interface: virtio_scsi
    storage_domain: depot_nvme
nics:
  - name: nic1
    network: lab
    profile: lab

# ---
# Virtual machines section
# ---
vms:
  - name: "{{ metadata.infraID }}-bootstrap"
    ocp_type: bootstrap
    profile: "{{ control_plane }}"
    type: server
  - name: "{{ metadata.infraID }}-master0"
    ocp_type: master
    profile: "{{ control_plane }}"
  - name: "{{ metadata.infraID }}-master1"
    ocp_type: master
    profile: "{{ control_plane }}"
- name: "{{ metadata.infraID }}-worker0"
  ocp_type: worker
  profile: "{{ compute }}"
- name: "{{ metadata.infraID }}-worker1"
  ocp_type: worker
  profile: "{{ compute }}"
- name: "{{ metadata.infraID }}-worker2"
  ocp_type: worker
  profile: "{{ compute }}"

**IMPORTANT**

Enter values for parameters whose descriptions begin with "Enter." Otherwise, you can use the default value or replace it with a new value.

**General section**

- **ovirt_cluster**: Enter the name of an existing RHV cluster in which to install the OpenShift Container Platform cluster.

- **ocp.assets_dir**: The path of a directory the `openshift-install` installation program creates to store the files that it generates.

- **ocp.ovirt_config_path**: The path of the `ovirt-config.yaml` file the installation program generates, for example, `./wrk/install-config.yaml`. This file contains the credentials required to interact with the REST API of the Manager.

**Red Hat Enterprise Linux CoreOS (RHCOS) section**

- **image_url**: Enter the URL of the RHCOS image you specified for download.

- **local_cmp_image_path**: The path of a local download directory for the compressed RHCOS image.

- **local_image_path**: The path of a local directory for the extracted RHCOS image.

**Profiles section**

This section consists of two profiles:

- **control_plane**: The profile of the bootstrap and control plane nodes.

- **compute**: The profile of workers nodes in the compute plane.

These profiles have the following parameters. The default values of the parameters meet the minimum requirements for running a production cluster. You can increase or customize these values to meet your workload requirements.

- **cluster**: The value gets the cluster name from `ovirt_cluster` in the General Section.

- **memory**: The amount of memory, in GB, for the virtual machine.

- **sockets**: The number of sockets for the virtual machine.
• **cores**: The number of cores for the virtual machine.

• **template**: The name of the virtual machine template. If plan to install multiple clusters, and these clusters use templates that contain different specifications, prepend the template name with the ID of the cluster.

• **operating_system**: The type of guest operating system in the virtual machine. With oVirt/RHV version 4.4, this value must be `rhcos_x64` so the value of Ignition script can be passed to the VM.

• **type**: Enter `server` as the type of the virtual machine.

**IMPORTANT**

You must change the value of the **type** parameter from `high_performance` to **server**.

• **disks**: The disk specifications. The **control_plane** and **compute** nodes can have different storage domains.

• **size**: The minimum disk size.

• **name**: Enter the name of a disk connected to the target cluster in RHV.

• **interface**: Enter the interface type of the disk you specified.

• **storage_domain**: Enter the storage domain of the disk you specified.

• **nics**: Enter the **name** and **network** the virtual machines use. You can also specify the virtual network interface profile. By default, NICs obtain their MAC addresses from the oVirt/RHV MAC pool.

**Virtual machines section**

This final section, **vms**, defines the virtual machines you plan to create and deploy in the cluster. By default, it provides the minimum number of control plane and worker nodes for a production environment.

**vms** contains three required elements:

• **name**: The name of the virtual machine. In this case, **metadata.infraID** prepends the virtual machine name with the infrastructure ID from the **metadata.yml** file.

• **ocp_type**: The role of the virtual machine in the OpenShift Container Platform cluster. Possible values are **bootstrap**, **master**, **worker**.

• **profile**: The name of the profile from which each virtual machine inherits specifications. Possible values in this example are **control_plane** or **compute**.

  You can override the value a virtual machine inherits from its profile. To do this, you add the name of the profile attribute to the virtual machine in **inventory.yml** and assign it an overriding value. To see an example of this, examine the **name**: "{{ metadata.infraID }}-bootstrap" virtual machine in the preceding inventory.yml example: It has a **type** attribute whose value, **server**, overrides the value of the **type** attribute this virtual machine would otherwise inherit from the **control_plane** profile.

**Metadata variables**
For virtual machines, `metadata.infraID` prepends the name of the virtual machine with the infrastructure ID from the `metadata.json` file you create when you build the Ignition files.

The playbooks use the following code to read `infraID` from the specific file located in the `ocp.assets_dir`.

```yaml
---
- name: include metadata.json vars
  include_vars:
    file: "{{ ocp.assets_dir }}/metadata.json"
  name: metadata

...  
```

### 18.5.13. Specifying the RHCOS image settings

Update the Red Hat Enterprise Linux CoreOS (RHCOS) image settings of the `inventory.yml` file. Later, when you run this file one of the playbooks, it downloads a compressed Red Hat Enterprise Linux CoreOS (RHCOS) image from the `image_url` URL to the `local_cmp_image_path` directory. The playbook then uncompresses the image to the `local_image_path` directory and uses it to create oVirt/RHV templates.

**Procedure**

1. Locate the RHCOS image download page for the version of OpenShift Container Platform you are installing, such as Index of /pub/openshift-v4/dependencies/rhcos/latest/latest.

2. From that download page, copy the URL of an OpenStack `qcow2` image, such as https://mirror.openshift.com/pub/openshift-v4/dependencies/rhcos/4.10/latest/rhcos-openstack.x86_64.qcow2.gz.

3. Edit the `inventory.yml` playbook you downloaded earlier. In it, paste the URL as the value for `image_url`. For example:

```yaml
rhcos:
  "https://mirror.openshift.com/pub/openshift-v4/dependencies/rhcos/4.10/latest/rhcos-openstack.x86_64.qcow2.gz"
```

### 18.5.14. Creating the install config file

You create an installation configuration file by running the installation program, `openshift-install`, and responding to its prompts with information you specified or gathered earlier.

When you finish responding to the prompts, the installation program creates an initial version of the `install-config.yaml` file in the assets directory you specified earlier, for example, `/wrk/install-config.yaml`.

The installation program also creates a file, `$HOME/.ovirt/ovirt-config.yaml`, that contains all the connection parameters that are required to reach the Manager and use its REST API.

**NOTE:** The installation process does not use values you supply for some parameters, such as Internal API virtual IP and Ingress virtual IP, because you have already configured them in your infrastructure DNS.
It also uses the values you supply for parameters in `inventory.yml`, like the ones for **oVirt cluster**, **oVirt storage**, and **oVirt network**. And uses a script to remove or replace these same values from `install-config.yaml` with the previously mentioned **virtual IPs**.

**Procedure**

1. Run the installation program:

```
$ openshift-install create install-config --dir $ASSETS_DIR
```

2. Respond to the installation program’s prompts with information about your system.

**Example output**

```
? SSH Public Key /home/user/.ssh/id_dsa.pub
? Platform <ovirt>
? Enter ovirt-engine username <ocpadmin@internal>
? Enter password <******>
? oVirt cluster <cluster>
? oVirt storage <storage>
? oVirt network <net>
? Internal API virtual IP <172.16.0.252>
? Ingress virtual IP <172.16.0.251>
? Base Domain <example.org>
? Cluster Name <ocp4>
? Pull Secret [? for help] <*******>
```

For **Internal API virtual IP** and **Ingress virtual IP**, supply the IP addresses you specified when you configured the DNS service.

Together, the values you enter for the **oVirt cluster** and **Base Domain** prompts form the FQDN portion of URLs for the REST API and any applications you create, such as `https://api.ocp4.example.org:6443/` and `https://console-openshift-console.apps.ocp4.example.org`.

You can get the pull secret from the Red Hat OpenShift Cluster Manager.

**18.5.15. Sample install-config.yaml file for IBM Z**
18.5.16. Sample install-config.yaml file for RHV

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute:
  - hyperthreading: Enabled
    name: worker
    replicas: 0
controlPlane:
  hyperthreading: Enabled
  name: master
  replicas: 3
metadata:
  name: test
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
      hostPrefix: 23
  networkType: OpenShiftSDN
  serviceNetwork:
    - 172.30.0.0/16
platform:
  none: {}
fips: false
pullSecret: '{"auths": ...}'
sshKey: 'ssh-ed25519 AAAA...
```

1. The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

2. The `controlPlane` section is a single mapping, but the `compute` section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the `compute` section must begin with a hyphen, `-`, and the first line of the `controlPlane` section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

3. Specifies whether to enable or disable simultaneous multithreading (SMT), or hyperthreading. By default, SMT is enabled to increase the performance of the cores in your machines. You can disable it by setting the parameter value to `Disabled`. If you disable SMT, you must disable it in all cluster machines; this includes both control plane and compute machines.

**NOTE**

Simultaneous multithreading (SMT) is enabled by default. If SMT is not available on your OpenShift Container Platform nodes, the `hyperthreading` parameter has no effect.
IMPORTANT

If you disable hyperthreading, whether on your OpenShift Container Platform nodes or in the `install-config.yaml` file, ensure that your capacity planning accounts for the dramatically decreased machine performance.

You must set this value to 0 when you install OpenShift Container Platform on user-provisioned infrastructure. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. In user-provisioned installations, you must manually deploy the compute machines before you finish installing the cluster.

NOTE

If you are installing a three-node cluster, do not deploy any compute machines when you install the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

The cluster name that you specified in your DNS records.

A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to access the pods from an external network, you must configure load balancers and routers to manage the traffic.

The subnet prefix length to assign to each individual node. For example, if `hostPrefix` is set to 23, then each node is assigned a /23 subnet out of the given `cidr`, which allows for $510 \left(2^n(32 - 23) - 2\right)$ pod IP addresses. If you are required to provide access to nodes from an external network, configure load balancers and routers to manage the traffic.

The IP address pool to use for service IP addresses. You can enter only one IP address pool. This block must not overlap with existing physical networks. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.

You must set the platform to none. You cannot provide additional platform configuration variables for IBM Z infrastructure. RHV infrastructure.
WARNING

Red Hat Virtualization does not currently support installation with user-provisioned infrastructure on the oVirt platform. Therefore, you must set the platform to `none`, allowing OpenShift Container Platform to identify each node as a bare-metal node and the cluster as a bare-metal cluster. This is the same as installing a cluster on any platform, and has the following limitations:

1. There will be no cluster provider so you must manually add each machine and there will be no node scaling capabilities.
2. The oVirt CSI driver will not be installed and there will be no CSI capabilities.

---

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the `x86_64` architecture.

---

The pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

---

The SSH public key for the `core` user in Red Hat Enterprise Linux CoreOS (RHCOS).

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

---

### 18.5.16.1. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**Prerequisites**

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to
hosting cloud provider APIs. You added sites to the **Proxy** object’s **spec.noProxy** field to bypass the proxy if necessary.

**NOTE**

The **Proxy** object **status.noProxy** field is populated with the values of the networking.markeNetwork[].cidr, networking.clusterNetwork[].cidr, and networking.serviceNetwork[] fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (169.254.169.254).

**Procedure**

1. Edit your **install-config.yaml** file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port> 1
  httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
  noProxy: example.com 3
additionalTrustBundle: | 4
  -----BEGIN CERTIFICATE-----
  <MY_TRUSTED_CA_CERT>
  -----END CERTIFICATE-----
...
```

1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**.

2. A proxy URL to use for creating HTTPS connections outside the cluster.

3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, `.y.com` matches `x.y.com`, but not `y.com`. Use `*` to bypass the proxy for all destinations.

4. If provided, the installation program generates a config map that is named **user-ca-bundle** in the **openshift-config** namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the **trustedCA** field of the **Proxy** object. The **additionalTrustBundle** field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

**NOTE**

The installation program does not support the proxy **readinessEndpoints** field.

2. Save the file and reference it when installing OpenShift Container Platform.
The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

**NOTE**

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

18.5.17. Customizing **install-config.yaml**

Here, you use three Python scripts to override some of the installation program’s default behaviors:

- By default, the installation program uses the machine API to create nodes. To override this default behavior, you set the number of compute nodes to zero replicas. Later, you use Ansible playbooks to create the compute nodes.

- By default, the installation program sets the IP range of the machine network for nodes. To override this default behavior, you set the IP range to match your infrastructure.

- By default, the installation program sets the platform to **ovirt**. However, installing a cluster on user-provisioned infrastructure is more similar to installing a cluster on bare metal. Therefore, you delete the ovirt platform section from **install-config.yaml** and change the platform to **none**. Instead, you use **inventory.yml** to specify all of the required settings.

**NOTE**

These snippets work with Python 3 and Python 2.

**Procedure**

1. Set the number of compute nodes to zero replicas:

   ```
   $ python3 -c 'import os, yaml
   path = "%s/install-config.yaml" % os.environ["ASSETS_DIR"]
   conf = yaml.safe_load(open(path))
   conf["compute"][0]["replicas"] = 0
   open(path, "w").write(yaml.dump(conf, default_flow_style=False))'
   ```

2. Set the IP range of the machine network. For example, to set the range to **172.16.0.0/16**, enter:

   ```
   $ python3 -c 'import os, yaml
   path = "%s/install-config.yaml" % os.environ["ASSETS_DIR"]
   conf = yaml.safe_load(open(path))
   conf["networking"]["machineNetwork"][0]["cidr"] = "172.16.0.0/16"
   open(path, "w").write(yaml.dump(conf, default_flow_style=False))'
   ```

3. Remove the **ovirt** section and change the platform to **none**:

   ```
   $ python3 -c 'import os, yaml
   path = "%s/install-config.yaml" % os.environ["ASSETS_DIR"]
   conf = yaml.safe_load(open(path))
   platform = conf["platform"]'
   ```
Red Hat Virtualization does not currently support installation with user-provisioned infrastructure on the oVirt platform. Therefore, you must set the platform to `none`, allowing OpenShift Container Platform to identify each node as a bare-metal node and the cluster as a bare-metal cluster. This is the same as installing a cluster on any platform, and has the following limitations:

1. There will be no cluster provider so you must manually add each machine and there will be no node scaling capabilities.

2. The oVirt CSI driver will not be installed and there will be no CSI capabilities.

18.5.18. Generate manifest files

Use the installation program to generate a set of manifest files in the assets directory.

The command to generate the manifest files displays a warning message before it consumes the `install-config.yaml` file.

If you plan to reuse the `install-config.yaml` file, create a backup copy of it before you back it up before you generate the manifest files.

Procedure

1. Optional: Create a backup copy of the `install-config.yaml` file:

   ```bash
   $ cp install-config.yaml install-config.yaml.backup
   ```

2. Generate a set of manifests in your assets directory:

   ```bash
   $ openshift-install create manifests --dir $ASSETS_DIR
   ```

   This command displays the following messages.

Example output

```bash
INFO Consuming Install Config from target directory
WARNING Making control-plane schedulable by setting MastersSchedulable to true for Scheduler cluster settings
```

The command generates the following manifest files:
Example output

$ tree
.
  wrk
   └── manifests

      │                 └── openshift-config-secret-pull-secret.yaml
      │                 └── openshift
      │                     └── 99_kubeadmin-password-secret.yaml
      │                     └── 99_openshift-cluster-api_master-user-data-secret.yaml
      │                     └── 99_openshift-cluster-api_worker-user-data-secret.yaml
      │                     └── 99_openshift-machineconfig_99-master-ssh.yaml
      │                     └── 99_openshift-machineconfig_99-worker-ssh.yaml
      │                     └── openshift-install-manifests.yaml

Next steps

- Make control plane nodes non-schedulable.

18.5.19. Making control-plane nodes non-schedulable

Because you are manually creating and deploying the control plane machines, you must configure a manifest file to make the control plane nodes non-schedulable.

Procedure

1. To make the control plane nodes non-schedulable, enter:

```bash
$ python3 -c 'import os, yaml
path = "%s/manifests/cluster-scheduler-02-config.yaml" % os.environ["ASSETS_DIR"]'
```
18.5.20. Building the Ignition files

To build the Ignition files from the manifest files you just generated and modified, you run the installation program. This action creates a Red Hat Enterprise Linux CoreOS (RHCOS) machine, initramfs, which fetches the Ignition files and performs the configurations needed to create a node.

In addition to the Ignition files, the installation program generates the following:

- An auth directory that contains the admin credentials for connecting to the cluster with the oc and kubectl utilities.
- A metadata.json file that contains information such as the OpenShift Container Platform cluster name, cluster ID, and infrastructure ID for the current installation.

The Ansible playbooks for this installation process use the value of infraID as a prefix for the virtual machines they create. This prevents naming conflicts when there are multiple installations in the same oVirt/RHV cluster.

NOTE

Certificates in Ignition configuration files expire after 24 hours. Complete the cluster installation and keep the cluster running in a non-degraded state for 24 hours so that the first certificate rotation can finish.

Procedure

1. To build the Ignition files, enter:

   ```bash
   $ openshift-install create ignition-configs --dir $ASSETS_DIR
   ```

   Example output

   ```
   $ tree
   .
   ├── wrk
   │   └── auth
   │       ├── kubeadmin-password
   │       └── kubeconfig
   │           └── bootstrap.ign
   │               └── master.ign
   │                   └── metadata.json
   │                       └── worker.ign
   ```

18.5.21. Creating templates and virtual machines

After confirming the variables in the inventory.yml, you run the first Ansible provisioning playbook, create-templates-and-vms.yml.

This playbook uses the connection parameters for the RHV Manager from $HOME/.ovirt/ovirt-config.yaml and reads metadata.json in the assets directory.
If a local Red Hat Enterprise Linux CoreOS (RHCOS) image is not already present, the playbook downloads one from the URL you specified for `image_url` in `inventory.yml`. It extracts the image and uploads it to RHV to create templates.

The playbook creates a template based on the `control_plane` and `compute` profiles in the `inventory.yml` file. If these profiles have different names, it creates two templates.

When the playbook finishes, the virtual machines it creates are stopped. You can get information from them to help configure other infrastructure elements. For example, you can get the virtual machines’ MAC addresses to configure DHCP to assign permanent IP addresses to the virtual machines.

**Procedure**

1. In `inventory.yml`, under the `control_plane` and `compute` variables, change both instances of `type: high_performance` to `type: server`.

2. Optional: If you plan to perform multiple installations to the same cluster, create different templates for each OpenShift Container Platform installation. In the `inventory.yml` file, prepend the value of `template` with `infraID`. For example:

   ```yaml
   control_plane:
     cluster: "{{ ovirt_cluster }}"
     memory: 16GiB
     sockets: 4
     cores: 1
     template: "{{ metadata.infraID }}-rhcos_tpl"
     operating_system: "rhcos_x64"
   ...
   ``

3. Create the templates and virtual machines:

   ```
   $ ansible-playbook -i inventory.yml create-templates-and-vms.yml
   ```

**18.5.22. Creating the bootstrap machine**

You create a bootstrap machine by running the `bootstrap.yml` playbook. This playbook starts the bootstrap virtual machine, and passes it the `bootstrap.ign` Ignition file from the assets directory. The bootstrap node configures itself so it can serve Ignition files to the control plane nodes.

To monitor the bootstrap process, you use the console in the RHV Administration Portal or connect to the virtual machine by using SSH.

**Procedure**

1. Create the bootstrap machine:

   ```
   $ ansible-playbook -i inventory.yml bootstrap.yml
   ```

2. Connect to the bootstrap machine using a console in the Administration Portal or SSH. Replace `<bootstrap_ip>` with the bootstrap node IP address. To use SSH, enter:

   ```
   $ ssh core@<bootstrap.ip>
   ```
3. Collect **bootkube.service** journald unit logs for the release image service from the bootstrap node:

```bash
[core@ocp4-lk6b4-bootstrap ~]$ journalctl -b -f -u release-image.service -u bootkube.service
```

**NOTE**

The **bootkube.service** log on the bootstrap node outputs etcd **connection refused** errors, indicating that the bootstrap server is unable to connect to etcd on control plane nodes. After etcd has started on each control plane node and the nodes have joined the cluster, the errors should stop.

18.5.23. Creating the control plane nodes

You create the control plane nodes by running the **masters.yml** playbook. This playbook passes the **master.ign** Ignition file to each of the virtual machines. The Ignition file contains a directive for the control plane node to get the Ignition from a URL such as **https://api-int.ocp4.example.org:22623/config/master**. The port number in this URL is managed by the load balancer, and is accessible only inside the cluster.

**Procedure**

1. Create the control plane nodes:

   ```bash
   $ ansible-playbook -i inventory.yml masters.yml
   ```

2. While the playbook creates your control plane, monitor the bootstrapping process:

   ```bash
   $ openshift-install wait-for bootstrap-complete --dir $ASSETS_DIR
   ```

**Example output**

```
INFO API v1.23.0 up
INFO Waiting up to 40m0s for bootstrapping to complete...
```

3. When all the pods on the control plane nodes and etcd are up and running, the installation program displays the following output.

**Example output**

```
INFO It is now safe to remove the bootstrap resources
```

18.5.24. Verifying cluster status

You can verify your OpenShift Container Platform cluster’s status during or after installation.

**Procedure**

1. In the cluster environment, export the administrator’s kubeconfig file:

   ```bash
   $ export KUBECONFIG=$ASSETS_DIR/auth/kubeconfig
   ```
The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server.

2. View the control plane and compute machines created after a deployment:

   ```bash
   $ oc get nodes
   ```

3. View your cluster’s version:

   ```bash
   $ oc get clusterversion
   ```

4. View your Operators’ status:

   ```bash
   $ oc get clusteroperator
   ```

5. View all running pods in the cluster:

   ```bash
   $ oc get pods -A
   ```

### 18.5.25. Removing the bootstrap machine

After the **wait-for** command shows that the bootstrap process is complete, you must remove the bootstrap virtual machine to free up compute, memory, and storage resources. Also, remove settings for the bootstrap machine from the load balancer directives.

**Procedure**

1. To remove the bootstrap machine from the cluster, enter:

   ```bash
   $ ansible-playbook -i inventory.yml retire-bootstrap.yml
   ```

2. Remove settings for the bootstrap machine from the load balancer directives.

### 18.5.26. Creating the worker nodes and completing the installation

Creating worker nodes is similar to creating control plane nodes. However, worker nodes workers do not automatically join the cluster. To add them to the cluster, you review and approve the workers’ pending CSRs (Certificate Signing Requests).

After approving the first requests, you continue approving CSR until all of the worker nodes are approved. When you complete this process, the worker nodes become **Ready** and can have pods scheduled to run on them.

Finally, monitor the command line to see when the installation process completes.

**Procedure**

1. Create the worker nodes:

   ```bash
   $ ansible-playbook -i inventory.yml workers.yml
   ```

2. To list all of the CSRs, enter:
Eventually, this command displays one CSR per node. For example:

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>SIGNERNAME</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-2lnxd</td>
<td>63m</td>
<td>kubernetes.io/kubelet-serving</td>
<td>system:node:ocp4-lk6b4-master0.ocp4.example.org</td>
<td>Approved,Issued</td>
</tr>
<tr>
<td>csr-hff4q</td>
<td>64m</td>
<td>kubernetes.io/kube-apiserver-client-kubelet</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Approved,Issued</td>
</tr>
<tr>
<td>csr-hsn96</td>
<td>60m</td>
<td>kubernetes.io/kubelet-serving</td>
<td>system:node:ocp4-lk6b4-master2.ocp4.example.org</td>
<td>Approved,Issued</td>
</tr>
<tr>
<td>csr-m724n</td>
<td>6m2s</td>
<td>kubernetes.io/kube-apiserver-client-kubelet</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-p4dz2</td>
<td>60m</td>
<td>kubernetes.io/kube-apiserver-client-kubelet</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Approved,Issued</td>
</tr>
<tr>
<td>csr-t9vfj</td>
<td>60m</td>
<td>kubernetes.io/kubelet-serving</td>
<td>system:node:ocp4-lk6b4-master1.ocp4.example.org</td>
<td>Approved,Issued</td>
</tr>
<tr>
<td>csr-tggtr</td>
<td>61m</td>
<td>kubernetes.io/kube-apiserver-client-kubelet</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Approved,Issued</td>
</tr>
<tr>
<td>csr-wcbrf</td>
<td>7m6s</td>
<td>kubernetes.io/kube-apiserver-client-kubelet</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Pending</td>
</tr>
</tbody>
</table>

To filter the list and see only pending CSRs, enter:

$ watch "oc get csr -A | grep pending -i"

This command refreshes the output every two seconds and displays only pending CSRs. For example:

Example output

Every 2.0s: oc get csr -A | grep pending -i

csr-m724n 10m kubernetes.io/kube-apiserver-client-kubelet
system:serviceaccount:openshift-machine-config-operator:node-bootstrapper Pending
csr-wcbrf 11m kubernetes.io/kube-apiserver-client-kubelet
system:serviceaccount:openshift-machine-config-operator:node-bootstrapper Pending

Inspect each pending request. For example:

Example output

$ oc describe csr csr-m724n

Example output

Name:            csr-m724n
Labels:          <none>
5. If the CSR information is correct, approve the request:

```bash
$ oc adm certificate approve csr-m724n
```

6. Wait for the installation process to finish:

```bash
$ openshift-install wait-for install-complete --dir $ASSETS_DIR --log-level debug
```

When the installation completes, the command line displays the URL of the OpenShift Container Platform web console and the administrator user name and password.

### 18.5.27. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.10, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use `subscription watch` to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- See [About remote health monitoring](#) for more information about the Telemetry service

### 18.5.28. Disabling the default OperatorHub sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

**Procedure**

- Disable the sources for the default catalogs by adding `disableAllDefaultSources: true` to the `OperatorHub` object:

  ```bash
  $ oc patch OperatorHub cluster --type json \
  -p '[{"op": "add", "path": "/spec/disableAllDefaultSources", "value": true}]'
  ```
TIP

Alternatively, you can use the web console to manage catalog sources. From the Administration → Cluster Settings → Configuration → OperatorHub page, click the Sources tab, where you can create, delete, disable, and enable individual sources.

18.6. UNINSTALLING A CLUSTER ON RHV

You can remove an OpenShift Container Platform cluster from Red Hat Virtualization (RHV).

18.6.1. Removing a cluster that uses installer-provisioned infrastructure

You can remove a cluster that uses installer-provisioned infrastructure from your cloud.

NOTE

After uninstallation, check your cloud provider for any resources not removed properly, especially with User Provisioned Infrastructure (UPI) clusters. There might be resources that the installer did not create or that the installer is unable to access.

Prerequisites

- Have a copy of the installation program that you used to deploy the cluster.
- Have the files that the installation program generated when you created your cluster.

Procedure

1. From the directory that contains the installation program on the computer that you used to install the cluster, run the following command:

```bash
$ ./openshift-install destroy cluster \
--dir <installation_directory> --log-level info
```

   1 For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   2 To view different details, specify `warn`, `debug`, or `error` instead of `info`.

   NOTE

   You must specify the directory that contains the cluster definition files for your cluster. The installation program requires the `metadata.json` file in this directory to delete the cluster.

   1. Optional: Delete the `<installation_directory>` directory and the OpenShift Container Platform installation program.

18.6.2. Removing a cluster that uses user-provisioned infrastructure

When you are finished using the cluster, you can remove a cluster that uses user-provisioned infrastructure from your cloud.
Prerequisites

- Have the original playbook files, assets directory and files, and $ASSETS_DIR environment variable that you used to install the cluster. Typically, you can achieve this by using the same computer you used when you installed the cluster.

Procedure

1. To remove the cluster, enter:

   ```bash
   $ ansible-playbook -i inventory.yml \
   retire-bootstrap.yml \
   retire-masters.yml \
   retire-workers.yml
   ```

2. Remove any configurations you added to DNS, load balancers, and any other infrastructure for this cluster.
CHAPTER 19. INSTALLING ON VSPHERE

19.1. PREPARING TO INSTALL ON VSPHERE

19.1.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- If you use a firewall and plan to use Telemetry, you configured the firewall to allow the sites required by your cluster.

19.1.2. Choosing a method to install OpenShift Container Platform on vSphere

You can install OpenShift Container Platform on vSphere by using installer-provisioned or user-provisioned infrastructure. The default installation type uses installer-provisioned infrastructure, where the installation program provisions the underlying infrastructure for the cluster. You can also install OpenShift Container Platform on infrastructure that you provide. If you do not use infrastructure that the installation program provisions, you must manage and maintain the cluster resources yourself.

See the Installation process for more information about installer-provisioned and user-provisioned installation processes.

**IMPORTANT**

The steps for performing a user-provisioned infrastructure installation are provided as an example only. Installing a cluster with infrastructure you provide requires knowledge of the vSphere platform and the installation process of OpenShift Container Platform. Use the user-provisioned infrastructure installation instructions as a guide; you are free to create the required resources through other methods.

19.1.2.1. Installer-provisioned infrastructure installation of OpenShift Container Platform on vSphere

Installer-provisioned infrastructure allows the installation program to pre-configure and automate the provisioning of resources required by OpenShift Container Platform.

- **Installing a cluster on vSphere** You can install OpenShift Container Platform on vSphere by using installer-provisioned infrastructure installation with no customization.
- **Installing a cluster on vSphere with customizations** You can install OpenShift Container Platform on vSphere by using installer-provisioned infrastructure installation with the default customization options.
- **Installing a cluster on vSphere with network customizations** You can install OpenShift Container Platform on installer-provisioned vSphere infrastructure, with network customizations. You can customize your OpenShift Container Platform network configuration during installation, so that your cluster can coexist with your existing IP address allocations and adhere to your network requirements.
- **Installing a cluster on vSphere in a restricted network** You can install a cluster on VMware
vSphere infrastructure in a restricted network by creating an internal mirror of the installation release content. You can use this method to deploy OpenShift Container Platform on an internal network that is not visible to the internet.

19.1.2.2. User-provisioned infrastructure installation of OpenShift Container Platform on vSphere

User-provisioned infrastructure requires the user to provision all resources required by OpenShift Container Platform.

- **Installing a cluster on vSphere with user-provisioned infrastructure** You can install OpenShift Container Platform on VMware vSphere infrastructure that you provision.

- **Installing a cluster on vSphere with network customizations with user-provisioned infrastructure**: You can install OpenShift Container Platform on VMware vSphere infrastructure that you provision with customized network configuration options.

- **Installing a cluster on vSphere in a restricted network with user-provisioned infrastructure** OpenShift Container Platform can be installed on VMware vSphere infrastructure that you provision in a restricted network.

19.1.3. VMware vSphere infrastructure requirements

You must install the OpenShift Container Platform cluster on a VMware vSphere version 6 or 7 instance that meets the requirements for the components that you use.

**Table 19.1. Version requirements for vSphere virtual environments**

<table>
<thead>
<tr>
<th>Virtual environment product</th>
<th>Required version</th>
</tr>
</thead>
<tbody>
<tr>
<td>VM hardware version</td>
<td>13 or later</td>
</tr>
<tr>
<td>vSphere ESXi hosts</td>
<td>6.5 or later</td>
</tr>
<tr>
<td>vCenter host</td>
<td>6.5 or later</td>
</tr>
</tbody>
</table>

**IMPORTANT**

Installing a cluster on VMware vSphere version 6.7U3 or earlier and virtual hardware version 13 is now deprecated. These versions are still fully supported, but version 4.11 of OpenShift Container Platform will require vSphere virtual hardware version 15 or later. Hardware version 15 is now the default for vSphere virtual machines in OpenShift Container Platform. To update the hardware version for your vSphere nodes, see the “Updating hardware on nodes running in vSphere” article.

If your vSphere nodes are below hardware version 15 or your VMware vSphere version is earlier than 6.7U3, upgrading from OpenShift Container Platform 4.10 to OpenShift Container Platform 4.11 is not available.

**Table 19.2. Minimum supported vSphere version for VMware components**
### Component

<table>
<thead>
<tr>
<th>Component</th>
<th>Minimum supported versions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hypervisor</td>
<td>vSphere 6.5 and later with HW version 13</td>
<td>This version is the minimum version that Red Hat Enterprise Linux CoreOS (RHCOS) supports. See the Red Hat Enterprise Linux 8 supported hypervisors list.</td>
</tr>
<tr>
<td>Storage with in-tree drivers</td>
<td>vSphere 6.5 and later</td>
<td>This plug-in creates vSphere storage by using the in-tree storage drivers for vSphere included in OpenShift Container Platform.</td>
</tr>
<tr>
<td>Optional: Networking (NSX-T)</td>
<td>vSphere 6.5U3 or vSphere 6.7U2 and later</td>
<td>vSphere 6.5U3 or vSphere 6.7U2+ are required for OpenShift Container Platform. VMware’s NSX Container Plug-in (NCP) is certified with OpenShift Container Platform 4.6 and NSX-T 3.x+.</td>
</tr>
</tbody>
</table>

If you use a vSphere version 6.5 instance, consider upgrading to 6.7U3 or 7.0 before you install OpenShift Container Platform.

#### IMPORTANT

You must ensure that the time on your ESXi hosts is synchronized before you install OpenShift Container Platform. See Edit Time Configuration for a Host in the VMware documentation.

### 19.1.4. VMware vSphere CSI Driver Operator requirements

The following requirements must be met in order to install the CSI Driver Operator:

- VMware vSphere version 6.7U3 or later
- Virtual machines of hardware version 15 or later
- No third-party CSI driver already installed in the cluster

If a third-party CSI driver is present in the cluster, OpenShift Container Platform does not overwrite it. The presence of a third-party CSI driver prevents OpenShift Container Platform from upgrading to 4.11.

#### Additional resources

- To remove a third-party CSI driver, see Removing a third-party vSphere CSI Driver.

### 19.1.5. Uninstalling an installer-provisioned infrastructure installation of OpenShift Container Platform on vSphere
Uninstalling a cluster on vSphere that uses installer-provisioned infrastructure: You can remove a cluster that you deployed on VMware vSphere infrastructure that used installer-provisioned infrastructure.

19.2. INSTALLING A CLUSTER ON VSPHERE

In OpenShift Container Platform version 4.10, you can install a cluster on your VMware vSphere instance by using installer-provisioned infrastructure.

19.2.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You provisioned persistent storage for your cluster. To deploy a private image registry, your storage must provide ReadWriteMany access modes.
- The OpenShift Container Platform installer requires access to port 443 on the vCenter and ESXi hosts. You verified that port 443 is accessible.
- If you use a firewall, you confirmed with the administrator that port 443 is accessible. Control plane nodes must be able to reach vCenter and ESXi hosts on port 443 for the installation to succeed.
- If you use a firewall, you configured it to allow the sites that your cluster requires access to.

NOTE

Be sure to also review this site list if you are configuring a proxy.

19.2.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.10, you require access to the internet to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.
19.2.3. VMware vSphere infrastructure requirements

You must install the OpenShift Container Platform cluster on a VMware vSphere version 6 or 7 instance that meets the requirements for the components that you use.

### Table 19.3. Version requirements for vSphere virtual environments

<table>
<thead>
<tr>
<th>Virtual environment product</th>
<th>Required version</th>
</tr>
</thead>
<tbody>
<tr>
<td>VM hardware version</td>
<td>13 or later</td>
</tr>
<tr>
<td>vSphere ESXi hosts</td>
<td>6.5 or later</td>
</tr>
<tr>
<td>vCenter host</td>
<td>6.5 or later</td>
</tr>
</tbody>
</table>

**IMPORTANT**

Installing a cluster on VMware vSphere version 6.7U3 or earlier and virtual hardware version 13 is now deprecated. These versions are still fully supported, but version 4.11 of OpenShift Container Platform will require vSphere virtual hardware version 15 or later. Hardware version 15 is now the default for vSphere virtual machines in OpenShift Container Platform. To update the hardware version for your vSphere nodes, see the "Updating hardware on nodes running in vSphere" article.

If your vSphere nodes are below hardware version 15 or your VMware vSphere version is earlier than 6.7U3, upgrading from OpenShift Container Platform 4.10 to OpenShift Container Platform 4.11 is not available.

### Table 19.4. Minimum supported vSphere version for VMware components

<table>
<thead>
<tr>
<th>Component</th>
<th>Minimum supported versions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hypervisor</td>
<td>vSphere 6.5 and later with HW version 13</td>
<td>This version is the minimum version that Red Hat Enterprise Linux CoreOS (RHCOS) supports. See the Red Hat Enterprise Linux 8 supported hypervisors list.</td>
</tr>
<tr>
<td>Storage with in-tree drivers</td>
<td>vSphere 6.5 and later</td>
<td>This plug-in creates vSphere storage by using the in-tree storage drivers for vSphere included in OpenShift Container Platform.</td>
</tr>
<tr>
<td>Optional: Networking (NSX-T)</td>
<td>vSphere 6.5U3 or vSphere 6.7U2 and later</td>
<td>vSphere 6.5U3 or vSphere 6.7U2+ are required for OpenShift Container Platform. VMware’s NSX Container Plug-in (NCP) is certified with OpenShift Container Platform 4.6 and NSX-T 3.x+.</td>
</tr>
</tbody>
</table>
If you use a vSphere version 6.5 instance, consider upgrading to 6.7U3 or 7.0 before you install OpenShift Container Platform.

**IMPORTANT**
You must ensure that the time on your ESXi hosts is synchronized before you install OpenShift Container Platform. See *Edit Time Configuration for a Host* in the VMware documentation.

### 19.2.4. VMware vSphere CSI Driver Operator requirements

The following requirements must be met in order to install the CSI Driver Operator:

- VMware vSphere version 6.7U3 or later
- Virtual machines of hardware version 15 or later
- No third-party CSI driver already installed in the cluster

If a third-party CSI driver is present in the cluster, OpenShift Container Platform does not overwrite it. The presence of a third-party CSI driver prevents OpenShift Container Platform from upgrading to 4.11.

**Additional resources**
- To remove a third-party CSI driver, see *Removing a third-party vSphere CSI Driver*.
- To update the hardware version for your vSphere nodes, see *Updating hardware on nodes running in vSphere*.

### 19.2.5. vCenter requirements

Before you install an OpenShift Container Platform cluster on your vCenter that uses infrastructure that the installer provisions, you must prepare your environment.

**Required vCenter account privileges**

To install an OpenShift Container Platform cluster in a vCenter, the installation program requires access to an account with privileges to read and create the required resources. Using an account that has global administrative privileges is the simplest way to access all of the necessary permissions.

If you cannot use an account with global administrative privileges, you must create roles to grant the privileges necessary for OpenShift Container Platform cluster installation. While most of the privileges are always required, some are required only if you plan for the installation program to provision a folder to contain the OpenShift Container Platform cluster on your vCenter instance, which is the default behavior. You must create or amend vSphere roles for the specified objects to grant the required privileges.

An additional role is required if the installation program is to create a vSphere virtual machine folder.

**Example 19.1. Roles and privileges required for installation**

<table>
<thead>
<tr>
<th>vSphere object for role</th>
<th>When required</th>
<th>Required privileges</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>

</tr>
<tr>
<td></td>
<td></td>
<td>CreateFromExisting, Inventory.Delete, Provisioning.Clone, Provisioning.DeployTemplate, Provisioning.Remove</td>
</tr>
</tbody>
</table>
Additionally, the user requires some **ReadOnly** permissions, and some of the roles require permission to propagate the permissions to child objects. These settings vary depending on whether or not you install the cluster into an existing folder.

### Example 19.2. Required permissions and propagation settings

<table>
<thead>
<tr>
<th>vSphere object</th>
<th>Folder type</th>
<th>Propagate to children</th>
<th>Permissions required</th>

<td>Existing folder</td>
<td>True</td>
<td>Listed required privileges</td>
</tr>
</tbody>
</table>

For more information about creating an account with only the required privileges, see [vSphere Permissions and User Management Tasks](#) in the vSphere documentation.

### Using OpenShift Container Platform with vMotion

**IMPORTANT**

OpenShift Container Platform generally supports compute-only vMotion. Using Storage vMotion can cause issues and is not supported.

If you are using vSphere volumes in your pods, migrating a VM across datastores either manually or through Storage vMotion causes invalid references within OpenShift Container Platform persistent volume (PV) objects. These references prevent affected pods from starting up and can result in data loss.
Similarly, OpenShift Container Platform does not support selective migration of VMDKs across datastores, using datastore clusters for VM provisioning or for dynamic or static provisioning of PVs, or using a datastore that is part of a datastore cluster for dynamic or static provisioning of PVs.

**Cluster resources**
When you deploy an OpenShift Container Platform cluster that uses installer-provisioned infrastructure, the installation program must be able to create several resources in your vCenter instance.

A standard OpenShift Container Platform installation creates the following vCenter resources:

- 1 Folder
- 1 Tag category
- 1 Tag
- Virtual machines:
  - 1 template
  - 1 temporary bootstrap node
  - 3 control plane nodes
  - 3 compute machines

Although these resources use 856 GB of storage, the bootstrap node is destroyed during the cluster installation process. A minimum of 800 GB of storage is required to use a standard cluster.

If you deploy more compute machines, the OpenShift Container Platform cluster will use more storage.

**Cluster limits**
Available resources vary between clusters. The number of possible clusters within a vCenter is limited primarily by available storage space and any limitations on the number of required resources. Be sure to consider both limitations to the vCenter resources that the cluster creates and the resources that you require to deploy a cluster, such as IP addresses and networks.

**Networking requirements**
You must use DHCP for the network and ensure that the DHCP server is configured to provide persistent IP addresses to the cluster machines. All nodes must be in the same VLAN. You cannot scale the cluster using a second VLAN as a Day 2 operation. Additionally, you must create the following networking resources before you install the OpenShift Container Platform cluster:

**NOTE**
It is recommended that each OpenShift Container Platform node in the cluster must have access to a Network Time Protocol (NTP) server that is discoverable via DHCP. Installation is possible without an NTP server. However, asynchronous server clocks will cause errors, which NTP server prevents.

**Required IP Addresses**
An installer-provisioned vSphere installation requires two static IP addresses:

- The **API** address is used to access the cluster API.
- The **Ingress** address is used for cluster ingress traffic.
You must provide these IP addresses to the installation program when you install the OpenShift Container Platform cluster.

DNS records
You must create DNS records for two static IP addresses in the appropriate DNS server for the vCenter instance that hosts your OpenShift Container Platform cluster. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the cluster base domain that you specify when you install the cluster. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>`.

Table 19.5. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>API VIP</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>This DNS A/AAAA or CNAME record must point to the load balancer for the control plane machines. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Ingress VIP</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A wildcard DNS A/AAAA or CNAME record that points to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>

19.2.6. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The ./openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.
Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   `$ ssh-keygen -t ed25519 -N " " -f <path>/<file_name> ①`

   ① Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   `$ cat <path>/<file_name>.pub`

   For example, run the following to view the `~/.ssh/id_rsa.pub` public key:

   `$ cat ~/.ssh/id_rsa.pub`

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

   **NOTE**

   On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

   a. If the `ssh-agent` process is not already running for your local user, start it as a background task:

   `$ eval "$(ssh-agent -s)"`

   **Example output**

   `Agent pid 31874`

   **NOTE**

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the `ssh-agent`:

   ```
Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

Example output

Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

19.2.7. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on your provisioning machine.

Prerequisites

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

   **IMPORTANT**

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   **IMPORTANT**

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   $ ssh-add <path>/<file_name>

   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

   $ tar -xvf openshift-install-linux.tar.gz
5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

19.2.8. Adding vCenter root CA certificates to your system trust

Because the installation program requires access to your vCenter’s API, you must add your vCenter’s trusted root CA certificates to your system trust before you install an OpenShift Container Platform cluster.

Procedure

1. From the vCenter home page, download the vCenter’s root CA certificates. Click Download trusted root CA certificates in the vSphere Web Services SDK section. The `<vCenter>/certs/download.zip` file downloads.

2. Extract the compressed file that contains the vCenter root CA certificates. The contents of the compressed file resemble the following file structure:

```
certs
├── lin
│   ├── 108f4d17.0
│   ├── 108f4d17.r1
│   ├── 7e757f6a.0
│   ├── 8e4f8471.0
│   └── 8e4f8471.r0
├── mac
│   ├── 108f4d17.0
│   ├── 108f4d17.r1
│   ├── 7e757f6a.0
│   ├── 8e4f8471.0
│   └── 8e4f8471.r0
└── win
    ├── 108f4d17.0.crt
    ├── 108f4d17.r1.crl
    ├── 7e757f6a.0.crt
    ├── 8e4f8471.0.crt
    └── 8e4f8471.r0.crl
```

3 directories, 15 files

3. Add the files for your operating system to the system trust. For example, on a Fedora operating system, run the following command:

```
# cp certs/lin/* /etc/pki/ca-trust/source/anchors
```

4. Update your system trust. For example, on a Fedora operating system, run the following command:

```
# update-ca-trust extract
```

19.2.9. Deploying the cluster
You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

**Prerequisites**

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Change to the directory that contains the installation program and initialize the cluster deployment:

   ```bash
   $ ./openshift-install create cluster --dir <installation_directory> \
   --log-level=info
   ```

   1. For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

   2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

   **IMPORTANT**

   Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

   Provide values at the prompts:

   a. Optional: Select an SSH key to use to access your cluster machines.

   **NOTE**

   For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

   b. Select `vsphere` as the platform to target.

   c. Specify the name of your vCenter instance.

   d. Specify the user name and password for the vCenter account that has the required permissions to create the cluster.

   The installation program connects to your vCenter instance.

   e. Select the datacenter in your vCenter instance to connect to.
f. Select the default vCenter datastore to use.

g. Select the vCenter cluster to install the OpenShift Container Platform cluster in. The installation program uses the root resource pool of the vSphere cluster as the default resource pool.

h. Select the network in the vCenter instance that contains the virtual IP addresses and DNS records that you configured.

i. Enter the virtual IP address that you configured for control plane API access.

j. Enter the virtual IP address that you configured for cluster ingress.

k. Enter the base domain. This base domain must be the same one that you used in the DNS records that you configured.

l. Enter a descriptive name for your cluster. The cluster name must be the same one that you used in the DNS records that you configured.

m. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

+ When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the kubeadmin user, display in your terminal.

+ Example output

```
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: “kubeadmin”, and password: “4vYBz-Ee6gm-ymBZj-Wt5A1”
INFO Time elapsed: 36m22s
```

+ NOTE

The cluster access and credential information also outputs to `<installation_directory>/openshift_install.log` when an installation succeeds.
IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

IMPORTANT

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

19.2.10. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

IMPORTANT

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.10. Download and install the new version of oc.

Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.10 Linux Client entry and save the file.

4. Unpack the archive:

   `$ tar xvzf <file>`

5. Place the oc binary in a directory that is on your PATH.

   To check your PATH, execute the following command:

   `$ echo $PATH`
After you install the OpenShift CLI, it is available using the `oc` command:

```
$ oc <command>
```

### Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (`oc`) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.
3. Click **Download Now** next to the **OpenShift v4.10 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the `oc` binary to a directory that is on your `PATH`.
   
   To check your `PATH`, open the command prompt and execute the following command:
   
   ```
   C:\> path
   ```

After you install the OpenShift CLI, it is available using the `oc` command:

```
C:\> oc <command>
```

### Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (`oc`) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.
3. Click **Download Now** next to the **OpenShift v4.10 MacOSX Client** entry and save the file.
4. Unpack and unzip the archive.
5. Move the `oc` binary to a directory on your `PATH`.
   
   To check your `PATH`, open a terminal and execute the following command:
   
   ```
   $ echo $PATH
   ```

After you install the OpenShift CLI, it is available using the `oc` command:

```
$ oc <command>
```

### 19.2.11. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The
**kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

**Procedure**

1. Export the **kubeadmin** credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ``

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   ```

   Example output
   ```
   system:admin
   ```

**19.2.12. Creating registry storage**

After you install the cluster, you must create storage for the registry Operator.

**19.2.12.1. Image registry removed during installation**

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as **Removed**. This allows **openshift-installer** to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the **managementState** from **Removed** to **Managed**.

**NOTE**

The Prometheus console provides an **ImageRegistryRemoved** alert, for example:

"Image Registry has been removed. **ImageStreamTags**, **BuildConfigs** and **DeploymentConfigs** which reference **ImageStreamTags** may not work as expected. Please configure storage and update the config to **Managed** state by editing configs.imageregistry.operator.openshift.io."

**19.2.12.2. Image registry storage configuration**
The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the **Recreate** rollout strategy during upgrades.

### 19.2.12.2.1. Configuring registry storage for VMware vSphere

As a cluster administrator, following installation you must configure your registry to use storage.

**Prerequisites**

- Cluster administrator permissions.
- A cluster on VMware vSphere.
- Persistent storage provisioned for your cluster, such as Red Hat OpenShift Data Foundation.

**IMPORTANT**

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have “100Gi” capacity.

**IMPORTANT**

Testing shows issues with using the NFS server on RHEL as storage backend for core services. This includes the OpenShift Container Registry and Quay, Prometheus for monitoring storage, and Elasticsearch for logging storage. Therefore, using RHEL NFS to back PVs used by core services is not recommended.

Other NFS implementations on the marketplace might not have these issues. Contact the individual NFS implementation vendor for more information on any testing that was possibly completed against these OpenShift Container Platform core components.

**Procedure**

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

   **NOTE**

   When using shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:
$ oc get pod -n openshift-image-registry -l docker-registry=default

Example output
No resources found in openshift-image-registry namespace

NOTE
If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

$ oc edit configs.imageregistry.operator.openshift.io

Example output

   storage:
     pvc:
       claim: 1

Leave the **claim** field blank to allow the automatic creation of an **image-registry-storage PVC**.

4. Check the **clusteroperator** status:

$ oc get clusteroperator image-registry

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
<th>SINCE</th>
<th>MESSAGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>image-registry</td>
<td>4.7</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>6h50m</td>
<td></td>
</tr>
</tbody>
</table>

19.2.12.2.2. Configuring block registry storage for VMware vSphere

To allow the image registry to use block storage types such as vSphere Virtual Machine Disk (VMDK) during upgrades as a cluster administrator, you can use the **Recreate** rollout strategy.

**IMPORTANT**

Block storage volumes are supported but not recommended for use with image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

**Procedure**

1. To set the image registry storage as a block storage type, patch the registry so that it uses the **Recreate** rollout strategy and runs with only **1** replica:
2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.

   a. Create a `pvc.yaml` file with the following contents to define a VMware vSphere PersistentVolumeClaim object:

   ```yaml
   kind: PersistentVolumeClaim
   apiVersion: v1
   metadata:
     name: image-registry-storage ①
     namespace: openshift-image-registry ②
   spec:
     accessModes:
     - ReadWriteOnce ③
     resources:
       requests:
         storage: 100Gi ④
   ``

   ① A unique name that represents the PersistentVolumeClaim object.
   ② The namespace for the PersistentVolumeClaim object, which is openshift-image-registry.
   ③ The access mode of the persistent volume claim. With ReadWriteOnce, the volume can be mounted with read and write permissions by a single node.
   ④ The size of the persistent volume claim.

   b. Create the PersistentVolumeClaim object from the file:

   ```bash
   $ oc create -f pvc.yaml -n openshift-image-registry
   ``

3. Edit the registry configuration so that it references the correct PVC:

   ```bash
   $ oc edit config.imageregistry.operator.openshift.io -o yaml
   ``

   **Example output**

   ```yaml
   storage:
   pvc:
     claim: ①
   ``

   ① Creating a custom PVC allows you to leave the claim field blank for the default automatic creation of an image-registry-storage PVC.

For instructions about configuring registry storage so that it references the correct PVC, see Configuring the registry for vSphere.
19.2.13. Backing up VMware vSphere volumes

OpenShift Container Platform provisions new volumes as independent persistent disks to freely attach and detach the volume on any node in the cluster. As a consequence, it is not possible to back up volumes that use snapshots, or to restore volumes from snapshots. See Snapshot Limitations for more information.

Procedure

To create a backup of persistent volumes:

1. Stop the application that is using the persistent volume.
2. Clone the persistent volume.
3. Restart the application.
4. Create a backup of the cloned volume.
5. Delete the cloned volume.

19.2.14. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.10, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service

19.2.15. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- Set up your registry and configure registry storage.
- Optional: View the events from the vSphere Problem Detector Operator to determine if the cluster has permission or storage configuration issues.

19.3. INSTALLING A CLUSTER ON VSPHERE WITH CUSTOMIZATIONS

In OpenShift Container Platform version 4.10, you can install a cluster on your VMware vSphere instance by using installer-provisioned infrastructure. To customize the installation, you modify parameters in the install-config.yaml file before you install the cluster.

19.3.1. Prerequisites
You reviewed details about the OpenShift Container Platform installation and update processes.

You read the documentation on selecting a cluster installation method and preparing it for users.

You provisioned persistent storage for your cluster. To deploy a private image registry, your storage must provide ReadWriteMany access modes.

The OpenShift Container Platform installer requires access to port 443 on the vCenter and ESXi hosts. You verified that port 443 is accessible.

If you use a firewall, you confirmed with the administrator that port 443 is accessible. Control plane nodes must be able to reach vCenter and ESXi hosts on port 443 for the installation to succeed.

If you use a firewall, you configured it to allow the sites that your cluster requires access to.

**NOTE**

Be sure to also review this site list if you are configuring a proxy.

### 19.3.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.10, you require access to the internet to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- Access Quay.io to obtain the packages that are required to install your cluster.

- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 19.3.3. VMware vSphere infrastructure requirements

You must install the OpenShift Container Platform cluster on a VMware vSphere version 6 or 7 instance that meets the requirements for the components that you use.

**Table 19.6. Version requirements for vSphere virtual environments**
Virtual environment product | Required version
--- | ---
VM hardware version | 13 or later
vSphere ESXi hosts | 6.5 or later
vCenter host | 6.5 or later

**IMPORTANT**

Installing a cluster on VMware vSphere version 6.7U3 or earlier and virtual hardware version 13 is now deprecated. These versions are still fully supported, but version 4.11 of OpenShift Container Platform will require vSphere virtual hardware version 15 or later. Hardware version 15 is now the default for vSphere virtual machines in OpenShift Container Platform. To update the hardware version for your vSphere nodes, see the “Updating hardware on nodes running in vSphere” article.

If your vSphere nodes are below hardware version 15 or your VMware vSphere version is earlier than 6.7U3, upgrading from OpenShift Container Platform 4.10 to OpenShift Container Platform 4.11 is not available.

Table 19.7. Minimum supported vSphere version for VMware components

<table>
<thead>
<tr>
<th>Component</th>
<th>Minimum supported versions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hypervisor</td>
<td>vSphere 6.5 and later with HW version 13</td>
<td>This version is the minimum version that Red Hat Enterprise Linux CoreOS (RHCOS) supports. See the Red Hat Enterprise Linux 8 supported hypervisors list.</td>
</tr>
<tr>
<td>Storage with in-tree drivers</td>
<td>vSphere 6.5 and later</td>
<td>This plug-in creates vSphere storage by using the in-tree storage drivers for vSphere included in OpenShift Container Platform.</td>
</tr>
<tr>
<td>Optional: Networking (NSX-T)</td>
<td>vSphere 6.5U3 or vSphere 6.7U2 and later</td>
<td>vSphere 6.5U3 or vSphere 6.7U2+ are required for OpenShift Container Platform. VMware’s NSX Container Plug-in (NCP) is certified with OpenShift Container Platform 4.6 and NSX-T 3.x+.</td>
</tr>
</tbody>
</table>

If you use a vSphere version 6.5 instance, consider upgrading to 6.7U3 or 7.0 before you install OpenShift Container Platform.
IMPORTANT

You must ensure that the time on your ESXi hosts is synchronized before you install OpenShift Container Platform. See Edit Time Configuration for a Host in the VMware documentation.

19.3.4. VMware vSphere CSI Driver Operator requirements

The following requirements must be met in order to install the CSI Driver Operator:

- VMware vSphere version 6.7U3 or later
- Virtual machines of hardware version 15 or later
- No third-party CSI driver already installed in the cluster

If a third-party CSI driver is present in the cluster, OpenShift Container Platform does not overwrite it. The presence of a third-party CSI driver prevents OpenShift Container Platform from upgrading to 4.11.

Additional resources

- To remove a third-party CSI driver, see Removing a third-party vSphere CSI Driver.
- To update the hardware version for your vSphere nodes, see Updating hardware on nodes running in vSphere.

19.3.5. vCenter requirements

Before you install an OpenShift Container Platform cluster on your vCenter that uses infrastructure that the installer provisions, you must prepare your environment.

Required vCenter account privileges

To install an OpenShift Container Platform cluster in a vCenter, the installation program requires access to an account with privileges to read and create the required resources. Using an account that has global administrative privileges is the simplest way to access all of the necessary permissions.

If you cannot use an account with global administrative privileges, you must create roles to grant the privileges necessary for OpenShift Container Platform cluster installation. While most of the privileges are always required, some are required only if you plan for the installation program to provision a folder to contain the OpenShift Container Platform cluster on your vCenter instance, which is the default behavior. You must create or amend vSphere roles for the specified objects to grant the required privileges.

An additional role is required if the installation program is to create a vSphere virtual machine folder.

Example 19.3. Roles and privileges required for installation

<table>
<thead>
<tr>
<th>vSphere object for role</th>
<th>When required</th>
<th>Required privileges</th>
</tr>
</thead>
<tbody>
<tr>
<td>vSphere object for role</td>

</tr>
<tr>
<td></td>
<td></td>
<td>VirtualMachine.Provisioning.Clone</td>
</tr>
<tr>
<td></td>
<td></td>
<td>VirtualMachine.Provisioning.DeployTemplate</td>
</tr>
</tbody>
</table>
Additionally, the user requires some **ReadOnly** permissions, and some of the roles require permission to propagate the permissions to child objects. These settings vary depending on whether or not you install the cluster into an existing folder.

### Example 19.4. Required permissions and propagation settings

<table>
<thead>
<tr>
<th>vSphere object</th>

<td>True</td>
<td>Listed required privileges</td>
</tr>
</tbody>
</table>

For more information about creating an account with only the required privileges, see **vSphere Permissions and User Management Tasks** in the vSphere documentation.

### Using OpenShift Container Platform with vMotion

**IMPORTANT**

OpenShift Container Platform generally supports compute-only vMotion. Using Storage vMotion can cause issues and is not supported.

If you are using vSphere volumes in your pods, migrating a VM across datastores either manually or through Storage vMotion causes invalid references within OpenShift Container Platform persistent volume (PV) objects. These references prevent affected pods from starting up and can result in data loss.
Similarly, OpenShift Container Platform does not support selective migration of VMDKs across datastores, using datastore clusters for VM provisioning or for dynamic or static provisioning of PVs, or using a datastore that is part of a datastore cluster for dynamic or static provisioning of PVs.

Cluster resources
When you deploy an OpenShift Container Platform cluster that uses installer-provisioned infrastructure, the installation program must be able to create several resources in your vCenter instance.

A standard OpenShift Container Platform installation creates the following vCenter resources:

- 1 Folder
- 1 Tag category
- 1 Tag
- Virtual machines:
  - 1 template
  - 1 temporary bootstrap node
  - 3 control plane nodes
  - 3 compute machines

Although these resources use 856 GB of storage, the bootstrap node is destroyed during the cluster installation process. A minimum of 800 GB of storage is required to use a standard cluster.

If you deploy more compute machines, the OpenShift Container Platform cluster will use more storage.

Cluster limits
Available resources vary between clusters. The number of possible clusters within a vCenter is limited primarily by available storage space and any limitations on the number of required resources. Be sure to consider both limitations to the vCenter resources that the cluster creates and the resources that you require to deploy a cluster, such as IP addresses and networks.

Networking requirements
You must use DHCP for the network and ensure that the DHCP server is configured to provide persistent IP addresses to the cluster machines. All nodes must be in the same VLAN. You cannot scale the cluster using a second VLAN as a Day 2 operation. Additionally, you must create the following networking resources before you install the OpenShift Container Platform cluster:

NOTE
It is recommended that each OpenShift Container Platform node in the cluster must have access to a Network Time Protocol (NTP) server that is discoverable via DHCP. Installation is possible without an NTP server. However, asynchronous server clocks will cause errors, which NTP server prevents.

Required IP Addresses
An installer-provisioned vSphere installation requires two static IP addresses:

- The **API** address is used to access the cluster API.
- The **Ingress** address is used for cluster ingress traffic.
You must provide these IP addresses to the installation program when you install the OpenShift Container Platform cluster.

**DNS records**
You must create DNS records for two static IP addresses in the appropriate DNS server for the vCenter instance that hosts your OpenShift Container Platform cluster. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the cluster base domain that you specify when you install the cluster. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>`.

**Table 19.8. Required DNS records**

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>API VIP</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>This DNS A/AAAA or CNAME record must point to the load balancer for the control plane machines. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Ingress VIP</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>A wildcard DNS A/AAAA or CNAME record that points to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**19.3.6. Generating a key pair for cluster node SSH access**

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the `core` user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user `core`. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.
Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>
   ```

   Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

   **NOTE**
   
   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   ```bash
   $ cat <path>/<file_name>.pub
   ```

   For example, run the following to view the `~/.ssh/id_rsa.pub` public key:

   ```bash
   $ cat ~/.ssh/id_rsa.pub
   ```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

   **NOTE**
   
   On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

   a. If the `ssh-agent` process is not already running for your local user, start it as a background task:

   ```bash
   $ eval "$(ssh-agent -s)"
   ```

   **Example output**

   ```
   Agent pid 31874
   ```

   **NOTE**
   
   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the `ssh-agent`:
Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

Example output

`Identity added: /home/<you>/<path>/<file_name> (<computer_name>)`

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

19.3.7. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on your provisioning machine.

Prerequisites

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

**IMPORTANT**

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```
5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

19.3.8. Adding vCenter root CA certificates to your system trust

Because the installation program requires access to your vCenter’s API, you must add your vCenter’s trusted root CA certificates to your system trust before you install an OpenShift Container Platform cluster.

Procedure

1. From the vCenter home page, download the vCenter’s root CA certificates. Click Download trusted root CA certificates in the vSphere Web Services SDK section. The `<vCenter>/certs/download.zip` file downloads.

2. Extract the compressed file that contains the vCenter root CA certificates. The contents of the compressed file resemble the following file structure:

   ```
   certs
   ├── lin
   │   ├── 108f4d17.0

   └── win
       ├── 108f4d17.0.crt
       └── 108f4d17.1.crt
   3 directories, 15 files
   ```

3. Add the files for your operating system to the system trust. For example, on a Fedora operating system, run the following command:

   ```
   # cp certs/lin/* /etc/pki/ca-trust/source/anchors
   ```

4. Update your system trust. For example, on a Fedora operating system, run the following command:

   ```
   # update-ca-trust extract
   ```

19.3.9. Creating the installation configuration file
You can customize the OpenShift Container Platform cluster you install on VMware vSphere.

**Prerequisites**

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.
- Obtain service principal permissions at the subscription level.

**Procedure**

1. Create the `install-config.yaml` file.
   
   a. Change to the directory that contains the installation program and run the following command:

   ```bash
   ./openshift-install create install-config --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

   **IMPORTANT**

   Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

   b. At the prompts, provide the configuration details for your cloud:

   i. Optional: Select an SSH key to use to access your cluster machines.

   **NOTE**

   For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

   ii. Select `vsphere` as the platform to target.

   iii. Specify the name of your vCenter instance.

   iv. Specify the user name and password for the vCenter account that has the required permissions to create the cluster.

   The installation program connects to your vCenter instance.

   v. Select the datacenter in your vCenter instance to connect to.

   vi. Select the default vCenter datastore to use.
vii. Select the vCenter cluster to install the OpenShift Container Platform cluster in. The installation program uses the root resource pool of the vSphere cluster as the default resource pool.

viii. Select the network in the vCenter instance that contains the virtual IP addresses and DNS records that you configured.

ix. Enter the virtual IP address that you configured for control plane API access.

x. Enter the virtual IP address that you configured for cluster ingress.

xi. Enter the base domain. This base domain must be the same one that you used in the DNS records that you configured.

xii. Enter a descriptive name for your cluster. The cluster name must be the same one that you used in the DNS records that you configured.

xiii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

2. Modify the install-config.yaml file. You can find more information about the available parameters in the "Installation configuration parameters" section.

3. Back up the install-config.yaml file so that you can use it to install multiple clusters.

   IMPORTANT

   The install-config.yaml file is consumed during the installation process. If you want to reuse the file, you must back it up now.

   19.3.9.1. Installation configuration parameters

   Before you deploy an OpenShift Container Platform cluster, you provide a customized install-config.yaml installation configuration file that describes the details for your environment.

   NOTE

   After installation, you cannot modify these parameters in the install-config.yaml file.

   19.3.9.1.1. Required configuration parameters

   Required installation configuration parameters are described in the following table:

   **Table 19.9. Required parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the install-config.yaml content. The current version is v1. The installer may also support older API versions.</td>
<td>String</td>
</tr>
</tbody>
</table>
The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the `baseDomain` and `metadata.name` parameter values that uses the `<metadata.name>.<baseDomain>` format.

A fully-qualified domain or subdomain name, such as `example.com`.

Kubernetes resource `ObjectMeta`, from which only the `name` parameter is consumed.

The name of the cluster. DNS records for the cluster are all subdomains of `{{.metadata.name}}.{{.baseDomain}}`.

String of lowercase letters, hyphens (-), and periods (.), such as `dev`.

The configuration for the specific platform upon which to perform the installation: `alibabacloud`, `aws`, `baremetal`, `azure`, `ibmcloud`, `openstack`, `ovirt`, `vsphere`, or `{}`. For additional information about `platform.<platform>` parameters, consult the table for your specific platform that follows.
### Pull Secret

Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.

```json
{
"auths":{
  "cloud.openshift.com":{
    "auth":"b3Blb=",
    "email":"you@example.com"
  },
  "quay.io":{
    "auth":"b3Blb=",
    "email":"you@example.com"
  }
}
```

### 19.3.9.1.2. Network Configuration Parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

#### Table 19.10. Network Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>networking</code></td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>NOTE</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>You cannot modify parameters specified by the <code>networking</code> object after installation.</td>
</tr>
<tr>
<td><code>networking.network</code></td>
<td>The cluster network provider.</td>
<td>Either <code>OpenShiftSDN</code> or <code>OVNKubernetes</code>. The default value is <code>OpenShiftSDN</code>.</td>
</tr>
<tr>
<td><code>networking.clusterNetwork</code></td>
<td>The IP address blocks for pods.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>networking:</code></td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>clusterNetwork:</code></td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>- cidr: 10.128.0.0/14</code></td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>hostPrefix: 23</code></td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td>networking.clusterNetwork.cidr</td>
<td>Required if you use <code>networking.clusterNetwork</code>. An IP address block.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td>networking.clusterNetwork.hostPrefix</td>
<td>The subnet prefix length to assign to each individual node. For example, if <code>hostPrefix</code> is set to 23 then each node is assigned a /23 subnet out of the given <code>cidr</code>. A <code>hostPrefix</code> value of 23 provides 510 (2^{(32 - 23)} - 2) pod IP addresses.</td>
<td>A subnet prefix. The default value is 23.</td>
</tr>
</tbody>
</table>
| networking.serviceNetwork | The IP address block for services. The default value is 172.30.0.0/16. | An array with an IP address block in CIDR format. For example:  
```yaml  
networking:  
serviceNetwork:  
- 172.30.0.0/16  
``` |
| networking.machineNetwork | The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap. If you specify multiple IP kernel arguments, the `machineNetwork.cidr` value must be the CIDR of the primary network. | An array of objects. For example:  
```yaml  
networking:  
machineNetwork:  
- cidr: 10.0.0.0/16  
``` |
| networking.machineNetwork.cidr | Required if you use `networking.machineNetwork`. An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24. | An IP network block in CIDR notation. For example, 10.0.0.0/16. |

### 19.3.9.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>cgroupsV2</td>
<td>Enables Linux control groups version 2 (cgroups v2) on specific nodes in your cluster. The OpenShift Container Platform process for enabling cgroups v2 disables all cgroup version 1 controllers and hierarchies. The OpenShift Container Platform cgroups version 2 feature is in Developer Preview and is not supported by Red Hat at this time.</td>
<td>true</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of MachinePool objects.</td>
</tr>
<tr>
<td>compute.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are s390x (the default).</td>
<td>String</td>
</tr>
<tr>
<td>compute.hyperthreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td></td>
</tr>
<tr>
<td>compute.name</td>
<td>Required if you use compute. The name of the machine pool.</td>
<td>worker</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td>compute.platform</td>
<td>Required if you use <code>compute</code>. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <code>controlPlane.platform</code> parameter value.</td>
<td>alibaba, aws, azure, gcp, ibmcloud, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td>compute.replicas</td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td>controlPlane</td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of MachinePool objects.</td>
</tr>
<tr>
<td>controlPlane.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are s390x (the default).</td>
<td>String</td>
</tr>
<tr>
<td>controlPlane.hypertreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>controlPlane.name</td>
<td>Required if you use <code>controlPlane</code>. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use <code>controlPlane</code>. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the <code>compute.platform</code> parameter value.</td>
<td>alibaba, aws, azure, gcp, ibmcloud, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------</td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (“”).</td>
</tr>
</tbody>
</table>

**NOTE**

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Platform Operators reference content.
### fips

Enable or disable FIPS mode. The default is **false** (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the **x86_64** architecture.

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>imageContentSources</strong></td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects.</td>
</tr>
<tr>
<td><strong>imageContentSources.source</strong></td>
<td>Required if you use <strong>imageContentSources</strong>. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td><strong>imageContentSources.mirrors</strong></td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
</tbody>
</table>
### publish

How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.

- **Internal** or **External**. The default value is **External**.

  Setting this field to **Internal** is not supported on non-cloud platforms and IBM Cloud.

**IMPORTANT**

If the value of the field is set to **Internal**, the cluster will become non-functional. For more information, refer to [BZ#1953035](#).

### sshKey

The SSH key or keys to authenticate access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

One or more keys. For example:

```
sshKey:
  <key1>
  <key2>
  <key3>
```

---

### 19.3.9.1.4. Additional VMware vSphere configuration parameters

Additional VMware vSphere configuration parameters are described in the following table:

#### Table 19.12. Additional VMware vSphere cluster parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>platform.vsphere.vCenter</code></td>
<td>The fully-qualified hostname or IP address of the vCenter server.</td>
<td>String</td>
</tr>
<tr>
<td><code>platform.vsphere.username</code></td>
<td>The user name to use to connect to the vCenter instance with. This user must have at least the roles and privileges that are required for static or dynamic persistent volume provisioning in vSphere.</td>
<td>String</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>---------------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------------------------------------------</td>
</tr>
<tr>
<td>platform.vsphere.password</td>
<td>The password for the vCenter username.</td>
<td>String</td>
</tr>
<tr>
<td>platform.vsphere.datacenter</td>
<td>The name of the datacenter to use in the vCenter instance.</td>
<td>String</td>
</tr>
<tr>
<td>platform.vsphere.defaultDatastore</td>
<td>The name of the default datastore to use for provisioning volumes.</td>
<td>String</td>
</tr>
<tr>
<td>platform.vsphere.folder</td>
<td>Optional. The absolute path of an existing folder where the installation program creates the virtual machines. If you do not provide this value, the installation program creates a folder that is named with the infrastructure ID in the datacenter virtual machine folder.</td>
<td>String, for example, /&lt;datacenter_name&gt;/vm/&lt;folder_name&gt;/&lt;subfolder_name&gt;.</td>
</tr>
<tr>
<td>platform.vsphere.network</td>
<td>The network in the vCenter instance that contains the virtual IP addresses and DNS records that you configured.</td>
<td>String</td>
</tr>
<tr>
<td>platform.vsphere.cluster</td>
<td>The vCenter cluster to install the OpenShift Container Platform cluster in.</td>
<td>String</td>
</tr>
<tr>
<td>platform.vsphere.apiVIP</td>
<td>The virtual IP (VIP) address that you configured for control plane API access.</td>
<td>An IP address, for example 128.0.0.1.</td>
</tr>
<tr>
<td>platform.vsphere.ingressVIP</td>
<td>The virtual IP (VIP) address that you configured for cluster ingress.</td>
<td>An IP address, for example 128.0.0.1.</td>
</tr>
<tr>
<td>platform.vsphere.diskType</td>
<td>Optional. The disk provisioning method. This value defaults to the vSphere default storage policy if not set.</td>
<td>Valid values are thin, thick, or eagerZeroedThick.</td>
</tr>
</tbody>
</table>

19.3.9.15. Optional VMware vSphere machine pool configuration parameters

Optional VMware vSphere machine pool configuration parameters are described in the following table:

Table 19.13. Optional VMware vSphere machine pool parameters
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>platform.vsphere.clusterOSImage</td>
<td>The location from which the installer downloads the RHCOS image. You must set this parameter to perform an installation in a restricted network.</td>
<td>An HTTP or HTTPS URL, optionally with a SHA-256 checksum. For example, <a href="https://mirror.openshift.com/images/rhcos-">https://mirror.openshift.com/images/rhcos-</a>&lt;version&gt;-vmware.&lt;architecture&gt;.ova.</td>
</tr>
<tr>
<td>platform.vsphere.osDisk.diskSizeGB</td>
<td>The size of the disk in gigabytes.</td>
<td>Integer</td>
</tr>
<tr>
<td>platform.vsphere.cpus</td>
<td>The total number of virtual processor cores to assign a virtual machine.</td>
<td>Integer</td>
</tr>
<tr>
<td>platform.vsphere.coresPerSocket</td>
<td>The number of cores per socket in a virtual machine. The number of virtual sockets on the virtual machine is platform.vsphere.cpus/platform.vsphere.coresPerSocket. The default value is 1</td>
<td>Integer</td>
</tr>
<tr>
<td>platform.vsphere.memoryMB</td>
<td>The size of a virtual machine’s memory in megabytes.</td>
<td>Integer</td>
</tr>
</tbody>
</table>

19.3.9.2. Sample install-config.yaml file for an installer-provisioned VMware vSphere cluster

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute: - hyperthreading: Enabled
  name: worker
  replicas: 3
platform:
  vsphere:
    cpus: 2
    coresPerSocket: 2
    memoryMB: 8196
    osDisk:
      diskSizeGB: 120
controlPlane: - hyperthreading: Enabled
  name: master
  replicas: 3
platform:
```
The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

The **controlPlane** section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -, and the first line of the **controlPlane** section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading, or **hyperthreading**. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to **Disabled**. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Your machines must use at least 8 CPUs and 32 GB of RAM if you disable simultaneous multithreading.

Optional: Provide additional configuration for the machine pool parameters for the compute and control plane machines.

The cluster name that you specified in your DNS records.

The vSphere disk provisioning method.

The vSphere cluster to install the OpenShift Container Platform cluster in. The installation program uses the root resource pool of the vSphere cluster as the default resource pool.
19.3.9.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the install-config.yaml file.

Prerequisites

- You have an existing install-config.yaml file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the Proxy object’s spec.noProxy field to bypass the proxy if necessary.

**NOTE**

The Proxy object status.noProxy field is populated with the values of the networking.machineNetwork[].cidr, networking.clusterNetwork[].cidr, and networking.serviceNetwork[] fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object status.noProxy field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your install-config.yaml file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
     httpProxy: http://<username>:<pswd>@<ip>:<port>  
     httpsProxy: https://<username>:<pswd>@<ip>:<port>  
     noProxy: example.com
     additionalTrustBundle:
       -----BEGIN CERTIFICATE-----
       <MY_TRUSTED_CA_CERT>
       -----END CERTIFICATE-----
   ...
   
   1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.

   2 A proxy URL to use for creating HTTPS connections outside the cluster.

   3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations. You must include vCenter's IP address and the IP range that you use for its machines.

   4 If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace that contains one or more additional CA certificates that are required for proxing HTTPS connections. The Cluster Network Operator then
that are required for proxying https connections. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the trustedCA field of the Proxy object. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

NOTE

The installation program does not support the proxy readinessEndpoints field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

NOTE

Only the Proxy object named cluster is supported, and no additional proxies can be created.

19.3.10. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

IMPORTANT

You can run the create cluster command of the installation program only once, during initial installation.

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Change to the directory that contains the installation program and initialize the cluster deployment:

   ```bash
   $ ./openshift-install create cluster --dir <installation_directory>  
   --log-level=info
   ```

   1 For <installation_directory>, specify the location of your customized ./install-config.yaml file.

   2 To view different installation details, specify warn, debug, or error instead of info.

   When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the kubeadmin user, display in your terminal.
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-Wt5AL"
INFO Time elapsed: 36m22s

NOTE
The cluster access and credential information also outputs to <installation_directory>/openshift_install.log when an installation succeeds.

IMPORTANT
- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.
- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

IMPORTANT
You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

19.3.11. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

IMPORTANT
If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.10. Download and install the new version of oc.

Installing the OpenShift CLI on Linux
You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.
Procedure

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.10 Linux Client entry and save the file.

4. Unpack the archive:

   $ tar xvzf <file>

5. Place the oc binary in a directory that is on your PATH.
   To check your PATH, execute the following command:

   $ echo $PATH

After you install the OpenShift CLI, it is available using the oc command:

$ oc <command>

Installing the OpenShift CLI on Windows
You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.10 Windows Client entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the oc binary to a directory that is on your PATH.
   To check your PATH, open the command prompt and execute the following command:

   C:\> path

After you install the OpenShift CLI, it is available using the oc command:

C:\> oc <command>

Installing the OpenShift CLI on macOS
You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.
3. Click Download Now next to the OpenShift v4.10 MacOSX Client entry and save the file.

4. Unpack and unzip the archive.

5. Move the oc binary to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:

   ```
   $ echo $PATH
   ```

   After you install the OpenShift CLI, it is available using the oc command:

   ```
   $ oc <command>
   ```

19.3.12. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster kubeconfig file. The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the oc CLI.

Procedure

1. Export the kubeadmin credentials:

   ```
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run oc commands successfully using the exported configuration:

   ```
   $ oc whoami
   ```

   Example output

   ```
   system:admin
   ```

19.3.13. Creating registry storage

After you install the cluster, you must create storage for the registry Operator.

19.3.13.1. Image registry removed during installation
On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as **Removed**. This allows **openshift-installer** to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the **managementState** from **Removed** to **Managed**.

**NOTE**

The Prometheus console provides an **ImageRegistryRemoved** alert, for example:

"Image Registry has been removed. **ImageStreamTags**, **BuildConfigs** and **DeploymentConfigs** which reference **ImageStreamTags** may not work as expected. Please configure storage and update the config to **Managed** state by editing configs.imageregistry.operator.openshift.io."

### 19.3.13.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the **Recreate** rollout strategy during upgrades.

### 19.3.13.2.1. Configuring registry storage for VMware vSphere

As a cluster administrator, following installation you must configure your registry to use storage.

**Prerequisites**

- Cluster administrator permissions.
- A cluster on VMware vSphere.
- Persistent storage provisioned for your cluster, such as Red Hat OpenShift Data Foundation.

**IMPORTANT**

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have “100Gi” capacity.
IMPORTANT

Testing shows issues with using the NFS server on RHEL as storage backend for core services. This includes the OpenShift Container Registry and Quay, Prometheus for monitoring storage, and Elasticsearch for logging storage. Therefore, using RHEL NFS to back PVs used by core services is not recommended.

Other NFS implementations on the marketplace might not have these issues. Contact the individual NFS implementation vendor for more information on any testing that was possibly completed against these OpenShift Container Platform core components.

Procedure

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

   ![NOTE](image)

   When using shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

   ```
   $ oc get pod -n openshift-image-registry -l docker-registry=default
   
   Example output
   
   No resources found in openshift-image-registry namespace
   
   ![NOTE](image)

   If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

   ```
   $ oc edit configs.imageregistry.operator.openshift.io
   
   Example output
   
   storage:
   pvc:
     claim: 1
   
   ![1](image)

   Leave the `claim` field blank to allow the automatic creation of an `image-registry-storage` PVC.

4. Check the `clusteroperator` status:

   ```
   $ oc get clusteroperator image-registry
   ```
Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
<th>SINCE</th>
<th>MESSAGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>image-registry</td>
<td>4.7</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>6h50m</td>
<td></td>
</tr>
</tbody>
</table>

19.3.13.2.2. Configuring block registry storage for VMware vSphere

To allow the image registry to use block storage types such as vSphere Virtual Machine Disk (VMDK) during upgrades as a cluster administrator, you can use the **Recreate** rollout strategy.

**IMPORTANT**

Block storage volumes are supported but not recommended for use with image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

**Procedure**

1. To set the image registry storage as a block storage type, patch the registry so that it uses the **Recreate** rollout strategy and runs with only 1 replica:

   ```
   $ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec":
   {"rolloutStrategy":"Recreate","replicas":1}}'
   ```

2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.

   a. Create a `pvc.yaml` file with the following contents to define a VMware vSphere
      **PersistentVolumeClaim** object:

      ```yaml
      kind: PersistentVolumeClaim
      apiVersion: v1
      metadata:
        name: image-registry-storage
        namespace: openshift-image-registry
      spec:
        accessModes:
        - ReadWriteOnce
        resources:
          requests:
            storage: 100Gi
      ```

      1. A unique name that represents the **PersistentVolumeClaim** object.
      2. The namespace for the **PersistentVolumeClaim** object, which is **openshift-image-registry**.
      3. The access mode of the persistent volume claim. With **ReadWriteOnce**, the volume can be mounted with read and write permissions by a single node.
      4. The size of the persistent volume claim.
b. Create the **PersistentVolumeClaim** object from the file:

```
$ oc create -f pvc.yaml -n openshift-image-registry
```

3. Edit the registry configuration so that it references the correct PVC:

```
$ oc edit config.imageregistry.operator.openshift.io -o yaml
```

**Example output**

```
storage:
  pvc:
    claim: 1
```

1. Creating a custom PVC allows you to leave the `claim` field blank for the default automatic creation of an `image-registry-storage` PVC.

For instructions about configuring registry storage so that it references the correct PVC, see Configuring the registry for vSphere.

### 19.3.14. Backing up VMware vSphere volumes

OpenShift Container Platform provisions new volumes as independent persistent disks to freely attach and detach the volume on any node in the cluster. As a consequence, it is not possible to back up volumes that use snapshots, or to restore volumes from snapshots. See **Snapshot Limitations** for more information.

**Procedure**

To create a backup of persistent volumes:

1. Stop the application that is using the persistent volume.
2. Clone the persistent volume.
3. Restart the application.
4. Create a backup of the cloned volume.
5. Delete the cloned volume.

### 19.3.15. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.10, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to **OpenShift Cluster Manager**.

After you confirm that your **OpenShift Cluster Manager** inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use **subscription watch** to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- See About remote health monitoring for more information about the Telemetry service
19.3.16. Next steps

- Customize your cluster.
- If necessary, you can **opt out of remote health reporting**.
- **Set up your registry and configure registry storage**.
- Optional: **View the events from the vSphere Problem Detector Operator** to determine if the cluster has permission or storage configuration issues.

19.4. INSTALLING A CLUSTER ON VSPHERE WITH NETWORK CUSTOMIZATIONS

In OpenShift Container Platform version 4.10, you can install a cluster on your VMware vSphere instance by using installer-provisioned infrastructure with customized network configuration options. By customizing your network configuration, your cluster can coexist with existing IP address allocations in your environment and integrate with existing MTU and VXLAN configurations. To customize the installation, you modify parameters in the `install-config.yaml` file before you install the cluster.

You must set most of the network configuration parameters during installation, and you can modify only `kubeProxy` configuration parameters in a running cluster.

19.4.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You provisioned **persistent storage** for your cluster. To deploy a private image registry, your storage must provide `ReadWriteMany` access modes.
- The OpenShift Container Platform installer requires access to port 443 on the vCenter and ESXi hosts. You verified that port 443 is accessible.
- If you use a firewall, confirm with the administrator that port 443 is accessible. Control plane nodes must be able to reach vCenter and ESXi hosts on port 443 for the installation to succeed.
- If you use a firewall, you **configured it to allow the sites** that your cluster requires access to.

**NOTE**

Be sure to also review this site list if you are configuring a proxy.

19.4.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.10, you require access to the internet to install your cluster.

You must have internet access to:

- Access **OpenShift Cluster Manager** to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 19.4.3. VMware vSphere infrastructure requirements

You must install the OpenShift Container Platform cluster on a VMware vSphere version 6 or 7 instance that meets the requirements for the components that you use.

**Table 19.14. Version requirements for vSphere virtual environments**

<table>
<thead>
<tr>
<th>Virtual environment product</th>
<th>Required version</th>
</tr>
</thead>
<tbody>
<tr>
<td>VM hardware version</td>
<td>13 or later</td>
</tr>
<tr>
<td>vSphere ESXi hosts</td>
<td>6.5 or later</td>
</tr>
<tr>
<td>vCenter host</td>
<td>6.5 or later</td>
</tr>
</tbody>
</table>

**IMPORTANT**

Installing a cluster on VMware vSphere version 6.7U3 or earlier and virtual hardware version 13 is now deprecated. These versions are still fully supported, but version 4.11 of OpenShift Container Platform will require vSphere virtual hardware version 15 or later. Hardware version 15 is now the default for vSphere virtual machines in OpenShift Container Platform. To update the hardware version for your vSphere nodes, see the "Updating hardware on nodes running in vSphere" article.

If your vSphere nodes are below hardware version 15 or your VMware vSphere version is earlier than 6.7U3, upgrading from OpenShift Container Platform 4.10 to OpenShift Container Platform 4.11 is not available.

**Table 19.15. Minimum supported vSphere version for VMware components**

<table>
<thead>
<tr>
<th>Component</th>
<th>Minimum supported versions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hypervisor</td>
<td>vSphere 6.5 and later with HW version 13</td>
<td>This version is the minimum version that Red Hat Enterprise Linux CoreOS (RHCOS) supports. See the Red Hat Enterprise Linux 8 supported hypervisors list.</td>
</tr>
</tbody>
</table>
### Component | Minimum supported versions | Description
--- | --- | ---
Storage with in-tree drivers | vSphere 6.5 and later | This plug-in creates vSphere storage by using the in-tree storage drivers for vSphere included in OpenShift Container Platform.
Optional: Networking (NSX-T) | vSphere 6.5U3 or vSphere 6.7U2 and later | vSphere 6.5U3 or vSphere 6.7U2+ are required for OpenShift Container Platform. VMware’s NSX Container Plug-in (NCP) is certified with OpenShift Container Platform 4.6 and NSX-T 3.x+.

If you use a vSphere version 6.5 instance, consider upgrading to 6.7U3 or 7.0 before you install OpenShift Container Platform.

**IMPORTANT**

You must ensure that the time on your ESXi hosts is synchronized before you install OpenShift Container Platform. See [Edit Time Configuration for a Host](#) in the VMware documentation.

#### 19.4.4. VMware vSphere CSI Driver Operator requirements

The following requirements must be met in order to install the CSI Driver Operator:

- VMware vSphere version 6.7U3 or later
- Virtual machines of hardware version 15 or later
- No third-party CSI driver already installed in the cluster

If a third-party CSI driver is present in the cluster, OpenShift Container Platform does not overwrite it. The presence of a third-party CSI driver prevents OpenShift Container Platform from upgrading to 4.11.

**Additional resources**

- To remove a third-party CSI driver, see [Removing a third-party vSphere CSI Driver](#).
- To update the hardware version for your vSphere nodes, see [Updating hardware on nodes running in vSphere](#).

#### 19.4.5. vCenter requirements

Before you install an OpenShift Container Platform cluster on your vCenter that uses infrastructure that the installer provisions, you must prepare your environment.

**Required vCenter account privileges**
To install an OpenShift Container Platform cluster in a vCenter, the installation program requires access to an account with privileges to read and create the required resources. Using an account that has global administrative privileges is the simplest way to access all of the necessary permissions.

If you cannot use an account with global administrative privileges, you must create roles to grant the privileges necessary for OpenShift Container Platform cluster installation. While most of the privileges are always required, some are required only if you plan for the installation program to provision a folder to contain the OpenShift Container Platform cluster on your vCenter instance, which is the default behavior. You must create or amend vSphere roles for the specified objects to grant the required privileges.

An additional role is required if the installation program is to create a vSphere virtual machine folder.

**Example 19.5. Roles and privileges required for installation**

<table>
<thead>
<tr>
<th>vSphere object for role</th>
<th>When required</th>
<th>Required privileges</th>
</tr>
</thead>
<tbody>
<tr>
<td>vSphere Port Group</td>
<td>Always</td>
<td>Network.Assign</td>
</tr>
<tr>
<td>vSphere object for role</td>
<td>When required</td>
<td>Required privileges</td>
</tr>
<tr>
<td>-------------------------</td>
<td>---------------</td>
<td>-------------------</td>
</tr>
</tbody>
</table>
| Virtual Machine Folder  | Always        | Resource.AssignVMToPool  
|                         |               | VApp.Import  
|                         |               | VirtualMachine.Config.AddExistingDisk  
|                         |               | VirtualMachine.Config.AddNewDisk  
|                         |               | VirtualMachine.Config.AddRemoveDevice  
|                         |               | VirtualMachine.Config.AdvancedConfig  
|                         |               | VirtualMachine.Config.Annotation  
|                         |               | VirtualMachine.Config.CPUCount  
|                         |               | VirtualMachine.Config.DiskExtend  
|                         |               | VirtualMachine.Config.DiskLease  
|                         |               | VirtualMachine.Config.EditDevice  
|                         |               | VirtualMachine.Config.Memory  
|                         |               | VirtualMachine.Config.RemoveDisk  
|                         |               | VirtualMachine.Config.Rename  
|                         |               | VirtualMachine.Config.RestGuestInfo  
|                         |               | VirtualMachine.Config.Restore  
|                         |               | VirtualMachine.Config.RestoreSettings  
|                         |               | VirtualMachine.Config.UpgradeVirtualHardware  
|                         |               | VirtualMachine.Interact.GuestControl  
|                         |               | VirtualMachine.Interact.PowerOff  
|                         |               | VirtualMachine.Interact.PowerOn  
|                         |               | VirtualMachine.Interact.Reset  
|                         |               | VirtualMachine.Inventory.Create  
|                         |               | VirtualMachine.Inventory.CreateFromExisting  
|                         |               | VirtualMachine.Inventory.Delete  
|                         |               | VirtualMachine.Provisioning.Clone  
<table>
<thead>
<tr>
<th>vSphere object for role</th>
<th>When required</th>
<th>Required privileges</th>
</tr>
</thead>
</table>
Additionally, the user requires some **ReadOnly** permissions, and some of the roles require permission to propagate the permissions to child objects. These settings vary depending on whether or not you install the cluster into an existing folder.

**Example 19.6. Required permissions and propagation settings**

<table>
<thead>
<tr>
<th>vSphere object</th>
<th>Folder type</th>
<th>Propagate to children</th>
<th>Permissions required</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td>vSphere vCenter</td>
<td>Existing folder</td>
<td>True</td>
<td>Listed required privileges</td>
</tr>
<tr>
<td>Virtual Machine Folder</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

For more information about creating an account with only the required privileges, see **vSphere Permissions and User Management Tasks** in the vSphere documentation.

**Using OpenShift Container Platform with vMotion**

**IMPORTANT**

OpenShift Container Platform generally supports compute-only vMotion. Using Storage vMotion can cause issues and is not supported.

If you are using vSphere volumes in your pods, migrating a VM across datastores either manually or through Storage vMotion causes invalid references within OpenShift Container Platform persistent volume (PV) objects. These references prevent affected pods from starting up and can result in data loss.
Similarly, OpenShift Container Platform does not support selective migration of VMDKs across datastores, using datastore clusters for VM provisioning or for dynamic or static provisioning of PVs, or using a datastore that is part of a datastore cluster for dynamic or static provisioning of PVs.

Cluster resources
When you deploy an OpenShift Container Platform cluster that uses installer-provisioned infrastructure, the installation program must be able to create several resources in your vCenter instance.

A standard OpenShift Container Platform installation creates the following vCenter resources:

- 1 Folder
- 1 Tag category
- 1 Tag
- Virtual machines:
  - 1 template
  - 1 temporary bootstrap node
  - 3 control plane nodes
  - 3 compute machines

Although these resources use 856 GB of storage, the bootstrap node is destroyed during the cluster installation process. A minimum of 800 GB of storage is required to use a standard cluster.

If you deploy more compute machines, the OpenShift Container Platform cluster will use more storage.

Cluster limits
Available resources vary between clusters. The number of possible clusters within a vCenter is limited primarily by available storage space and any limitations on the number of required resources. Be sure to consider both limitations to the vCenter resources that the cluster creates and the resources that you require to deploy a cluster, such as IP addresses and networks.

Networking requirements
You must use DHCP for the network and ensure that the DHCP server is configured to provide persistent IP addresses to the cluster machines. All nodes must be in the same VLAN. You cannot scale the cluster using a second VLAN as a Day 2 operation. Additionally, you must create the following networking resources before you install the OpenShift Container Platform cluster:

**NOTE**

It is recommended that each OpenShift Container Platform node in the cluster must have access to a Network Time Protocol (NTP) server that is discoverable via DHCP. Installation is possible without an NTP server. However, asynchronous server clocks will cause errors, which NTP server prevents.

Required IP Addresses
An installer-provisioned vSphere installation requires two static IP addresses:

- The **API** address is used to access the cluster API.
- The **Ingress** address is used for cluster ingress traffic.
You must provide these IP addresses to the installation program when you install the OpenShift Container Platform cluster.

**DNS records**
You must create DNS records for two static IP addresses in the appropriate DNS server for the vCenter instance that hosts your OpenShift Container Platform cluster. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the cluster base domain that you specify when you install the cluster. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>`.

### Table 19.16. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>API VIP</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>This DNS A/AAAA or CNAME record must point to the load balancer for the control plane machines. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Ingress VIP</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A wildcard DNS A/AAAA or CNAME record that points to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>

### 19.4.6. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.
Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>
   ```

   Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the `x86_64` architecture, do not create a key that uses the `ed25519` algorithm. Instead, create a key that uses the `rsa` or `ecdsa` algorithm.

2. View the public SSH key:

   ```bash
   $ cat <path>/<file_name>.pub
   ```

   For example, run the following to view the `~/.ssh/id_rsa.pub` public key:

   ```bash
   $ cat ~/.ssh/id_rsa.pub
   ```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

   **NOTE**

   On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

   a. If the `ssh-agent` process is not already running for your local user, start it as a background task:

   ```bash
   $ eval "$(ssh-agent -s)"
   ```

   **Example output**

   ```bash
   Agent pid 31874
   ```

   **NOTE**

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the `ssh-agent`:

   ```bash
   $ cat ~/.ssh/id_rsa.pub
   ```
Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

Example output

Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

19.4.7. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on your provisioning machine.

Prerequisites

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   $ ssh-add <path>/<file_name>  
   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

   $ tar -xvf openshift-install-linux.tar.gz

2578
5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

19.4.8. Adding vCenter root CA certificates to your system trust

Because the installation program requires access to your vCenter’s API, you must add your vCenter’s trusted root CA certificates to your system trust before you install an OpenShift Container Platform cluster.

Procedure

1. From the vCenter home page, download the vCenter’s root CA certificates. Click Download trusted root CA certificates in the vSphere Web Services SDK section. The <vCenter>/certs/download.zip file downloads.

2. Extract the compressed file that contains the vCenter root CA certificates. The contents of the compressed file resemble the following file structure:

   certs
     └── lin
         ├── 108f4d17.0
         │     ├── 108f4d17.r1
         │     └── 7e757f6a.0
         │             ├── 8e4f8471.0
         │             └── 8e4f8471.r0
         └── mac
             ├── 108f4d17.0
             │     ├── 108f4d17.r1
             │     └── 7e757f6a.0
             │             ├── 8e4f8471.0
             │             └── 8e4f8471.r0
             └── win
                 ├── 108f4d17.0.crt
                 │     ├── 108f4d17.r1.crt
                 │     └── 7e757f6a.0.crt
                 │             ├── 8e4f8471.0.crt
                 │             └── 8e4f8471.r0.crt

   3 directories, 15 files

3. Add the files for your operating system to the system trust. For example, on a Fedora operating system, run the following command:

   # cp certs/lin/* /etc/pki/ca-trust/source/anchors

4. Update your system trust. For example, on a Fedora operating system, run the following command:

   # update-ca-trust extract

19.4.9. Creating the installation configuration file
You can customize the OpenShift Container Platform cluster you install on VMware vSphere.

**Prerequisites**

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.
- Obtain service principal permissions at the subscription level.

**Procedure**

1. Create the `install-config.yaml` file.
   
   a. Change to the directory that contains the installation program and run the following command:

   ```bash
   $ ./openshift-install create install-config --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

   **IMPORTANT**
   
   Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

   b. At the prompts, provide the configuration details for your cloud:

   i. Optional: Select an SSH key to use to access your cluster machines.

   **NOTE**
   
   For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

   ii. Select `vsphere` as the platform to target.

   iii. Specify the name of your vCenter instance.

   iv. Specify the user name and password for the vCenter account that has the required permissions to create the cluster.

   The installation program connects to your vCenter instance.

   v. Select the datacenter in your vCenter instance to connect to.

   vi. Select the default vCenter datastore to use.
vii. Select the vCenter cluster to install the OpenShift Container Platform cluster in. The installation program uses the root resource pool of the vSphere cluster as the default resource pool.

viii. Select the network in the vCenter instance that contains the virtual IP addresses and DNS records that you configured.

ix. Enter the virtual IP address that you configured for control plane API access.

x. Enter the virtual IP address that you configured for cluster ingress.

xi. Enter the base domain. This base domain must be the same one that you used in the DNS records that you configured.

xii. Enter a descriptive name for your cluster. The cluster name must be the same one that you used in the DNS records that you configured.

xiii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

2. Modify the `install-config.yaml` file. You can find more information about the available parameters in the "Installation configuration parameters" section.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

**IMPORTANT**

The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

19.4.9.1. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide a customized `install-config.yaml` installation configuration file that describes the details for your environment.

**NOTE**

After installation, you cannot modify these parameters in the `install-config.yaml` file.

19.4.9.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

**Table 19.17. Required parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is v1. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------</td>
</tr>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the baseDomain and metadata.name parameter values that uses the &lt;metadata.name&gt;. &lt;baseDomain&gt; format.</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
</tr>
<tr>
<td>metadata</td>
<td>Kubernetes resource ObjectMeta, from which only the name parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of {{.metadata.name}}. {{.baseDomain}}.</td>
<td>String of lowercase letters, hyphens (-), and periods (.), such as dev.</td>
</tr>
<tr>
<td>platform</td>
<td>The configuration for the specific platform upon which to perform the installation: alibabacloud, aws, baremetal, azure, ibmcloud, openstack, ovirt, vsphere, or {}. For additional information about platform.&lt;platform&gt; parameters, consult the table for your specific platform that follows.</td>
<td>Object</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------</td>
</tr>
<tr>
<td>pullSecret</td>
<td>Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate</td>
<td>{</td>
</tr>
<tr>
<td></td>
<td>downloading container images for OpenShift Container Platform components from</td>

<td></td>
<td>}</td>
</tr>
</tbody>
</table>

19.4.9.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

Table 19.18. Network parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td></td>
<td></td>
<td>NOTE</td>
</tr>
<tr>
<td></td>
<td></td>
<td>You cannot modify parameters specified by the networking object after installation.</td>
</tr>
<tr>
<td>networking.network</td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to</td>
<td>Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN.</td>
</tr>
<tr>
<td>Type</td>
<td>install.</td>
<td></td>
</tr>
<tr>
<td>networking.clusterNetwork</td>
<td>The IP address blocks for pods.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td>The default value is <strong>10.128.0.0/14</strong> with a host prefix of <strong>/23</strong>.</td>
<td>networking:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>clusterNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- cidr: <strong>10.128.0.0/14</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>hostPrefix: <strong>23</strong></td>
</tr>
</tbody>
</table>
### Parameter Description Values

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking.clusterNetwork.cidr</td>
<td>Required if you use <code>networking.clusterNetwork</code>. An IP address block. An IPv4 network.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td>networking.clusterNetwork.hostPrefix</td>
<td>The subnet prefix length to assign to each individual node. For example, if <code>hostPrefix</code> is set to 23 then each node is assigned a /23 subnet out of the given <code>cidr</code>. A <code>hostPrefix</code> value of 23 provides 510 ((2^{32} - 23 - 2)) pod IP addresses.</td>
<td>A subnet prefix. The default value is 23.</td>
</tr>
<tr>
<td>networking.serviceNetwork</td>
<td>The IP address block for services. The default value is 172.30.0.0/16.</td>
<td>An array with an IP address block in CIDR format. For example:</td>
</tr>
<tr>
<td></td>
<td>The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.</td>
<td>networking: serviceNetwork: - 172.30.0.0/16</td>
</tr>
<tr>
<td>networking.machineNetwork</td>
<td>The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap. If you specify multiple IP kernel arguments, the <code>machineNetwork.cidr</code> value must be the CIDR of the primary network.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>networking: machineNetwork: - cidr: 10.0.0.0/16</td>
</tr>
<tr>
<td>networking.machineNetwork.cidr</td>
<td>Required if you use <code>networking.machineNetwork</code>. An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24.</td>
<td>An IP network block in CIDR notation. For example, 10.0.0.0/16.</td>
</tr>
</tbody>
</table>

### 19.4.9.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>cgroupsV2</td>
<td>Enables Linux control groups version 2 (cgroups v2) on specific nodes in your cluster. The OpenShift Container Platform process for enabling cgroups v2 disables all cgroup version 1 controllers and hierarchies. The OpenShift Container Platform cgroups version 2 feature is in Developer Preview and is not supported by Red Hat at this time.</td>
<td>true</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of MachinePool objects.</td>
</tr>
<tr>
<td>compute.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are s390x (the default).</td>
<td>String</td>
</tr>
<tr>
<td>compute.hyperthreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td></td>
</tr>
<tr>
<td>compute.name</td>
<td>Required if you use compute. The name of the machine pool.</td>
<td>worker</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>------------------------</td>
<td>------------------------------------------------------------------------------</td>
<td>---------------------------------------------</td>
</tr>
<tr>
<td><strong>compute.platform</strong></td>
<td>Required if you use <code>compute</code>. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <code>controlPlane.platform</code> parameter value.</td>
<td><code>alibaba, aws, azure, gcp, ibmcloud, openstack, ovirt, vsphere, or {}</code></td>
</tr>
<tr>
<td><strong>compute.replicas</strong></td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td><strong>controlPlane</strong></td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of <code>MachinePool</code> objects.</td>
</tr>
<tr>
<td><strong>controlPlane.architecture</strong></td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are s390x (the default).</td>
<td>String</td>
</tr>
<tr>
<td><strong>controlPlane.hypertreading</strong></td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td><strong>controlPlane.name</strong></td>
<td>Required if you use <code>controlPlane</code>. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td><strong>controlPlane.platform</strong></td>
<td>Required if you use <code>controlPlane</code>. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the <code>compute.platform</code> parameter value.</td>
<td><code>alibaba, aws, azure, gcp, ibmcloud, openstack, ovirt, vsphere, or {}</code></td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>----------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------</td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO</td>
<td>Mint, Passthrough, Manual, or an empty string (&quot;&quot;).</td>
</tr>
<tr>
<td></td>
<td>dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td></td>
</tr>
</tbody>
</table>

**NOTE**

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Platform Operators reference content.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>fips</strong></td>
<td>Enable or disable FIPS mode. The default is <em>false</em> (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</td>
<td><em>false</em> or <em>true</em></td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the <em>x86_64</em> architecture.</td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you are using Azure File storage, you cannot enable FIPS mode.</td>
<td></td>
</tr>
<tr>
<td><strong>imageContentSources</strong></td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects. Includes a <em>source</em> and, optionally, <em>mirrors</em>, as described in the following rows of this table.</td>
</tr>
<tr>
<td><strong>imageContentSources.source</strong></td>
<td>Required if you use <em>imageContentSources</em>. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td><strong>imageContentSources.mirrors</strong></td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
</tbody>
</table>
### How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.

**publish**

How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.

- **Internal** or **External**. The default value is **External**.
- Setting this field to **Internal** is not supported on non-cloud platforms and IBM Cloud.

**IMPORTANT**

If the value of the field is set to **Internal**, the cluster will become non-functional. For more information, refer to [BZ#1953035](#).

**sshKey**

The SSH key or keys to authenticate access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

- One or more keys. For example:

  ```
  sshKey:
  <key1>
  <key2>
  <key3>
  ```

### 19.4.9.1.4. Additional VMware vSphere configuration parameters

Additional VMware vSphere configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>platform.vsphere.vCenter</td>
<td>The fully-qualified hostname or IP address of the vCenter server.</td>
<td>String</td>
</tr>
<tr>
<td>platform.vsphere.username</td>
<td>The user name to use to connect to the vCenter instance with. This user must have at least the roles and privileges that are required for static or dynamic persistent volume provisioning in vSphere.</td>
<td>String</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>---------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------</td>
</tr>
<tr>
<td>platform.vsphere.password</td>
<td>The password for the vCenter user name.</td>
<td>String</td>
</tr>
<tr>
<td>platform.vsphere.datacenter</td>
<td>The name of the datacenter to use in the vCenter instance.</td>
<td>String</td>
</tr>
<tr>
<td>platform.vsphere.defaultDatastore</td>
<td>The name of the default datastore to use for provisioning volumes.</td>
<td>String</td>
</tr>
<tr>
<td>platform.vsphere.folder</td>
<td>Optional. The absolute path of an existing folder where the installation program creates the virtual machines. If you do not provide this value, the installation program creates a folder that is named with the infrastructure ID in the datacenter virtual machine folder.</td>
<td>String, for example, <code>&lt;datacenter_name&gt;/vm/&lt;folder_name&gt;/&lt;subfolder_name&gt;</code></td>
</tr>
<tr>
<td>platform.vsphere.network</td>
<td>The network in the vCenter instance that contains the virtual IP addresses and DNS records that you configured.</td>
<td>String</td>
</tr>
<tr>
<td>platform.vsphere.cluster</td>
<td>The vCenter cluster to install the OpenShift Container Platform cluster in.</td>
<td>String</td>
</tr>
<tr>
<td>platform.vsphere.apiVIP</td>
<td>The virtual IP (VIP) address that you configured for control plane API access.</td>
<td>An IP address, for example 128.0.0.1</td>
</tr>
<tr>
<td>platform.vsphere.ingressVIP</td>
<td>The virtual IP (VIP) address that you configured for cluster ingress.</td>
<td>An IP address, for example 128.0.0.1</td>
</tr>
<tr>
<td>platform.vsphere.diskType</td>
<td>Optional. The disk provisioning method. This value defaults to the vSphere default storage policy if not set.</td>
<td>Valid values are thin, thick, or eagerZeroedThick.</td>
</tr>
</tbody>
</table>

### 19.4.9.1.5. Optional VMware vSphere machine pool configuration parameters

Optional VMware vSphere machine pool configuration parameters are described in the following table:

**Table 19.21. Optional VMware vSphere machine pool parameters**
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>platform.vsphere.clusterOSImage</td>
<td>The location from which the installer downloads the RHCOS image. You must set this parameter to perform an installation in a restricted network.</td>
<td>An HTTP or HTTPS URL, optionally with a SHA-256 checksum. For example, <a href="https://mirror.openshift.com/images/rhcos-">https://mirror.openshift.com/images/rhcos-</a>&lt;version&gt;-vmware.&lt;architecture&gt;.ova.</td>
</tr>
<tr>
<td>platform.vsphere.osDisk.diskSizeGB</td>
<td>The size of the disk in gigabytes.</td>
<td>Integer</td>
</tr>
<tr>
<td>platform.vsphere.cpus</td>
<td>The total number of virtual processor cores to assign a virtual machine.</td>
<td>Integer</td>
</tr>
<tr>
<td>platform.vsphere.coresPerSocket</td>
<td>The number of cores per socket in a virtual machine. The number of virtual sockets on the virtual machine is platform.vsphere.cpus/platform.vsphere.coresPerSocket. The default value is 1</td>
<td>Integer</td>
</tr>
<tr>
<td>platform.vsphere.memoryMB</td>
<td>The size of a virtual machine’s memory in megabytes.</td>
<td>Integer</td>
</tr>
</tbody>
</table>

19.4.9.2. Sample install-config.yaml file for an installer-provisioned VMware vSphere cluster

You can customize the install-config.yaml file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute:
  - hyperthreading: Enabled
    name: worker
    replicas: 3
    platform:
      vsphere:
        cpus: 2
        coresPerSocket: 2
        memoryMB: 8196
        osDisk:
          diskSizeGB: 120
    controlPlane:
      hyperthreading: Enabled
      name: master
      replicas: 3
      platform:
```

CHAPTER 19. INSTALLING ON VSPHERE
The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

The `controlPlane` section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the `compute` section must begin with a hyphen, `-`, and the first line of the `controlPlane` section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading, or **hyperthreading**. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to **Disabled**. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Your machines must use at least 8 CPUs and 32 GB of RAM if you disable simultaneous multithreading.
Optional: Provide additional configuration for the machine pool parameters for the compute and control plane machines.

The cluster name that you specified in your DNS records.

The vSphere disk provisioning method.

The vSphere cluster to install the OpenShift Container Platform cluster in. The installation program uses the root resource pool of the vSphere cluster as the default resource pool.

19.4.9.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

Prerequisites

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the Proxy object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The Proxy object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
     httpProxy: http://<username>:<pswd>@<ip>:<port> 1
     httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
     noProxy: example.com 3
   additionalTrustBundle:
     -----BEGIN CERTIFICATE-----
     <MY_TRUSTED_CA_CERT>
     -----END CERTIFICATE-----
   
   1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.
A proxy URL to use for creating HTTPS connections outside the cluster.

A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations. You must include vCenter’s IP address and the IP range that you use for its machines.

If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the trustedCA field of the Proxy object. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

NOTE

The installation program does not support the proxy readinessEndpoints field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

NOTE

Only the Proxy object named cluster is supported, and no additional proxies can be created.

19.4.10. Network configuration phases

There are two phases prior to OpenShift Container Platform installation where you can customize the network configuration.

Phase 1

You can customize the following network-related fields in the install-config.yaml file before you create the manifest files:

- networking.networkType
- networking.clusterNetwork
- networking.serviceNetwork
- networking.machineNetwork

For more information on these fields, refer to Installation configuration parameters.

NOTE

Set the networking.machineNetwork to match the CIDR that the preferred NIC resides in.
Phase 2

After creating the manifest files by running `openshift-install create manifests`, you can define a customized Cluster Network Operator manifest with only the fields you want to modify. You can use the manifest to specify advanced network configuration.

You cannot override the values specified in phase 1 in the `install-config.yaml` file during phase 2. However, you can further customize the cluster network provider during phase 2.

19.4.11. Specifying advanced network configuration

You can use advanced network configuration for your cluster network provider to integrate your cluster into your existing network environment. You can specify advanced network configuration only before you install the cluster.

IMPORTANT

Customizing your network configuration by modifying the OpenShift Container Platform manifest files created by the installation program is not supported. Applying a manifest file that you create, as in the following procedure, is supported.

Prerequisites

- You have created the `install-config.yaml` file and completed any modifications to it.

Procedure

1. Change to the directory that contains the installation program and create the manifests:

   ```bash
   $ ./openshift-install create manifests --dir <installation_directory>  
   ```

   `<installation_directory>` specifies the name of the directory that contains the `install-config.yaml` file for your cluster.

2. Create a stub manifest file for the advanced network configuration that is named `cluster-network-03-config.yml` in the `<installation_directory>/manifests/` directory:

   ```yaml
   apiVersion: operator.openshift.io/v1
   kind: Network
   metadata:
     name: cluster
   spec:
   ```

3. Specify the advanced network configuration for your cluster in the `cluster-network-03-config.yml` file, such as in the following examples:

   **Specify a different VXLAN port for the OpenShift SDN network provider**

   ```yaml
   apiVersion: operator.openshift.io/v1
   kind: Network
   metadata:
     name: cluster
   spec:
   ```
Enable IPsec for the OVN-Kubernetes network provider

```yaml
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
  name: cluster
spec:
defaultNetwork:
  ovnKubernetesConfig:
    ipsecConfig: {}
```

4. Optional: Back up the `manifests/cluster-network-03-config.yml` file. The installation program consumes the `manifests/` directory when you create the Ignition config files.

### 19.4.12. Cluster Network Operator configuration

The configuration for the cluster network is specified as part of the Cluster Network Operator (CNO) configuration and stored in a custom resource (CR) object that is named `cluster`. The CR specifies the fields for the `Network` API in the `operator.openshift.io` API group.

The CNO configuration inherits the following fields during cluster installation from the `Network` API in the `Network.config.openshift.io` API group and these fields cannot be changed:

- **clusterNetwork**: IP address pools from which pod IP addresses are allocated.
- **serviceNetwork**: IP address pool for services.
- **defaultNetwork.type**: Cluster network provider, such as OpenShift SDN or OVN-Kubernetes.

You can specify the cluster network provider configuration for your cluster by setting the fields for the `defaultNetwork` object in the CNO object named `cluster`.

#### 19.4.12.1. Cluster Network Operator configuration object

The fields for the Cluster Network Operator (CNO) are described in the following table:

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>metadata.name</code></td>
<td>string</td>
<td>The name of the CNO object. This name is always <code>cluster</code>.</td>
</tr>
</tbody>
</table>
spec.clusterNetwork

**array**

A list specifying the blocks of IP addresses from which pod IP addresses are allocated and the subnet prefix length assigned to each individual node in the cluster. For example:

```yaml
spec:
  clusterNetwork:
    - cidr: 10.128.0.0/19
      hostPrefix: 23
    - cidr: 10.128.32.0/19
      hostPrefix: 23
```

You can customize this field only in the `install-config.yaml` file before you create the manifests. The value is read-only in the manifest file.

spec.serviceNetwork

**array**

A block of IP addresses for services. The OpenShift SDN and OVN-Kubernetes Container Network Interface (CNI) network providers support only a single IP address block for the service network. For example:

```yaml
spec:
  serviceNetwork:
    - 172.30.0.0/14
```

You can customize this field only in the `install-config.yaml` file before you create the manifests. The value is read-only in the manifest file.

spec.defaultNetwork

**object**

Configures the Container Network Interface (CNI) cluster network provider for the cluster network.

spec.kubeProxyConfig

**object**

The fields for this object specify the kube-proxy configuration. If you are using the OVN-Kubernetes cluster network provider, the kube-proxy configuration has no effect.

defaultNetwork object configuration

The values for the `defaultNetwork` object are defined in the following table:

### Table 19.23. defaultNetwork object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>spec.clusterNetwork</td>
<td>array</td>
<td>A list specifying the blocks of IP addresses from which pod IP addresses are allocated and the subnet prefix length assigned to each individual node in the cluster. For example:</td>
</tr>
<tr>
<td>spec.serviceNetwork</td>
<td>array</td>
<td>A block of IP addresses for services. The OpenShift SDN and OVN-Kubernetes Container Network Interface (CNI) network providers support only a single IP address block for the service network. For example:</td>
</tr>
<tr>
<td>spec.defaultNetwork</td>
<td>object</td>
<td>Configures the Container Network Interface (CNI) cluster network provider for the cluster network.</td>
</tr>
<tr>
<td>spec.kubeProxyConfig</td>
<td>object</td>
<td>The fields for this object specify the kube-proxy configuration. If you are using the OVN-Kubernetes cluster network provider, the kube-proxy configuration has no effect.</td>
</tr>
</tbody>
</table>
Either **OpenShiftSDN** or **OVNKubernetes**. The cluster network provider is selected during installation. This value cannot be changed after cluster installation.

**NOTE**

OpenShift Container Platform uses the OpenShift SDN Container Network Interface (CNI) cluster network provider by default.

This object is only valid for the OpenShift SDN cluster network provider.

This object is only valid for the OVN-Kubernetes cluster network provider.

### Configuration for the OpenShift SDN CNI cluster network provider

The following table describes the configuration fields for the OpenShift SDN Container Network Interface (CNI) cluster network provider.

**Table 19.24. openshiftSDNConfig object**

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>mode</strong></td>
<td><em>string</em></td>
<td>Configures the network isolation mode for OpenShift SDN. The default value is <strong>NetworkPolicy</strong>. The values <strong>Multitenant</strong> and <strong>Subnet</strong> are available for backwards compatibility with OpenShift Container Platform 3.x but are not recommended. This value cannot be changed after cluster installation.</td>
</tr>
</tbody>
</table>
### Field | Type | Description
--- | --- | ---
**mtu** | integer | The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.

If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.

If your cluster requires different MTU values for different nodes, you must set this value to 50 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1450.

This value cannot be changed after cluster installation.

**vxlanPort** | integer | The port to use for all VXLAN packets. The default value is 4789. This value cannot be changed after cluster installation.

If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number.

On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port 9000 and port 9999.

---

**Example OpenShift SDN configuration**

defaultNetwork:
    type: OpenShiftSDN
    openshiftSDNConfig:
        mode: NetworkPolicy
        mtu: 1450
        vxlanPort: 4789

**Configuration for the OVN-Kubernetes CNI cluster network provider**
The following table describes the configuration fields for the OVN-Kubernetes CNI cluster network provider.

**Table 19.25. ovnKubernetesConfig object**

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>defaultNetwork</td>
<td>string</td>
<td></td>
</tr>
<tr>
<td>type</td>
<td>string</td>
<td>OpenShiftSDN</td>
</tr>
<tr>
<td>openshiftSDNConfig</td>
<td>object</td>
<td></td>
</tr>
<tr>
<td>mode</td>
<td>string</td>
<td>NetworkPolicy</td>
</tr>
<tr>
<td>mtu</td>
<td>integer</td>
<td>1450</td>
</tr>
<tr>
<td>vxlanPort</td>
<td>integer</td>
<td>4789</td>
</tr>
</tbody>
</table>
The maximum transmission unit (MTU) for the Geneve (Generic Network Virtualization Encapsulation) overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.

If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.

If your cluster requires different MTU values for different nodes, you must set this value to 100 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1400.

table

<table>
<thead>
<tr>
<th>Field</th>

</tr>
<tr>
<td>ipsecConfig</td>
<td>object</td>
<td>Specify an empty object to enable IPsec encryption. This value cannot be changed after cluster installation.</td>
</tr>
<tr>
<td>policyAuditConfig</td>
<td>object</td>
<td>Specify a configuration object for customizing network policy audit logging. If unset, the defaults audit log settings are used.</td>
</tr>
<tr>
<td>gatewayConfig</td>
<td>object</td>
<td>Optional: Specify a configuration object for customizing how egress traffic is sent to the node gateway. NOTE While migrating egress traffic, you can expect some disruption to workloads and service traffic until the Cluster Network Operator (CNO) successfully rolls out the changes.</td>
</tr>
</tbody>
</table>

Table 19.26. policyAuditConfig object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rateLimit</td>
<td>integer</td>
<td>The maximum number of messages to generate every second per node. The default value is 20 messages per second.</td>
</tr>
<tr>
<td>maxFileSize</td>
<td>integer</td>
<td>The maximum size for the audit log in bytes. The default value is 50000000 or 50 MB.</td>
</tr>
</tbody>
</table>
### Table 19.27. gatewayConfig object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>routingViaHost</td>
<td>boolean</td>
<td>Set this field to <strong>true</strong> to send egress traffic from pods to the host networking stack. For highly-specialized installations and applications that rely on manually configured routes in the kernel routing table, you might want to route egress traffic to the host networking stack. By default, egress traffic is processed in OVN to exit the cluster and is not affected by specialized routes in the kernel routing table. The default value is <strong>false</strong>. This field has an interaction with the Open vSwitch hardware offloading feature. If you set this field to <strong>true</strong>, you do not receive the performance benefits of the offloading because egress traffic is processed by the host networking stack.</td>
</tr>
</tbody>
</table>

#### Example OVN-Kubernetes configuration with IPSec enabled

```
defaultNetwork:
  type: OVNKubernetes
  ovnKubernetesConfig:
    mtu: 1400
    genevePort: 6081
    ipsecConfig: {}
```

---

### Table 19.28. kubeProxyConfig object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>

---
### Field Type Description

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>iptablesSyncPeriod</td>
<td>string</td>
<td>The refresh period for iptables rules. The default value is <strong>30s</strong>. Valid suffixes include <strong>s</strong>, <strong>m</strong>, and <strong>h</strong> and are described in the Go time package documentation.</td>
</tr>
<tr>
<td>proxyArguments.iptables-min-sync-period</td>
<td>array</td>
<td>The minimum duration before refreshing iptables rules. This field ensures that the refresh does not happen too frequently. Valid suffixes include <strong>s</strong>, <strong>m</strong>, and <strong>h</strong> and are described in the Go time package. The default value is:</td>
</tr>
</tbody>
</table>

```yaml
kubeProxyConfig:
  proxyArguments:
    iptables-min-sync-period:
      - 0s
```

### IMPORTANT
You can run the `create cluster` command of the installation program only once, during initial installation.

### Prerequisites
- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

### Procedure

1. Change to the directory that contains the installation program and initialize the cluster deployment:

   ```bash
   $ ./openshift-install create cluster --dir <installation_directory> \  
   --log-level=info
   ```

   **1** For `<installation_directory>`, specify the location of your customized `/install-config.yaml` file.
To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the `kubeadmin` user, display in your terminal.

```
... INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-Wt5AL"
INFO Time elapsed: 36m22s
```

**NOTE**

The cluster access and credential information also outputs to `<installation_directory>/openshift_install.log` when an installation succeeds.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kublet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

**IMPORTANT**

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

### 19.4.14. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.
IMPORTANT

If you installed an earlier version of `oc`, you cannot use it to complete all of the commands in OpenShift Container Platform 4.10. Download and install the new version of `oc`.

Installing the OpenShift CLI on Linux
You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.
3. Click Download Now next to the OpenShift v4.10 Linux Client entry and save the file.
4. Unpack the archive:
   ```
   $ tar xvzf <file>
   ```
5. Place the oc binary in a directory that is on your PATH.
   To check your PATH, execute the following command:
   ```
   $ echo $PATH
   ```

After you install the OpenShift CLI, it is available using the `oc` command:

```
$ oc <command>
```

Installing the OpenShift CLI on Windows
You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.
3. Click Download Now next to the OpenShift v4.10 Windows Client entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the oc binary to a directory that is on your PATH.
   To check your PATH, open the command prompt and execute the following command:
   ```
   C:\> path
   ```

After you install the OpenShift CLI, it is available using the `oc` command:

```
C:\> oc <command>
```
Installing the OpenShift CLI on macOS
You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.

Procedure
2. Select the appropriate version in the Version drop-down menu.
3. Click Download Now next to the OpenShift v4.10 MacOSX Client entry and save the file.
4. Unpack and unzip the archive.
5. Move the oc binary to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:

   ```
   $ echo $PATH
   ```

After you install the OpenShift CLI, it is available using the oc command:

```
$ oc <command>
```

19.4.15. Logging in to the cluster by using the CLI
You can log in to your cluster as a default system user by exporting the cluster kubeconfig file. The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites
- You deployed an OpenShift Container Platform cluster.
- You installed the oc CLI.

Procedure
1. Export the kubeadmin credentials:

   ```
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For <installation_directory>, specify the path to the directory that you stored the installation files in.

2. Verify you can run oc commands successfully using the exported configuration:

   ```
   $ oc whoami
   ```

   Example output

   ```
   system:admin
   ```
19.4.16. Creating registry storage

After you install the cluster, you must create storage for the registry Operator.

19.4.16.1. Image registry removed during installation

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as **Removed**. This allows `openshift-installer` to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the `managementState` from **Removed** to **Managed**.

**NOTE**

The Prometheus console provides an `ImageRegistryRemoved` alert, for example:

"Image Registry has been removed. ImageStreamTags, BuildConfigs and DeploymentConfigs which reference ImageStreamTags may not work as expected. Please configure storage and update the config to Managed state by editing configs.imageregistry.operator.openshift.io."

19.4.16.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the **Recreate** rollout strategy during upgrades.

19.4.16.2.1. Configuring registry storage for VMware vSphere

As a cluster administrator, following installation you must configure your registry to use storage.

**Prerequisites**

- Cluster administrator permissions.
- A cluster on VMware vSphere.
- Persistent storage provisioned for your cluster, such as Red Hat OpenShift Data Foundation.

**IMPORTANT**

OpenShift Container Platform supports `ReadWriteOnce` access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, `ReadWriteMany` access is required.
• Must have "100Gi" capacity.

**IMPORTANT**

Testing shows issues with using the NFS server on RHEL as storage backend for core services. This includes the OpenShift Container Registry and Quay, Prometheus for monitoring storage, and Elasticsearch for logging storage. Therefore, using RHEL NFS to back PVs used by core services is not recommended.

Other NFS implementations on the marketplace might not have these issues. Contact the individual NFS implementation vendor for more information on any testing that was possibly completed against these OpenShift Container Platform core components.

**Procedure**

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

   **NOTE**

   When using shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

   ```
   $ oc get pod -n openshift-image-registry -l docker-registry=default
   ```

   **Example output**

   ```
   No resources found in openshift-image-registry namespace
   ```

   **NOTE**

   If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

   ```
   $ oc edit configs.imageregistry.operator.openshift.io
   ```

   **Example output**

   ```
   storage:
   pvc:
   claim: 1
   ```

   Leave the `claim` field blank to allow the automatic creation of an `image-registry-storage` PVC.

4. Check the `clusteroperator` status:
19.4.16.2.2. Configuring block registry storage for VMware vSphere

To allow the image registry to use block storage types such as vSphere Virtual Machine Disk (VMDK) during upgrades as a cluster administrator, you can use the **Recreate** rollout strategy.

**IMPORTANT**

Block storage volumes are supported but not recommended for use with image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

**Procedure**

1. To set the image registry storage as a block storage type, patch the registry so that it uses the **Recreate** rollout strategy and runs with only 1 replica:

   ```bash
   $ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec":{"rolloutStrategy":"Recreate","replicas":1}}'
   ```

2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.
   
   a. Create a `pvc.yaml` file with the following contents to define a VMware vSphere **PersistentVolumeClaim** object:

   ```yaml
   kind: PersistentVolumeClaim
   apiVersion: v1
   metadata:
     name: image-registry-storage
     namespace: openshift-image-registry
   spec:
     accessModes:
     - ReadWriteOnce
     resources:
       requests:
         storage: 100Gi
   ```

   **1** A unique name that represents the **PersistentVolumeClaim** object.

   **2** The namespace for the **PersistentVolumeClaim** object, which is **openshift-image-registry**.

   **3** The access mode of the persistent volume claim. With **ReadWriteOnce**, the volume can be mounted with read and write permissions by a single node.
4  The size of the persistent volume claim.

b. Create the PersistentVolumeClaim object from the file:

```bash
$ oc create -f pvc.yaml -n openshift-image-registry
```

3. Edit the registry configuration so that it references the correct PVC:

```bash
$ oc edit config.imageregistry.operator.openshift.io -o yaml
```

**Example output**

```
storage:
  pvc:
    claim: 1
```

Creating a custom PVC allows you to leave the `claim` field blank for the default automatic creation of an `image-registry-storage` PVC.

For instructions about configuring registry storage so that it references the correct PVC, see [Configuring the registry for vSphere](#).

### 19.4.17. Backing up VMware vSphere volumes

OpenShift Container Platform provisions new volumes as independent persistent disks to freely attach and detach the volume on any node in the cluster. As a consequence, it is not possible to back up volumes that use snapshots, or to restore volumes from snapshots. See [Snapshot Limitations](#) for more information.

**Procedure**

To create a backup of persistent volumes:

1. Stop the application that is using the persistent volume.
2. Clone the persistent volume.
3. Restart the application.
4. Create a backup of the cloned volume.
5. Delete the cloned volume.

### 19.4.18. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.10, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use `subscription watch` to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.
19.4.19. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- Set up your registry and configure registry storage.
- Optional: View the events from the vSphere Problem Detector Operator to determine if the cluster has permission or storage configuration issues.

19.5. INSTALLING A CLUSTER ON VSPHERE WITH USER-PROVISIONED INFRASTRUCTURE

In OpenShift Container Platform version 4.10, you can install a cluster on VMware vSphere infrastructure that you provision.

**IMPORTANT**

The steps for performing a user-provisioned infrastructure installation are provided as an example only. Installing a cluster with infrastructure you provide requires knowledge of the vSphere platform and the installation process of OpenShift Container Platform. Use the user-provisioned infrastructure installation instructions as a guide; you are free to create the required resources through other methods.

19.5.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You provisioned persistent storage for your cluster. To deploy a private image registry, your storage must provide ReadWriteMany access modes.
- Completing the installation requires that you upload the Red Hat Enterprise Linux CoreOS (RHCOS) OVA on vSphere hosts. The machine from which you complete this process requires access to port 443 on the vCenter and ESXi hosts. You verified that port 443 is accessible.
- If you use a firewall, you confirmed with the administrator that port 443 is accessible. Control plane nodes must be able to reach vCenter and ESXi hosts on port 443 for the installation to succeed.
- If you use a firewall, you configured it to allow the sites that your cluster requires access to.

**NOTE**

Be sure to also review this site list if you are configuring a proxy.
19.5.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.10, you require access to the internet to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- Access Quay.io to obtain the packages that are required to install your cluster.

- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

19.5.3. VMware vSphere infrastructure requirements

You must install the OpenShift Container Platform cluster on a VMware vSphere version 6 or 7 instance that meets the requirements for the components that you use.

**Table 19.29. Version requirements for vSphere virtual environments**

<table>
<thead>
<tr>
<th>Virtual environment product</th>
<th>Required version</th>
</tr>
</thead>
<tbody>
<tr>
<td>VM hardware version</td>
<td>13 or later</td>
</tr>
<tr>
<td>vSphere ESXi hosts</td>
<td>6.5 or later</td>
</tr>
<tr>
<td>vCenter host</td>
<td>6.5 or later</td>
</tr>
</tbody>
</table>

**IMPORTANT**

Installing a cluster on VMware vSphere version 6.7U3 or earlier and virtual hardware version 13 is now deprecated. These versions are still fully supported, but version 4.11 of OpenShift Container Platform will require vSphere virtual hardware version 15 or later. Hardware version 15 is now the default for vSphere virtual machines in OpenShift Container Platform. To update the hardware version for your vSphere nodes, see the "Updating hardware on nodes running in vSphere" article.

If your vSphere nodes are below hardware version 15 or your VMware vSphere version is earlier than 6.7U3, upgrading from OpenShift Container Platform 4.10 to OpenShift Container Platform 4.11 is not available.

**Table 19.30. Minimum supported vSphere version for VMware components**
<table>
<thead>
<tr>
<th>Component</th>
<th>Minimum supported versions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hypervisor</td>
<td>vSphere 6.5 and later with HW version 13</td>
<td>This version is the minimum version that Red Hat Enterprise Linux CoreOS (RHCOS) supports. See the Red Hat Enterprise Linux 8 supported hypervisors list.</td>
</tr>
<tr>
<td>Storage with in-tree drivers</td>
<td>vSphere 6.5 and later</td>
<td>This plug-in creates vSphere storage by using the in-tree storage drivers for vSphere included in OpenShift Container Platform.</td>
</tr>
<tr>
<td>Optional: Networking (NSX-T)</td>
<td>vSphere 6.5U3 or vSphere 6.7U2 and later</td>
<td>vSphere 6.5U3 or vSphere 6.7U2+ are required for OpenShift Container Platform. VMware’s NSX Container Plug-in (NCP) is certified with OpenShift Container Platform 4.6 and NSX-T 3.x+.</td>
</tr>
</tbody>
</table>

If you use a vSphere version 6.5 instance, consider upgrading to 6.7U3 or 7.0 before you install OpenShift Container Platform.

**IMPORTANT**

You must ensure that the time on your ESXi hosts is synchronized before you install OpenShift Container Platform. See Edit Time Configuration for a Host in the VMware documentation.

**19.5.4. VMware vSphere CSI Driver Operator requirements**

The following requirements must be met in order to install the CSI Driver Operator:

- VMware vSphere version 6.7U3 or later
- Virtual machines of hardware version 15 or later
- No third-party CSI driver already installed in the cluster

If a third-party CSI driver is present in the cluster, OpenShift Container Platform does not overwrite it. The presence of a third-party CSI driver prevents OpenShift Container Platform from upgrading to 4.11.

**Additional resources**

- To remove a third-party CSI driver, see Removing a third-party vSphere CSI Driver.
- To update the hardware version for your vSphere nodes, see Updating hardware on nodes running in vSphere.
19.5.5. Requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

This section describes the requirements for deploying OpenShift Container Platform on user-provisioned infrastructure.

19.5.5.1. Required machines for cluster installation

The smallest OpenShift Container Platform clusters require the following hosts:

Table 19.31. Minimum required hosts

<table>
<thead>
<tr>
<th>Hosts</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>One temporary bootstrap machine</td>
<td>The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.</td>
</tr>
<tr>
<td>Three control plane machines</td>
<td>The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.</td>
</tr>
<tr>
<td>At least two compute machines, which are also known as worker machines.</td>
<td>The workloads requested by OpenShift Container Platform users run on the compute machines.</td>
</tr>
</tbody>
</table>

IMPORTANT

To improve high availability of your cluster, distribute the control plane machines over different z/VM instances on at least two physical machines.

The bootstrap, control plane, and compute machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 8 and inherits all of its hardware certifications and requirements. See [Red Hat Enterprise Linux technology capabilities and limits](#).

IMPORTANT

All virtual machines must reside in the same datastore and in the same folder as the installer. Ensure that all virtual machine names across a vSphere installation are unique.

19.5.5.2. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
</tbody>
</table>
1. One physical core (IFL) provides two logical cores (threads) when SMT-2 is enabled. The hypervisor can provide two or more vCPUs.

### 19.5.5.3. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The `kube-controller-manager` only approves the kubelet client CSRs. The `machine-approver` cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

### 19.5.5.4. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in `initramfs` during boot to fetch their Ignition config files.

During the initial boot, the machines require an HTTP or HTTPS server to establish a network connection to download their Ignition config files.

The machines are configured with static IP addresses. No DHCP server is required. Ensure that the machines have persistent IP addresses and hostnames.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

#### 19.5.5.4.1. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

**IMPORTANT**

In connected OpenShift Container Platform environments, all nodes are required to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

### Table 19.32. Ports used for all-machine to all-machine communications

</tr>
</tbody>
</table>

Ethernet adaptor hardware address requirements
When provisioning VMs for the cluster, the ethernet interfaces configured for each VM must use a MAC address from the VMware Organizationally Unique Identifier (OUI) allocation ranges:

- 00:05:69:00:00:00 to 00:05:69:FF:FF
- 00:0c:29:00:00:00 to 00:0c:29:FF:FF
- 00:1c:14:00:00:00 to 00:1c:14:FF:FF
- 00:50:56:00:00:00 to 00:50:56:FF:FF

If a MAC address outside the VMware OUI is used, the cluster installation will not succeed.

NTP configuration for user-provisioned infrastructure
OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for Configuring chrony time service.

Additional resources

- Configuring chrony time service

19.5.5.5. User-provisioned DNS requirements

In OpenShift Container Platform deployments, DNS name resolution is required for the following components:

- The Kubernetes API
- The OpenShift Container Platform application wildcard
- The bootstrap, control plane, and compute machines

Reverse DNS resolution is also required for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the hostnames for all the nodes, unless the hostnames are provided by DHCP. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

The following DNS records are required for a user-provisioned OpenShift Container Platform cluster and they must be in place before installation. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>.

Table 19.35. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes API</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the API load balancer. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Component</td>
<td>Record</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>--------</td>
<td>-------------</td>
</tr>
<tr>
<td>API load balancer</td>
<td>api-int.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to internally identify the API load balancer. These records must be resolvable from all the nodes within the cluster. <strong>IMPORTANT</strong> The API server must be able to resolve the worker nodes by the hostnames that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.</td>
</tr>
<tr>
<td>Routes</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>A wildcard DNS A/AAAA or CNAME record that refers to the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster. For example, console-openshift-console.apps.&lt;cluster_name&gt;.&lt;base_domain&gt; is used as a wildcard route to the OpenShift Container Platform console.</td>
</tr>
<tr>
<td>Bootstrap machine</td>
<td>bootstrap.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Control plane machines</td>
<td>&lt;master&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Compute machines</td>
<td>&lt;worker&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**NOTE**

In OpenShift Container Platform 4.4 and later, you do not need to specify etcd host and SRV records in your DNS configuration.

**TIP**

You can use the `dig` command to verify name and reverse name resolution. See the section on Validating DNS resolution for user-provisioned infrastructure for detailed validation steps.
19.5.5.5.1. Example DNS configuration for user-provisioned clusters

This section provides A and PTR record configuration samples that meet the DNS requirements for deploying OpenShift Container Platform on user-provisioned infrastructure. The samples are not meant to provide advice for choosing one DNS solution over another.

In the examples, the cluster name is ocp4 and the base domain is example.com.

Example DNS A record configuration for a user-provisioned cluster

The following example is a BIND zone file that shows sample A records for name resolution in a user-provisioned cluster.

Example 19.7. Sample DNS zone database

```
$TTL 1W

7.1.168.192.in-addr.arpa. IN PTR worker1.ocp4.example.com. 8
; ;EOF
```

---

**1** Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer.

**2** Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer and is used for internal cluster communications.

**3** Provides reverse DNS resolution for the bootstrap machine.

**4 5 6** Provides reverse DNS resolution for the control plane machines.
Provides reverse DNS resolution for the compute machines.

**NOTE**

A PTR record is not required for the OpenShift Container Platform application wildcard.

19.5.5.6. Load balancing requirements for user-provisioned infrastructure

Before you install OpenShift Container Platform, you must provision the API and application ingress load balancing infrastructure. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

The load balancing infrastructure must meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:

   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.

   - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

   **NOTE**

   Session persistence is not required for the API load balancer to function properly.

Configure the following ports on both the front and back of the load balancers:

**Table 19.36. API load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the <em>/readyz</em> endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>
NOTE

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the /readyz endpoint to the removal of the API server instance from the pool. Within the time frame after /readyz returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. Application ingress load balancer: Provides an ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

TIP

If the true IP address of the client can be seen by the application ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

Configure the following ports on both the front and back of the load balancers:

Table 19.37. Application ingress load balancer

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
<tr>
<td>1936</td>
<td>The worker nodes that run the Ingress Controller pods, by default. You must configure the /healthz/ready endpoint for the ingress health check probe.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>

NOTE

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.
A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

19.5.5.6.1. Example load balancer configuration for user-provisioned clusters

This section provides an example API and application ingress load balancer configuration that meets the load balancing requirements for user-provisioned clusters. The sample is an `/etc/haproxy/haproxy.cfg` configuration for an HAProxy load balancer. The example is not meant to provide advice for choosing one load balancing solution over another.

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

Example 19.9. Sample API and application ingress load balancer configuration

```
global
  log         127.0.0.1 local2
  pidfile     /var/run/haproxy.pid
  maxconn     4000
  daemon

defaults
  mode                    http
  log                     global
  option                  dontlognull
  option http-server-close
  option                  redispatch
  retries                 3
  timeout http-request    10s
  timeout queue           1m
  timeout connect         10s
  timeout client          1m
  timeout server          1m
  timeout http-keep-alive 10s
  timeout check           10s
  maxconn                 3000

frontend stats
  bind *:1936
  mode            http
  log             global
  maxconn 10

stats enable
stats hide-version
stats refresh 30s
stats show-node
stats show-desc Stats for ocp4 cluster
stats auth admin:ocp4
stats uri /stats

listen api-server-6443
```
In the example, the cluster name is ocp4.

Port 6443 handles the Kubernetes API traffic and points to the control plane machines.

The bootstrap entries must be in place before the OpenShift Container Platform cluster installation and they must be removed after the bootstrap process is complete.

Port 22623 handles the machine config server traffic and points to the control plane machines.

Port 443 handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

Port 80 handles the HTTP traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

**TIP**

If you are using HAProxy as a load balancer, you can check that the haproxy process is listening on ports 6443, 22623, 443, and 80 by running `netstat -nltpu` on the HAProxy node.
If you are using HAProxy as a load balancer and SELinux is set to enforcing, you must ensure that the HAProxy service can bind to the configured TCP port by running `setsebool -P haproxy_connect_any=1`.

19.5.6. Preparing the user-provisioned infrastructure

Before you install OpenShift Container Platform on user-provisioned infrastructure, you must prepare the underlying infrastructure.

This section provides details about the high-level steps required to set up your cluster infrastructure in preparation for an OpenShift Container Platform installation. This includes configuring IP networking and network connectivity for your cluster nodes, preparing a web server for the Ignition files, enabling the required ports through your firewall, and setting up the required DNS and load balancing infrastructure.

After preparation, your cluster infrastructure must meet the requirements outlined in the Requirements for a cluster with user-provisioned infrastructure section.

Prerequisites

- You have reviewed the OpenShift Container Platform 4.x Tested Integrations page.
- You have reviewed the infrastructure requirements detailed in the Requirements for a cluster with user-provisioned infrastructure section.

Procedure

1. Set up static IP addresses.
2. Set up an HTTP or HTTPS server to provide Ignition files to the cluster nodes.
3. Ensure that your network infrastructure provides the required network connectivity between the cluster components. See the Networking requirements for user-provisioned infrastructure section for details about the requirements.
4. Configure your firewall to enable the ports required for the OpenShift Container Platform cluster components to communicate. See Networking requirements for user-provisioned infrastructure section for details about the ports that are required.
5. Setup the required DNS infrastructure for your cluster.
   a. Configure DNS name resolution for the Kubernetes API, the application wildcard, the bootstrap machine, the control plane machines, and the compute machines.
   b. Configure reverse DNS resolution for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.
      See the User-provisioned DNS requirements section for more information about the OpenShift Container Platform DNS requirements.
6. Validate your DNS configuration.
   a. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses in the responses correspond to the correct components.
b. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names in the responses correspond to the correct components.
See the Validating DNS resolution for user-provisioned infrastructure section for detailed DNS validation steps.

7. Provision the required API and application ingress load balancing infrastructure. See the Load balancing requirements for user-provisioned infrastructure section for more information about the requirements.

NOTE

Some load balancing solutions require the DNS name resolution for the cluster nodes to be in place before the load balancing is initialized.

19.5.7. Validating DNS resolution for user-provisioned infrastructure

You can validate your DNS configuration before installing OpenShift Container Platform on user-provisioned infrastructure.

IMPORTANT

The validation steps detailed in this section must succeed before you install your cluster.

Prerequisites

- You have configured the required DNS records for your user-provisioned infrastructure.

Procedure

1. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses contained in the responses correspond to the correct components.

   a. Perform a lookup against the Kubernetes API record name. Check that the result points to the IP address of the API load balancer:

      ```
      $ dig +noall +answer @<nameserver_ip> api.<cluster_name>.<base_domain> 1
      
      Replace <nameserver_ip> with the IP address of the nameserver, <cluster_name> with your cluster name, and <base_domain> with your base domain name.
      ```

      **Example output**

      ```
      api.ocp4.example.com. 0 IN A 192.168.1.5
      ```

   b. Perform a lookup against the Kubernetes internal API record name. Check that the result points to the IP address of the API load balancer:

      ```
      $ dig +noall +answer @<nameserver_ip> api-int.<cluster_name>.<base_domain>
      
      Example output
      ```
c. Test an example `*.apps.<cluster_name>.<base_domain>` DNS wildcard lookup. All of the application wildcard lookups must resolve to the IP address of the application ingress load balancer:

```bash
$ dig +noall +answer @<nameserver_ip> random.apps.<cluster_name>.<base_domain>
```

**Example output**

```
random.apps.ocp4.example.com. 0 IN A 192.168.1.5
```

**NOTE**

In the example outputs, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

You can replace `random` with another wildcard value. For example, you can query the route to the OpenShift Container Platform console:

```bash
$ dig +noall +answer @<nameserver_ip> console-openshift-console.apps.<cluster_name>.<base_domain>
```

**Example output**

```
console-openshift-console.apps.ocp4.example.com. 0 IN A 192.168.1.5
```

d. Run a lookup against the bootstrap DNS record name. Check that the result points to the IP address of the bootstrap node:

```bash
$ dig +noall +answer @<nameserver_ip> bootstrap.<cluster_name>.<base_domain>
```

**Example output**

```
bootstrap.ocp4.example.com. 0 IN A 192.168.1.96
```

e. Use this method to perform lookups against the DNS record names for the control plane and compute nodes. Check that the results correspond to the IP addresses of each node.

2. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names contained in the responses correspond to the correct components.

a. Perform a reverse lookup against the IP address of the API load balancer. Check that the response includes the record names for the Kubernetes API and the Kubernetes internal API:

```bash
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.5
```

$ dig +noall +answer @<nameserver_ip> random.apps.<cluster_name>.<base_domain>
1. Provides the record name for the Kubernetes internal API.

2. Provides the record name for the Kubernetes API.

**NOTE**

A PTR record is not required for the OpenShift Container Platform application wildcard. No validation step is needed for reverse DNS resolution against the IP address of the application ingress load balancer.

b. Perform a reverse lookup against the IP address of the bootstrap node. Check that the result points to the DNS record name of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.96
```

**Example output**

```
96.1.168.192.in-addr.arpa. 0 IN PTR bootstrap.ocp4.example.com.
```

c. Use this method to perform reverse lookups against the IP addresses for the control plane and compute nodes. Check that the results correspond to the DNS record names of each node.

19.5.8. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the `core` user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user `core`. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**Procedure**

- If you do not have an existing SSH key pair on your local machine to use for authentication onto
1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N " " -f <path>/<file_name>
```

Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

**NOTE**

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the ~/.ssh/id_rsa.pub public key:

```
$ cat ~/.ssh/id_rsa.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the ./openshift-install gather command.

**NOTE**

On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.

a. If the ssh-agent process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

**Example output**

```
Agent pid 31874
```

**NOTE**

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the ssh-agent:

```
$ ssh-add <path>/<file_name>
```

Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

Example output

Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program. If you install a cluster on infrastructure that you provision, you must provide the key to the installation program.

19.5.9. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on your provisioning machine.

Prerequisites

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

   **IMPORTANT**

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   **IMPORTANT**

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   `$ tar -xvf openshift-install-linux.tar.gz`
5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

19.5.10. Manually creating the installation configuration file

For user-provisioned installations of OpenShift Container Platform, you manually generate your installation configuration file.

Prerequisites

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.
- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Create an installation directory to store your required installation assets in:

   ```
   $ mkdir <installation_directory>
   ```

   **IMPORTANT**

   You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample `install-config.yaml` file template that is provided and save it in the `<installation_directory>`.

   **NOTE**

   You must name this configuration file `install-config.yaml`.

   **NOTE**

   For some platform types, you can alternatively run `./openshift-install create install-config --dir <installation_directory>` to generate an `install-config.yaml` file. You can provide details about your cluster configuration at the prompts.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

   **IMPORTANT**

   The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.
19.5.10.1. Sample install-config.yaml file for VMware vSphere

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute:
  - hyperthreading: Enabled
    name: worker
    replicas: 0
  controlPlane:
    hyperthreading: Enabled
    name: master
    replicas: 3
metadata:
  name: test
platform:
  vsphere:
    vcenter: your.vcenter.server
    username: username
    password: password
    datacenter: datacenter
    defaultDatastore: datastore
    folder: "/<datacenter_name>/vm/<folder_name>/<subfolder_name>"
    diskType: thin
    fips: false
    pullSecret: '{"auths": ...}'
    sshKey: 'ssh-ed25519 AAAA...'
```

1. The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

2. The `controlPlane` section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the `compute` section must begin with a hyphen, `-`, and the first line of the `controlPlane` section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

3. Whether to enable or disable simultaneous multithreading, or `hyperthreading`. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to `Disabled`. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

   **IMPORTANT**

   If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Your machines must use at least 8 CPUs and 32 GB of RAM if you disable simultaneous multithreading.

4. You must set the value of the `replicas` parameter to 0. This parameter controls the number of workers that the cluster creates and manages for you, which are functions that the cluster does not
perform when you use user-provisioned infrastructure. You must manually deploy worker machines for the cluster to use before you finish installing OpenShift Container Platform.

7. The number of control plane machines that you add to the cluster. Because the cluster uses this values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

8. The cluster name that you specified in your DNS records.

9. The fully-qualified hostname or IP address of the vCenter server.

10. The name of the user for accessing the server. This user must have at least the roles and privileges that are required for static or dynamic persistent volume provisioning in vSphere.

11. The password associated with the vSphere user.

12. The vSphere datacenter.

13. The default vSphere datastore to use.

14. Optional: For installer-provisioned infrastructure, the absolute path of an existing folder where the installation program creates the virtual machines, for example, /<datacenter_name>/vm/<folder_name>/<subfolder_name>. If you do not provide this value, the installation program creates a top-level folder in the datacenter virtual machine folder that is named with the infrastructure ID. If you are providing the infrastructure for the cluster, omit this parameter.

15. The vSphere disk provisioning method.

16. Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

17. The pull secret that you obtained from OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

18. The public portion of the default SSH key for the core user in Red Hat Enterprise Linux CoreOS (RHCOS).

19.5.10.2. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**Prerequisites**
• You have an existing `install-config.yaml` file.

• You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

NOTE

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port>
  httpsProxy: https://<username>:<pswd>@<ip>:<port>
  noProxy: example.com
additionalTrustBundle: |
    -----BEGIN CERTIFICATE-----
    <MY_TRUSTED_CA_CERT>
    -----END CERTIFICATE-----
```

1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.

2. A proxy URL to use for creating HTTPS connections outside the cluster.

3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, `.y.com` matches `x.y.com`, but not `y.com`. Use * to bypass the proxy for all destinations. You must include vCenter’s IP address and the IP range that you use for its machines.

4. If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the `trustedCA` field of the `Proxy` object. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.
NOTE

The installation program does not support the proxy `readinessEndpoints` field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

NOTE

Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

19.5.11. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

IMPORTANT

- The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

NOTE

The installation program that generates the manifest and Ignition files is architecture specific and can be obtained from the client image mirror. The Linux version of the installation program runs on s390x only. This installer program is also available as a Mac OS version.

Prerequisites

- You obtained the OpenShift Container Platform installation program.
- You created the `install-config.yaml` installation configuration file.

Procedure
1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

```
$ ./openshift-install create manifests --dir <installation_directory>
```

**Example output**

```
INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
INFO Consuming Install Config from target directory
INFO Manifests created in: install_dir/manifests and install_dir/openshift
```

For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.

2. Remove the Kubernetes manifest files that define the control plane machines and compute machine sets:

```
$ rm -f openshift/99_openshift-cluster-api_master-machines-*.yaml openshift/99_openshift-cluster-api_worker-machineset-*.yaml
```

Because you create and manage these resources yourself, you do not have to initialize them.

- You can preserve the machine set files to create compute machines by using the machine API, but you must update references to them to match your environment.

**WARNING**

If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.

**IMPORTANT**

When you configure control plane nodes from the default unschedulable to schedulable, additional subscriptions are required. This is because control plane nodes then become worker nodes.

3. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:

   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.
   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.
   c. Save and exit the file.

4. To create the Ignition configuration files, run the following command from the directory that contains the installation program:
For `<installation_directory>`, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The `kubeadmin-password` and `kubeconfig` files are created in the `./<installation_directory>/auth` directory:

```
├── auth
│   ├── kubeadmin-password
│   │   └── kubeconfig
│   ├── bootstrap.ign
│   ├── master.ign
│   ├── metadata.json
│   └── worker.ign
```

19.5.12. Extracting the infrastructure name

The Ignition config files contain a unique cluster identifier that you can use to uniquely identify your cluster in VMware vSphere. If you plan to use the cluster identifier as the name of your virtual machine folder, you must extract it.

**Prerequisites**

- You obtained the OpenShift Container Platform installation program and the pull secret for your cluster.
- You generated the Ignition config files for your cluster.
- You installed the `jq` package.

**Procedure**

- To extract and view the infrastructure name from the Ignition config file metadata, run the following command:

  ```
  $ jq -r .infraID <installation_directory>/metadata.json
  ```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

**Example output**

```
openshift-vw9j6
```

The output of this command is your cluster name and a random string.

19.5.13. Installing RHCOS and starting the OpenShift Container Platform bootstrap process
To install OpenShift Container Platform on user-provisioned infrastructure on VMware vSphere, you must install Red Hat Enterprise Linux CoreOS (RHCOS) on vSphere hosts. When you install RHCOS, you must provide the ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS machines have rebooted.

Prerequisites

- You have obtained the Ignition config files for your cluster.
- You have access to an HTTP server that you can access from your computer and that the machines that you create can access.
- You have created a vSphere cluster.

Procedure

1. Upload the bootstrap Ignition config file, which is named `<installation_directory>/bootstrap.ign`, that the installation program created to your HTTP server. Note the URL of this file.

2. Save the following secondary Ignition config file for your bootstrap node to your computer as `<installation_directory>/merge-bootstrap.ign`:

   ```json
   {
   "ignition": {
   "config": {
   "merge": [
   {
   "source": "<bootstrap_ignition_config_url>",
   "verification": {}  
   }
   ],
   "timeouts": {},
   "version": "3.2.0"
   },
   "networkd": {},
   "passwd": {},
   "storage": {},
   "systemd": {}  
   }
   }
   
   1 Specify the URL of the bootstrap Ignition config file that you hosted.
   
   When you create the virtual machine (VM) for the bootstrap machine, you use this Ignition config file.

3. Locate the following Ignition config files that the installation program created:
   - `<installation_directory>/master.ign`
   - `<installation_directory>/worker.ign`
4. Convert the Ignition config files to Base64 encoding. Later in this procedure, you must add these files to the extra configuration parameter `guestinfo.ignition.config.data` in your VM. For example, if you use a Linux operating system, you can use the `base64` command to encode the files.

```
$ base64 -w0 <installation_directory>/master.ign > <installation_directory>/master.64
$ base64 -w0 <installation_directory>/worker.ign > <installation_directory>/worker.64
$ base64 -w0 <installation_directory>/merge-bootstrap.ign > <installation_directory>/merge-bootstrap.64
```

**IMPORTANT**

If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

5. Obtain the RHCOS OVA image. Images are available from the [RHCOS image mirror](#) page.

**IMPORTANT**

The RHCOS images might not change with every release of OpenShift Container Platform. You must download an image with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image version that matches your OpenShift Container Platform version if it is available.

The filename contains the OpenShift Container Platform version number in the format `rhcos-vmware.<architecture>.ova`.

6. In the vSphere Client, create a folder in your datacenter to store your VMs.

   a. Click the **VMs and Templates** view.

   b. Right-click the name of your datacenter.

   c. Click **New Folder ➔ New VM and Template Folder**.

   d. In the window that is displayed, enter the folder name. If you did not specify an existing folder in the `install-config.yaml` file, then create a folder with the same name as the infrastructure ID. You use this folder name so vCenter dynamically provisions storage in the appropriate location for its Workspace configuration.

7. In the vSphere Client, create a template for the OVA image and then clone the template as needed.

**NOTE**

In the following steps, you create a template and then clone the template for all of your cluster machines. You then provide the location for the Ignition config file for that cloned machine type when you provision the VMs.
a. From the **Hosts and Clusters** tab, right-click your cluster name and select **Deploy OVF Template**.

b. On the **Select an OVF** tab, specify the name of the RHCOS OVA file that you downloaded.

c. On the **Select a name and folder** tab, set a **Virtual machine name** for your template, such as **Template-RHCOS**. Click the name of your vSphere cluster and select the folder you created in the previous step.

d. On the **Select a compute resource** tab, click the name of your vSphere cluster.

e. On the **Select storage** tab, configure the storage options for your VM.
   
   - Select **Thin Provision** or **Thick Provision**, based on your storage preferences.
   
   - Select the datastore that you specified in your **install-config.yaml** file.

g. When creating the OVF template, do not specify values on the **Customize template** tab or configure the template any further.

**IMPORTANT**

Do not start the original VM template. The VM template must remain off and must be cloned for new RHCOS machines. Starting the VM template configures the VM template as a VM on the platform, which prevents it from being used as a template that machine sets can apply configurations to.

8. Optional: Update the configured virtual hardware version in the VM template, if necessary. Follow [Upgrading a virtual machine to the latest hardware version](#) in the VMware documentation for more information.

**IMPORTANT**

It is recommended that you update the hardware version of the VM template to version 15 before creating VMs from it, if necessary. Using hardware version 13 for your cluster nodes running on vSphere is now deprecated. If your imported template defaults to hardware version 13, you must ensure that your ESXi host is on 6.7U3 or later before upgrading the VM template to hardware version 15. If your vSphere version is less than 6.7U3, you can skip this upgrade step; however, a future version of OpenShift Container Platform is scheduled to remove support for hardware version 13 and vSphere versions less than 6.7U3.

9. After the template deploys, deploy a VM for a machine in the cluster.

   a. Right-click the template name and click **Clone → Clone to Virtual Machine**

   b. On the **Select a name and folder** tab, specify a name for the VM. You might include the machine type in the name, such as **control-plane-0** or **compute-1**.
NOTE

Ensure that all virtual machine names across a vSphere installation are unique.

c. On the Select a name and folder tab, select the name of the folder that you created for the cluster.

d. On the Select a compute resource tab, select the name of a host in your datacenter.

e. Optional: On the Select storage tab, customize the storage options.

f. On the Select clone options, select Customize this virtual machine’s hardware.

g. On the Customize hardware tab, click VM Options → Advanced.

   • Optional: Override default DHCP networking in vSphere. To enable static IP networking:

      i. Set your static IP configuration:

         $ export IPCFG="ip=<ip>::<gateway>::<netmask>::<hostname>::<iface>::none
         nameserver=srv1 [nameserver=srv2 [nameserver=srv3 [...]]]"

         Example command

         $ export IPCFG="ip=192.168.100.101::192.168.100.254:255.255.255.0:::none
         nameserver=8.8.8.8"

      ii. Set the guestinfo.afterburn.initrd.network-kargs property before booting a VM from an OVA in vSphere:

         $ govc vm.change -vm "<vm_name>" -e "guestinfo.afterburn.initrd.network-kargs=${IPCFG}" 

   • Optional: In the event of cluster performance issues, from the Latency Sensitivity list, select High. Ensure that your VM’s CPU and memory reservation have the following values:

      • Memory reservation value must be equal to its configured memory size.

      • CPU reservation value must be at least the number of low latency virtual CPUs multiplied by the measured physical CPU speed.

   • Click Edit Configuration, and on the Configuration Parameters window, click Add Configuration Params. Define the following parameter names and values:

      • guestinfo.ignition.config.data: Locate the base-64 encoded files that you created previously in this procedure, and paste the contents of the base64-encoded Ignition config file for this machine type.

      • guestinfo.ignition.config.data.encoding: Specify base64.

      • disk.EnableUUID: Specify TRUE.
In the Virtual Hardware panel of the Customize hardware tab, modify the specified values as required. Ensure that the amount of RAM, CPU, and disk storage meets the minimum requirements for the machine type.

i. Complete the configuration and power on the VM.

j. Check the console output to verify that Ignition ran.

Example command

```
Ignition: ran on 2022/03/14 14:48:33 UTC (this boot)
Ignition: user-provided config was applied
```

10. Create the rest of the machines for your cluster by following the preceding steps for each machine.

**IMPORTANT**

You must create the bootstrap and control plane machines at this time. Because some pods are deployed on compute machines by default, also create at least two compute machines before you install the cluster.

### 19.5.14. Adding more compute machines to a cluster in vSphere

You can add more compute machines to a user-provisioned OpenShift Container Platform cluster on VMware vSphere.

**Prerequisites**

- Obtain the base64-encoded Ignition file for your compute machines.
- You have access to the vSphere template that you created for your cluster.

**Procedure**

1. After the template deploys, deploy a VM for a machine in the cluster.
   a. Right-click the template’s name and click **Clone → Clone to Virtual Machine**
   b. On the **Select a name and folder** tab, specify a name for the VM. You might include the machine type in the name, such as **compute-1**.

   **NOTE**

   Ensure that all virtual machine names across a vSphere installation are unique.

   c. On the **Select a name and folder** tab, select the name of the folder that you created for the cluster.
   d. On the **Select a compute resource** tab, select the name of a host in your datacenter.
   e. Optional: On the **Select storage** tab, customize the storage options.
   f. On the **Select clone options**, select **Customize this virtual machine’s hardware**
g. On the Customise hardware tab, click VM Options → Advanced.
   - From the Latency Sensitivity list, select High.
   - Click Edit Configuration, and on the Configuration Parameters window, click Add Configuration Params. Define the following parameter names and values:
     - guestinfo.ignition.config.data: Paste the contents of the base64-encoded compute Ignition config file for this machine type.
     - guestinfo.ignition.config.data.encoding: Specify base64.
     - disk.EnableUUID: Specify TRUE.

h. In the Virtual Hardware panel of the Customise hardware tab, modify the specified values as required. Ensure that the amount of RAM, CPU, and disk storage meets the minimum requirements for the machine type. Also, make sure to select the correct network under Add network adapter if there are multiple networks available.

i. Complete the configuration and power on the VM.

2. Continue to create more compute machines for your cluster.

19.5.15. Disk partitioning

In most cases, data partitions are originally created by installing RHCOS, rather than by installing another operating system. In such cases, the OpenShift Container Platform installer should be allowed to configure your disk partitions.

However, there are two cases where you might want to intervene to override the default partitioning when installing an OpenShift Container Platform node:

- Create separate partitions: For greenfield installations on an empty disk, you might want to add separate storage to a partition. This is officially supported for making /var or a subdirectory of /var, such as /var/lib/etcd, a separate partition, but not both.

  IMPORTANT

  Kubernetes supports only two filesystem partitions. If you add more than one partition to the original configuration, Kubernetes cannot monitor all of them.

- Retain existing partitions: For a brownfield installation where you are reinstalling OpenShift Container Platform on an existing node and want to retain data partitions installed from your previous operating system, there are both boot arguments and options to coreos-installer that allow you to retain existing data partitions.

Creating a separate /var partition

In general, disk partitioning for OpenShift Container Platform should be left to the installer. However, there are cases where you might want to create separate partitions in a part of the filesystem that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the /var partition or a subdirectory of /var. For example:

- /var/lib/containers: Holds container-related content that can grow as more images and containers are added to a system.
• /var/lib/etcd: Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.

• /var: Holds data that you might want to keep separate for purposes such as auditing.

Storing the contents of a /var directory separately makes it easier to grow storage for those areas as needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

Because /var must be in place before a fresh installation of Red Hat Enterprise Linux CoreOS (RHCOS), the following procedure sets up the separate /var partition by creating a machine config manifest that is inserted during the openshift-install preparation phases of an OpenShift Container Platform installation.

Procedure

1. Create a directory to hold the OpenShift Container Platform installation files:

   $ mkdir $HOME/clusterconfig

2. Run openshift-install to create a set of files in the manifest and openshift subdirectories. Answer the system questions as you are prompted:

   $ openshift-install create manifests --dir $HOME/clusterconfig
   ? SSH Public Key ...
   $ ls $HOME/clusterconfig/openshift/
   99_kubeadmin-password-secret.yaml
   99_openshift-cluster-api_master-machines-0.yaml
   99_openshift-cluster-api_master-machines-1.yaml
   99_openshift-cluster-api_master-machines-2.yaml
   ...

3. Create a Butane config that configures the additional partition. For example, name the file $HOME/clusterconfig/98-var-partition.bu, change the disk device name to the name of the storage device on the worker systems, and set the storage size as appropriate. This example places the /var directory on a separate partition:

   variant: openshift
   version: 4.10.0
   metadata:
     labels:
       machineconfiguration.openshift.io/role: worker
     name: 98-var-partition
   storage:
     disks:
       - device: /dev/<device_name>  
         partitions:
           - label: var
             start_mib: <partition_start_offset>  
             size_mib: <partition_size>  
       filesystems:
         - device: /dev/disk/by-partlabel/var
           path: /var
The storage device name of the disk that you want to partition.

When adding a data partition to the boot disk, a minimum value of 25000 mebibytes is recommended. The root file system is automatically resized to fill all available space up to the specified offset. If no value is specified, or if the specified value is smaller than the recommended minimum, the resulting root file system will be too small, and future reinstalls of RHCOS might overwrite the beginning of the data partition.

The size of the data partition in mebibytes.

The `prjquota` mount option must be enabled for filesystems used for container storage.

**NOTE**

When creating a separate `/var` partition, you cannot use different instance types for worker nodes, if the different instance types do not have the same device name.

4. Create a manifest from the Butane config and save it to the `clusterconfig/openshift` directory. For example, run the following command:

   ```bash
   $ butane $HOME/clusterconfig/98-var-partition.bu -o $HOME/clusterconfig/openshift/98-var-partition.yaml
   ```

5. Run `openshift-install` again to create Ignition configs from a set of files in the `manifest` and `openshift` subdirectories:

   ```bash
   $ openshift-install create ignition-configs --dir $HOME/clusterconfig
   $ ls $HOME/clusterconfig/
   auth bootstrap.ign master.ign metadata.json worker.ign
   ```

Now you can use the Ignition config files as input to the vSphere installation procedures to install Red Hat Enterprise Linux CoreOS (RHCOS) systems.

**19.5.16. Updating the bootloader using bootupd**

To update the bootloader by using `bootupd`, you must either install `bootupd` on RHCOS machines manually or provide a machine config with the enabled `systemd` unit. Unlike `grubby` or other bootloader tools, `bootupd` does not manage kernel space configuration such as passing kernel arguments.

After you have installed `bootupd`, you can manage it remotely from the OpenShift Container Platform cluster.

**NOTE**

It is recommended that you use `bootupd` only on bare metal or virtualized hypervisor installations, such as for protection against the BootHole vulnerability.
Manual install method

You can manually install `bootupd` by using the `bootctl` command-line tool.

1. Inspect the system status:

   ```
   # bootupctl status
   ```

   **Example output for x86_64**

   Component EFI
   Installed: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
   Update: At latest version

   **Example output for arm64**

   Component EFI
   Installed: grub2-efi-aa64-1:2.02-99.el8_4.1.aarch64,shim-aa64-15.4-2.el8_1.aarch64
   Update: At latest version

2. RHCOS images created without `bootupd` installed on them require an explicit adoption phase. If the system status is **Adoptable**, perform the adoption:

   ```
   # bootupctl adopt-and-update
   ```

   **Example output**

   Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64

3. If an update is available, apply the update so that the changes take effect on the next reboot:

   ```
   # bootupctl update
   ```

   **Example output**

   Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64

Machine config method

Another way to enable `bootupd` is by providing a machine config.

- Provide a machine config file with the enabled `systemd` unit, as shown in the following example:

```
# Example output

variant: rhcos
version: 1.1.0
systemd:
  units:
    - name: custom-bootupd-auto.service
      enabled: true
      contents: |
```
19.5.17. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

IMPORTANT

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.10. Download and install the new version of oc.

Installing the OpenShift CLI on Linux
You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.10 Linux Client entry and save the file.

4. Unpack the archive:

   $ tar xvzf <file>

5. Place the oc binary in a directory that is on your PATH. To check your PATH, execute the following command:

   $ echo $PATH

After you install the OpenShift CLI, it is available using the oc command:

   $ oc <command>

Installing the OpenShift CLI on Windows
You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.10 Windows Client entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the oc binary to a directory that is on your PATH. To check your PATH, open the command prompt and execute the following command:

   C:\> path

After you install the OpenShift CLI, it is available using the oc command:

   C:\> oc <command>

Installing the OpenShift CLI on macOS
You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.10 MacOSX Client entry and save the file.

4. Unpack and unzip the archive.

5. Move the oc binary to a directory on your PATH. To check your PATH, open a terminal and execute the following command:

   $ echo $PATH

After you install the OpenShift CLI, it is available using the oc command:

   $ oc <command>

19.5.18. Waiting for the bootstrap process to complete

The OpenShift Container Platform bootstrap process begins after the cluster nodes first boot into the persistent RHCOS environment that has been installed to disk. The configuration information provided through the Ignition config files is used to initialize the bootstrap process and install OpenShift Container Platform on the machines. You must wait for the bootstrap process to complete.

Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have obtained the installation program and generated the Ignition config files for your cluster.
You installed RHCOS on your cluster machines and provided the Ignition config files that the OpenShift Container Platform installation program generated.

Your machines have direct internet access or have an HTTP or HTTPS proxy available.

**Procedure**

1. Monitor the bootstrap process:

   ```bash
   $ ./openshift-install --dir <installation_directory> wait-for bootstrap-complete --log-level=info
   ```

   1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

**Example output**

```
INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
INFO API v1.23.0 up
INFO Waiting up to 30m0s for bootstrapping to complete...
INFO It is now safe to remove the bootstrap resources
```

The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After bootstrap process is complete, remove the bootstrap machine from the load balancer.

   **IMPORTANT**

   You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the bootstrap machine itself.

**19.5.19. Logging in to the cluster by using the CLI**

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```
For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

```
$ oc whoami
Example output
system:admin
```

19.5.20. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

Prerequisites

- You added machines to your cluster.

Procedure

1. Confirm that the cluster recognizes the machines:

```
$ oc get nodes
Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.23.0</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.23.0</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>64m</td>
<td>v1.23.0</td>
</tr>
</tbody>
</table>
```

The output lists all of the machines that you created.

**NOTE**

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```
$ oc get csr
Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-mddf5</td>
<td>20m</td>
<td>system:node:master-01.example.com</td>
<td>Approved,Issued</td>
</tr>
<tr>
<td>csr-z5rln</td>
<td>16m</td>
<td>system:node:worker-21.example.com</td>
<td>Approved,Issued</td>
</tr>
</tbody>
</table>
```
3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

**NOTE**

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

**NOTE**

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrapper** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

  ```
  $ oc adm certificate approve <csr_name>  
  ```

  `<csr_name>` is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

  ```
  $ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
  ```

**NOTE**

Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

  ```
  $ oc get csr
  ```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td></td>
</tr>
</tbody>
</table>
CHAPTER 19. INSTALLING ON VSPHERE

Pending
csr-c57lv 5m26s system:node:ip-10-0-95-157.us-east-2.compute.internal
Pending
...
5. If the remaining CSRs are not approved, and are in the Pending status, approve the CSRs for
your cluster machines:
To approve them individually, run the following command for each valid CSR:
$ oc adm certificate approve <csr_name> 1
1

<csr_name> is the name of a CSR from the list of current CSRs.

To approve all pending CSRs, run the following command:
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}
{{end}}{{end}}' | xargs oc adm certificate approve
6. After all client and server CSRs have been approved, the machines have the Ready status.
Verify this by running the following command:
$ oc get nodes

Example output
NAME
master-0
master-1
master-2
worker-0
worker-1

STATUS ROLES AGE VERSION
Ready master 73m v1.23.0
Ready master 73m v1.23.0
Ready master 74m v1.23.0
Ready worker 11m v1.23.0
Ready worker 11m v1.23.0

NOTE
It can take a few minutes after approval of the server CSRs for the machines to
transition to the Ready status.
Additional information
For more information on CSRs, see Certificate Signing Requests .

19.5.21. Initial Operator configuration
After the control plane initializes, you must immediately configure some Operators so that they all
become available.
Prerequisites
Your control plane has initialized.
Procedure

2651


1. Watch the cluster components come online:

```bash
$ watch -n5 oc get clusteroperators
```

**Example output**

2. Configure the Operators that are not available.

### 19.5.21.1. Image registry removed during installation

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as **Removed**. This allows **openshift-installer** to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the `managementState` from **Removed** to **Managed**.
NOTE

The Prometheus console provides an `ImageRegistryRemoved` alert, for example:

"Image Registry has been removed. ImageStreamTags, BuildConfigs and DeploymentConfigs which reference ImageStreamTags may not work as expected. Please configure storage and update the config to Managed state by editing configs.imagerepertoire.operator.openshift.io."

19.5.21.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the `Recreate` rollout strategy during upgrades.

19.5.21.2.1. Configuring registry storage for VMware vSphere

As a cluster administrator, following installation you must configure your registry to use storage.

Prerequisites

- Cluster administrator permissions.
- A cluster on VMware vSphere.
- Persistent storage provisioned for your cluster, such as Red Hat OpenShift Data Foundation.

**IMPORTANT**

OpenShift Container Platform supports `ReadWriteOnce` access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, `ReadWriteMany` access is required.

- Must have "100Gi" capacity.

**IMPORTANT**

Testing shows issues with using the NFS server on RHEL as storage backend for core services. This includes the OpenShift Container Registry and Quay, Prometheus for monitoring storage, and Elasticsearch for logging storage. Therefore, using RHEL NFS to back PVs used by core services is not recommended.

Other NFS implementations on the marketplace might not have these issues. Contact the individual NFS implementation vendor for more information on any testing that was possibly completed against these OpenShift Container Platform core components.
Procedure

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

   **NOTE**
   
   When using shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

   ```
   $ oc get pod -n openshift-image-registry -l docker-registry=default
   
   No resources found in openshift-image-registry namespace
   
   **NOTE**
   
   If you do have a registry pod in your output, you do not need to continue with this procedure.
   
3. Check the registry configuration:

   ```
   $ oc edit configs.imageregistry.operator.openshift.io
   
   Example output
   
   ```
   storage:
   pvc:
   claim: 1
   ```

   Leave the `claim` field blank to allow the automatic creation of an `image-registry-storage` PVC.

4. Check the `clusteroperator` status:

   ```
   $ oc get clusteroperator image-registry
   
   Example output
   
   ```
   NAME VERSION AVAILABLE PROGRESSING DEGRADED SINCE MESSAGE
   image-registry 4.7 True False False 6h50m
   ```

19.5.21.2.2. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.
**Procedure**

- To set the image registry storage to an empty directory:
  
  ```bash
  $ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec": {"storage": {"emptyDir": {}}}}'
  ```

**WARNING**

Configure this option for only non-production clusters.

If you run this command before the Image Registry Operator initializes its components, the `oc patch` command fails with the following error:

```
Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
```

Wait a few minutes and run the command again.

19.5.21.2.3. Configuring block registry storage for VMware vSphere

To allow the image registry to use block storage types such as vSphere Virtual Machine Disk (VMDK) during upgrades as a cluster administrator, you can use the `Recreate` rollout strategy.

**IMPORTANT**

Block storage volumes are supported but not recommended for use with image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

**Procedure**

1. To set the image registry storage as a block storage type, patch the registry so that it uses the `Recreate` rollout strategy and runs with only 1 replica:

  ```bash
  $ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec": {"rolloutStrategy": "Recreate","replicas":1}}'
  ```

2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.

   a. Create a `pvc.yaml` file with the following contents to define a VMware vSphere `PersistentVolumeClaim` object:

   ```yaml
   apiVersion: v1
   kind: PersistentVolumeClaim
   metadata:
     name: image-registry-storage
   namespace: openshift-image-registry
   spec:
   ```
A unique name that represents the `PersistentVolumeClaim` object.

The namespace for the `PersistentVolumeClaim` object, which is `openshift-image-registry`.

The access mode of the persistent volume claim. With `ReadWriteOnce`, the volume can be mounted with read and write permissions by a single node.

The size of the persistent volume claim.

b. Create the `PersistentVolumeClaim` object from the file:

```bash
$ oc create -f pvc.yaml -n openshift-image-registry
```

3. Edit the registry configuration so that it references the correct PVC:

```bash
$ oc edit config.imageregistry.operator.openshift.io -o yaml
```

**Example output**

```
storage:
pvc:
  claim: 1
```

Creating a custom PVC allows you to leave the `claim` field blank for the default automatic creation of an `image-registry-storage` PVC.

For instructions about configuring registry storage so that it references the correct PVC, see [Configuring the registry for vSphere](#).

### 19.5.22. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

**Prerequisites**

- Your control plane has initialized.
- You have completed the initial Operator configuration.

**Procedure**

1. Confirm that all the cluster components are online with the following command:

   ```bash
   $ watch -n5 oc get clusteroperators
   ```
Example output

</tbody>
</table>

Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```bash
$ ./openshift-install --dir <installation_directory> wait-for install-complete
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

**Example output**

INFO Waiting up to 30m0s for the cluster to initialize...

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.
IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

2. Confirm that the Kubernetes API server is communicating with the pods.

   a. To view a list of all pods, use the following command:

      ```
      $ oc get pods --all-namespaces
      ```

   Example output

<table>
<thead>
<tr>
<th>NAMESPACE</th>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>openshift-apiserver-operator</td>
<td>openshift-apiserver-operator-85cb746d55-zqhs8</td>

<td></td>
<td></td>
<td>0</td>
</tr>
<tr>
<td>openshift-authentication-operator</td>
<td>authentication-operator-69d5d8bf84-vh2n8</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>5m</td>
</tr>
<tr>
<td></td>
<td>...</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

   b. View the logs for a pod that is listed in the output of the previous command by using the following command:

      ```
      $ oc logs <pod_name> -n <namespace>
      ```

      Specify the pod name and namespace, as shown in the output of the previous command.

      If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation.

   See “Enabling multipathing with kernel arguments on RHCOS” in the Post-installation machine configuration tasks documentation for more information.
You can add extra compute machines after the cluster installation is completed by following Adding compute machines to vSphere.

19.5.23. Backing up VMware vSphere volumes

OpenShift Container Platform provisions new volumes as independent persistent disks to freely attach and detach the volume on any node in the cluster. As a consequence, it is not possible to back up volumes that use snapshots, or to restore volumes from snapshots. See Snapshot Limitations for more information.

Procedure
To create a backup of persistent volumes:

1. Stop the application that is using the persistent volume.
2. Clone the persistent volume.
3. Restart the application.
4. Create a backup of the cloned volume.
5. Delete the cloned volume.

19.5.24. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.10, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources
- See About remote health monitoring for more information about the Telemetry service

19.5.25. Next steps
- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- Set up your registry and configure registry storage.
- Optional: View the events from the vSphere Problem Detector Operator to determine if the cluster has permission or storage configuration issues.

19.6. INSTALLING A CLUSTER ON VSPHERE WITH NETWORK CUSTOMIZATIONS

In OpenShift Container Platform version 4.10, you can install a cluster on VMware vSphere infrastructure that you provision with customized network configuration options. By customizing your network configuration, your cluster can coexist with existing IP address allocations in your environment and
integrate with existing MTU and VXLAN configurations.

You must set most of the network configuration parameters during installation, and you can modify only `kubeProxy` configuration parameters in a running cluster.

**IMPORTANT**

The steps for performing a user-provisioned infrastructure installation are provided as an example only. Installing a cluster with infrastructure you provide requires knowledge of the vSphere platform and the installation process of OpenShift Container Platform. Use the user-provisioned infrastructure installation instructions as a guide; you are free to create the required resources through other methods.

### 19.6.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- Completing the installation requires that you upload the Red Hat Enterprise Linux CoreOS (RHCOS) OVA on vSphere hosts. The machine from which you complete this process requires access to port 443 on the vCenter and ESXi hosts. Verify that port 443 is accessible.
- If you use a firewall, you confirmed with the administrator that port 443 is accessible. Control plane nodes must be able to reach vCenter and ESXi hosts on port 443 for the installation to succeed.
- If you use a firewall, you configured it to allow the sites that your cluster requires access to.

### 19.6.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.10, you require access to the internet to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 19.6.3. VMware vSphere infrastructure requirements
You must install the OpenShift Container Platform cluster on a VMware vSphere version 6 or 7 instance that meets the requirements for the components that you use.

Table 19.38. Version requirements for vSphere virtual environments

<table>
<thead>
<tr>
<th>Virtual environment product</th>
<th>Required version</th>
</tr>
</thead>
<tbody>
<tr>
<td>VM hardware version</td>
<td>13 or later</td>
</tr>
<tr>
<td>vSphere ESXi hosts</td>
<td>6.5 or later</td>
</tr>
<tr>
<td>vCenter host</td>
<td>6.5 or later</td>
</tr>
</tbody>
</table>

**IMPORTANT**

Installing a cluster on VMware vSphere version 6.7U3 or earlier and virtual hardware version 13 is now deprecated. These versions are still fully supported, but version 4.11 of OpenShift Container Platform will require vSphere virtual hardware version 15 or later. Hardware version 15 is now the default for vSphere virtual machines in OpenShift Container Platform. To update the hardware version for your vSphere nodes, see the “Updating hardware on nodes running in vSphere” article.

If your vSphere nodes are below hardware version 15 or your VMware vSphere version is earlier than 6.7U3, upgrading from OpenShift Container Platform 4.10 to OpenShift Container Platform 4.11 is not available.

Table 19.39. Minimum supported vSphere version for VMware components

<table>
<thead>
<tr>
<th>Component</th>
<th>Minimum supported versions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hypervisor</td>
<td>vSphere 6.5 and later with HW version 13</td>
<td>This version is the minimum version that Red Hat Enterprise Linux CoreOS (RHCOS) supports. See the Red Hat Enterprise Linux 8 supported hypervisors list.</td>
</tr>
<tr>
<td>Storage with in-tree drivers</td>
<td>vSphere 6.5 and later</td>
<td>This plug-in creates vSphere storage by using the in-tree storage drivers for vSphere included in OpenShift Container Platform.</td>
</tr>
<tr>
<td>Optional: Networking (NSX-T)</td>
<td>vSphere 6.5U3 or vSphere 6.7U2 and later</td>
<td>vSphere 6.5U3 or vSphere 6.7U2+ are required for OpenShift Container Platform. VMware’s NSX Container Plug-in (NCP) is certified with OpenShift Container Platform 4.6 and NSX-T 3.x+.</td>
</tr>
</tbody>
</table>
If you use a vSphere version 6.5 instance, consider upgrading to 6.7U3 or 7.0 before you install OpenShift Container Platform.

**IMPORTANT**

You must ensure that the time on your ESXi hosts is synchronized before you install OpenShift Container Platform. See Edit Time Configuration for a Host in the VMware documentation.

19.6.4. VMware vSphere CSI Driver Operator requirements

The following requirements must be met in order to install the CSI Driver Operator:

- VMware vSphere version 6.7U3 or later
- Virtual machines of hardware version 15 or later
- No third-party CSI driver already installed in the cluster

If a third-party CSI driver is present in the cluster, OpenShift Container Platform does not overwrite it. The presence of a third-party CSI driver prevents OpenShift Container Platform from upgrading to 4.11.

Additional resources

- To remove a third-party CSI driver, see Removing a third-party vSphere CSI Driver.
- To update the hardware version for your vSphere nodes, see Updating hardware on nodes running in vSphere.

19.6.5. Requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

This section describes the requirements for deploying OpenShift Container Platform on user-provisioned infrastructure.

19.6.5.1. Required machines for cluster installation

The smallest OpenShift Container Platform clusters require the following hosts:

**Table 19.40. Minimum required hosts**

<table>
<thead>
<tr>
<th>Hosts</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>One temporary bootstrap machine</td>
<td>The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.</td>
</tr>
<tr>
<td>Three control plane machines</td>
<td>The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.</td>
</tr>
</tbody>
</table>
At least two compute machines, which are also known as worker machines.

The workloads requested by OpenShift Container Platform users run on the compute machines.

<table>
<thead>
<tr>
<th>Hosts</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>At least two compute machines, which are also known as worker machines.</td>
<td>The workloads requested by OpenShift Container Platform users run on the compute machines.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

To improve high availability of your cluster, distribute the control plane machines over different z/VM instances on at least two physical machines.

The bootstrap, control plane, and compute machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 8 and inherits all of its hardware certifications and requirements. See Red Hat Enterprise Linux technology capabilities and limits.

**IMPORTANT**

All virtual machines must reside in the same datastore and in the same folder as the installer. Ensure that all virtual machine names across a vSphere installation are unique.

19.6.5.2. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS</td>
<td>2</td>
<td>8 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
</tbody>
</table>

1. One physical core (IFL) provides two logical cores (threads) when SMT-2 is enabled. The hypervisor can provide two or more vCPUs.

19.6.5.3. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The `kube-controller-manager` only approves the kubelet client CSRs. The `machine-approver` cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

19.6.5.4. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in
All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in initramfs during boot to fetch their Ignition config files.

During the initial boot, the machines require an HTTP or HTTPS server to establish a network connection to download their Ignition config files.

The machines are configured with static IP addresses. No DHCP server is required. Ensure that the machines have persistent IP addresses and hostnames.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

19.6.5.4.1. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

**IMPORTANT**

In connected OpenShift Container Platform environments, all nodes are required to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

### Table 19.41. Ports used for all-machine to all-machine communications

</tbody>
</table>

**Ethernet adaptor hardware address requirements**

When provisioning VMs for the cluster, the ethernet interfaces configured for each VM must use a MAC address from the VMware Organizationally Unique Identifier (OUI) allocation ranges:

- 00:05:69:00:00:00 to 00:05:69:FF:FF
- 00:0c:29:00:00:00 to 00:0c:29:FF:FF
- 00:1c:14:00:00:00 to 00:1c:14:FF:FF
- 00:50:56:00:00:00 to 00:50:56:FF:FF

If a MAC address outside the VMware OUI is used, the cluster installation will not succeed.

**NTP configuration for user-provisioned infrastructure**

OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for Configuring chrony time service.

**Additional resources**

- Configuring chrony time service

**19.6.5.5. User-provisioned DNS requirements**

In OpenShift Container Platform deployments, DNS name resolution is required for the following components:

- The Kubernetes API
- The OpenShift Container Platform application wildcard
- The bootstrap, control plane, and compute machines

Reverse DNS resolution is also required for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the hostnames for all the nodes, unless the hostnames are
provided by DHCP. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

The following DNS records are required for a user-provisioned OpenShift Container Platform cluster and they must be in place before installation. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>`.

Table 19.44. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes API</td>
<td><code>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</code></td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the API load balancer. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td></td>
<td><code>api-int.&lt;cluster_name&gt;.&lt;base_domain&gt;.</code></td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to internally identify the API load balancer. These records must be resolvable from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Routes</td>
<td><code>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</code></td>
<td>A wildcard DNS A/AAAA or CNAME record that refers to the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster. For example, <code>console-openshift-console.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;</code> is used as a wildcard route to the OpenShift Container Platform console.</td>
</tr>
<tr>
<td>Bootstrap machine</td>
<td><code>bootstrap.&lt;cluster_name&gt;.&lt;base_domain&gt;.</code></td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Control plane machines</td>
<td><code>&lt;master&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</code></td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
</tbody>
</table>
### Component Record Description

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compute machine</td>
<td><code>&lt;worker&gt;&lt;n&gt;</code>, <code>&lt;cluster_name&gt;</code>, <code>&lt;base_domain&gt;</code></td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**NOTE**

In OpenShift Container Platform 4.4 and later, you do not need to specify etcd host and SRV records in your DNS configuration.

**TIP**

You can use the `dig` command to verify name and reverse name resolution. See the section on *Validating DNS resolution for user-provisioned infrastructure* for detailed validation steps.

#### 19.6.5.5.1. Example DNS configuration for user-provisioned clusters

This section provides A and PTR record configuration samples that meet the DNS requirements for deploying OpenShift Container Platform on user-provisioned infrastructure. The samples are not meant to provide advice for choosing one DNS solution over another.

In the examples, the cluster name is `ocp4` and the base domain is `example.com`.

**Example DNS A record configuration for a user-provisioned cluster**

The following example is a BIND zone file that shows sample A records for name resolution in a user-provisioned cluster.

**Example 19.10. Sample DNS zone database**

```
$TTL 1W
@ IN SOA ns1.example.com. root (  
2019070700 ; serial 
3H ; refresh (3 hours) 
30M ; retry (30 minutes) 
2W ; expiry (2 weeks) 
1W ) ; minimum (1 week) 
IN NS ns1.example.com.  
IN MX 10 smtp.example.com. ; 
; 
ns1.example.com. IN A 192.168.1.5 
smtp.example.com. IN A 192.168.1.5 
; 
helper.example.com. IN A 192.168.1.5 
helper.ocp4.example.com. IN A 192.168.1.5 
; 
api.ocp4.example.com. IN A 192.168.1.5
```
Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer.

Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer and is used for internal cluster communications.

Provides name resolution for the wildcard routes. The record refers to the IP address of the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

NOTE

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

Provides name resolution for the bootstrap machine.

Provides name resolution for the control plane machines.

Provides name resolution for the compute machines.

Example DNS PTR record configuration for a user-provisioned cluster

The following example BIND zone file shows sample PTR records for reverse name resolution in a user-provisioned cluster.

Example 19.11. Sample DNS zone database for reverse records

```
$TTL 1W
@ IN SOA ns1.example.com. root (
  2019070700 ; serial
  3H ; refresh (3 hours)
  30M ; retry (30 minutes)
  2W ; expiry (2 weeks)
)
```
Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer.

Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer and is used for internal cluster communications.

Provides reverse DNS resolution for the bootstrap machine.

Provides reverse DNS resolution for the control plane machines.

Provides reverse DNS resolution for the compute machines.

NOTE

A PTR record is not required for the OpenShift Container Platform application wildcard.

19.6.5.6. Load balancing requirements for user-provisioned infrastructure

Before you install OpenShift Container Platform, you must provision the API and application ingress load balancing infrastructure. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

The load balancing infrastructure must meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.
   - A stateless load balancing algorithm. The options vary based on the load balancer implementation.
Session persistence is not required for the API load balancer to function properly.

Configure the following ports on both the front and back of the load balancers:

Table 19.45. API load balancer

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the /readyz endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>

NOTE

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the /readyz endpoint to the removal of the API server instance from the pool. Within the time frame after /readyz returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application ingress load balancer** Provides an ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

TIP

If the true IP address of the client can be seen by the application ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

Configure the following ports on both the front and back of the load balancers:

Table 19.46. Application ingress load balancer
<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
<tr>
<td>1936</td>
<td>The worker nodes that run the Ingress Controller pods, by default. You must configure the /healthz/ready endpoint for the ingress health check probe.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>

**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

**NOTE**

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

### 19.6.5.6.1. Example load balancer configuration for user-provisioned clusters

This section provides an example API and application ingress load balancer configuration that meets the load balancing requirements for user-provisioned clusters. The sample is an `/etc/haproxy/haproxy.cfg` configuration for an HAProxy load balancer. The example is not meant to provide advice for choosing one load balancing solution over another.

**NOTE**

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

**Example 19.12. Sample API and application ingress load balancer configuration**

```text
global
log 127.0.0.1 local2
pidfile /var/run/haproxy.pid
maxconn 4000
daemon
defaults
mode http
```
In the example, the cluster name is `ocp4`.

Port 6443 handles the Kubernetes API traffic and points to the control plane machines.
The bootstrap entries must be in place before the OpenShift Container Platform cluster installation and they must be removed after the bootstrap process is complete.

Port 22623 handles the machine config server traffic and points to the control plane machines.

Port 443 handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

Port 80 handles the HTTP traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

NOTE
If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

TIP
If you are using HAProxy as a load balancer, you can check that the haproxy process is listening on ports 6443, 22623, 443, and 80 by running netstat -nltpu on the HAProxy node.

NOTE
If you are using HAProxy as a load balancer and SELinux is set to enforcing, you must ensure that the HAProxy service can bind to the configured TCP port by running setsebool -P haproxy_connect_any=1.

19.6.6. Preparing the user-provisioned infrastructure

Before you install OpenShift Container Platform on user-provisioned infrastructure, you must prepare the underlying infrastructure.

This section provides details about the high-level steps required to set up your cluster infrastructure in preparation for an OpenShift Container Platform installation. This includes configuring IP networking and network connectivity for your cluster nodes, preparing a web server for the Ignition files, enabling the required ports through your firewall, and setting up the required DNS and load balancing infrastructure.

After preparation, your cluster infrastructure must meet the requirements outlined in the Requirements for a cluster with user-provisioned infrastructure section.

Prerequisites

- You have reviewed the OpenShift Container Platform 4.x Tested Integrations page.
- You have reviewed the infrastructure requirements detailed in the Requirements for a cluster with user-provisioned infrastructure section.

Procedure
1. Set up static IP addresses.

2. Set up an HTTP or HTTPS server to provide Ignition files to the cluster nodes.

3. Ensure that your network infrastructure provides the required network connectivity between the cluster components. See the Networking requirements for user-provisioned infrastructure section for details about the requirements.

4. Configure your firewall to enable the ports required for the OpenShift Container Platform cluster components to communicate. See Networking requirements for user-provisioned infrastructure section for details about the ports that are required.

5. Setup the required DNS infrastructure for your cluster.
   a. Configure DNS name resolution for the Kubernetes API, the application wildcard, the bootstrap machine, the control plane machines, and the compute machines.
   b. Configure reverse DNS resolution for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.
      See the User-provisioned DNS requirements section for more information about the OpenShift Container Platform DNS requirements.

6. Validate your DNS configuration.
   a. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses in the responses correspond to the correct components.
   b. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names in the responses correspond to the correct components.
      See the Validating DNS resolution for user-provisioned infrastructure section for detailed DNS validation steps.

7. Provision the required API and application ingress load balancing infrastructure. See the Load balancing requirements for user-provisioned infrastructure section for more information about the requirements.

**NOTE**

Some load balancing solutions require the DNS name resolution for the cluster nodes to be in place before the load balancing is initialized.

19.6.7. Validating DNS resolution for user-provisioned infrastructure

You can validate your DNS configuration before installing OpenShift Container Platform on user-provisioned infrastructure.

**IMPORTANT**

The validation steps detailed in this section must succeed before you install your cluster.

**Prerequisites**

- You have configured the required DNS records for your user-provisioned infrastructure.
Procedure

1. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses contained in the responses correspond to the correct components.

   a. Perform a lookup against the Kubernetes API record name. Check that the result points to the IP address of the API load balancer:

   ```
   $ dig +noall +answer @<nameserver_ip> api.<cluster_name>.<base_domain>
   
   Replace `<nameserver_ip>` with the IP address of the nameserver, `<cluster_name>` with your cluster name, and `<base_domain>` with your base domain name.
   ```

   Example output

   ```
   api.ocp4.example.com. 0 IN A 192.168.1.5
   ```

   b. Perform a lookup against the Kubernetes internal API record name. Check that the result points to the IP address of the API load balancer:

   ```
   $ dig +noall +answer @<nameserver_ip> api-int.<cluster_name>.<base_domain>
   ```

   Example output

   ```
   api-int.ocp4.example.com. 0 IN A 192.168.1.5
   ```

   c. Test an example `*.apps.<cluster_name>.<base_domain>` DNS wildcard lookup. All of the application wildcard lookups must resolve to the IP address of the application ingress load balancer:

   ```
   $ dig +noall +answer @<nameserver_ip> random.apps.<cluster_name>.<base_domain>
   ```

   Example output

   ```
   random.apps.ocp4.example.com. 0 IN A 192.168.1.5
   ```

   NOTE

   In the example outputs, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

   You can replace `random` with another wildcard value. For example, you can query the route to the OpenShift Container Platform console:

   ```
   $ dig +noall +answer @<nameserver_ip> console-openshift-console.apps.<cluster_name>.<base_domain>
   ```

   Example output
d. Run a lookup against the bootstrap DNS record name. Check that the result points to the IP address of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> bootstrap.<cluster_name>.<base_domain>
```

**Example output**

```
bootstrap.ocp4.example.com. 0 IN A 192.168.1.96
```

e. Use this method to perform lookups against the DNS record names for the control plane and compute nodes. Check that the results correspond to the IP addresses of each node.

2. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names contained in the responses correspond to the correct components.

a. Perform a reverse lookup against the IP address of the API load balancer. Check that the response includes the record names for the Kubernetes API and the Kubernetes internal API:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.5
```

**Example output**

```
5.1.168.192.in-addr.arpa. 0 IN PTR api-int.ocp4.example.com. 1
5.1.168.192.in-addr.arpa. 0 IN PTR api.ocp4.example.com. 2
```

1. Provides the record name for the Kubernetes internal API.

2. Provides the record name for the Kubernetes API.

**NOTE**

A PTR record is not required for the OpenShift Container Platform application wildcard. No validation step is needed for reverse DNS resolution against the IP address of the application ingress load balancer.

b. Perform a reverse lookup against the IP address of the bootstrap node. Check that the result points to the DNS record name of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.96
```

**Example output**

```
96.1.168.192.in-addr.arpa. 0 IN PTR bootstrap.ocp4.example.com.
```

c. Use this method to perform reverse lookups against the IP addresses for the control plane and compute nodes. Check that the results correspond to the DNS record names of each node.
19.6.8. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The ./openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   `$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>`

   Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   `$ cat <path>/<file_name>.pub`

   For example, run the following to view the ~/.ssh/id_rsa.pub public key:

   `$ cat ~/.ssh/id_rsa.pub`

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the ./openshift-install gather command.
NOTE
On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

a. If the `ssh-agent` process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

Example output

```
Agent pid 31874
```

NOTE
If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the `ssh-agent`:

```
$ ssh-add <path>/<file_name>
```

Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

19.6.9. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on your provisioning machine.

Prerequisites

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.
3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

**IMPORTANT**

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 19.6.10. Manually creating the installation configuration file

For user-provisioned installations of OpenShift Container Platform, you manually generate your installation configuration file.

**Prerequisites**

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.

- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Create an installation directory to store your required installation assets in:

```
$ mkdir <installation_directory>
```
IMPORTANT

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample `install-config.yaml` file template that is provided and save it in the `<installation_directory>`.

NOTE

You must name this configuration file `install-config.yaml`.

NOTE

For some platform types, you can alternatively run `./openshift-install create install-config --dir <installation_directory>` to generate an `install-config.yaml` file. You can provide details about your cluster configuration at the prompts.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

IMPORTANT

The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.

19.6.10.1. Sample `install-config.yaml` file for VMware vSphere

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute:
  - hyperthreading: Enabled
    name: worker
    replicas: 0
controlPlane:
  hyperthreading: Enabled
  name: master
  replicas: 3
metadata:
  name: test
platform:
  vsphere:
    vcenter: your.vcenter.server
    username: username
    password: password
    datacenter: datacenter
```
The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

The **controlPlane** section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -, and the first line of the **controlPlane** section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading, or **hyperthreading**. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to **Disabled**. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

<table>
<thead>
<tr>
<th>defaultDatastore: datastore</th>
<th>13</th>
</tr>
</thead>
<tbody>
<tr>
<td>folder: &quot;&lt;datacenter_name&gt;/vm/&lt;folder_name&gt;/&lt;subfolder_name&gt;&quot;</td>
<td>14</td>
</tr>
<tr>
<td>diskType: thin</td>
<td>15</td>
</tr>
<tr>
<td>fips: false</td>
<td>16</td>
</tr>
<tr>
<td>pullSecret: '{&quot;auths&quot;: ...}'</td>
<td>17</td>
</tr>
<tr>
<td>sshKey: 'ssh-ed25519 AAAA...'</td>
<td>18</td>
</tr>
</tbody>
</table>

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Your machines must use at least 8 CPUs and 32 GB of RAM if you disable simultaneous multithreading.

You must set the value of the **replicas** parameter to **0**. This parameter controls the number of workers that the cluster creates and manages for you, which are functions that the cluster does not perform when you use user-provisioned infrastructure. You must manually deploy worker machines for the cluster to use before you finish installing OpenShift Container Platform.

The number of control plane machines that you add to the cluster. Because the cluster uses this values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

The cluster name that you specified in your DNS records.

The fully-qualified hostname or IP address of the vCenter server.

The name of the user for accessing the server. This user must have at least the roles and privileges that are required for **static or dynamic persistent volume provisioning** in vSphere.

The password associated with the vSphere user.

The vSphere datacenter.

The default vSphere datastore to use.

Optional: For installer-provisioned infrastructure, the absolute path of an existing folder where the installation program creates the virtual machines, for example, 

`
/<datacenter_name>/vm/<folder_name>/<subfolder_name>
`

If you do not provide this value, the installation program creates a top-level folder in the datacenter virtual machine folder that is named with the infrastructure ID. If you are providing the infrastructure for the cluster, omit this.
The vsphere disk provisioning method.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

The pull secret that you obtained from OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

The public portion of the default SSH key for the core user in Red Hat Enterprise Linux CoreOS (RHCOS).

### 19.6.10.2. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**Prerequisites**

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the Proxy object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The Proxy object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

**Procedure**

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
```
A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.

A proxy URL to use for creating HTTPS connections outside the cluster.

A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with `.` to match subdomains only. For example, `.y.com` matches `x.y.com`, but not `y.com`. Use `*` to bypass the proxy for all destinations. You must include vCenter’s IP address and the IP range that you use for its machines.

If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the `trustedCA` field of the `Proxy` object. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

**NOTE**

The installation program does not support the proxy `readinessEndpoints` field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster` `Proxy` object is still created, but it will have a nil `spec`.

**NOTE**

Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

19.6.11. Network configuration phases

There are two phases prior to OpenShift Container Platform installation where you can customize the network configuration.

Phase 1

You can customize the following network-related fields in the `install-config.yaml` file before you create the manifest files:

- `networking.networkType`
Phase 2

After creating the manifest files by running `openshift-install create manifests`, you can define a customized Cluster Network Operator manifest with only the fields you want to modify. You can use the manifest to specify advanced network configuration.

You cannot override the values specified in phase 1 in the `install-config.yaml` file during phase 2. However, you can further customize the cluster network provider during phase 2.

19.6.12. Specifying advanced network configuration

You can use advanced network configuration for your cluster network provider to integrate your cluster into your existing network environment. You can specify advanced network configuration only before you install the cluster.

**IMPORTANT**

Customizing your network configuration by modifying the OpenShift Container Platform manifest files created by the installation program is not supported. Applying a manifest file that you create, as in the following procedure, is supported.

**Prerequisites**

- You have created the `install-config.yaml` file and completed any modifications to it.

**Procedure**

1. Change to the directory that contains the installation program and create the manifests:

   ```
   $ ./openshift-install create manifests --dir <installation_directory>  
   
   <installation_directory> specifies the name of the directory that contains the install-config.yaml file for your cluster.
   ```

2. Create a stub manifest file for the advanced network configuration that is named `cluster-network-03-config.yml` in the `<installation_directory>/manifests/` directory:

   ```yaml
   apiVersion: operator.openshift.io/v1
   kind: Network
   metadata:
   ```
3. Specify the advanced network configuration for your cluster in the `cluster-network-03-config.yml` file, such as in the following examples:

**Specify a different VXLAN port for the OpenShift SDN network provider**

```yaml
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
  name: cluster
spec:
defaultNetwork:
  openshiftSDNConfig:
    vxlanPort: 4800
```

**Enable IPsec for the OVN-Kubernetes network provider**

```yaml
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
  name: cluster
spec:
defaultNetwork:
  ovnKubernetesConfig:
    ipsecConfig: {}
```

4. Optional: Back up the `manifests/cluster-network-03-config.yml` file. The installation program consumes the `manifests/` directory when you create the Ignition config files.

5. Remove the Kubernetes manifest files that define the control plane machines and compute machineSets:

   ```bash
   $ rm -f openshift/99_openshift-cluster-api_master-machines-*.yaml openshift/99_openshift-cluster-api_worker-machineset-*.yaml
   ```

   Because you create and manage these resources yourself, you do not have to initialize them.
   
   - You can preserve the MachineSet files to create compute machines by using the machine API, but you must update references to them to match your environment.

### 19.6.13. Cluster Network Operator configuration

The configuration for the cluster network is specified as part of the Cluster Network Operator (CNO) configuration and stored in a custom resource (CR) object that is named `cluster`. The CR specifies the fields for the `Network` API in the `operator.openshift.io` API group.

The CNO configuration inherits the following fields during cluster installation from the `Network` API in the `Network.config.openshift.io` API group and these fields cannot be changed:

- `clusterNetwork`: IP address pools from which pod IP addresses are allocated.
- `serviceNetwork`: ...
IP address pool for services.

**defaultNetwork.type**

Cluster network provider, such as OpenShift SDN or OVN-Kubernetes.

You can specify the cluster network provider configuration for your cluster by setting the fields for the `defaultNetwork` object in the CNO object named `cluster`.

### 19.6.13.1. Cluster Network Operator configuration object

The fields for the Cluster Network Operator (CNO) are described in the following table:

#### Table 19.47. Cluster Network Operator configuration object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>metadata.name</td>
<td>string</td>
<td>The name of the CNO object. This name is always <code>cluster</code>.</td>
</tr>
<tr>
<td>spec.clusterNetwork</td>
<td>array</td>
<td>A list specifying the blocks of IP addresses from which pod IP addresses are allocated and the subnet prefix length assigned to each individual node in the cluster. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>spec:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>clusterNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- cidr: 10.128.0.0/19</td>
</tr>
<tr>
<td></td>
<td></td>
<td>hostPrefix: 23</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- cidr: 10.128.32.0/19</td>
</tr>
<tr>
<td></td>
<td></td>
<td>hostPrefix: 23</td>
</tr>
<tr>
<td></td>
<td></td>
<td>You can customize this field only in the <code>install-config.yaml</code> file before you create the manifests. The value is read-only in the manifest file.</td>
</tr>
<tr>
<td>spec.serviceNetwork</td>
<td>array</td>
<td>A block of IP addresses for services. The OpenShift SDN and OVN-Kubernetes Container Network Interface (CNI) network providers support only a single IP address block for the service network. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>spec:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>serviceNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- 172.30.0.0/14</td>
</tr>
<tr>
<td></td>
<td></td>
<td>You can customize this field only in the <code>install-config.yaml</code> file before you create the manifests. The value is read-only in the manifest file.</td>
</tr>
<tr>
<td>spec.defaultNetwork</td>
<td>object</td>
<td>Configures the Container Network Interface (CNI) cluster network provider for the cluster network.</td>
</tr>
<tr>
<td>spec.kubeProxyConfig</td>
<td>object</td>
<td>The fields for this object specify the kube-proxy configuration. If you are using the OVN-Kubernetes cluster network provider, the kube-proxy configuration has no effect.</td>
</tr>
</tbody>
</table>
The values for the `defaultNetwork` object are defined in the following table:

**Table 19.48. defaultNetwork object**

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>string</td>
<td>Either OpenShiftSDN or OVNKubernetes. The cluster network provider is selected during installation. This value cannot be changed after cluster installation.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>NOTE</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>OpenShift Container Platform uses the OpenShift SDN Container Network Interface (CNI) cluster network provider by default.</td>
</tr>
<tr>
<td>openshiftSDNConfig</td>
<td>object</td>
<td>This object is only valid for the OpenShift SDN cluster network provider.</td>
</tr>
<tr>
<td>ovnKubernetesConfig</td>
<td>object</td>
<td>This object is only valid for the OVN-Kubernetes cluster network provider.</td>
</tr>
</tbody>
</table>

**Configuration for the OpenShift SDN CNI cluster network provider**

The following table describes the configuration fields for the OpenShift SDN Container Network Interface (CNI) cluster network provider.

**Table 19.49. openshiftSDNConfig object**

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mode</td>
<td>string</td>
<td>Configures the network isolation mode for OpenShift SDN. The default value is <strong>NetworkPolicy</strong>.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The values <strong>Multitenant</strong> and <strong>Subnet</strong> are available for backwards compatibility with OpenShift Container Platform 3.x but are not recommended. This value cannot be changed after cluster installation.</td>
</tr>
</tbody>
</table>
The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.

If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.

If your cluster requires different MTU values for different nodes, you must set this value to 50 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1450.

This value cannot be changed after cluster installation.

The port to use for all VXLAN packets. The default value is 4789. This value cannot be changed after cluster installation.

If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number.

On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port 9000 and port 9999.

Example OpenShift SDN configuration

```yaml
defaultNetwork:
  type: OpenShiftSDN
  openshiftSDNConfig:
    mode: NetworkPolicy
    mtu: 1450
    vxlanPort: 4789
```

Configuration for the OVN-Kubernetes CNI cluster network provider

The following table describes the configuration fields for the OVN-Kubernetes CNI cluster network provider.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mtu</td>
<td>integer</td>
<td>The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU. If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes. If your cluster requires different MTU values for different nodes, you must set this value to 50 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1450. This value cannot be changed after cluster installation.</td>
</tr>
<tr>
<td>vxlanPort</td>
<td>integer</td>
<td>The port to use for all VXLAN packets. The default value is 4789. This value cannot be changed after cluster installation. If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number. On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port 9000 and port 9999.</td>
</tr>
</tbody>
</table>
### Field Description

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mtu</td>
<td>integer</td>
<td>The maximum transmission unit (MTU) for the Geneve (Generic Network Virtualization Encapsulation) overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU. If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes. If your cluster requires different MTU values for different nodes, you must set this value to 100 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1400.</td>
</tr>
<tr>
<td>genevePort</td>
<td>integer</td>
<td>The port to use for all Geneve packets. The default value is 6081. This value cannot be changed after cluster installation.</td>
</tr>
<tr>
<td>ipsecConfig</td>
<td>object</td>
<td>Specify an empty object to enable IPsec encryption. This value cannot be changed after cluster installation.</td>
</tr>
<tr>
<td>policyAuditConfig</td>
<td>object</td>
<td>Specify a configuration object for customizing network policy audit logging. If unset, the defaults audit log settings are used.</td>
</tr>
<tr>
<td>gatewayConfig</td>
<td>object</td>
<td>Optional: Specify a configuration object for customizing how egress traffic is sent to the node gateway.</td>
</tr>
</tbody>
</table>

**NOTE**

While migrating egress traffic, you can expect some disruption to workloads and service traffic until the Cluster Network Operator (CNO) successfully rolls out the changes.

### Table 19.51. policyAuditConfig object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rateLimit</td>
<td>integer</td>
<td>The maximum number of messages to generate every second per node. The default value is 20 messages per second.</td>
</tr>
<tr>
<td>maxFileSize</td>
<td>integer</td>
<td>The maximum size for the audit log in bytes. The default value is 50000000 or 50 MB.</td>
</tr>
</tbody>
</table>
### Field: `destination`  
**Type:** string  
**Description:** One of the following additional audit log targets:
- **`libc`**  
  The libc `syslog()` function of the journald process on the host.
- **`udp:<host>:<port>`**  
  A syslog server. Replace `<host>:<port>` with the host and port of the syslog server.
- **`unix:<file>`**  
  A Unix Domain Socket file specified by `<file>`.
- **null**  
  Do not send the audit logs to any additional target.

### Field: `syslogFacility`  
**Type:** string  
**Description:** The syslog facility, such as `kern`, as defined by RFC5424. The default value is `local0`.

### Table 19.52. gatewayConfig object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>routingViaHost</code></td>
<td>boolean</td>
<td>Set this field to true to send egress traffic from pods to the host networking stack. For highly-specialized installations and applications that rely on manually configured routes in the kernel routing table, you might want to route egress traffic to the host networking stack. By default, egress traffic is processed in OVN to exit the cluster and is not affected by specialized routes in the kernel routing table. The default value is false. This field has an interaction with the Open vSwitch hardware offloading feature. If you set this field to true, you do not receive the performance benefits of the offloading because egress traffic is processed by the host networking stack.</td>
</tr>
</tbody>
</table>

### Example OVN–Kubernetes configuration with IPSec enabled

```yaml
defaultNetwork:
type: OVNKubernetes
ovnKubernetesConfig:
  mtu: 1400
genevePort: 6081
ipsecConfig: {}
```

### kubeProxyConfig object configuration

The values for the `kubeProxyConfig` object are defined in the following table:

### Table 19.53. kubeProxyConfig object
<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>iptablesSyncPeriod</td>
<td>string</td>
<td>The refresh period for <code>iptables</code> rules. The default value is <strong>30s</strong>. Valid suffixes include <code>s</code>, <code>m</code>, and <code>h</code> and are described in the Go time package documentation.</td>
</tr>
<tr>
<td>proxyArguments.iptables-min-sync-period</td>
<td>array</td>
<td>The minimum duration before refreshing <code>iptables</code> rules. This field ensures that the refresh does not happen too frequently. Valid suffixes include <code>s</code>, <code>m</code>, and <code>h</code> and are described in the Go time package. The default value is:</td>
</tr>
</tbody>
</table>

```yaml
kubeProxyConfig:
  proxyArguments:
    iptables-min-sync-period:
      - 0s
```

### 19.6.14. Creating the Ignition config files

Because you must manually start the cluster machines, you must generate the Ignition config files that the cluster needs to make its machines.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

### Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.
Procedure

- Obtain the Ignition config files:

  ```
  $ ./openshift-install create ignition-configs --dir <installation_directory>
  ```

  For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

**IMPORTANT**

If you created an `install-config.yaml` file, specify the directory that contains it. Otherwise, specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

The following files are generated in the directory:

```
├── auth
│   ├── kubeadmin-password
│   └── kubeconfig
├── bootstrap.ign
├── master.ign
├── metadata.json
└── worker.ign
```

19.6.15. Extracting the infrastructure name

The Ignition config files contain a unique cluster identifier that you can use to uniquely identify your cluster in VMware vSphere. If you plan to use the cluster identifier as the name of your virtual machine folder, you must extract it.

**Prerequisites**

- You obtained the OpenShift Container Platform installation program and the pull secret for your cluster.
- You generated the Ignition config files for your cluster.
- You installed the `jq` package.

**Procedure**

- To extract and view the infrastructure name from the Ignition config file metadata, run the following command:

  ```
  $ jq -r .infraID <installation_directory>/metadata.json
  ```
For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

Example output

```bash
openshift-vw9j6
```

The output of this command is your cluster name and a random string.

19.6.16. Installing RHCOS and starting the OpenShift Container Platform bootstrap process

To install OpenShift Container Platform on user-provisioned infrastructure on VMware vSphere, you must install Red Hat Enterprise Linux CoreOS (RHCOS) on vSphere hosts. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS machines have rebooted.

Prerequisites

- You have obtained the Ignition config files for your cluster.
- You have access to an HTTP server that you can access from your computer and that the machines that you create can access.
- You have created a vSphere cluster.

Procedure

1. Upload the bootstrap Ignition config file, which is named `<installation_directory>/bootstrap.ign`, that the installation program created to your HTTP server. Note the URL of this file.

2. Save the following secondary Ignition config file for your bootstrap node to your computer as `<installation_directory>/merge-bootstrap.ign`:

```json
{
  "ignition": {
    "config": {
      "merge": [
        {
          "source": "<bootstrap_ignition_config_url>",
          "verification": {}
        }
      ],
      "timeouts": {},
      "version": "3.2.0"
    },
    "networkd": {},
    "passwd": {}
  }
}
```
Specify the URL of the bootstrap Ignition config file that you hosted.

When you create the virtual machine (VM) for the bootstrap machine, you use this Ignition config file.

3. Locate the following Ignition config files that the installation program created:
   - `<installation_directory>/master.ign`
   - `<installation_directory>/worker.ign`
   - `<installation_directory>/merge-bootstrap.ign`

4. Convert the Ignition config files to Base64 encoding. Later in this procedure, you must add these files to the extra configuration parameter `guestinfo.ignition.config.data` in your VM. For example, if you use a Linux operating system, you can use the `base64` command to encode the files.

   ```bash
   $ base64 -w0 <installation_directory>/master.ign > <installation_directory>/master.64
   $ base64 -w0 <installation_directory>/worker.ign > <installation_directory>/worker.64
   $ base64 -w0 <installation_directory>/merge-bootstrap.ign > <installation_directory>/merge-bootstrap.64
   ```

   **IMPORTANT**

   If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

5. Obtain the RHCOS OVA image. Images are available from the RHCOS image mirror page.

   **IMPORTANT**

   The RHCOS images might not change with every release of OpenShift Container Platform. You must download an image with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image version that matches your OpenShift Container Platform version if it is available.

   The filename contains the OpenShift Container Platform version number in the format `rhcos-{architecture}.ova`.

6. In the vSphere Client, create a folder in your datacenter to store your VMs.
   a. Click the **VMs and Templates** view.
   b. Right-click the name of your datacenter.
c. Click New Folder → New VM and Template Folder.

d. In the window that is displayed, enter the folder name. If you did not specify an existing folder in the install-config.yaml file, then create a folder with the same name as the infrastructure ID. You use this folder name so vCenter dynamically provisions storage in the appropriate location for its Workspace configuration.

7. In the vSphere Client, create a template for the OVA image and then clone the template as needed.

**NOTE**

In the following steps, you create a template and then clone the template for all of your cluster machines. You then provide the location for the Ignition config file for that cloned machine type when you provision the VMs.

a. From the Hosts and Clusters tab, right-click your cluster name and select Deploy OVF Template.

b. On the Select an OVF tab, specify the name of the RHCOS OVA file that you downloaded.

c. On the Select a name and folder tab, set a Virtual machine name for your template, such as Template-RHCOS. Click the name of your vSphere cluster and select the folder you created in the previous step.

d. On the Select a compute resource tab, click the name of your vSphere cluster.

e. On the Select storage tab, configure the storage options for your VM.

- Select Thin Provision or Thick Provision, based on your storage preferences.
- Select the datastore that you specified in your install-config.yaml file.

f. On the Select network tab, specify the network that you configured for the cluster, if available.

g. When creating the OVF template, do not specify values on the Customize template tab or configure the template any further.

**IMPORTANT**

Do not start the original VM template. The VM template must remain off and must be cloned for new RHCOS machines. Starting the VM template configures the VM template as a VM on the platform, which prevents it from being used as a template that machine sets can apply configurations to.

8. Optional: Update the configured virtual hardware version in the VM template, if necessary. Follow Upgrading a virtual machine to the latest hardware version in the VMware documentation for more information.
IMPORTANT

It is recommended that you update the hardware version of the VM template to version 15 before creating VMs from it, if necessary. Using hardware version 13 for your cluster nodes running on vSphere is now deprecated. If your imported template defaults to hardware version 13, you must ensure that your ESXi host is on 6.7U3 or later before upgrading the VM template to hardware version 15. If your vSphere version is less than 6.7U3, you can skip this upgrade step; however, a future version of OpenShift Container Platform is scheduled to remove support for hardware version 13 and vSphere versions less than 6.7U3.

9. After the template deploys, deploy a VM for a machine in the cluster.
   a. Right-click the template name and click **Clone** → **Clone to Virtual Machine**
   b. On the **Select a name and folder** tab, specify a name for the VM. You might include the machine type in the name, such as `control-plane-0` or `compute-1`.

   **NOTE**
   
   Ensure that all virtual machine names across a vSphere installation are unique.

   c. On the **Select a name and folder** tab, select the name of the folder that you created for the cluster.
   d. On the **Select a compute resource** tab, select the name of a host in your datacenter.
   e. Optional: On the **Select storage** tab, customize the storage options.
   f. On the **Select clone options**, select **Customize this virtual machine’s hardware**
   g. On the **Customize hardware** tab, click **VM Options** → **Advanced**.
      - Optional: Override default DHCP networking in vSphere. To enable static IP networking:
         i. Set your static IP configuration:

         ```
         $ export IPCFG="ip=<ip>::<gateway>::<netmask>::<hostname>::<iface>::none
         nameserver=srv1 [nameserver=srv2 [nameserver=srv3 [...]]]"
         
         Example command
         ```

         ```
         $ export IPCFG="ip=192.168.100.101::192.168.100.254:255.255.255.0:::none
         nameserver=8.8.8.8"
         
         ii. Set the **guestinfo.afterburn.initrd.network-kargs** property before booting a VM from an OVA in vSphere:

         ```
         $ govc vm.change -vm "<vm_name>" -e "guestinfo.afterburn.initrd.network-kargs=${IPCFG}"
         ```
Optional: in the event of cluster performance issues, from the Latency Sensitivity list, select High. Ensure that your VM’s CPU and memory reservation have the following values:

- Memory reservation value must be equal to its configured memory size.
- CPU reservation value must be at least the number of low latency virtual CPUs multiplied by the measured physical CPU speed.

Click Edit Configuration, and on the Configuration Parameters window, click Add Configuration Params. Define the following parameter names and values:

- guestinfo.ignition.config.data: Locate the base-64 encoded files that you created previously in this procedure, and paste the contents of the base64-encoded Ignition config file for this machine type.

- guestinfo.ignition.config.data.encoding: Specify base64.

- disk.EnableUUID: Specify TRUE.

h. In the Virtual Hardware panel of the Customize hardware tab, modify the specified values as required. Ensure that the amount of RAM, CPU, and disk storage meets the minimum requirements for the machine type.

i. Complete the configuration and power on the VM.

j. Check the console output to verify that Ignition ran.

Example command

```
Ignition: ran on 2022/03/14 14:48:33 UTC (this boot)
Ignition: user-provided config was applied
```

10. Create the rest of the machines for your cluster by following the preceding steps for each machine.

**IMPORTANT**

You must create the bootstrap and control plane machines at this time. Because some pods are deployed on compute machines by default, also create at least two compute machines before you install the cluster.

19.6.17. Adding more compute machines to a cluster in vSphere

You can add more compute machines to a user-provisioned OpenShift Container Platform cluster on VMware vSphere.

**Prerequisites**

- Obtain the base64-encoded Ignition file for your compute machines.
- You have access to the vSphere template that you created for your cluster.

**Procedure**

1. After the template deploys, deploy a VM for a machine in the cluster.
a. Right-click the template’s name and click Clone → Clone to Virtual Machine

b. On the Select a name and folder tab, specify a name for the VM. You might include the machine type in the name, such as compute-1.

NOTE

Ensure that all virtual machine names across a vSphere installation are unique.

c. On the Select a name and folder tab, select the name of the folder that you created for the cluster.

d. On the Select a compute resource tab, select the name of a host in your datacenter.

e. Optional: On the Select storage tab, customize the storage options.

f. On the Select clone options, select Customize this virtual machine’s hardware.

g. On the Customize hardware tab, click VM Options → Advanced.

- From the Latency Sensitivity list, select High.

- Click Edit Configuration, and on the Configuration Parameters window, click Add Configuration Params. Define the following parameter names and values:

  - guestinfo.ignition.config.data: Paste the contents of the base64-encoded compute ignition config file for this machine type.

  - guestinfo.ignition.config.data.encoding: Specify base64.

  - disk.EnableUUID: Specify TRUE.

h. In the Virtual Hardware panel of the Customize hardware tab, modify the specified values as required. Ensure that the amount of RAM, CPU, and disk storage meets the minimum requirements for the machine type. Also, make sure to select the correct network under Add network adapter if there are multiple networks available.

i. Complete the configuration and power on the VM.

2. Continue to create more compute machines for your cluster.

19.6.18. Disk partitioning

In most cases, data partitions are originally created by installing RHCOS, rather than by installing another operating system. In such cases, the OpenShift Container Platform installer should be allowed to configure your disk partitions.

However, there are two cases where you might want to intervene to override the default partitioning when installing an OpenShift Container Platform node:

- Create separate partitions: For greenfield installations on an empty disk, you might want to add separate storage to a partition. This is officially supported for making /var or a subdirectory of /var, such as /var/lib/etcd, a separate partition, but not both.
IMPORTANT

Kubernetes supports only two filesystem partitions. If you add more than one partition to the original configuration, Kubernetes cannot monitor all of them.

- Retain existing partitions: For a brownfield installation where you are reinstalling OpenShift Container Platform on an existing node and want to retain data partitions installed from your previous operating system, there are both boot arguments and options to `coreos-installer` that allow you to retain existing data partitions.

Creating a separate /var partition

In general, disk partitioning for OpenShift Container Platform should be left to the installer. However, there are cases where you might want to create separate partitions in a part of the filesystem that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the /var partition or a subdirectory of /var. For example:

- /var/lib/containers: Holds container-related content that can grow as more images and containers are added to a system.
- /var/lib/etcd: Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.
- /var: Holds data that you might want to keep separate for purposes such as auditing.

Storing the contents of a /var directory separately makes it easier to grow storage for those areas as needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

Because /var must be in place before a fresh installation of Red Hat Enterprise Linux CoreOS (RHCOS), the following procedure sets up the separate /var partition by creating a machine config manifest that is inserted during the `openshift-install` preparation phases of an OpenShift Container Platform installation.

Procedure

1. Create a directory to hold the OpenShift Container Platform installation files:

   ```
   $ mkdir $HOME/clusterconfig
   ```

2. Run `openshift-install` to create a set of files in the `manifest` and `openshift` subdirectories. Answer the system questions as you are prompted:

   ```
   $ openshift-install create manifests --dir $HOME/clusterconfig
   ? SSH Public Key ...
   $ ls $HOME/clusterconfig/openshift/
   99_kubeadmin-password-secret.yaml
   99_openshift-cluster-api_master-machines-0.yaml
   99_openshift-cluster-api_master-machines-1.yaml
   99_openshift-cluster-api_master-machines-2.yaml
   ...
   ```

3. Create a Butane config that configures the additional partition. For example, name the file
$HOME/clusterconfig/98-var-partition.bu, change the disk device name to the name of the storage device on the worker systems, and set the storage size as appropriate. This example places the /var directory on a separate partition:

```yaml
variant: openshift
version: 4.10.0
metadata:
  labels:
    machineconfiguration.openshift.io/role: worker
  name: 98-var-partition
storage:
  disks:
    - device: /dev/<device_name> ①
      partitions:
        - label: var
          start_mib: <partition_start_offset> ②
          size_mib: <partition_size> ③
      filesystems:
        - device: /dev/disk/by-partlabel/var
          path: /var
          format: xfs
          mount_options: [defaults, prjquota] ④
          with_mount_unit: true

① The storage device name of the disk that you want to partition.
② When adding a data partition to the boot disk, a minimum value of 25000 mebibytes is recommended. The root file system is automatically resized to fill all available space up to the specified offset. If no value is specified, or if the specified value is smaller than the recommended minimum, the resulting root file system will be too small, and future reinstalls of RHCOS might overwrite the beginning of the data partition.
③ The size of the data partition in mebibytes.
④ The prjquota mount option must be enabled for filesystems used for container storage.

NOTE
When creating a separate /var partition, you cannot use different instance types for worker nodes, if the different instance types do not have the same device name.

4. Create a manifest from the Butane config and save it to the clusterconfig/openshift directory. For example, run the following command:

```
$ butane $HOME/clusterconfig/98-var-partition.bu -o $HOME/clusterconfig/openshift/98-var-partition.yaml
```

5. Run openshift-install again to create Ignition configs from a set of files in the manifest and openshift subdirectories:
Now you can use the Ignition config files as input to the vSphere installation procedures to install Red Hat Enterprise Linux CoreOS (RHCOS) systems.

### 19.6.19. Updating the bootloader using bootupd

To update the bootloader by using `bootupd`, you must either install `bootupd` on RHCOS machines manually or provide a machine config with the enabled `systemd` unit. Unlike `grubby` or other bootloader tools, `bootupd` does not manage kernel space configuration such as passing kernel arguments.

After you have installed `bootupd`, you can manage it remotely from the OpenShift Container Platform cluster.

#### NOTE

It is recommended that you use `bootupd` only on bare metal or virtualized hypervisor installations, such as for protection against the BootHole vulnerability.

#### Manual install method

You can manually install `bootupd` by using the `bootctl` command-line tool.

1. Inspect the system status:

   ```
   # bootupctl status
   ``

   **Example output for x86_64**

   Component EFI
   Installed: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
   Update: At latest version

   **Example output for arm64**

   Component EFI
   Installed: grub2-efi-aa64-1:2.02-99.el8_4.1.aarch64,shim-aa64-15-4-2.el8_1.aarch64
   Update: At latest version

2. RHCOS images created without `bootupd` installed on them require an explicit adoption phase. If the system status is Adoptable, perform the adoption:

   ```
   # bootupctl adopt-and-update
   ``

   **Example output**

   Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64

3. If an update is available, apply the update so that the changes take effect on the next reboot:
Machine config method

Another way to enable **bootupd** is by providing a machine config.

- Provide a machine config file with the enabled **systemd** unit, as shown in the following example:

```bash
# bootupctl update

Example output

Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64

variant: rhcos
version: 1.1.0
systemd:
units:
  - name: custom-bootupd-auto.service
    enabled: true
    contents: |
      [Unit]
      Description=Bootupd automatic update

      [Service]
      ExecStart=/usr/bin/bootupctl update
      RemainAfterExit=yes

      [Install]
      WantedBy=multi-user.target
```

### 19.6.20. Waiting for the bootstrap process to complete

The OpenShift Container Platform bootstrap process begins after the cluster nodes first boot into the persistent RHCOS environment that has been installed to disk. The configuration information provided through the Ignition config files is used to initialize the bootstrap process and install OpenShift Container Platform on the machines. You must wait for the bootstrap process to complete.

**Prerequisites**

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have obtained the installation program and generated the Ignition config files for your cluster.
- You installed RHCOS on your cluster machines and provided the Ignition config files that the OpenShift Container Platform installation program generated.
- Your machines have direct internet access or have an HTTP or HTTPS proxy available.

**Procedure**
1. Monitor the bootstrap process:

```
$ ./openshift-install --dir <installation_directory> wait-for bootstrap-complete \\
   --log-level=info
```

1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

**Example output**

```
INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
INFO API v1.23.0 up
INFO Waiting up to 30m0s for bootstrapping to complete...
INFO It is now safe to remove the bootstrap resources
```

The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After bootstrap process is complete, remove the bootstrap machine from the load balancer.

**IMPORTANT**

You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the bootstrap machine itself.

### 19.6.21. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig
```

1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

```
$ oc whoami
```
Example output

$ oc get nodes

```
NAME      STATUS    ROLES   AGE  VERSION
master-0  Ready     master  63m  v1.23.0
master-1  Ready     master  63m  v1.23.0
master-2  Ready     master  64m  v1.23.0
```

The output lists all of the machines that you created.

**NOTE**

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```
$ oc get csr
```

Example output

```
NAME        AGE   REQUESTOR                                   CONDITION
csr-mddf5   20m   system:node:master-01.example.com   Approved,Issued
csr-z5rln   16m   system:node:worker-21.example.com   Approved,Issued
```

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:
CHAPTER 19. INSTALLING ON VSPHERE

NOTE
Because the CSRs rotate automatically, approve your CSRs within an hour of
adding the machines to the cluster. If you do not approve them within an hour, the
certificates will rotate, and more than two certificates will be present for each
node. You must approve all of these certificates. After the client CSR is
approved, the Kubelet creates a secondary CSR for the serving certificate, which
requires manual approval. Then, subsequent serving certificate renewal requests
are automatically approved by the machine-approver if the Kubelet requests a
new certificate with identical parameters.

NOTE
For clusters running on platforms that are not machine API enabled, such as bare
metal and other user-provisioned infrastructure, you must implement a method
of automatically approving the kubelet serving certificate requests (CSRs). If a
request is not approved, then the oc exec, oc rsh, and oc logs commands
cannot succeed, because a serving certificate is required when the API server
connects to the kubelet. Any operation that contacts the Kubelet endpoint
requires this certificate approval to be in place. The method must watch for new
CSRs, confirm that the CSR was submitted by the node-bootstrapper service
account in the system:node or system:admin groups, and confirm the identity
of the node.
To approve them individually, run the following command for each valid CSR:
$ oc adm certificate approve <csr_name> 1
1

<csr_name> is the name of a CSR from the list of current CSRs.

To approve all pending CSRs, run the following command:
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}
{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve

NOTE
Some Operators might not become available until some CSRs are approved.
4. Now that your client requests are approved, you must review the server requests for each
machine that you added to the cluster:
$ oc get csr

Example output
NAME
AGE REQUESTOR
CONDITION
csr-bfd72 5m26s system:node:ip-10-0-50-126.us-east-2.compute.internal
Pending
csr-c57lv 5m26s system:node:ip-10-0-95-157.us-east-2.compute.internal
Pending
...

2705


5. If the remaining CSRs are not approved, and are in the Pending status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

  ```
  $ oc adm certificate approve <csr_name>  
  ```

  `<csr_name>` is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

  ```
  $ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs oc adm certificate approve
  ```

6. After all client and server CSRs have been approved, the machines have the Ready status. Verify this by running the following command:

  ```
  $ oc get nodes
  ```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.23.0</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.23.0</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>74m</td>
<td>v1.23.0</td>

<td>v1.23.0</td>
</tr>
<tr>
<td>worker-1</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.23.0</td>
</tr>
</tbody>
</table>

**NOTE**

- It can take a few minutes after approval of the server CSRs for the machines to transition to the Ready status.

**Additional information**

- For more information on CSRs, see [Certificate Signing Requests](#).

**19.6.22.1. Initial Operator configuration**

After the control plane initializes, you must immediately configure some Operators so that they all become available.

**Prerequisites**

- Your control plane has initialized.

**Procedure**

1. Watch the cluster components come online:

   ```
   $ watch -n5 oc get clusteroperators
   ```
Example output

<table>

2. Configure the Operators that are not available.

19.6.22.2. Image registry removed during installation

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as Removed. This allows openshift-installer to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the managementState from Removed to Managed.

NOTE

The Prometheus console provides an ImageRegistryRemoved alert, for example:

"Image Registry has been removed. ImageStreamTags, BuildConfigs and DeploymentConfigs which reference ImageStreamTags may not work as expected. Please configure storage and update the config to Managed state by editing configs.imageregistry.operator.openshift.io."
19.6.22.3. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the `Recreate` rollout strategy during upgrades.

19.6.22.3.1. Configuring block registry storage for VMware vSphere

To allow the image registry to use block storage types such as vSphere Virtual Machine Disk (VMDK) during upgrades as a cluster administrator, you can use the `Recreate` rollout strategy.

**IMPORTANT**

Block storage volumes are supported but not recommended for use with image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

Procedure

1. To set the image registry storage as a block storage type, patch the registry so that it uses the `Recreate` rollout strategy and runs with only 1 replica:

   ```bash
   $ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec":
   
   "rolloutStrategy":"Recreate","replicas":1}'}
   ```

2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.

   a. Create a `pvc.yaml` file with the following contents to define a VMware vSphere PersistentVolumeClaim object:

   ```yaml
   kind: PersistentVolumeClaim
   apiVersion: v1
   metadata:
     name: image-registry-storage
   namespace: openshift-image-registry
   spec:
     accessModes:
     - ReadWriteOnce
     resources:
       requests:
         storage: 100Gi
   ```

   1. A unique name that represents the PersistentVolumeClaim object.
   2. The namespace for the PersistentVolumeClaim object, which is openshift-image-registry.
The access mode of the persistent volume claim. With **ReadWriteOnce**, the volume can be mounted with read and write permissions by a single node.

The size of the persistent volume claim.

b. Create the **PersistentVolumeClaim** object from the file:

```sh
$ oc create -f pvc.yaml -n openshift-image-registry
```

3. Edit the registry configuration so that it references the correct PVC:

```sh
$ oc edit config.imageregistry.operator.openshift.io -o yaml
```

**Example output**

```
storage:
pvc:
  claim: 1
```

Creating a custom PVC allows you to leave the `claim` field blank for the default automatic creation of an `image-registry-storage` PVC.

For instructions about configuring registry storage so that it references the correct PVC, see Configuring the registry for vSphere.

### 19.6.23. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

#### Prerequisites

- Your control plane has initialized.
- You have completed the initial Operator configuration.

#### Procedure

1. Confirm that all the cluster components are online with the following command:

```sh
$ watch -n5 oc get clusteroperators
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
</tr>
</thead>
<tbody>
<tr>
<td>authentication</td>
<td>4.10.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>baremetal</td>
<td>4.10.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>cloud-credential</td>
<td>4.10.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>cluster-autoscaler</td>
<td>4.10.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>config-operator</td>
<td>4.10.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
</tbody>
</table>
Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```
$ ./openshift-install --dir <installation_directory> wait-for install-complete
```

1 For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

**Example output**

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.
IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

2. Confirm that the Kubernetes API server is communicating with the pods.
   a. To view a list of all pods, use the following command:

   ```
   $ oc get pods --all-namespaces
   ```

   **Example output**

   ```
   NAMESPACE                         NAME                                            READY   STATUS      RESTARTS AGE
   openShift-apiserver-operator      openShift-apiserver-operator-85cb746d55-zqhs8   1/1     Running     1          9m
   openShift-apiserver               apiserver-67b9g                                 1/1     Running     0          3m
   openShift-apiserver               apiserver-ljcmx                                 1/1     Running     0          1m
   openShift-apiserver               apiserver-z25h4                                 1/1     Running     0          2m
   openShift-authentication-operator  authentication-operator-69d5d8bf84-vh2n8      1/1     Running     0          5m
   ...                                
   ```

   b. View the logs for a pod that is listed in the output of the previous command by using the following command:

   ```
   $ oc logs <pod_name> -n <namespace>
   ```

   Specify the pod name and namespace, as shown in the output of the previous command.

   If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation.

   See "Enabling multipathing with kernel arguments on RHCOS" in the Post-installation machine configuration tasks documentation for more information.
You can add extra compute machines after the cluster installation is completed by following Adding compute machines to vSphere.

19.6.24. Backing up VMware vSphere volumes

OpenShift Container Platform provisions new volumes as independent persistent disks to freely attach and detach the volume on any node in the cluster. As a consequence, it is not possible to back up volumes that use snapshots, or to restore volumes from snapshots. See Snapshot Limitations for more information.

**Procedure**

To create a backup of persistent volumes:

1. Stop the application that is using the persistent volume.
2. Clone the persistent volume.
3. Restart the application.
4. Create a backup of the cloned volume.
5. Delete the cloned volume.

19.6.25. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.10, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- See About remote health monitoring for more information about the Telemetry service

19.6.26. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- Set up your registry and configure registry storage.
- Optional: View the events from the vSphere Problem Detector Operator to determine if the cluster has permission or storage configuration issues.

19.7. INSTALLING A CLUSTER ON VSPHERE IN A RESTRICTED NETWORK

In OpenShift Container Platform 4.10, you can install a cluster on VMware vSphere infrastructure in a restricted network by creating an internal mirror of the installation release content.
19.7.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.

- You read the documentation on selecting a cluster installation method and preparing it for users.

- You created a registry on your mirror host and obtained the `imageContentSources` data for your version of OpenShift Container Platform.

**IMPORTANT**

Because the installation media is on the mirror host, you can use that computer to complete all installation steps.

- You provisioned persistent storage for your cluster. To deploy a private image registry, your storage must provide the ReadWriteMany access mode.

- The OpenShift Container Platform installer requires access to port 443 on the vCenter and ESXi hosts. You verified that port 443 is accessible.

- If you use a firewall, you confirmed with the administrator that port 443 is accessible. Control plane nodes must be able to reach vCenter and ESXi hosts on port 443 for the installation to succeed.

- If you use a firewall and plan to use the Telemetry service, you configured the firewall to allow the sites that your cluster requires access to.

**NOTE**

If you are configuring a proxy, be sure to also review this site list.

19.7.2. About installations in restricted networks

In OpenShift Container Platform 4.10, you can perform an installation that does not require an active connection to the internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service’s IAM service, require internet access, so you might still require internet access. Depending on your network, you might require less internet access for an installation on bare metal hardware or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift Container Platform registry and contains the installation media. You can create this registry on a mirror host, which can access both the internet and your closed network, or by using other methods that meet your restrictions.

19.7.2.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The `ClusterVersion` status includes an `Unable to retrieve available updates` error.
By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

19.7.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.10, you require access to the internet to obtain the images that are necessary to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- Access Quay.io to obtain the packages that are required to install your cluster.

- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

19.7.4. VMware vSphere infrastructure requirements

You must install the OpenShift Container Platform cluster on a VMware vSphere version 6 or 7 instance that meets the requirements for the components that you use.

Table 19.54. Version requirements for vSphere virtual environments

<table>
<thead>
<tr>
<th>Virtual environment product</th>
<th>Required version</th>
</tr>
</thead>
<tbody>
<tr>
<td>VM hardware version</td>
<td>13 or later</td>
</tr>
<tr>
<td>vSphere ESXi hosts</td>
<td>6.5 or later</td>
</tr>
<tr>
<td>vCenter host</td>
<td>6.5 or later</td>
</tr>
</tbody>
</table>
**IMPORTANT**

Installing a cluster on VMware vSphere version 6.7U3 or earlier and virtual hardware version 13 is now deprecated. These versions are still fully supported, but version 4.11 of OpenShift Container Platform will require vSphere virtual hardware version 15 or later. Hardware version 15 is now the default for vSphere virtual machines in OpenShift Container Platform. To update the hardware version for your vSphere nodes, see the “Updating hardware on nodes running in vSphere” article.

If your vSphere nodes are below hardware version 15 or your VMware vSphere version is earlier than 6.7U3, upgrading from OpenShift Container Platform 4.10 to OpenShift Container Platform 4.11 is not available.

**Table 19.55. Minimum supported vSphere version for VMware components**

<table>
<thead>
<tr>
<th>Component</th>
<th>Minimum supported versions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hypervisor</td>
<td>vSphere 6.5 and later with HW version 13</td>
<td>This version is the minimum version that Red Hat Enterprise Linux CoreOS (RHCOS) supports. See the Red Hat Enterprise Linux 8 supported hypervisors list.</td>
</tr>
<tr>
<td>Storage with in-tree drivers</td>
<td>vSphere 6.5 and later</td>
<td>This plug-in creates vSphere storage by using the in-tree storage drivers for vSphere included in OpenShift Container Platform.</td>
</tr>
<tr>
<td>Optional: Networking (NSX-T)</td>
<td>vSphere 6.5U3 or vSphere 6.7U2 and later</td>
<td>vSphere 6.5U3 or vSphere 6.7U2+ are required for OpenShift Container Platform. VMware’s NSX Container Plug-in (NCP) is certified with OpenShift Container Platform 4.6 and NSX-T 3.x+.</td>
</tr>
</tbody>
</table>

If you use a vSphere version 6.5 instance, consider upgrading to 6.7U3 or 7.0 before you install OpenShift Container Platform.

**IMPORTANT**

You must ensure that the time on your ESXi hosts is synchronized before you install OpenShift Container Platform. See Edit Time Configuration for a Host in the VMware documentation.

**19.7.5. VMware vSphere CSI Driver Operator requirements**

The following requirements must be met in order to install the CSI Driver Operator:

- VMware vSphere version 6.7U3 or later
• Virtual machines of hardware version 15 or later
• No third-party CSI driver already installed in the cluster

If a third-party CSI driver is present in the cluster, OpenShift Container Platform does not overwrite it. The presence of a third-party CSI driver prevents OpenShift Container Platform from upgrading to 4.11.

Additional resources
• To remove a third-party CSI driver, see Removing a third-party vSphere CSI Driver.
• To update the hardware version for your vSphere nodes, see Updating hardware on nodes running in vSphere.

19.7.6. vCenter requirements

Before you install an OpenShift Container Platform cluster on your vCenter that uses infrastructure that the installer provisions, you must prepare your environment.

Required vCenter account privileges
To install an OpenShift Container Platform cluster in a vCenter, the installation program requires access to an account with privileges to read and create the required resources. Using an account that has global administrative privileges is the simplest way to access all of the necessary permissions.

If you cannot use an account with global administrative privileges, you must create roles to grant the privileges necessary for OpenShift Container Platform cluster installation. While most of the privileges are always required, some are required only if you plan for the installation program to provision a folder to contain the OpenShift Container Platform cluster on your vCenter instance, which is the default behavior. You must create or amend vSphere roles for the specified objects to grant the required privileges.

An additional role is required if the installation program is to create a vSphere virtual machine folder.

Example 19.13. Roles and privileges required for installation

<table>
<thead>
<tr>
<th>vSphere object for role</th>
<th>When required</th>
<th>Required privileges</th>
</tr>
</thead>
</table>

</tr>
</tbody>
</table>

For more information about creating an account with only the required privileges, see [vSphere Permissions and User Management Tasks](#) in the vSphere documentation.

### Using OpenShift Container Platform with vMotion

**IMPORTANT**

OpenShift Container Platform generally supports compute-only vMotion. Using Storage vMotion can cause issues and is not supported.

If you are using vSphere volumes in your pods, migrating a VM across datastores either manually or through Storage vMotion causes invalid references within OpenShift Container Platform persistent volume (PV) objects. These references prevent affected pods from starting up and can result in data loss.
Similarly, OpenShift Container Platform does not support selective migration of VMDKs across datastores, using datastore clusters for VM provisioning or for dynamic or static provisioning of PVs, or using a datastore that is part of a datastore cluster for dynamic or static provisioning of PVs.

Cluster resources
When you deploy an OpenShift Container Platform cluster that uses installer-provisioned infrastructure, the installation program must be able to create several resources in your vCenter instance.

A standard OpenShift Container Platform installation creates the following vCenter resources:

- 1 Folder
- 1 Tag category
- 1 Tag
- Virtual machines:
  - 1 template
  - 1 temporary bootstrap node
  - 3 control plane nodes
  - 3 compute machines

Although these resources use 856 GB of storage, the bootstrap node is destroyed during the cluster installation process. A minimum of 800 GB of storage is required to use a standard cluster.

If you deploy more compute machines, the OpenShift Container Platform cluster will use more storage.

Cluster limits
Available resources vary between clusters. The number of possible clusters within a vCenter is limited primarily by available storage space and any limitations on the number of required resources. Be sure to consider both limitations to the vCenter resources that the cluster creates and the resources that you require to deploy a cluster, such as IP addresses and networks.

Networking requirements
You must use DHCP for the network and ensure that the DHCP server is configured to provide persistent IP addresses to the cluster machines. All nodes must be in the same VLAN. You cannot scale the cluster using a second VLAN as a Day 2 operation. The VM in your restricted network must have access to vCenter so that it can provision and manage nodes, persistent volume claims (PVCs), and other resources. Additionally, you must create the following networking resources before you install the OpenShift Container Platform cluster:

**NOTE**
It is recommended that each OpenShift Container Platform node in the cluster must have access to a Network Time Protocol (NTP) server that is discoverable via DHCP. Installation is possible without an NTP server. However, asynchronous server clocks will cause errors, which NTP server prevents.

Required IP Addresses
An installer-provisioned vSphere installation requires two static IP addresses:

- The **API** address is used to access the cluster API.
The Ingress address is used for cluster ingress traffic.

You must provide these IP addresses to the installation program when you install the OpenShift Container Platform cluster.

DNS records
You must create DNS records for two static IP addresses in the appropriate DNS server for the vCenter instance that hosts your OpenShift Container Platform cluster. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the cluster base domain that you specify when you install the cluster. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>`.

Table 19.56. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>API VIP</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>This DNS A/AAAA or CNAME record must point to the load balancer for the control plane machines. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Ingress VIP</td>
<td>*apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A wildcard DNS A/AAAA or CNAME record that points to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>

19.7.7. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.
IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```bash
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>
```

Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

NOTE

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the `x86_64` architecture, do not create a key that uses the `ed25519` algorithm. Instead, create a key that uses the `rsa` or `ecdsa` algorithm.

2. View the public SSH key:

```bash
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_rsa.pub` public key:

```bash
$ cat ~/.ssh/id_rsa.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

NOTE

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

a. If the `ssh-agent` process is not already running for your local user, start it as a background task:

```bash
$ eval "$(ssh-agent -s)"
```

Example output

Agent pid 31874
NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name>
```

   Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

**Example output**

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

**19.7.8. Adding vCenter root CA certificates to your system trust**

Because the installation program requires access to your vCenter’s API, you must add your vCenter’s trusted root CA certificates to your system trust before you install an OpenShift Container Platform cluster.

**Procedure**

1. From the vCenter home page, download the vCenter’s root CA certificates. Click **Download trusted root CA certificates** in the vSphere Web Services SDK section. The `<vCenter>/certs/download.zip` file downloads.

2. Extract the compressed file that contains the vCenter root CA certificates. The contents of the compressed file resemble the following file structure:

```
certs
  └── lin
      ├── 108f4d17.0
      │    ├── 108f4d17.r1
      │    └── 7e757f6a.0
      │         └── 8e4f8471.0
      │                 └── 8e4f8471.r0
      └── mac
          ├── 108f4d17.0
          │    ├── 108f4d17.r1
          │    └── 7e757f6a.0
          │         └── 8e4f8471.0
          │                 └── 8e4f8471.r0
          └── win
              └── 108f4d17.0.crt
```

   ```
   $ ssh-add <path>/<file_name>
   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
   ```
3. Add the files for your operating system to the system trust. For example, on a Fedora operating system, run the following command:

```
# cp certs/lin/* /etc/pki/ca-trust/source/anchors
```

4. Update your system trust. For example, on a Fedora operating system, run the following command:

```
# update-ca-trust extract
```

19.7.9. Creating the RHCOS image for restricted network installations

Download the Red Hat Enterprise Linux CoreOS (RHCOS) image to install OpenShift Container Platform on a restricted network VMware vSphere environment.

**Prerequisites**

- Obtain the OpenShift Container Platform installation program. For a restricted network installation, the program is on your mirror registry host.

**Procedure**

2. Under **Version**, select the most recent release of OpenShift Container Platform 4.10 for RHEL 8.

**IMPORTANT**

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available.

3. Download the **Red Hat Enterprise Linux CoreOS (RHCOS) - vSphere** image.

4. Upload the image you downloaded to a location that is accessible from the bastion server.

The image is now available for a restricted installation. Note the image name or location for use in OpenShift Container Platform deployment.

19.7.10. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on VMware vSphere.

**Prerequisites**
Obtain the OpenShift Container Platform installation program and the pull secret for your cluster. For a restricted network installation, these files are on your mirror host.

- Have the `imageContentSources` values that were generated during mirror registry creation.
- Obtain the contents of the certificate for your mirror registry.
- Retrieve a Red Hat Enterprise Linux CoreOS (RHCOS) image and upload it to an accessible location.
- Obtain service principal permissions at the subscription level.

**Procedure**

1. Create the `install-config.yaml` file.
   a. Change to the directory that contains the installation program and run the following command:

   ```bash
   $ ./openshift-install create install-config --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

   **IMPORTANT**
   
   Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

   b. At the prompts, provide the configuration details for your cloud:

   i. Optional: Select an SSH key to use to access your cluster machines.

   **NOTE**

   For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

   ii. Select `vsphere` as the platform to target.

   iii. Specify the name of your vCenter instance.

   iv. Specify the user name and password for the vCenter account that has the required permissions to create the cluster.

   The installation program connects to your vCenter instance.

   v. Select the datacenter in your vCenter instance to connect to.
vi. Select the default vCenter datastore to use.

vii. Select the vCenter cluster to install the OpenShift Container Platform cluster in. The installation program uses the root resource pool of the vSphere cluster as the default resource pool.

viii. Select the network in the vCenter instance that contains the virtual IP addresses and DNS records that you configured.

ix. Enter the virtual IP address that you configured for control plane API access.

x. Enter the virtual IP address that you configured for cluster ingress.

xi. Enter the base domain. This base domain must be the same one that you used in the DNS records that you configured.

xii. Enter a descriptive name for your cluster. The cluster name must be the same one that you used in the DNS records that you configured.

xiii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

2. In the `install-config.yaml` file, set the value of `platform.vsphere.clusterOSImage` to the image location or name. For example:

```yaml
platform:
  vsphere:
    clusterOSImage: http://mirror.example.com/images/rhcos-43.81.201912131630.0-vmware.x86_64.ova?sha256=febb68e8a1f2a245ca19522c16c86f67f9ac8e4e0c1f0a812b068b16f7265d
```

3. Edit the `install-config.yaml` file to provide the additional information that is required for an installation in a restricted network.

   a. Update the `pullSecret` value to contain the authentication information for your registry:

   ```yaml
   pullSecret: "{"auths":{"<mirror_host_name>:5000": {"auth": "{credentials","email":
   "you@example.com"}}}"
   ``

   For `<mirror_host_name>`, specify the registry domain name that you specified in the certificate for your mirror registry, and for `<credentials>`, specify the base64-encoded user name and password for your mirror registry.

   b. Add the `additionalTrustBundle` parameter and value.

   ```yaml
   additionalTrustBundle: |
   -----BEGIN CERTIFICATE-----
   ZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZ
   -----END CERTIFICATE-----
   ``

   The value must be the contents of the certificate file that you used for your mirror registry, which can be an existing, trusted certificate authority or the self-signed certificate that you generated for the mirror registry.

   c. Add the image content resources, which look like this excerpt:
To complete these values, use the `imageContentSources` that you recorded during mirror registry creation.

4. Make any other modifications to the `install-config.yaml` file that you require. You can find more information about the available parameters in the `Installation configuration parameters` section.

5. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

**IMPORTANT**

The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

### 19.7.10.1. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide a customized `install-config.yaml` installation configuration file that describes the details for your environment.

**NOTE**

After installation, you cannot modify these parameters in the `install-config.yaml` file.

#### 19.7.10.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is v1. The installer may also support older API versions.</td>
<td>String</td>
</tr>
</tbody>
</table>
### Parameter Description Values

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the <code>baseDomain</code> and <code>metadata.name</code> parameter values that uses the <code>&lt;metadata.name&gt;</code>, <code>&lt;baseDomain&gt;</code> format.</td>
<td>A fully-qualified domain or subdomain name, such as <code>example.com</code>.</td>
</tr>
<tr>
<td>metadata</td>
<td>Kubernetes resource <code>ObjectMeta</code>, from which only the <code>name</code> parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of <code>{{.metadata.name}}</code>, <code>{{.baseDomain}}</code>.</td>
<td>String of lowercase letters, hyphens (-), and periods (.), such as <code>dev</code>.</td>
</tr>
<tr>
<td>platform</td>
<td>The configuration for the specific platform upon which to perform the installation: <code>alibabacloud</code>, <code>aws</code>, <code>baremetal</code>, <code>azure</code>, <code>ibmcloud</code>, <code>openstack</code>, <code>ovirt</code>, <code>vsphere</code>, or <code>{}</code>. For additional information about <code>platform.&lt;platform&gt;</code> parameters, consult the table for your specific platform that follows.</td>
<td>Object</td>
</tr>
</tbody>
</table>
19.7.10.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

### Table 19.58. Network parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td>networking.network</td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN.</td>
</tr>
</tbody>
</table>
| networking.clusterNetwork | The IP address blocks for pods. | An array of objects. For example: 

```yaml
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
      hostPrefix: 23
```

**NOTE**

You cannot modify parameters specified by the `networking` object after installation.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking.clusterNetwork.cidr</td>
<td>Required if you use networking.clusterNetwork. An IP address block. An IPv4 network.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td>networking.clusterNetwork.hostPrefix</td>
<td>The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given cidr. A hostPrefix value of 23 provides 510 (2^{(32 - 23) - 2}) pod IP addresses.</td>
<td>A subnet prefix. The default value is 23.</td>
</tr>
<tr>
<td>networking.serviceNetwork</td>
<td>The IP address block for services. The default value is 172.30.0.0/16. The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.</td>
<td>An array with an IP address block in CIDR format. For example:</td>
</tr>
<tr>
<td>networking: serviceNetwork: - 172.30.0.0/16</td>
<td></td>
<td></td>
</tr>
<tr>
<td>networking.machineNetwork</td>
<td>The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap. If you specify multiple IP kernel arguments, the machineNetwork.cidr value must be the CIDR of the primary network.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td>networking: machineNetwork: - cidr: 10.0.0.0/16</td>
<td></td>
<td></td>
</tr>
<tr>
<td>networking.machineNetwork.cidr</td>
<td>Required if you use networking.machineNetwork. An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24.</td>
<td>An IP network block in CIDR notation. For example, 10.0.0.0/16.</td>
</tr>
</tbody>
</table>

**NOTE**
Set the networking.machineNetwork to match the CIDR that the preferred NIC resides in.

### 19.7.10.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>cgroupsV2</td>
<td>Enables Linux control groups version 2 (cgroups v2) on specific nodes in your cluster. The OpenShift Container Platform process for enabling cgroups v2 disables all cgroup version 1 controllers and hierarchies. The OpenShift Container Platform cgroups version 2 feature is in Developer Preview and is not supported by Red Hat at this time.</td>
<td>true</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of MachinePool objects.</td>
</tr>
<tr>
<td>compute.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are s390x (the default).</td>
<td>String</td>
</tr>
<tr>
<td>compute.hyperthreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>compute.name</td>
<td>Required if you use compute. The name of the machine pool.</td>
<td>worker</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------</td>
</tr>
<tr>
<td>compute.platform</td>
<td>Required if you use <code>compute</code>. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <code>controlPlane.platform</code> parameter value.</td>
<td>alibaba, aws, azure, gcp, ibmcloud, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td>compute.replicas</td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td>controlPlane</td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of <code>MachinePool</code> objects.</td>
</tr>
<tr>
<td>controlPlane.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>s390x</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td>controlPlane.hypertreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>IMPORTANT</td>
<td>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td></td>
</tr>
<tr>
<td>controlPlane.name</td>
<td>Required if you use <code>controlPlane</code>. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use <code>controlPlane</code>. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the <code>compute.platform</code> parameter value.</td>
<td>alibaba, aws, azure, gcp, ibmcloud, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>--------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>controlPlane.replicas</code></td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
<tr>
<td><code>credentialsMode</code></td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (&quot;&quot;).</td>
</tr>
</tbody>
</table>

**NOTE**

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Platform Operators reference content.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>fips</td>
<td>Enable or disable FIPS mode. The default is <strong>false</strong> (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</td>
<td><strong>false</strong> or <strong>true</strong></td>
</tr>
</tbody>
</table>

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the **x86_64** architecture.

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.

<table>
<thead>
<tr>
<th>imageContentSources</th>
<th>Sources and repositories for the release-image content.</th>
<th>Array of objects. Includes a <strong>source</strong> and, optionally, <strong>mirrors</strong>, as described in the following rows of this table.</th>
</tr>
</thead>
<tbody>
<tr>
<td>imageContentSources.source</td>
<td>Required if you use <strong>imageContentSources</strong>. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td><strong>String</strong></td>
</tr>
<tr>
<td>imageContentSources.mirrors</td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td><strong>Array of strings</strong></td>
</tr>
</tbody>
</table>
How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.

**Internal** or **External**. The default value is **External**.

Setting this field to **Internal** is not supported on non-cloud platforms and IBM Cloud.

**IMPORTANT**

If the value of the field is set to **Internal**, the
cluster will become non-functional. For more information, refer to **BZ#1953035**.

The SSH key or keys to authenticate access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

One or more keys. For example:

```
sshKey:
  <key1>
  <key2>
  <key3>
```

### 19.7.10.1.4. Additional VMware vSphere configuration parameters

Additional VMware vSphere configuration parameters are described in the following table:

**Table 19.60. Additional VMware vSphere cluster parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>platform.vsphere.vCenter</strong></td>
<td>The fully-qualified hostname or IP address of the vCenter server.</td>
<td>String</td>
</tr>
<tr>
<td><strong>platform.vsphere.username</strong></td>
<td>The user name to use to connect to the vCenter instance with. This user must have at least the roles and privileges that are required for static or dynamic persistent volume provisioning in vSphere.</td>
<td>String</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------</td>
</tr>
<tr>
<td>platform.vsphere.password</td>
<td>The password for the vCenter user name.</td>
<td>String</td>
</tr>
<tr>
<td>platform.vsphere.datacenter</td>
<td>The name of the datacenter to use in the vCenter instance.</td>
<td>String</td>
</tr>
<tr>
<td>platform.vsphere.defaultDatastore</td>
<td>The name of the default datastore to use for provisioning volumes.</td>
<td>String</td>
</tr>
<tr>
<td>platform.vsphere.folder</td>
<td>Optional. The absolute path of an existing folder where the installation program creates the virtual machines. If you do not provide this value, the installation program creates a folder that is named with the infrastructure ID in the datacenter virtual machine folder.</td>
<td>String, for example, <code>&lt;datacenter_name&gt;/vm/&lt;folder_name&gt;/&lt;subfolder_name&gt;</code>.</td>
</tr>
<tr>
<td>platform.vsphere.network</td>
<td>The network in the vCenter instance that contains the virtual IP addresses and DNS records that you configured.</td>
<td>String</td>
</tr>
<tr>
<td>platform.vsphere.cluster</td>
<td>The vCenter cluster to install the OpenShift Container Platform cluster in.</td>
<td>String</td>
</tr>
<tr>
<td>platform.vsphere.apiVIP</td>
<td>The virtual IP (VIP) address that you configured for control plane API access.</td>
<td>An IP address, for example 128.0.0.1.</td>
</tr>
<tr>
<td>platform.vsphere.ingressVIP</td>
<td>The virtual IP (VIP) address that you configured for cluster ingress.</td>
<td>An IP address, for example 128.0.0.1.</td>
</tr>
<tr>
<td>platform.vsphere.diskType</td>
<td>Optional. The disk provisioning method. This value defaults to the vSphere default storage policy if not set.</td>
<td>Valid values are thin, thick, or eagerZeroedThick.</td>
</tr>
</tbody>
</table>

19.7.10.1.5. Optional VMware vSphere machine pool configuration parameters

Optional VMware vSphere machine pool configuration parameters are described in the following table:

Table 19.61. Optional VMware vSphere machine pool parameters
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>platform.vsphere.clusterOSImage</code></td>
<td>The location from which the installer downloads the RHCOS image. You must set this parameter to perform an installation in a restricted network.</td>
<td>An HTTP or HTTPS URL, optionally with a SHA-256 checksum. For example, <a href="https://mirror.openshift.com/images/rhcos-">https://mirror.openshift.com/images/rhcos-</a>&lt;version&gt;-vmware.&lt;architecture&gt;.ova.</td>
</tr>
<tr>
<td><code>platform.vsphere.osDisk.diskSizeGB</code></td>
<td>The size of the disk in gigabytes.</td>
<td>Integer</td>
</tr>
<tr>
<td><code>platform.vsphere.cpus</code></td>
<td>The total number of virtual processor cores to assign a virtual machine.</td>
<td>Integer</td>
</tr>
<tr>
<td><code>platform.vsphere.coresPerSocket</code></td>
<td>The number of cores per socket in a virtual machine. The number of virtual sockets on the virtual machine is <code>platform.vsphere.cpus/platform.vsphere.coresPerSocket</code>. The default value is 1.</td>
<td>Integer</td>
</tr>
<tr>
<td><code>platform.vsphere.memoryMB</code></td>
<td>The size of a virtual machine’s memory in megabytes.</td>
<td>Integer</td>
</tr>
</tbody>
</table>

19.7.10.2. Sample `install-config.yaml` file for an installer-provisioned VMware vSphere cluster

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute:
  - name: worker
    replicas: 3
    platform:
      vsphere:
        cpus: 2
        coresPerSocket: 2
        memoryMB: 8196
        osDisk:
          diskSizeGB: 120
controlPlane:
  hyperthreading: Enabled
  name: master
  replicas: 3
  platform:
```

2738
The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, -, and the first line of the controlPlane section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading, or hyperthreading. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to Disabled. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.
**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Your machines must use at least 8 CPUs and 32 GB of RAM if you disable simultaneous multithreading.

4. Optional: Provide additional configuration for the machine pool parameters for the compute and control plane machines.

7. The cluster name that you specified in your DNS records.

8. The vSphere disk provisioning method.

9. The vSphere cluster to install the OpenShift Container Platform cluster in. The installation program uses the root resource pool of the vSphere cluster as the default resource pool.

11. The location of the Red Hat Enterprise Linux CoreOS (RHCOS) image that is accessible from the bastion server.

12. For `<local_registry>`, specify the registry domain name, and optionally the port, that your mirror registry uses to serve content. For example `registry.example.com` or `registry.example.com:5000`. For `<credentials>`, specify the base64-encoded user name and password for your mirror registry.

13. Provide the contents of the certificate file that you used for your mirror registry.

14. Provide the `imageContentSources` section from the output of the command to mirror the repository.

19.7.10.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**Prerequisites**

- You have an existing `install-config.yaml` file.

- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).
Procedure

1. Edit your install-config.yaml file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
     httpProxy: http://<username>:<pswd>@<ip>:<port>
     httpsProxy: https://<username>:<pswd>@<ip>:<port>
   noProxy: example.com
   additionalTrustBundle: |
     -----BEGIN CERTIFICATE-----
     <MY_TRUSTED_CA_CERT>
     -----END CERTIFICATE-----
   ...
   ```

   1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.
   2. A proxy URL to use for creating HTTPS connections outside the cluster.
   3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations. You must include vCenter's IP address and the IP range that you use for its machines.
   4. If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the trustedCA field of the Proxy object. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

   **NOTE**

   The installation program does not support the proxy readinessEndpoints field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

   **NOTE**

   Only the Proxy object named cluster is supported, and no additional proxies can be created.

19.7.11. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.
IMPORTANT

You can run the create cluster command of the installation program only once, during initial installation.

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Change to the directory that contains the installation program and initialize the cluster deployment:

   ```
   $ ./openshift-install create cluster --dir <installation_directory> \
     --log-level=info
   ```

   1 For `<installation_directory>`, specify the location of your customized `./install-config.yaml` file.

   2 To view different installation details, specify warn, debug, or error instead of info.

   When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the kubeadmin user, display in your terminal.

   ```
   INFO Install complete!
   INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
   INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
   INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-Wt5AL"
   INFO Time elapsed: 36m22s
   ```

   +

   NOTE

   The cluster access and credential information also outputs to `<installation_directory>/openshift_install.log` when an installation succeeds.

   +
The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

19.7.12. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (`oc`) to interact with OpenShift Container Platform from a command-line interface. You can install `oc` on Linux, Windows, or macOS.

If you installed an earlier version of `oc`, you cannot use it to complete all of the commands in OpenShift Container Platform 4.10. Download and install the new version of `oc`.

Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (`oc`) binary on Linux by using the following procedure.

**Procedure**

2. Select the appropriate version in the Version drop-down menu.
3. Click Download Now next to the OpenShift v4.10 Linux Client entry and save the file.
4. Unpack the archive:
   
   ```bash
   $ tar xvzf <file>
   ```
5. Place the `oc` binary in a directory that is on your `PATH`.
   To check your `PATH`, execute the following command:

   ```bash
   $ echo $PATH
   ```
After you install the OpenShift CLI, it is available using the `oc` command:

```
$ oc <command>
```

**Installing the OpenShift CLI on Windows**
You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.
3. Click **Download Now** next to the **OpenShift v4.10 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the `oc` binary to a directory that is on your `PATH`. To check your `PATH`, open the command prompt and execute the following command:

```
C:\> path
```

After you install the OpenShift CLI, it is available using the `oc` command:

```
C:\> oc <command>
```

**Installing the OpenShift CLI on macOS**
You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.
3. Click **Download Now** next to the **OpenShift v4.10 MacOSX Client** entry and save the file.
4. Unpack and unzip the archive.
5. Move the `oc` binary to a directory on your `PATH`. To check your `PATH`, open a terminal and execute the following command:

```
$ echo $PATH
```

After you install the OpenShift CLI, it is available using the `oc` command:

```
$ oc <command>
```

**19.7.13. Logging in to the cluster by using the CLI**

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The
kubconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the oc CLI.

Procedure

1. Export the kubeadmin credentials:

   `$ export KUBECONFIG=<installation_directory>/auth/kubeconfig`  

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run oc commands successfully using the exported configuration:

   `$ oc whoami`

   Example output

   `system:admin`

19.7.14. Disabling the default OperatorHub sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

Procedure

- Disable the sources for the default catalogs by adding `disableAllDefaultSources: true` to the OperatorHub object:

  `$ oc patch OperatorHub cluster --type json \  -p '[{"op": "add", "path": "/spec/disableAllDefaultSources", "value": true}]'`

TIP

Alternatively, you can use the web console to manage catalog sources. From the Administration → Cluster Settings → Configuration → OperatorHub page, click the Sources tab, where you can create, delete, disable, and enable individual sources.

19.7.15. Creating registry storage

After you install the cluster, you must create storage for the Registry Operator.
19.7.15.1. Image registry removed during installation

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as Removed. This allows openshift-installer to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the managementState from Removed to Managed.

NOTE

The Prometheus console provides an ImageRegistryRemoved alert, for example:

"Image Registry has been removed. ImageStreamTags, BuildConfigs and DeploymentConfigs which reference ImageStreamTags may not work as expected. Please configure storage and update the config to Managed state by editing configs.imageregistry.operator.openshift.io."

19.7.15.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the Recreate rollout strategy during upgrades.

19.7.15.2.1. Configuring registry storage for VMware vSphere

As a cluster administrator, following installation you must configure your registry to use storage.

Prerequisites

- Cluster administrator permissions.
- A cluster on VMware vSphere.
- Persistent storage provisioned for your cluster, such as Red Hat OpenShift Data Foundation.

IMPORTANT

OpenShift Container Platform supports ReadWriteOnce access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, ReadWriteMany access is required.

- Must have "100Gi" capacity.
IMPORTANT

Testing shows issues with using the NFS server on RHEL as storage backend for core services. This includes the OpenShift Container Registry and Quay, Prometheus for monitoring storage, and Elasticsearch for logging storage. Therefore, using RHEL NFS to back PVs used by core services is not recommended.

Other NFS implementations on the marketplace might not have these issues. Contact the individual NFS implementation vendor for more information on any testing that was possibly completed against these OpenShift Container Platform core components.

Procedure

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

   **NOTE**
   When using shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

   ```
   $ oc get pod -n openshift-image-registry -l docker-registry=default
   
   Example output
   
   No resources found in openshift-image-registry namespace
   
   **NOTE**
   If you do have a registry pod in your output, you do not need to continue with this procedure.
   
3. Check the registry configuration:

   ```
   $ oc edit configs.imageregistry.operator.openshift.io
   
   Example output
   
   storage:
   pvc:
   claim: 1
   
   Leave the `claim` field blank to allow the automatic creation of an `image-registry-storage` PVC.

4. Check the `clusteroperator` status:

   ```
   $ oc get clusteroperator image-registry
   ```
### Example output

<table>
<thead>

#### 19.7.16. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.10, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use `subscription watch` to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- See [About remote health monitoring](#) for more information about the Telemetry service.

#### 19.7.17. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- Set up your registry and configure registry storage.

#### 19.8. INSTALLING A CLUSTER ON VSPHERE IN A RESTRICTED NETWORK WITH USER-PROVISIONED INFRASTRUCTURE

In OpenShift Container Platform version 4.10, you can install a cluster on VMware vSphere infrastructure that you provision in a restricted network.

**IMPORTANT**

The steps for performing a user-provisioned infrastructure installation are provided as an example only. Installing a cluster with infrastructure you provide requires knowledge of the vSphere platform and the installation process of OpenShift Container Platform. Use the user-provisioned infrastructure installation instructions as a guide; you are free to create the required resources through other methods.

#### 19.8.1. Prerequisites

- You reviewed details about the [OpenShift Container Platform installation and update processes](#).
- You read the documentation on [selecting a cluster installation method and preparing it for users](#).
- You created a registry on your mirror host and obtained the `imageContentSources` data for your version of OpenShift Container Platform.
IMPORTANT

Because the installation media is on the mirror host, you can use that computer to complete all installation steps.

- You provisioned persistent storage for your cluster. To deploy a private image registry, your storage must provide ReadWriteMany access modes.

- Completing the installation requires that you upload the Red Hat Enterprise Linux CoreOS (RHCOS) OVA on vSphere hosts. The machine from which you complete this process requires access to port 443 on the vCenter and ESXi hosts. You verified that port 443 is accessible.

- If you use a firewall, you confirmed with the administrator that port 443 is accessible. Control plane nodes must be able to reach vCenter and ESXi hosts on port 443 for the installation to succeed.

- If you use a firewall and plan to use the Telemetry service, you configured the firewall to allow the sites that your cluster requires access to.

NOTE

Be sure to also review this site list if you are configuring a proxy.

19.8.2. About installations in restricted networks

In OpenShift Container Platform 4.10, you can perform an installation that does not require an active connection to the internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service’s IAM service, require internet access, so you might still require internet access. Depending on your network, you might require less internet access for an installation on bare metal hardware or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift Container Platform registry and contains the installation media. You can create this registry on a mirror host, which can access both the internet and your closed network, or by using other methods that meet your restrictions.

IMPORTANT

Because of the complexity of the configuration for user-provisioned installations, consider completing a standard user-provisioned infrastructure installation before you attempt a restricted network installation using user-provisioned infrastructure. Completing this test installation might make it easier to isolate and troubleshoot any issues that might arise during your installation in a restricted network.

19.8.2.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The ClusterVersion status includes an Unable to retrieve available updates error.
By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

19.8.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.10, you require access to the internet to obtain the images that are necessary to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- Access Quay.io to obtain the packages that are required to install your cluster.

- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

19.8.4. VMware vSphere infrastructure requirements

You must install the OpenShift Container Platform cluster on a VMware vSphere version 6 or 7 instance that meets the requirements for the components that you use.

Table 19.62. Version requirements for vSphere virtual environments

<table>
<thead>
<tr>
<th>Virtual environment product</th>
<th>Required version</th>
</tr>
</thead>
<tbody>
<tr>
<td>VM hardware version</td>
<td>13 or later</td>
</tr>
<tr>
<td>vSphere ESXi hosts</td>
<td>6.5 or later</td>
</tr>
<tr>
<td>vCenter host</td>
<td>6.5 or later</td>
</tr>
</tbody>
</table>
Installing a cluster on VMware vSphere version 6.7U3 or earlier and virtual hardware version 13 is now deprecated. These versions are still fully supported, but version 4.11 of OpenShift Container Platform will require vSphere virtual hardware version 15 or later. Hardware version 15 is now the default for vSphere virtual machines in OpenShift Container Platform. To update the hardware version for your vSphere nodes, see the “Updating hardware on nodes running in vSphere” article.

If your vSphere nodes are below hardware version 15 or your VMware vSphere version is earlier than 6.7U3, upgrading from OpenShift Container Platform 4.10 to OpenShift Container Platform 4.11 is not available.

Table 19.63. Minimum supported vSphere version for VMware components

<table>
<thead>
<tr>
<th>Component</th>
<th>Minimum supported versions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hypervisor</td>
<td>vSphere 6.5 and later with HW version 13</td>
<td>This version is the minimum version that Red Hat Enterprise Linux CoreOS (RHCOS) supports. See the Red Hat Enterprise Linux 8 supported hypervisors list.</td>
</tr>
<tr>
<td>Storage with in-tree drivers</td>
<td>vSphere 6.5 and later</td>
<td>This plug-in creates vSphere storage by using the in-tree storage drivers for vSphere included in OpenShift Container Platform.</td>
</tr>
<tr>
<td>Optional: Networking (NSX-T)</td>
<td>vSphere 6.5U3 or vSphere 6.7U2 and later</td>
<td>vSphere 6.5U3 or vSphere 6.7U2+ are required for OpenShift Container Platform. VMware’s NSX Container Plug-in (NCP) is certified with OpenShift Container Platform 4.6 and NSX-T 3.x+.</td>
</tr>
</tbody>
</table>

If you use a vSphere version 6.5 instance, consider upgrading to 6.7U3 or 7.0 before you install OpenShift Container Platform.

**IMPORTANT**

You must ensure that the time on your ESXi hosts is synchronized before you install OpenShift Container Platform. See Edit Time Configuration for a Host in the VMware documentation.

**19.8.5. VMware vSphere CSI Driver Operator requirements**

The following requirements must be met in order to install the CSI Driver Operator:

- VMware vSphere version 6.7U3 or later
• Virtual machines of hardware version 15 or later
• No third-party CSI driver already installed in the cluster

If a third-party CSI driver is present in the cluster, OpenShift Container Platform does not overwrite it. The presence of a third-party CSI driver prevents OpenShift Container Platform from upgrading to 4.11.

Additional resources
• To remove a third-party CSI driver, see Removing a third-party vSphere CSI Driver.
• To update the hardware version for your vSphere nodes, see Updating hardware on nodes running in vSphere.

19.8.6. Requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

This section describes the requirements for deploying OpenShift Container Platform on user-provisioned infrastructure.

19.8.6.1. Required machines for cluster installation

The smallest OpenShift Container Platform clusters require the following hosts:

Table 19.64. Minimum required hosts

<table>
<thead>
<tr>
<th>Hosts</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>One temporary bootstrap machine</td>
<td>The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.</td>
</tr>
<tr>
<td>Three control plane machines</td>
<td>The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.</td>
</tr>
<tr>
<td>At least two compute machines, which are also known as worker machines.</td>
<td>The workloads requested by OpenShift Container Platform users run on the compute machines.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

To improve high availability of your cluster, distribute the control plane machines over different z/VM instances on at least two physical machines.

The bootstrap, control plane, and compute machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 8 and inherits all of its hardware certifications and requirements. See Red Hat Enterprise Linux technology capabilities and limits.
IMPORTANT

All virtual machines must reside in the same datastore and in the same folder as the installer. Ensure that all virtual machine names across a vSphere installation are unique.

19.8.6.2. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

<table>
<thead>
<tr>
<th>Machine</th>
<th>Operating System</th>
<th>vCPU</th>
<th>Virtual RAM</th>
<th>Storage</th>
<th>IOPS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS</td>
<td>2</td>
<td>8 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
</tbody>
</table>

1. One physical core (IFL) provides two logical cores (threads) when SMT-2 is enabled. The hypervisor can provide two or more vCPUs.

19.8.6.3. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The `kube-controller-manager` only approves the kubelet client CSRs. The `machine-approver` cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

19.8.6.4. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in `initramfs` during boot to fetch their Ignition config files.

During the initial boot, the machines require an HTTP or HTTPS server to establish a network connection to download their Ignition config files.

The machines are configured with static IP addresses. No DHCP server is required. Ensure that the machines have persistent IP addresses and hostnames.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

19.8.6.4.1. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.
This section provides details about the ports that are required.

**IMPORTANT**

In connected OpenShift Container Platform environments, all nodes are required to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

### Table 19.65. Ports used for all-machine to all-machine communications

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Port</th>
<th>Description</th>
</tr>

<th>Protocol</th>
<th>Port</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>2379-2380</td>
<td>etcd server and peer ports</td>
</tr>
</tbody>
</table>

**Ethernet adaptor hardware address requirements**

When provisioning VMs for the cluster, the ethernet interfaces configured for each VM must use a MAC address from the VMware Organizationally Unique Identifier (OUI) allocation ranges:
If a MAC address outside the VMware OUI is used, the cluster installation will not succeed.

**NTP configuration for user-provisioned infrastructure**

OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for *Configuring chrony time service*.

**Additional resources**

- Configuring chrony time service

### 19.8.6.5. User-provisioned DNS requirements

In OpenShift Container Platform deployments, DNS name resolution is required for the following components:

- The Kubernetes API
- The OpenShift Container Platform application wildcard
- The bootstrap, control plane, and compute machines

Reverse DNS resolution is also required for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the hostnames for all the nodes, unless the hostnames are provided by DHCP. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

The following DNS records are required for a user-provisioned OpenShift Container Platform cluster and they must be in place before installation. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>.

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the API load balancer. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Component</td>
<td>Record</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>---------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>api-int.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to internally identify the API load balancer. These records must be resolvable from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Routes</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A wildcard DNS A/AAAA or CNAME record that refers to the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster. For example, console-openshift-console.apps.&lt;cluster_name&gt;.&lt;base_domain&gt; is used as a wildcard route to the OpenShift Container Platform console.</td>
</tr>
<tr>
<td>Bootstrap machine</td>
<td>bootstrap.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Control plane machines</td>
<td>&lt;master&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Compute machines</td>
<td>&lt;worker&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**NOTE**

In OpenShift Container Platform 4.4 and later, you do not need to specify etcd host and SRV records in your DNS configuration.
TIP

You can use the `dig` command to verify name and reverse name resolution. See the section on *Validating DNS resolution for user-provisioned infrastructure* for detailed validation steps.

19.8.6.5.1. Example DNS configuration for user-provisioned clusters

This section provides A and PTR record configuration samples that meet the DNS requirements for deploying OpenShift Container Platform on user-provisioned infrastructure. The samples are not meant to provide advice for choosing one DNS solution over another.

In the examples, the cluster name is `ocp4` and the base domain is `example.com`.

Example DNS A record configuration for a user-provisioned cluster

The following example is a BIND zone file that shows sample A records for name resolution in a user-provisioned cluster.

```
Example 19.15. Sample DNS zone database

$TTL 1W
@ IN SOA ns1.example.com. root (  
 2019070700 ; serial

```

1 Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer.
Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer and is used for internal cluster communications.

Provides name resolution for the wildcard routes. The record refers to the IP address of the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

**NOTE**

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

Provides name resolution for the bootstrap machine.

Provides name resolution for the control plane machines.

Provides name resolution for the compute machines.

---

**Example DNS PTR record configuration for a user-provisioned cluster**

The following example BIND zone file shows sample PTR records for reverse name resolution in a user-provisioned cluster.

**Example 19.16. Sample DNS zone database for reverse records**

```
$TTL 1W
@ IN SOA ns1.example.com. root (2019070700 ; serial 3H ; refresh (3 hours) 30M ; retry (30 minutes) 2W ; expiry (2 weeks) 1W ) ; minimum (1 week)
IN NS ns1.example.com.
;
5.1.168.192.in-addr.arpa. IN PTR api.ocp4.example.com. 1
5.1.168.192.in-addr.arpa. IN PTR api-int.ocp4.example.com. 2
;
96.1.168.192.in-addr.arpa. IN PTR bootstrap.ocp4.example.com. 3
;
97.1.168.192.in-addr.arpa. IN PTR master0.ocp4.example.com. 4
98.1.168.192.in-addr.arpa. IN PTR master1.ocp4.example.com. 5
99.1.168.192.in-addr.arpa. IN PTR master2.ocp4.example.com. 6
;
11.1.168.192.in-addr.arpa. IN PTR worker0.ocp4.example.com. 7
7.1.168.192.in-addr.arpa. IN PTR worker1.ocp4.example.com. 8
;
;EOF
```
Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer.

Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer and is used for internal cluster communications.

Provides reverse DNS resolution for the bootstrap machine.

Provides reverse DNS resolution for the control plane machines.

Provides reverse DNS resolution for the compute machines.

NOTE

A PTR record is not required for the OpenShift Container Platform application wildcard.

19.8.6.6. Load balancing requirements for user-provisioned infrastructure

Before you install OpenShift Container Platform, you must provision the API and application ingress load balancing infrastructure. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

The load balancing infrastructure must meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:

   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.
   
   - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

   NOTE

   Session persistence is not required for the API load balancer to function properly.

Configure the following ports on both the front and back of the load balancers:

Table 19.69. API load balancer

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the /readyz endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
</tbody>
</table>
Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>

**NOTE**

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the `/readyz` endpoint to the removal of the API server instance from the pool. Within the time frame after `/readyz` returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application ingress load balancer**: Provides an ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

**TIP**

If the true IP address of the client can be seen by the application ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

Configure the following ports on both the front and back of the load balancers:

**Table 19.70. Application ingress load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>

<td>1936</td>
<td>The worker nodes that run the Ingress Controller pods, by default. You must configure the <code>/healthz/ready</code> endpoint for the ingress health check probe.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>

**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

**NOTE**

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

### 19.8.6.6.1. Example load balancer configuration for user-provisioned clusters

This section provides an example API and application ingress load balancer configuration that meets the load balancing requirements for user-provisioned clusters. The sample is an `/etc/haproxy/haproxy.cfg` configuration for an HAProxy load balancer. The example is not meant to provide advice for choosing one load balancing solution over another.

**NOTE**

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

#### Example 19.17. Sample API and application ingress load balancer configuration

```plaintext
global
log 127.0.0.1 local2
pidfile /var/run/haproxy.pid
maxconn 4000
daemon
defaults
mode http
log global
option dontlognull
option http-server-close
option redispatch
retries 3
timeout http-request 10s
timeout queue 1m
timeout connect 10s
timeout client 1m
```
In the example, the cluster name is `ocp4`.

Port **6443** handles the Kubernetes API traffic and points to the control plane machines.

The bootstrap entries must be in place before the OpenShift Container Platform cluster installation and they must be removed after the bootstrap process is complete.

Port **22623** handles the machine config server traffic and points to the control plane machines.

Port **443** handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.
Port 80 handles the HTTP traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

**TIP**

If you are using HAProxy as a load balancer, you can check that the `haproxy` process is listening on ports 6443, 22623, 443, and 80 by running `netstat -nltpu` on the HAProxy node.

**NOTE**

If you are using HAProxy as a load balancer and SELinux is set to `enforcing`, you must ensure that the HAProxy service can bind to the configured TCP port by running `setsebool -P haproxy_connect_any=1`.

### 19.8.7. Preparing the user-provisioned infrastructure

Before you install OpenShift Container Platform on user-provisioned infrastructure, you must prepare the underlying infrastructure.

This section provides details about the high-level steps required to set up your cluster infrastructure in preparation for an OpenShift Container Platform installation. This includes configuring IP networking and network connectivity for your cluster nodes, preparing a web server for the Ignition files, enabling the required ports through your firewall, and setting up the required DNS and load balancing infrastructure.

After preparation, your cluster infrastructure must meet the requirements outlined in the Requirements for a cluster with user-provisioned infrastructure section.

**Prerequisites**

- You have reviewed the OpenShift Container Platform 4.x Tested Integrations page.
- You have reviewed the infrastructure requirements detailed in the Requirements for a cluster with user-provisioned infrastructure section.

**Procedure**

1. Set up static IP addresses.
2. Set up an HTTP or HTTPS server to provide Ignition files to the cluster nodes.
3. Ensure that your network infrastructure provides the required network connectivity between the cluster components. See the Networking requirements for user-provisioned infrastructure section for details about the requirements.
4. Configure your firewall to enable the ports required for the OpenShift Container Platform cluster components to communicate. See Networking requirements for user-provisioned infrastructure section for details about the ports that are required.

5. Setup the required DNS infrastructure for your cluster.
   a. Configure DNS name resolution for the Kubernetes API, the application wildcard, the bootstrap machine, the control plane machines, and the compute machines.
   b. Configure reverse DNS resolution for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.
      See the User-provisioned DNS requirements section for more information about the OpenShift Container Platform DNS requirements.

6. Validate your DNS configuration.
   a. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses in the responses correspond to the correct components.
   b. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names in the responses correspond to the correct components.
      See the Validating DNS resolution for user-provisioned infrastructure section for detailed DNS validation steps.

7. Provision the required API and application ingress load balancing infrastructure. See the Load balancing requirements for user-provisioned infrastructure section for more information about the requirements.

   **NOTE**
   Some load balancing solutions require the DNS name resolution for the cluster nodes to be in place before the load balancing is initialized.

19.8.8. Validating DNS resolution for user-provisioned infrastructure

You can validate your DNS configuration before installing OpenShift Container Platform on user-provisioned infrastructure.

   **IMPORTANT**
   The validation steps detailed in this section must succeed before you install your cluster.

**Prerequisites**

- You have configured the required DNS records for your user-provisioned infrastructure.

**Procedure**

1. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses contained in the responses correspond to the correct components.
   a. Perform a lookup against the Kubernetes API record name. Check that the result points to the IP address of the API load balancer:
Replace `<nameserver_ip>` with the IP address of the nameserver, `<cluster_name>` with your cluster name, and `<base_domain>` with your base domain name.

Example output

```
api.ocp4.example.com. 0 IN A 192.168.1.5
```

b. Perform a lookup against the Kubernetes internal API record name. Check that the result points to the IP address of the API load balancer:

```
$ dig +noall +answer @<nameserver_ip> api-int.<cluster_name>.<base_domain>
```

Example output

```
api-int.ocp4.example.com. 0 IN A 192.168.1.5
```

c. Test an example `*.apps.<cluster_name>.<base_domain>` DNS wildcard lookup. All of the application wildcard lookups must resolve to the IP address of the application ingress load balancer:

```
$ dig +noall +answer @<nameserver_ip> random.apps.<cluster_name>.<base_domain>
```

Example output

```
random.apps.ocp4.example.com. 0 IN A 192.168.1.5
```

**NOTE**

In the example outputs, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

You can replace `random` with another wildcard value. For example, you can query the route to the OpenShift Container Platform console:

```
$ dig +noall +answer @<nameserver_ip> console-openshift-console.apps.<cluster_name>.<base_domain>
```

Example output

```
console-openshift-console.apps.ocp4.example.com. 0 IN A 192.168.1.5
```

d. Run a lookup against the bootstrap DNS record name. Check that the result points to the IP address of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> bootstrap.<cluster_name>.<base_domain>
```
Example output

- bootstrap.ocp4.example.com. 0 IN A 192.168.1.96

1. Use this method to perform lookups against the DNS record names for the control plane and compute nodes. Check that the results correspond to the IP addresses of each node.

2. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names contained in the responses correspond to the correct components.

   a. Perform a reverse lookup against the IP address of the API load balancer. Check that the response includes the record names for the Kubernetes API and the Kubernetes internal API:

      ```
      $ dig +noall +answer @<nameserver_ip> -x 192.168.1.5
      ```

      Example output

      - 5.1.168.192.in-addr.arpa. 0 IN PTR api-int.ocp4.example.com. 1
      - 5.1.168.192.in-addr.arpa. 0 IN PTR api.ocp4.example.com. 2

      1. Provides the record name for the Kubernetes internal API.
      2. Provides the record name for the Kubernetes API.

   b. Perform a reverse lookup against the IP address of the bootstrap node. Check that the result points to the DNS record name of the bootstrap node:

      ```
      $ dig +noall +answer @<nameserver_ip> -x 192.168.1.96
      ```

      Example output

      - 96.1.168.192.in-addr.arpa. 0 IN PTR bootstrap.ocp4.example.com.

   c. Use this method to perform reverse lookups against the IP addresses for the control plane and compute nodes. Check that the results correspond to the DNS record names of each node.

**NOTE**

A PTR record is not required for the OpenShift Container Platform application wildcard. No validation step is needed for reverse DNS resolution against the IP address of the application ingress load balancer.

2. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names contained in the responses correspond to the correct components.

   a. Perform a reverse lookup against the IP address of the API load balancer. Check that the response includes the record names for the Kubernetes API and the Kubernetes internal API:

      ```
      $ dig +noall +answer @<nameserver_ip> -x 192.168.1.5
      ```

      Example output

      - 5.1.168.192.in-addr.arpa. 0 IN PTR api-int.ocp4.example.com. 1
      - 5.1.168.192.in-addr.arpa. 0 IN PTR api.ocp4.example.com. 2

      1. Provides the record name for the Kubernetes internal API.
      2. Provides the record name for the Kubernetes API.

   b. Perform a reverse lookup against the IP address of the bootstrap node. Check that the result points to the DNS record name of the bootstrap node:

      ```
      $ dig +noall +answer @<nameserver_ip> -x 192.168.1.96
      ```

      Example output

      - 96.1.168.192.in-addr.arpa. 0 IN PTR bootstrap.ocp4.example.com.

   c. Use this method to perform reverse lookups against the IP addresses for the control plane and compute nodes. Check that the results correspond to the DNS record names of each node.

**19.8.9. Generating a key pair for cluster node SSH access**

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added
to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The ./openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

IMPORTANT
Do not skip this procedure in production environments, where disaster recovery and debugging is required.

Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```bash
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>
```

Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

**NOTE**
If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

```bash
$ cat <path>/<file_name>.pub
```

For example, run the following to view the ~/.ssh/id_rsa.pub public key:

```bash
$ cat ~/.ssh/id_rsa.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the ./openshift-install gather command.

**NOTE**
On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.
a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

**Example output**

```
Agent pid 31874
```

**NOTE**

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name> 1
```

1 Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

**Example output**

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program. If you install a cluster on infrastructure that you provision, you must provide the key to the installation program.

**19.8.10. Manually creating the installation configuration file**

For user-provisioned installations of OpenShift Container Platform, you manually generate your installation configuration file.

**Prerequisites**

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.

- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

- Obtain the **imageContentSources** section from the output of the command to mirror the repository.

- Obtain the contents of the certificate for your mirror registry.

**Procedure**

1. Create an installation directory to store your required installation assets in:
IMPORTANT

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample `install-config.yaml` file template that is provided and save it in the `<installation_directory>`.

NOTE

You must name this configuration file `install-config.yaml`.

- Unless you use a registry that RHCOS trusts by default, such as `docker.io`, you must provide the contents of the certificate for your mirror repository in the `additionalTrustBundle` section. In most cases, you must provide the certificate for your mirror.

- You must include the `imageContentSources` section from the output of the command to mirror the repository.

NOTE

For some platform types, you can alternatively run `./openshift-install create install-config --dir <installation_directory>` to generate an `install-config.yaml` file. You can provide details about your cluster configuration at the prompts.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

IMPORTANT

The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.

19.8.10.1. Sample `install-config.yaml` file for VMware vSphere

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute:
  - hyperthreading: Enabled
    name: worker
    replicas: 0
controlPlane:
```

1. Enter your base domain.
2. Configure your compute nodes.
3. Enable hyperthreading on worker nodes.
4. Specify the number of worker replicas.
5. Configure your control plane.
The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, -, and the first line of the controlPlane section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading, or hyperthreading. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to Disabled. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Your machines must use at least 8 CPUs and 32 GB of RAM if you disable simultaneous multithreading.

You must set the value of the replicas parameter to 0. This parameter controls the number of workers that the cluster creates and manages for you, which are functions that the cluster does not perform when you use user-provisioned infrastructure. You must manually deploy worker machines...
for the cluster to use before you finish installing OpenShift Container Platform.

7 The number of control plane machines that you add to the cluster. Because the cluster uses this values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

8 The cluster name that you specified in your DNS records.

9 The fully-qualified hostname or IP address of the vCenter server.

10 The name of the user for accessing the server. This user must have at least the roles and privileges that are required for static or dynamic persistent volume provisioning in vSphere.

11 The password associated with the vSphere user.

12 The vSphere datacenter.

13 The default vSphere datastore to use.

14 Optional: For installer-provisioned infrastructure, the absolute path of an existing folder where the installation program creates the virtual machines, for example, `/<datacenter_name>/vm/<folder_name>/<subfolder_name>`. If you do not provide this value, the installation program creates a top-level folder in the datacenter virtual machine folder that is named with the infrastructure ID. If you are providing the infrastructure for the cluster, omit this parameter.

15 The vSphere disk provisioning method.

16 Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the **x86_64** architecture.

17 For `<local_registry>`, specify the registry domain name, and optionally the port, that your mirror registry uses to serve content. For example `registry.example.com` or `registry.example.com:5000`. For `<credentials>`, specify the base64-encoded user name and password for your mirror registry.

18 The public portion of the default SSH key for the **core** user in Red Hat Enterprise Linux CoreOS (RHCOS).

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

19 Provide the contents of the certificate file that you used for your mirror registry.
19.8.10.2. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the install-config.yaml file.

Prerequisites

- You have an existing install-config.yaml file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the Proxy object’s spec.noProxy field to bypass the proxy if necessary.

NOTE

The Proxy object status.noProxy field is populated with the values of the networking.machineNetwork[].cidr, networking.clusterNetwork[].cidr, and networking.serviceNetwork[] fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object status.noProxy field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your install-config.yaml file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port> 1
  httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
  noProxy: example.com 3
additionalTrustBundle: | 4
    -----BEGIN CERTIFICATE-----
    <MY_TRUSTED_CA_CERT>
    -----END CERTIFICATE-----
...
```

1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.
2. A proxy URL to use for creating HTTPS connections outside the cluster.
3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations. You must include vCenter’s IP address and the IP range that you use for its
If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace that contains one or more additional CA certificates.

**NOTE**

The installation program does not support the proxy `readinessEndpoints` field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster` Proxy object is still created, but it will have a nil `spec`.

**NOTE**

Only the Proxy object named `cluster` is supported, and no additional proxies can be created.

19.8.11. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

**IMPORTANT**

- The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

**NOTE**

The installation program that generates the manifest and Ignition files is architecture specific and can be obtained from the client image mirror. The Linux version of the installation program runs on s390x only. This installer program is also available as a Mac OS version.

**Prerequisites**

- You obtained the OpenShift Container Platform installation program. For a restricted network installation, these files are on your mirror host.

- You created the **install-config.yaml** installation configuration file.

### Procedure

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

   ```shell
   $ ./openshift-install create manifests --dir <installation_directory>
   ```

   **Example output**

   ```none
   INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
   INFO Consuming Install Config from target directory
   INFO Manifests created in: install_dir/manifests and install_dir/openshift
   ```

   **WARNING**

   For `<installation_directory>`, specify the installation directory that contains the **install-config.yaml** file you created.

2. Remove the Kubernetes manifest files that define the control plane machines and compute machine sets:

   ```shell
   $ rm -f openshift/99_openshift-cluster-api_master-machines-*yaml openshift/99_openshift-cluster-api_worker-machineset-*yaml
   ```

   Because you create and manage these resources yourself, you do not have to initialize them.

   - You can preserve the machine set files to create compute machines by using the machine API, but you must update references to them to match your environment.

   **WARNING**

   If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.

   **IMPORTANT**

   When you configure control plane nodes from the default unschedulable to schedulable, additional subscriptions are required. This is because control plane nodes then become worker nodes.

3. Check that the **mastersSchedulable** parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to **false**. This setting prevents pods from being scheduled on the control plane machines:
a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.

b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.

c. Save and exit the file.

4. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

```bash
$ ./openshift-install create ignition-configs --dir <installation_directory>
```

For `<installation_directory>`, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The `kubeadmin-password` and `kubeconfig` files are created in the `.<installation_directory>/auth` directory:

```plaintext
├── auth
│   └── kubeadmin-password
│       └── kubeconfig
├── bootstrap.ign
├── master.ign
├── metadata.json
└── worker.ign
```

### 19.8.12. Configuring chrony time service

You must set the time server and related settings used by the chrony time service (`chronyd`) by modifying the contents of the `chrony.conf` file and passing those contents to your nodes as a machine config.

**Procedure**

1. Create a Butane config including the contents of the `chrony.conf` file. For example, to configure chrony on worker nodes, create a `99-worker-chrony.bu` file.

**NOTE**

See "Creating machine configs with Butane" for information about Butane.
On control plane nodes, substitute **master** for **worker** in both of these locations.

Specify an octal value mode for the **mode** field in the machine config file. After creating the file and applying the changes, the **mode** is converted to a decimal value. You can check the YAML file with the command `oc get mc <mc-name> -o yaml`.

Specify any valid, reachable time source, such as the one provided by your DHCP server.

2. Use Butane to generate a **MachineConfig** object file, **99-worker-chrony.yaml**, containing the configuration to be delivered to the nodes:

   ```bash
   $ butane 99-worker-chrony.bu -o 99-worker-chrony.yaml
   ``

3. Apply the configurations in one of two ways:

   - If the cluster is not running yet, after you generate manifest files, add the **MachineConfig** object file to the `<installation_directory>/openshift` directory, and then continue to create the cluster.

   ```bash
   $ oc apply -f ./99-worker-chrony.yaml
   ```

   - If the cluster is already running, apply the file:

   ```bash
   $ oc apply -f ./99-worker-chrony.yaml
   ```

19.8.13. Extracting the infrastructure name

The Ignition config files contain a unique cluster identifier that you can use to uniquely identify your cluster in VMware vSphere. If you plan to use the cluster identifier as the name of your virtual machine folder, you must extract it.

**Prerequisites**

- You obtained the OpenShift Container Platform installation program and the pull secret for your cluster.
- You generated the Ignition config files for your cluster.
- You installed the **jq** package.

**Procedure**

- To extract and view the infrastructure name from the Ignition config file metadata, run the following command:

  ```bash
  $ jq -r .infraID <installation_directory>/metadata.json
  ```
For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

Example output

`openshift-vw9j6`

The output of this command is your cluster name and a random string.

To install OpenShift Container Platform on user-provisioned infrastructure on VMware vSphere, you must install Red Hat Enterprise Linux CoreOS (RHCOS) on vSphere hosts. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS machines have rebooted.

Prerequisites

- You have obtained the Ignition config files for your cluster.
- You have access to an HTTP server that you can access from your computer and that the machines that you create can access.
- You have created a vSphere cluster.

Procedure

1. Upload the bootstrap Ignition config file, which is named `<installation_directory>/bootstrap.ign`, that the installation program created to your HTTP server. Note the URL of this file.

2. Save the following secondary Ignition config file for your bootstrap node to your computer as `<installation_directory>/merge-bootstrap.ign`:

```json
{
  "ignition": {
    "config": {
      "merge": [
        {
          "source": "<bootstrap_ignition_config_url>",
          "verification": {}
        }
      ],
      "timeouts": {},
      "version": "3.2.0"
    },
    "networkd": {},
    "passwd": {}
  }
}
```
1. Specify the URL of the bootstrap Ignition config file that you hosted. When you create the virtual machine (VM) for the bootstrap machine, you use this Ignition config file.

3. Locate the following Ignition config files that the installation program created:
   - `<installation_directory>/master.ign`
   - `<installation_directory>/worker.ign`
   - `<installation_directory>/merge-bootstrap.ign`

4. Convert the Ignition config files to Base64 encoding. Later in this procedure, you must add these files to the extra configuration parameter `guestinfo.ignition.config.data` in your VM. For example, if you use a Linux operating system, you can use the `base64` command to encode the files.

   ```
   $ base64 -w0 <installation_directory>/master.ign > <installation_directory>/master.64
   $ base64 -w0 <installation_directory>/worker.ign > <installation_directory>/worker.64
   $ base64 -w0 <installation_directory>/merge-bootstrap.ign > <installation_directory>/merge-bootstrap.64
   ```

   **IMPORTANT**
   If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

5. Obtain the RHCOS OVA image. Images are available from the RHCOS image mirror page.

   **IMPORTANT**
   The RHCOS images might not change with every release of OpenShift Container Platform. You must download an image with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image version that matches your OpenShift Container Platform version if it is available.

   The filename contains the OpenShift Container Platform version number in the format `rhcos-vmware.<architecture>.ova`.

6. In the vSphere Client, create a folder in your datacenter to store your VMs.
   a. Click the **VMs and Templates** view.
   b. Right-click the name of your datacenter.
c. Click New Folder → New VM and Template Folder.

d. In the window that is displayed, enter the folder name. If you did not specify an existing folder in the install-config.yaml file, then create a folder with the same name as the infrastructure ID. You use this folder name so vCenter dynamically provisions storage in the appropriate location for its Workspace configuration.

7. In the vSphere Client, create a template for the OVA image and then clone the template as needed.

**NOTE**

In the following steps, you create a template and then clone the template for all of your cluster machines. You then provide the location for the Ignition config file for that cloned machine type when you provision the VMs.

a. From the Hosts and Clusters tab, right-click your cluster name and select Deploy OVF Template.

b. On the Select an OVF tab, specify the name of the RHCOS OVA file that you downloaded.

c. On the Select a name and folder tab, set a Virtual machine name for your template, such as Template-RHCOS. Click the name of your vSphere cluster and select the folder you created in the previous step.

d. On the Select a compute resource tab, click the name of your vSphere cluster.

e. On the Select storage tab, configure the storage options for your VM.

   - Select Thin Provision or Thick Provision, based on your storage preferences.

   - Select the datastore that you specified in your install-config.yaml file.

f. On the Select network tab, specify the network that you configured for the cluster, if available.

g. When creating the OVF template, do not specify values on the Customize template tab or configure the template any further.

**IMPORTANT**

Do not start the original VM template. The VM template must remain off and must be cloned for new RHCOS machines. Starting the VM template configures the VM template as a VM on the platform, which prevents it from being used as a template that machine sets can apply configurations to.

8. Optional: Update the configured virtual hardware version in the VM template, if necessary. Follow Upgrading a virtual machine to the latest hardware version in the VMware documentation for more information.
It is recommended that you update the hardware version of the VM template to version 15 before creating VMs from it, if necessary. Using hardware version 13 for your cluster nodes running on vSphere is now deprecated. If your imported template defaults to hardware version 13, you must ensure that your ESXi host is on 6.7U3 or later before upgrading the VM template to hardware version 15. If your vSphere version is less than 6.7U3, you can skip this upgrade step; however, a future version of OpenShift Container Platform is scheduled to remove support for hardware version 13 and vSphere versions less than 6.7U3.

9. After the template deploys, deploy a VM for a machine in the cluster.

   a. Right-click the template name and click **Clone → Clone to Virtual Machine**

   b. On the **Select a name and folder** tab, specify a name for the VM. You might include the machine type in the name, such as **control-plane-0** or **compute-1**.

   c. On the **Select a name and folder** tab, select the name of the folder that you created for the cluster.

   d. On the **Select a compute resource** tab, select the name of a host in your datacenter.

   e. Optional: On the **Select storage** tab, customize the storage options.

   f. On the **Select clone options**, select **Customize this virtual machine's hardware**

   g. On the **Customize hardware** tab, click **VM Options → Advanced**.

      i. Optional: Override default DHCP networking in vSphere. To enable static IP networking:

         ```
         $ export IPCFG="ip=192.168.100.101::192.168.100.254:255.255.255.0::none
         nameserver=8.8.8.8"
         $ govc vm.change -vm "<vm_name>" -e "guestinfo.afterburn.initrd.network-kargs=${IPCFG}"
         ```
• Optional: In the event of cluster performance issues, from the Latency Sensitivity list, select High. Ensure that your VM’s CPU and memory reservation have the following values:
  - Memory reservation value must be equal to its configured memory size.
  - CPU reservation value must be at least the number of low latency virtual CPUs multiplied by the measured physical CPU speed.

• Click Edit Configuration, and on the Configuration Parameters window, click Add Configuration Params. Define the following parameter names and values:
  - guestinfo.ignition.config.data: Locate the base-64 encoded files that you created previously in this procedure, and paste the contents of the base64-encoded Ignition config file for this machine type.
  - guestinfo.ignition.config.data.encoding: Specify base64.
  - disk.EnableUUID: Specify TRUE.

h. In the Virtual Hardware panel of the Customize hardware tab, modify the specified values as required. Ensure that the amount of RAM, CPU, and disk storage meets the minimum requirements for the machine type.

i. Complete the configuration and power on the VM.

j. Check the console output to verify that Ignition ran.

Example command

```
Ignition: ran on 2022/03/14 14:48:33 UTC (this boot)
Ignition: user-provided config was applied
```

10. Create the rest of the machines for your cluster by following the preceding steps for each machine.

**IMPORTANT**

You must create the bootstrap and control plane machines at this time. Because some pods are deployed on compute machines by default, also create at least two compute machines before you install the cluster.

19.8.15. Adding more compute machines to a cluster in vSphere

You can add more compute machines to a user-provisioned OpenShift Container Platform cluster on VMware vSphere.

**Prerequisites**

- Obtain the base64-encoded Ignition file for your compute machines.
- You have access to the vSphere template that you created for your cluster.

**Procedure**

1. After the template deploys, deploy a VM for a machine in the cluster.
a. Right-click the template’s name and click Clone → Clone to Virtual Machine

b. On the Select a name and folder tab, specify a name for the VM. You might include the machine type in the name, such as compute-1.

   **NOTE**
   Ensure that all virtual machine names across a vSphere installation are unique.

c. On the Select a name and folder tab, select the name of the folder that you created for the cluster.

d. On the Select a compute resource tab, select the name of a host in your datacenter.

e. Optional: On the Select storage tab, customize the storage options.

f. On the Select clone options, select Customize this virtual machine’s hardware.

g. On the Customize hardware tab, click VM Options → Advanced.
   - From the Latency Sensitivity list, select High.
   - Click Edit Configuration, and on the Configuration Parameters window, click Add Configuration Params. Define the following parameter names and values:
     - guestinfo.ignition.config.data: Paste the contents of the base64-encoded compute Ignition config file for this machine type.
     - guestinfo.ignition.config.data.encoding: Specify base64.
     - disk.EnableUUID: Specify TRUE.

h. In the Virtual Hardware panel of the Customize hardware tab, modify the specified values as required. Ensure that the amount of RAM, CPU, and disk storage meets the minimum requirements for the machine type. Also, make sure to select the correct network under Add network adapter if there are multiple networks available.

   i. Complete the configuration and power on the VM.

2. Continue to create more compute machines for your cluster.

### 19.8.16. Disk partitioning

In most cases, data partitions are originally created by installing RHCOS, rather than by installing another operating system. In such cases, the OpenShift Container Platform installer should be allowed to configure your disk partitions.

However, there are two cases where you might want to intervene to override the default partitioning when installing an OpenShift Container Platform node:

- Create separate partitions: For greenfield installations on an empty disk, you might want to add separate storage to a partition. This is officially supported for making /var or a subdirectory of /var, such as /var/lib/etcd, a separate partition, but not both.
IMPORTANT

Kubernetes supports only two filesystem partitions. If you add more than one partition to the original configuration, Kubernetes cannot monitor all of them.

- Retain existing partitions: For a brownfield installation where you are reinstalling OpenShift Container Platform on an existing node and want to retain data partitions installed from your previous operating system, there are both boot arguments and options to `coreos-installer` that allow you to retain existing data partitions.

Creating a separate /var partition

In general, disk partitioning for OpenShift Container Platform should be left to the installer. However, there are cases where you might want to create separate partitions in a part of the filesystem that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the /var partition or a subdirectory of /var. For example:

- `/var/lib/containers`: Holds container-related content that can grow as more images and containers are added to a system.
- `/var/lib/etcd`: Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.
- `/var`: Holds data that you might want to keep separate for purposes such as auditing.

Storing the contents of a /var directory separately makes it easier to grow storage for those areas as needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

Because /var must be in place before a fresh installation of Red Hat Enterprise Linux CoreOS (RHCOS), the following procedure sets up the separate /var partition by creating a machine config manifest that is inserted during the `openshift-install` preparation phases of an OpenShift Container Platform installation.

Procedure

1. Create a directory to hold the OpenShift Container Platform installation files:

   $ mkdir $HOME/clusterconfig

2. Run `openshift-install` to create a set of files in the manifest and openshift subdirectories. Answer the system questions as you are prompted:

   $ openshift-install create manifests --dir $HOME/clusterconfig

   ? SSH Public Key ...
   $ ls $HOME/clusterconfig/openshift/
   99_kubeadmin-password-secret.yaml
   99_openshift-cluster-api_master-machines-0.yaml
   99_openshift-cluster-api_master-machines-1.yaml
   99_openshift-cluster-api_master-machines-2.yaml
   ...

3. Create a Butane config that configures the additional partition. For example, name the file...
$HOME/clusterconfig/98-var-partition.bu, change the disk device name to the name of the storage device on the worker systems, and set the storage size as appropriate. This example places the /var directory on a separate partition:

```yaml
variant: openshift
version: 4.10.0
metadata:
  machineconfiguration.openshift.io/role: worker
name: 98-var-partition
storage:
disks:
  - device: /dev/<device_name> 1
    partitions:
      - label: var
        start_mib: <partition_start_offset> 2
        size_mib: <partition_size> 3
    filesystems:
      - device: /dev/disk/by-partlabel/var
        path: /var
        format: xfs
        mount_options: [defaults, prjquota] 4
        with_mount_unit: true
```

1. The storage device name of the disk that you want to partition.
2. When adding a data partition to the boot disk, a minimum value of 25000 mebibytes is recommended. The root file system is automatically resized to fill all available space up to the specified offset. If no value is specified, or if the specified value is smaller than the recommended minimum, the resulting root file system will be too small, and future reinstalls of RHCOS might overwrite the beginning of the data partition.
3. The size of the data partition in mebibytes.
4. The `prjquota` mount option must be enabled for filesystems used for container storage.

**NOTE**

When creating a separate /var partition, you cannot use different instance types for worker nodes, if the different instance types do not have the same device name.

4. Create a manifest from the Butane config and save it to the `clusterconfig/openshift` directory. For example, run the following command:

   ```sh
   $ butane $HOME/clusterconfig/98-var-partition.bu -o $HOME/clusterconfig/openshift/98-var-partition.yaml
   ```

5. Run `openshift-install` again to create Ignition configs from a set of files in the `manifest` and `openshift` subdirectories:
Now you can use the Ignition config files as input to the vSphere installation procedures to install Red Hat Enterprise Linux CoreOS (RHCOS) systems.

19.8.17. Updating the bootloader using bootupd

To update the bootloader by using bootupd, you must either install bootupd on RHCOS machines manually or provide a machine config with the enabled systemd unit. Unlike grubby or other bootloader tools, bootupd does not manage kernel space configuration such as passing kernel arguments.

After you have installed bootupd, you can manage it remotely from the OpenShift Container Platform cluster.

NOTE

It is recommended that you use bootupd only on bare metal or virtualized hypervisor installations, such as for protection against the BootHole vulnerability.

Manual install method

You can manually install bootupd by using the bootctl command-line tool.

1. Inspect the system status:

   $ bootupctl status

   **Example output for x86_64**

   Component EFI
   Installed: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
   Update: At latest version

   **Example output for arm64**

   Component EFI
   Installed: grub2-efi-aa64-1:2.02-99.el8_4.1.aarch64,shim-aa64-15.4-2.el8_1.aarch64
   Update: At latest version

2. RHCOS images created without bootupd installed on them require an explicit adoption phase. If the system status is Adoptable, perform the adoption:

   $ bootupctl adopt-and-update

   **Example output**

   Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64

3. If an update is available, apply the update so that the changes take effect on the next reboot:
Machine config method

Another way to enable `bootupd` is by providing a machine config.

- Provide a machine config file with the enabled `systemd` unit, as shown in the following example:

```
Example output

variant: rhcos
version: 1.1.0
systemd:
  units:
    - name: custom-bootupd-auto.service
      enabled: true
      contents: |
        [Unit]
        Description=Bootupd automatic update
        [Service]
        ExecStart=/usr/bin/bootupctl update
        RemainAfterExit=yes
        [Install]
        WantedBy=multi-user.target
```

19.8.18. Waiting for the bootstrap process to complete

The OpenShift Container Platform bootstrap process begins after the cluster nodes first boot into the persistent RHCOs environment that has been installed to disk. The configuration information provided through the Ignition config files is used to initialize the bootstrap process and install OpenShift Container Platform on the machines. You must wait for the bootstrap process to complete.

Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have obtained the installation program and generated the Ignition config files for your cluster.
- You installed RHCOs on your cluster machines and provided the Ignition config files that the OpenShift Container Platform installation program generated.

Procedure

1. Monitor the bootstrap process:
For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

### Example output

```
INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
INFO API v1.23.0 up
INFO Waiting up to 30m0s for bootstrapping to complete...
INFO It is now safe to remove the bootstrap resources
```

The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After bootstrap process is complete, remove the bootstrap machine from the load balancer.

**IMPORTANT**

You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the bootstrap machine itself.

### 19.8.19. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

#### Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

#### Procedure

1. Export the `kubeadmin` credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   ```
19.8.20. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

Prerequisites

- You added machines to your cluster.

Procedure

1. Confirm that the cluster recognizes the machines:

   ```
   $ oc get nodes
   
   Example output
   
   NAME      STATUS    ROLES   AGE  VERSION
   master-0  Ready     master  63m  v1.23.0
   master-1  Ready     master  63m  v1.23.0
   master-2  Ready     master  64m  v1.23.0
   
   The output lists all of the machines that you created.
   
   NOTE
   
   The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.
   
2. Review the pending CSRs and ensure that you see the client requests with the Pending or Approved status for each machine that you added to the cluster:

   ```
   $ oc get csr
   
   Example output
   
   NAME        AGE   REQUESTOR                                   CONDITION
   csr-mddf5   20m   system:node:master-01.example.com   Approved,Issued
   csr-z5rln   16m   system:node:worker-21.example.com   Approved,Issued
   
3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in Pending status, approve the CSRs for your cluster machines:
NOTE
Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

NOTE
For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the `oc exec`, `oc rsh`, and `oc logs` commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrapper** service account in the `system:node` or `system:admin` groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

  ```
  $ oc adm certificate approve <csr_name> ¹
  ```

  ¹ `<csr_name>` is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

  ```
  $ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{
  if .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
  ```

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

  ```
  $ oc get csr
  ```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-c57lv</td>
<td>5m26s</td>
<td>system:node:ip-10-0-95-157.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

   - To approve them individually, run the following command for each valid CSR:

     ```
     $ oc adm certificate approve <csr_name>
     ```

     **<csr_name>** is the name of a CSR from the list of current CSRs.

   - To approve all pending CSRs, run the following command:

     ```
     $ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs oc adm certificate approve
     ```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

   ```
   $ oc get nodes
   ```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.23.0</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.23.0</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>74m</td>
<td>v1.23.0</td>
</tr>
<tr>
<td>worker-0</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.23.0</td>
</tr>
<tr>
<td>worker-1</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.23.0</td>
</tr>
</tbody>
</table>

**NOTE**

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

**Additional information**

- For more information on CSRs, see [Certificate Signing Requests](#).

### 19.8.21. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

**Prerequisites**

- Your control plane has initialized.

**Procedure**

1. Watch the cluster components come online:

   ```
   $ watch -n5 oc get clusteroperators
   ```
Example output

<table>
<thead>
<tr>

2. Configure the Operators that are not available.

19.8.21.1. Disabling the default OperatorHub sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

Procedure

- Disable the sources for the default catalogs by adding `disableAllDefaultSources: true` to the `OperatorHub` object:

  ```
  $ oc patch OperatorHub cluster --type json \
  -p '["op": "add", "path": "/spec/disableAllDefaultSources", "value": true]'
  ```
TIP

Alternatively, you can use the web console to manage catalog sources. From the Administration → Cluster Settings → Configuration → OperatorHub page, click the Sources tab, where you can create, delete, disable, and enable individual sources.

19.8.21.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the Recreate rollout strategy during upgrades.

19.8.21.2.1. Configuring registry storage for VMware vSphere

As a cluster administrator, following installation you must configure your registry to use storage.

Prerequisites

- Cluster administrator permissions.
- A cluster on VMware vSphere.
- Persistent storage provisioned for your cluster, such as Red Hat OpenShift Data Foundation.

IMPORTANT

OpenShift Container Platform supports ReadWriteOnce access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, ReadWriteMany access is required.

- Must have “100Gi” capacity.

IMPORTANT

Testing shows issues with using the NFS server on RHEL as storage backend for core services. This includes the OpenShift Container Registry and Quay, Prometheus for monitoring storage, and Elasticsearch for logging storage. Therefore, using RHEL NFS to back PVs used by core services is not recommended.

Other NFS implementations on the marketplace might not have these issues. Contact the individual NFS implementation vendor for more information on any testing that was possibly completed against these OpenShift Container Platform core components.

Procedure

1. To configure your registry to use storage, change the spec.storage.pvc in the configs.imageregistry/cluster resource.
NOTE
When using shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

   $ oc get pod -n openshift-image-registry -l docker-registry=default

   **Example output**

   No resources found in openshift-image-registry namespace

   **NOTE**
   If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

   $ oc edit configs.imageregistry.operator.openshift.io

   **Example output**

   storage:
   pvc:
   claim: 1

   Leave the `claim` field blank to allow the automatic creation of an `image-registry-storage PVC`.

4. Check the `clusteroperator` status:

   $ oc get clusteroperator image-registry

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
<th>SINCE</th>
<th>MESSAGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>image-registry</td>
<td>4.7</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>6h50m</td>
<td>6h50m</td>
</tr>
</tbody>
</table>

19.8.21.2.2. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

**Procedure**

- To set the image registry storage to an empty directory:
19.8.21.2.3. Configuring block registry storage for VMware vSphere

To allow the image registry to use block storage types such as vSphere Virtual Machine Disk (VMDK) during upgrades as a cluster administrator, you can use the **Recreate** rollout strategy.

**IMPORTANT**

Block storage volumes are supported but not recommended for use with image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

**Procedure**

1. To set the image registry storage as a block storage type, patch the registry so that it uses the **Recreate** rollout strategy and runs with only 1 replica:

   ```bash
   $ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec":
   {"rolloutStrategy":"Recreate","replicas":1}}'
   ```

2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.

   a. Create a `pvc.yaml` file with the following contents to define a VMware vSphere **PersistentVolumeClaim** object:

   ```yaml
   kind: PersistentVolumeClaim
   apiVersion: v1
   metadata:
     name: image-registry-storage
   namespace: openshift-image-registry
   spec:
     accessModes:
     - ReadWriteOnce
   ```
A unique name that represents the PersistentVolumeClaim object.

The namespace for the PersistentVolumeClaim object, which is openshift-image-registry.

The access mode of the persistent volume claim. With ReadWriteOnce, the volume can be mounted with read and write permissions by a single node.

The size of the persistent volume claim.

b. Create the PersistentVolumeClaim object from the file:

```
$ oc create -f pvc.yaml -n openshift-image-registry
```

3. Edit the registry configuration so that it references the correct PVC:

```
$ oc edit config.imageregistry.operator.openshift.io -o yaml
```

Example output

```
storage:
pvc:
  claim: 1
```

Creating a custom PVC allows you to leave the claim field blank for the default automatic creation of an image-registry-storage PVC.

For instructions about configuring registry storage so that it references the correct PVC, see Configuring the registry for vSphere.

19.8.22. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

Prerequisites

- Your control plane has initialized.
- You have completed the initial Operator configuration.

Procedure

1. Confirm that all the cluster components are online with the following command:

```
$ watch -n5 oc get clusteroperators
```

Example output
Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```
$ ./openshift-install --dir <installation_directory> wait-for install-complete
```

1 For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

### Example output

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.
IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

2. Confirm that the Kubernetes API server is communicating with the pods.
   a. To view a list of all pods, use the following command:

   ```bash
   $ oc get pods --all-namespaces
   ```

   **Example output**

   ```
   NAMESPACE                         NAME                                            READY   STATUS
   RESTARTS AGE
   openshift-apiserver-operator      openshift-apiserver-operator-85cb746d55-zqhs8   1/1 Running     1         9m
   openshift-apiserver               apiserver-67b9g                                 1/1 Running     0         3m
   openshift-apiserver               apiserver-ljcmx                                 1/1 Running     0         1m
   openshift-apiserver               apiserver-z25h4                                 1/1 Running     0         2m
   openshift-authentication-operator authentication-operator-69d5d8bf84-vh2n8       1/1 Running     0         5m
   ...
   ```

   b. View the logs for a pod that is listed in the output of the previous command by using the following command:

   ```bash
   $ oc logs <pod_name> -n <namespace>
   ```

   Specify the pod name and namespace, as shown in the output of the previous command.

   If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation. See "Enabling multipathing with kernel arguments on RHCOS" in the Post-installation machine configuration tasks documentation for more information.
4. Register your cluster on the Cluster registration page.

You can add extra compute machines after the cluster installation is completed by following Adding compute machines to vSphere.

19.8.23. Backing up VMware vSphere volumes

OpenShift Container Platform provisions new volumes as independent persistent disks to freely attach and detach the volume on any node in the cluster. As a consequence, it is not possible to back up volumes that use snapshots, or to restore volumes from snapshots. See Snapshot Limitations for more information.

Procedure

To create a backup of persistent volumes:

1. Stop the application that is using the persistent volume.
2. Clone the persistent volume.
3. Restart the application.
4. Create a backup of the cloned volume.
5. Delete the cloned volume.

19.8.24. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.10, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service

19.8.25. Next steps

- Customize your cluster.
- If the mirror registry that you used to install your cluster has a trusted CA, add it to the cluster by configuring additional trust stores.
- If necessary, you can opt out of remote health reporting.
- Optional: View the events from the vSphere Problem Detector Operator to determine if the cluster has permission or storage configuration issues.

19.9. UNINSTALLING A CLUSTER ON VSPHERE THAT USES INSTALLER-PROVISIONED INFRASTRUCTURE
You can remove a cluster that you deployed in your VMware vSphere instance by using installer-provisioned infrastructure.

**NOTE**

When you run the `openshift-install destroy cluster` command to uninstall OpenShift Container Platform, vSphere volumes are not automatically deleted. The cluster administrator must manually find the vSphere volumes and delete them.

19.9.1. Removing a cluster that uses installer-provisioned infrastructure

You can remove a cluster that uses installer-provisioned infrastructure from your cloud.

**NOTE**

After uninstallation, check your cloud provider for any resources not removed properly, especially with User Provisioned Infrastructure (UPI) clusters. There might be resources that the installer did not create or that the installer is unable to access.

### Prerequisites

- Have a copy of the installation program that you used to deploy the cluster.
- Have the files that the installation program generated when you created your cluster.

### Procedure

1. From the directory that contains the installation program on the computer that you used to install the cluster, run the following command:

   ```bash
   $ ./openshift-install destroy cluster \
   --dir <installation_directory> --log-level info
   ```

   **1** For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   **2** To view different details, specify `warn`, `debug`, or `error` instead of `info`.

   **NOTE**

   You must specify the directory that contains the cluster definition files for your cluster. The installation program requires the `metadata.json` file in this directory to delete the cluster.

1. Optional: Delete the `<installation_directory>` directory and the OpenShift Container Platform installation program.

19.10. USING THE VSPHERE PROBLEM DETECTOR OPERATOR

19.10.1. About the vSphere Problem Detector Operator
The vSphere Problem Detector Operator checks clusters that are deployed on vSphere for common installation and misconfiguration issues that are related to storage.

The Operator runs in the *openshift-cluster-storage-operator* namespace and is started by the Cluster Storage Operator when the Cluster Storage Operator detects that the cluster is deployed on vSphere. The vSphere Problem Detector Operator communicates with the vSphere vCenter Server to determine the virtual machines in the cluster, the default datastore, and other information about the vSphere vCenter Server configuration. The Operator uses the credentials from the Cloud Credential Operator to connect to vSphere.

The Operator runs the checks according to the following schedule:

- The checks run every 8 hours.
- If any check fails, the Operator runs the checks again in intervals of 1 minute, 2 minutes, 4, 8, and so on. The Operator doubles the interval up to a maximum interval of 8 hours.
- When all checks pass, the schedule returns to an 8 hour interval.

The Operator increases the frequency of the checks after a failure so that the Operator can report success quickly after the failure condition is remedied. You can run the Operator manually for immediate troubleshooting information.

19.10.2. Running the vSphere Problem Detector Operator checks

You can override the schedule for running the vSphere Problem Detector Operator checks and run the checks immediately.

The vSphere Problem Detector Operator automatically runs the checks every 8 hours. However, when the Operator starts, it runs the checks immediately. The Operator is started by the Cluster Storage Operator when the Cluster Storage Operator starts and determines that the cluster is running on vSphere. To run the checks immediately, you can scale the vSphere Problem Detector Operator to 0 and back to 1 so that it restarts the vSphere Problem Detector Operator.

**Prerequisites**

- Access to the cluster as a user with the *cluster-admin* role.

**Procedure**

1. Scale the Operator to 0:

   ```
   $ oc scale deployment/vsphere-problem-detector-operator --replicas=0  
   -n openshift-cluster-storage-operator
   ```

   If the deployment does not scale to zero immediately, you can run the following command to wait for the pods to exit:

   ```
   $ oc wait pods -l name=vsphere-problem-detector-operator  
   --for=delete --timeout=5m -n openshift-cluster-storage-operator
   ```

2. Scale the Operator back to 1:

   ```
   $ oc scale deployment/vsphere-problem-detector-operator --replicas=1  
   -n openshift-cluster-storage-operator
   ```
3. Delete the old leader lock to speed up the new leader election for the Cluster Storage Operator:

   $ oc delete -n openshift-cluster-storage-operator cm vsphere-problem-detector-lock

Verifications

- View the events or logs that are generated by the vSphere Problem Detector Operator. Confirm that the events or logs have recent timestamps.

19.10.3. Viewing the events from the vSphere Problem Detector Operator

After the vSphere Problem Detector Operator runs and performs the configuration checks, it creates events that can be viewed from the command line or from the OpenShift Container Platform web console.

Procedure

- To view the events by using the command line, run the following command:

  $ oc get event -n openshift-cluster-storage-operator --sort-by={.metadata.creationTimestamp}

  Example output

  16m Normal Started pod/vsphere-problem-detector-operator-xxxxx Started container vsphere-problem-detector
  16m Normal Created pod/vsphere-problem-detector-operator-xxxxx Created container vsphere-problem-detector
  16m Normal LeaderElection configmap/vsphere-problem-detector-lock vsphere-problem-detector-operator-xxxxx became leader

- To view the events by using the OpenShift Container Platform web console, navigate to Home → Events and select openshift-cluster-storage-operator from the Project menu.

19.10.4. Viewing the logs from the vSphere Problem Detector Operator

After the vSphere Problem Detector Operator runs and performs the configuration checks, it creates log records that can be viewed from the command line or from the OpenShift Container Platform web console.

Procedure

- To view the logs by using the command line, run the following command:

  $ oc logs deployment/vsphere-problem-detector-operator -n openshift-cluster-storage-operator

  Example output

  I0108 08:32:28.445696       1 operator.go:209] ClusterInfo passed
  I0108 08:32:28.451029       1 datastore.go:57] CheckStorageClasses checked 1 storage
To view the Operator logs with the OpenShift Container Platform web console, perform the following steps:

a. Navigate to Workloads → Pods.

b. Select openshift-cluster-storage-operator from the Projects menu.

c. Click the link for the vsphere-problem-detector-operator pod.

d. Click the Logs tab on the Pod details page to view the logs.

19.10.5. Configuration checks run by the vSphere Problem Detector Operator

The following tables identify the configuration checks that the vSphere Problem Detector Operator runs. Some checks verify the configuration of the cluster. Other checks verify the configuration of each node in the cluster.

Table 19.71. Cluster configuration checks

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| CheckDefaultDatastore | Verifies that the default datastore name in the vSphere configuration is short enough for use with dynamic provisioning. If this check fails, you can expect the following:  

- **systemd** logs errors to the journal such as Failed to set up mount unit: Invalid argument.

- **systemd** does not unmount volumes if the virtual machine is shut down or rebooted without draining all the pods from the node.  

If this check fails, reconfigure vSphere with a shorter name for the default datastore. |

| CheckFolderPermissions | Verifies the permission to list volumes in the default datastore. This permission is required to create volumes. The Operator verifies the permission by listing the / and /kubevols directories. The root directory must exist. It is acceptable if the /kubevols directory does not exist when the check runs. The /kubevols directory is created when the datastore is used with dynamic provisioning if the directory does not already exist. If this check fails, review the required permissions for the vCenter account that was specified during the OpenShift Container Platform installation. |
CheckStorageClasses
Verifies the following:

- The fully qualified path to each persistent volume that is provisioned by this storage class is less than 255 characters.
- If a storage class uses a storage policy, the storage class must use one policy only and that policy must be defined.

CheckTaskPermissions
Verifies the permission to list recent tasks and datastores.

ClusterInfo
Collects the cluster version and UUID from vSphere vCenter.

Table 19.72. Node configuration checks

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CheckNodeDiskUUID</td>
<td>Verifies that all the vSphere virtual machines are configured with</td>
</tr>
<tr>
<td></td>
<td>disk.enableUUID=TRUE.</td>
</tr>
<tr>
<td></td>
<td>If this check fails, see the How to check 'disk.EnableUUID' parameter from VM in vSphere Red Hat Knowledgebase solution.</td>
</tr>
<tr>
<td>CheckNodeProviderID</td>
<td>Verifies that all nodes are configured with the ProviderID from vSphere vCenter. This check fails when the output from the following command does not include a provider ID for each node.</td>
</tr>
<tr>
<td></td>
<td>$ oc get nodes -o custom-columns=NAME:.metadata.name,PROVIDER_ID:.spec.providerID,UUID:.status.nodeInfo.systemUUID</td>
</tr>
<tr>
<td></td>
<td>If this check fails, refer to the vSphere product documentation for information about setting the provider ID for each node in the cluster.</td>
</tr>
<tr>
<td>CollectNodeESXiVersion</td>
<td>Reports the version of the ESXi hosts that run nodes.</td>
</tr>
<tr>
<td>CollectNodeHWVersion</td>
<td>Reports the virtual machine hardware version for a node.</td>
</tr>
</tbody>
</table>

19.10.6. About the storage class configuration check

The names for persistent volumes that use vSphere storage are related to the datastore name and cluster ID.

When a persistent volume is created, **systemd** creates a mount unit for the persistent volume. The **systemd** process has a 255 character limit for the length of the fully qualified path to the VDMK file that is used for the persistent volume.
The fully qualified path is based on the naming conventions for **systemd** and vSphere. The naming conventions use the following pattern:

```
/var/lib/kubelet/plugins/kubernetes.io/vsphere-volume/mounts/<datastore> 00000000-0000-0000-0000-000000000000/<cluster_id>-dynamic-pvc-00000000-0000-0000-0000-000000000000.vmdk
```

- The naming conventions require 205 characters of the 255 character limit.
- The datastore name and the cluster ID are determined from the deployment.
- The datastore name and cluster ID are substituted into the preceding pattern. Then the path is processed with the `systemd-escape` command to escape special characters. For example, a hyphen character uses four characters after it is escaped. The escaped value is `\x2d`.
- After processing with `systemd-escape` to ensure that **systemd** can access the fully qualified path to the VDMK file, the length of the path must be less than 255 characters.

### 19.10.7. Metrics for the vSphere Problem Detector Operator

The vSphere Problem Detector Operator exposes the following metrics for use by the OpenShift Container Platform monitoring stack.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>vsphere_cluster_check_total</code></td>
<td>Cumulative number of cluster-level checks that the vSphere Problem Detector Operator performed. This count includes both successes and failures.</td>
</tr>
<tr>
<td><code>vsphere_cluster_check_errors</code></td>
<td>Number of failed cluster-level checks that the vSphere Problem Detector Operator performed. For example, a value of 1 indicates that one cluster-level check failed.</td>
</tr>
<tr>
<td><code>vsphere_esxi_version_total</code></td>
<td>Number of ESXi hosts with a specific version. Be aware that if a host runs more than one node, the host is counted only once.</td>
</tr>
<tr>
<td><code>vsphere_node_check_total</code></td>
<td>Cumulative number of node-level checks that the vSphere Problem Detector Operator performed. This count includes both successes and failures.</td>
</tr>
<tr>
<td><code>vsphere_node_check_errors</code></td>
<td>Number of failed node-level checks that the vSphere Problem Detector Operator performed. For example, a value of 1 indicates that one node-level check failed.</td>
</tr>
<tr>
<td><code>vsphere_node_hw_version_total</code></td>
<td>Number of vSphere nodes with a specific hardware version.</td>
</tr>
<tr>
<td><code>vsphere_vcenter_info</code></td>
<td>Information about the vSphere vCenter Server.</td>
</tr>
</tbody>
</table>

### 19.10.8. Additional resources

- [Monitoring overview](#)
CHAPTER 20. INSTALLING ON VMC

20.1. PREPARING TO INSTALL ON VMC

20.1.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- If you use a firewall and plan to use Telemetry, you configured the firewall to allow the sites required by your cluster.

20.1.2. Choosing a method to install OpenShift Container Platform on VMC

You can install OpenShift Container Platform on VMC by using installer-provisioned or user-provisioned infrastructure. The default installation type uses installer-provisioned infrastructure, where the installation program provisions the underlying infrastructure for the cluster. You can also install OpenShift Container Platform on infrastructure that you provide. If you do not use infrastructure that the installation program provisions, you must manage and maintain the cluster resources yourself.

See the Installation process for more information about installer-provisioned and user-provisioned installation processes.

IMPORTANT

The steps for performing a user-provisioned infrastructure installation are provided as an example only. Installing a cluster with infrastructure you provide requires knowledge of the VMC platform and the installation process of OpenShift Container Platform. Use the user-provisioned infrastructure installation instructions as a guide; you are free to create the required resources through other methods.

20.1.2.1. Installer-provisioned infrastructure installation of OpenShift Container Platform on VMC

Installer-provisioned infrastructure allows the installation program to pre-configure and automate the provisioning of resources required by OpenShift Container Platform.

- Installing a cluster on VMC You can install OpenShift Container Platform on VMC by using installer-provisioned infrastructure installation with no customization.
- Installing a cluster on VMC with customizations You can install OpenShift Container Platform on VMC by using installer-provisioned infrastructure installation with the default customization options.
- Installing a cluster on VMC with network customizations You can install OpenShift Container Platform on installer-provisioned VMC infrastructure, with network customizations. You can customize your OpenShift Container Platform network configuration during installation, so that your cluster can coexist with your existing IP address allocations and adhere to your network requirements.
- Installing a cluster on VMC in a restricted network You can install a cluster on VMC...
infrastructure in a restricted network by creating an internal mirror of the installation release content. You can use this method to deploy OpenShift Container Platform on an internal network that is not visible to the internet.

20.1.2.2. User-provisioned infrastructure installation of OpenShift Container Platform on VMC

User-provisioned infrastructure requires the user to provision all resources required by OpenShift Container Platform.

- **Installing a cluster on VMC with user-provisioned infrastructure**: You can install OpenShift Container Platform on VMC infrastructure that you provision.

- **Installing a cluster on VMC with user-provisioned infrastructure and network customizations**: You can install OpenShift Container Platform on VMC infrastructure that you provision with customized network configuration options.

- **Installing a cluster on VMC in a restricted network with user-provisioned infrastructure**: OpenShift Container Platform can be installed on VMC infrastructure that you provision in a restricted network.

20.1.3. VMware vSphere infrastructure requirements

You must install the OpenShift Container Platform cluster on a VMware vSphere version 6 or 7 instance that meets the requirements for the components that you use.

**Table 20.1. Version requirements for vSphere virtual environments**

<table>
<thead>
<tr>
<th>Virtual environment product</th>
<th>Required version</th>
</tr>
</thead>
<tbody>
<tr>
<td>VM hardware version</td>
<td>13 or later</td>
</tr>
<tr>
<td>vSphere ESXi hosts</td>
<td>6.5 or later</td>
</tr>
<tr>
<td>vCenter host</td>
<td>6.5 or later</td>
</tr>
</tbody>
</table>

**IMPORTANT**

Installing a cluster on VMware vSphere version 6.7U3 or earlier and virtual hardware version 13 is now deprecated. These versions are still fully supported, but version 4.11 of OpenShift Container Platform will require vSphere virtual hardware version 15 or later. Hardware version 15 is now the default for vSphere virtual machines in OpenShift Container Platform. To update the hardware version for your vSphere nodes, see the "Updating hardware on nodes running in vSphere" article.

If your vSphere nodes are below hardware version 15 or your VMware vSphere version is earlier than 6.7U3, upgrading from OpenShift Container Platform 4.10 to OpenShift Container Platform 4.11 is not available.

**Table 20.2. Minimum supported vSphere version for VMware components**
### Component

<table>
<thead>
<tr>
<th>Component</th>
<th>Minimum supported versions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hypervisor</td>
<td>vSphere 6.5 and later with HW version 13</td>
<td>This version is the minimum version that Red Hat Enterprise Linux CoreOS (RHCOS) supports. See the Red Hat Enterprise Linux 8 supported hypervisors list.</td>
</tr>
<tr>
<td>Storage with in-tree drivers</td>
<td>vSphere 6.5 and later</td>
<td>This plug-in creates vSphere storage by using the in-tree storage drivers for vSphere included in OpenShift Container Platform.</td>
</tr>
</tbody>
</table>

If you use a vSphere version 6.5 instance, consider upgrading to 6.7U3 or 7.0 before you install OpenShift Container Platform.

**IMPORTANT**

You must ensure that the time on your ESXi hosts is synchronized before you install OpenShift Container Platform. See *Edit Time Configuration for a Host* in the VMware documentation.

#### 20.1.4. VMware vSphere CSI Driver Operator requirements

The following requirements must be met in order to install the CSI Driver Operator:

- VMware vSphere version 6.7U3 or later
- Virtual machines of hardware version 15 or later
- No third-party CSI driver already installed in the cluster

If a third-party CSI driver is present in the cluster, OpenShift Container Platform does not overwrite it. The presence of a third-party CSI driver prevents OpenShift Container Platform from upgrading to 4.11.

Additional resources

- To remove a third-party CSI driver, see *Removing a third-party vSphere CSI Driver*.

#### 20.1.5. Uninstalling an installer-provisioned infrastructure installation of OpenShift Container Platform on VMC

- **Uninstalling a cluster on VMC that uses installer-provisioned infrastructure** You can remove a cluster that you deployed on VMC infrastructure that used installer-provisioned infrastructure.

#### 20.2. INSTALLING A CLUSTER ON VMC

In OpenShift Container Platform version 4.10, you can install a cluster on VMware vSphere by deploying it to *VMware Cloud (VMC) on AWS*. 

---

2807
Once you have configured your VMC environment for OpenShift Container Platform deployment, you use the OpenShift Container Platform installation program from the bastion management host, co-located in the VMC environment. The installation program and control plane automates the process of deploying and managing the resources needed for the OpenShift Container Platform cluster.

### 20.2.1. Setting up VMC for vSphere

You can install OpenShift Container Platform on VMware Cloud (VMC) on AWS hosted vSphere clusters to enable applications to be deployed and managed both on-premise and off-premise, across the hybrid cloud.

You must configure several options in your VMC environment prior to installing OpenShift Container Platform on VMware vSphere. Ensure your VMC environment has the following prerequisites:

- Create a non-exclusive, DHCP-enabled, NSX-T network segment and subnet. Other virtual machines (VMs) can be hosted on the subnet, but at least eight IP addresses must be available for the OpenShift Container Platform deployment.

- Allocate two IP addresses, outside the DHCP range, and configure them with reverse DNS records.
  - A DNS record for `api.<cluster_name>.<base_domain>` pointing to the allocated IP address.
  - A DNS record for `*.apps.<cluster_name>.<base_domain>` pointing to the allocated IP address.

- Configure the following firewall rules:
  - An ANY:ANY firewall rule between the OpenShift Container Platform compute network and the internet. This is used by nodes and applications to download container images.
  - An ANY:ANY firewall rule between the installation host and the software-defined data center (SDDC) management network on port 443. This allows you to upload the Red Hat Enterprise Linux CoreOS (RHCOS) OVA during deployment.
  - An HTTPS firewall rule between the OpenShift Container Platform compute network and vCenter. This connection allows OpenShift Container Platform to communicate with vCenter for provisioning and managing nodes, persistent volume claims (PVCs), and other resources.

- You must have the following information to deploy OpenShift Container Platform:
  - The OpenShift Container Platform cluster name, such as `vmc-prod-1`. 

OpenShift Container Platform 4.10 Installing
- The base DNS name, such as companyname.com.

- If not using the default, the pod network CIDR and services network CIDR must be identified, which are set by default to 10.128.0.0/14 and 172.30.0.0/16, respectively. These CIDRs are used for pod-to-pod and pod-to-service communication and are not accessible externally; however, they must not overlap with existing subnets in your organization.

- The following vCenter information:
  - vCenter hostname, username, and password
  - Datacenter name, such as SDDC-Datacenter
  - Cluster name, such as Cluster-1
  - Network name
  - Datastore name, such as WorkloadDatastore

**NOTE**

It is recommended to move your vSphere cluster to the VMC Compute-ResourcePool resource pool after your cluster installation is finished.

- A Linux-based host deployed to VMC as a bastion.
  - The bastion host can be Red Hat Enterprise Linux (RHEL) or any another Linux-based host; it must have internet connectivity and the ability to upload an OVA to the ESXi hosts.

- Download and install the OpenShift CLI tools to the bastion host.
  - The openshift-install installation program
  - The OpenShift CLI (oc) tool

**NOTE**

You cannot use the VMware NSX Container Plug-in for Kubernetes (NCP), and NSX is not used as the OpenShift SDN. The version of NSX currently available with VMC is incompatible with the version of NCP certified with OpenShift Container Platform.

However, the NSX DHCP service is used for virtual machine IP management with the full-stack automated OpenShift Container Platform deployment and with nodes provisioned, either manually or automatically, by the Machine API integration with vSphere. Additionally, NSX firewall rules are created to enable access with the OpenShift Container Platform cluster and between the bastion host and the VMC vSphere hosts.

### 20.2.1. VMC Sizer tool

VMware Cloud on AWS is built on top of AWS bare metal infrastructure; this is the same bare metal infrastructure which runs AWS native services. When a VMware cloud on AWS software-defined data center (SDDC) is deployed, you consume these physical server nodes and run the VMware ESXi hypervisor in a single tenant fashion. This means the physical infrastructure is not accessible to anyone else using VMC. It is important to consider how many physical hosts you will need to host your virtual infrastructure.
To determine this, VMware provides the VMC on AWS Sizer. With this tool, you can define the resources you intend to host on VMC:

- Types of workloads
- Total number of virtual machines
- Specification information such as:
  - Storage requirements
  - vCPUs
  - vRAM
  - Overcommit ratios

With these details, the sizer tool can generate a report, based on VMware best practices, and recommend your cluster configuration and the number of hosts you will need.

### 20.2.2. vSphere prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You provisioned block registry storage. For more information on persistent storage, see Understanding persistent storage.
- If you use a firewall, you configured it to allow the sites that your cluster requires access to.

> **NOTE**
>
> Be sure to also review this site list if you are configuring a proxy.

### 20.2.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.10, you require access to the internet to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.
IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

20.2.4. VMware vSphere infrastructure requirements

You must install the OpenShift Container Platform cluster on a VMware vSphere version 6 or 7 instance that meets the requirements for the components that you use.

Table 20.3. Version requirements for vSphere virtual environments

<table>
<thead>
<tr>
<th>Virtual environment product</th>
<th>Required version</th>
</tr>
</thead>
<tbody>
<tr>
<td>VM hardware version</td>
<td>13 or later</td>
</tr>
<tr>
<td>vSphere ESXi hosts</td>
<td>6.5 or later</td>
</tr>
<tr>
<td>vCenter host</td>
<td>6.5 or later</td>
</tr>
</tbody>
</table>

IMPORTANT

Installing a cluster on VMware vSphere version 6.7U3 or earlier and virtual hardware version 13 is now deprecated. These versions are still fully supported, but version 4.11 of OpenShift Container Platform will require vSphere virtual hardware version 15 or later. Hardware version 15 is now the default for vSphere virtual machines in OpenShift Container Platform. To update the hardware version for your vSphere nodes, see the "Updating hardware on nodes running in vSphere" article.

If your vSphere nodes are below hardware version 15 or your VMware vSphere version is earlier than 6.7U3, upgrading from OpenShift Container Platform 4.10 to OpenShift Container Platform 4.11 is not available.

Table 20.4. Minimum supported vSphere version for VMware components

<table>
<thead>
<tr>
<th>Component</th>
<th>Minimum supported versions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hypervisor</td>
<td>vSphere 6.5 and later with HW version 13</td>
<td>This version is the minimum version that Red Hat Enterprise Linux CoreOS (RHCOS) supports. See the Red Hat Enterprise Linux 8 supported hypervisors list.</td>
</tr>
</tbody>
</table>
If you use a vSphere version 6.5 instance, consider upgrading to 6.7U3 or 7.0 before you install OpenShift Container Platform.

**IMPORTANT**
You must ensure that the time on your ESXi hosts is synchronized before you install OpenShift Container Platform. See *Edit Time Configuration for a Host* in the VMware documentation.

### 20.2.5. VMware vSphere CSI Driver Operator requirements

The following requirements must be met in order to install the CSI Driver Operator:

- VMware vSphere version 6.7U3 or later
- Virtual machines of hardware version 15 or later
- No third-party CSI driver already installed in the cluster

If a third-party CSI driver is present in the cluster, OpenShift Container Platform does not overwrite it. The presence of a third-party CSI driver prevents OpenShift Container Platform from upgrading to 4.11.

**Additional resources**

- To remove a third-party CSI driver, see *Removing a third-party vSphere CSI Driver*.
- To update the hardware version for your vSphere nodes, see *Updating hardware on nodes running in vSphere*.

### 20.2.6. vCenter requirements

Before you install an OpenShift Container Platform cluster on your vCenter that uses infrastructure that the installer provisions, you must prepare your environment.

**Required vCenter account privileges**

To install an OpenShift Container Platform cluster in a vCenter, the installation program requires access to an account with privileges to read and create the required resources. Using an account that has global administrative privileges is the simplest way to access all of the necessary permissions.

If you cannot use an account with global administrative privileges, you must create roles to grant the privileges necessary for OpenShift Container Platform cluster installation. While most of the privileges are always required, some are required only if you plan for the installation program to provision a folder
to contain the OpenShift Container Platform cluster on your vCenter instance, which is the default behavior. You must create or amend vSphere roles for the specified objects to grant the required privileges.

An additional role is required if the installation program is to create a vSphere virtual machine folder.

**Example 20.1. Roles and privileges required for installation**

<table>
<thead>
<tr>
<th>vSphere object for role</th>
<th>When required</th>
<th>Required privileges</th>
</tr>
</thead>
<tbody>
<tr>
<td>vSphere Port Group</td>
<td>Always</td>
<td>Network.Assign</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>vSphere object for role</th>
<th>When required</th>
<th>Required privileges</th>
</tr>
</thead>
<tbody>
<tr>
<td>vSphere object for role</td>
<td>When required</td>
<td>Required privileges</td>
</tr>
<tr>
<td>------------------------</td>
<td>--------------</td>
<td>--------------------</td>
</tr>
</tbody>
</table>
Additionally, the user requires some **ReadOnly** permissions, and some of the roles require permission to propagate the permissions to child objects. These settings vary depending on whether or not you install the cluster into an existing folder.

### Example 20.2. Required permissions and propagation settings

<table>
<thead>
<tr>
<th>vSphere object for role</th>
<th>When required</th>
<th>Propagate to children</th>
<th>Permissions required</th>
</tr>
</thead>
<tbody>
<tr>
<td>vSphere vCenter</td>
<td>Always</td>
<td>False</td>
<td>Listed required privileges</td>
</tr>
<tr>
<td>vSphere vCenter Datacenter</td>
<td>Existing folder</td>
<td>False</td>
<td><strong>ReadOnly</strong> permission</td>
</tr>
<tr>
<td></td>
<td>Installation program creates the folder</td>
<td>True</td>
<td>Listed required privileges</td>
</tr>
<tr>
<td>vSphere vCenter Cluster</td>
<td>Always</td>
<td>True</td>
<td>Listed required privileges</td>
</tr>
<tr>
<td>vSphere vCenter Datastore</td>
<td>Always</td>
<td>False</td>
<td>Listed required privileges</td>
</tr>
<tr>
<td>vSphere Switch</td>
<td>Always</td>
<td>False</td>
<td><strong>ReadOnly</strong> permission</td>
</tr>
<tr>
<td>vSphere Port Group</td>
<td>Always</td>
<td>False</td>
<td>Listed required privileges</td>
</tr>
<tr>
<td>vSphere vCenter Virtual Machine Folder</td>
<td>Existing folder</td>
<td>True</td>
<td>Listed required privileges</td>
</tr>
</tbody>
</table>

For more information about creating an account with only the required privileges, see [vSphere Permissions and User Management Tasks](#) in the vSphere documentation.

### Using OpenShift Container Platform with vMotion

**IMPORTANT**

OpenShift Container Platform generally supports compute-only vMotion. Using Storage vMotion can cause issues and is not supported.

If you are using vSphere volumes in your pods, migrating a VM across datastores either manually or through Storage vMotion causes invalid references within OpenShift Container Platform persistent volume (PV) objects. These references prevent affected pods from starting up and can result in data loss.
Similarly, OpenShift Container Platform does not support selective migration of VMDKs across datastores, using datastore clusters for VM provisioning or for dynamic or static provisioning of PVs, or using a datastore that is part of a datastore cluster for dynamic or static provisioning of PVs.

**Cluster resources**

When you deploy an OpenShift Container Platform cluster that uses installer-provisioned infrastructure, the installation program must be able to create several resources in your vCenter instance.

A standard OpenShift Container Platform installation creates the following vCenter resources:

- 1 Folder
- 1 Tag category
- 1 Tag
- Virtual machines:
  - 1 template
  - 1 temporary bootstrap node
  - 3 control plane nodes
  - 3 compute machines

Although these resources use 856 GB of storage, the bootstrap node is destroyed during the cluster installation process. A minimum of 800 GB of storage is required to use a standard cluster.

If you deploy more compute machines, the OpenShift Container Platform cluster will use more storage.

**Cluster limits**

Available resources vary between clusters. The number of possible clusters within a vCenter is limited primarily by available storage space and any limitations on the number of required resources. Be sure to consider both limitations to the vCenter resources that the cluster creates and the resources that you require to deploy a cluster, such as IP addresses and networks.

**Networking requirements**

You must use DHCP for the network and ensure that the DHCP server is configured to provide persistent IP addresses to the cluster machines. All nodes must be in the same VLAN. You cannot scale the cluster using a second VLAN as a Day 2 operation. Additionally, you must create the following networking resources before you install the OpenShift Container Platform cluster:

**NOTE**

It is recommended that each OpenShift Container Platform node in the cluster must have access to a Network Time Protocol (NTP) server that is discoverable via DHCP. Installation is possible without an NTP server. However, asynchronous server clocks will cause errors, which NTP server prevents.

**Required IP Addresses**

An installer-provisioned vSphere installation requires two static IP addresses:

- The **API** address is used to access the cluster API.
- The **Ingress** address is used for cluster ingress traffic.
You must provide these IP addresses to the installation program when you install the OpenShift Container Platform cluster.

DNS records
You must create DNS records for two static IP addresses in the appropriate DNS server for the vCenter instance that hosts your OpenShift Container Platform cluster. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the cluster base domain that you specify when you install the cluster. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>`.

Table 20.5. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>API VIP</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>This DNS A/AAAA or CNAME record must point to the load balancer for the control plane machines. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Ingress VIP</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A wildcard DNS A/AAAA or CNAME record that points to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>

20.2.7. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the `core` user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user `core`. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.
Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N " " -f <path>/<file_name>
   ```

   Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the `x86_64` architecture, do not create a key that uses the `ed25519` algorithm. Instead, create a key that uses the `rsa` or `ecdsa` algorithm.

2. View the public SSH key:

   ```bash
   $ cat <path>/<file_name>.pub
   ```

   For example, run the following to view the `~/.ssh/id_rsa.pub` public key:

   ```bash
   $ cat ~/.ssh/id_rsa.pub
   ```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

   **NOTE**

   On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

   a. If the `ssh-agent` process is not already running for your local user, start it as a background task:

   ```bash
   $ eval "$(ssh-agent -s)"
   ```

   **Example output**

   ```bash
   Agent pid 31874
   ```

   **NOTE**

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the `ssh-agent`:
Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

Example output

Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

20.2.8. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on your provisioning machine.

Prerequisites

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

   IMPORTANT

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   IMPORTANT

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   $ ssh-add <path>/<file_name>
5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

20.2.9. Adding vCenter root CA certificates to your system trust

Because the installation program requires access to your vCenter’s API, you must add your vCenter’s trusted root CA certificates to your system trust before you install an OpenShift Container Platform cluster.

Procedure

1. From the vCenter home page, download the vCenter’s root CA certificates. Click Download trusted root CA certificates in the vSphere Web Services SDK section. The <vCenter>/certs/download.zip file downloads.

2. Extract the compressed file that contains the vCenter root CA certificates. The contents of the compressed file resemble the following file structure:

   ```
certs
   ├── lin
   │   ├── 108f4d17.0
   │   ├── 108f4d17.r1
   │   └── 7e757f6a.0
   │         ├── 8e4f8471.0
   │         └── 8e4f8471.r0
   └── mac
        ├── 108f4d17.0
        ├── 108f4d17.r1
        └── 7e757f6a.0
            ├── 8e4f8471.0
            └── 8e4f8471.r0
   └── win
        ├── 108f4d17.0.crt
        ├── 108f4d17.r1.crl
        └── 7e757f6a.0.crt
            └── 8e4f8471.0.crt
                └── 8e4f8471.r0.crl
```

3 directories, 15 files

3. Add the files for your operating system to the system trust. For example, on a Fedora operating system, run the following command:

   ```
   # cp certs/lin/* /etc/pki/ca-trust/source/anchors
   ```

4. Update your system trust. For example, on a Fedora operating system, run the following command:

   ```
   # update-ca-trust extract
   ```

20.2.10. Deploying the cluster
You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

**Prerequisites**

- Configure an account with the cloud platform that hosts your cluster.
- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Change to the directory that contains the installation program and initialize the cluster deployment:

   ```bash
   $ ./openshift-install create cluster --dir <installation_directory> \
   --log-level=info
   ```

   1. For `<installation_directory>`, specify the directory name to store the files that the installation program creates.
   2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

   **IMPORTANT**

   Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

   Provide values at the prompts:

   a. Optional: Select an SSH key to use to access your cluster machines.

      **NOTE**

      For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

   b. Select `vsphere` as the platform to target.

   c. Specify the name of your vCenter instance.

   d. Specify the user name and password for the vCenter account that has the required permissions to create the cluster.

      The installation program connects to your vCenter instance.
e. Select the datacenter in your vCenter instance to connect to.

f. Select the default vCenter datastore to use.

g. Select the vCenter cluster to install the OpenShift Container Platform cluster in. The installation program uses the root resource pool of the vSphere cluster as the default resource pool.

h. Select the network in the vCenter instance that contains the virtual IP addresses and DNS records that you configured.

i. Enter the virtual IP address that you configured for control plane API access.

j. Enter the virtual IP address that you configured for cluster ingress.

k. Enter the base domain. This base domain must be the same one that you used in the DNS records that you configured.

l. Enter a descriptive name for your cluster. The cluster name must be the same one that you used in the DNS records that you configured.

m. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

**IMPORTANT**

Use the openshift-install command from the bastion hosted in the VMC environment.

**NOTE**

If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.

When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the kubeadmin user, display in your terminal.

**Example output**

```
... INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-Wt5AL"
INFO Time elapsed: 36m22s
```

**NOTE**

The cluster access and credential information also outputs to `<installation_directory>/openshift_install.log` when an installation succeeds.
The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

20.2.11. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.10. Download and install the new version of oc.

Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.10 Linux Client entry and save the file.

4. Unpack the archive:

   
   $ tar xvzf <file>

5. Place the oc binary in a directory that is on your PATH.
   To check your PATH, execute the following command:

   
   $ echo $PATH

After you install the OpenShift CLI, it is available using the oc command:
Installing the OpenShift CLI on Windows
You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.
3. Click Download Now next to the OpenShift v4.10 Windows Client entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the oc binary to a directory that is on your PATH.
   To check your PATH, open the command prompt and execute the following command:

   $ path

After you install the OpenShift CLI, it is available using the oc command:

$ oc <command>

Installing the OpenShift CLI on macOS
You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.
3. Click Download Now next to the OpenShift v4.10 MacOSX Client entry and save the file.
4. Unpack and unzip the archive.
5. Move the oc binary to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:

   $ echo $PATH

After you install the OpenShift CLI, it is available using the oc command:

$ oc <command>

20.2.12. Logging in to the cluster by using the CLI
You can log in to your cluster as a default system user by exporting the cluster kubeconfig file. The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container
Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the oc CLI.

Procedure

1. Export the kubeadmin credentials:

   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run oc commands successfully using the exported configuration:

   $ oc whoami

   Example output

   system:admin

20.2.13. Creating registry storage

After you install the cluster, you must create storage for the registry Operator.

20.2.13.1. Image registry removed during installation

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as Removed. This allows openshift-installer to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the managementState from Removed to Managed.

NOTE

The Prometheus console provides an ImageRegistryRemoved alert, for example:

"Image Registry has been removed. ImageStreamTags, BuildConfigs and DeploymentConfigs which reference ImageStreamTags may not work as expected. Please configure storage and update the config to Managed state by editing configs.imageregistry.operator.openshift.io."

20.2.13.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.
Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the **Recreate** rollout strategy during upgrades.

### 20.2.13.2.1 Configuring registry storage for VMware vSphere

As a cluster administrator, following installation you must configure your registry to use storage.

**Prerequisites**

- Cluster administrator permissions.
- A cluster on VMware vSphere.
- Persistent storage provisioned for your cluster, such as Red Hat OpenShift Data Foundation.

**IMPORTANT**

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have "100Gi" capacity.

**IMPORTANT**

Testing shows issues with using the NFS server on RHEL as storage backend for core services. This includes the OpenShift Container Registry and Quay, Prometheus for monitoring storage, and Elasticsearch for logging storage. Therefore, using RHEL NFS to back PVs used by core services is not recommended.

Other NFS implementations on the marketplace might not have these issues. Contact the individual NFS implementation vendor for more information on any testing that was possibly completed against these OpenShift Container Platform core components.

**Procedure**

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

   **NOTE**

   When using shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

   ```bash
   $ oc get pod -n openshift-image-registry -l docker-registry=default
   ```
Example output

No resources found in openshift-image-registry namespace

NOTE

If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

$ oc edit configs.imageregistry.operator.openshift.io

Example output

storage:
pvc:
  claim: 1

Leave the **claim** field blank to allow the automatic creation of an `image-registry-storage` PVC.

4. Check the **clusteroperator** status:

$ oc get clusteroperator image-registry

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
<th>SINCE</th>
<th>MESSAGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>image-registry</td>
<td>4.7</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>6h50m</td>
<td></td>
</tr>
</tbody>
</table>

20.2.13.2.2. Configuring block registry storage for VMware vSphere

To allow the image registry to use block storage types such as vSphere Virtual Machine Disk (VMDK) during upgrades as a cluster administrator, you can use the **Recreate** rollout strategy.

**IMPORTANT**

Block storage volumes are supported but not recommended for use with image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

**Procedure**

1. To set the image registry storage as a block storage type, patch the registry so that it uses the **Recreate** rollout strategy and runs with only 1 replica:

   $ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec": {
   "rolloutStrategy": "Recreate",
   "replicas": 1
   }}'}
2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.

   a. Create a **pvc.yaml** file with the following contents to define a VMware vSphere *PersistentVolumeClaim* object:

      ```yaml
      kind: PersistentVolumeClaim
      apiVersion: v1
      metadata:
        name: image-registry-storage
        namespace: openshift-image-registry
      spec:
        accessModes:
          - ReadWriteOnce
        resources:
          requests:
            storage: 100Gi
      ```

      1. A unique name that represents the *PersistentVolumeClaim* object.
      2. The namespace for the *PersistentVolumeClaim* object, which is *openshift-image-registry*.
      3. The access mode of the persistent volume claim. With *ReadWriteOnce*, the volume can be mounted with read and write permissions by a single node.
      4. The size of the persistent volume claim.

   b. Create the *PersistentVolumeClaim* object from the file:

      ```bash
      $ oc create -f pvc.yaml -n openshift-image-registry
      ```

3. Edit the registry configuration so that it references the correct PVC:

      ```bash
      $ oc edit config.imageregistry.operator.openshift.io -o yaml
      ```

   **Example output**

      ```yaml
      storage:
      pvc:
        claim: image-registry-storage
      ```

      1. Creating a custom PVC allows you to leave the **claim** field blank for the default automatic creation of an **image-registry-storage** PVC.

For instructions about configuring registry storage so that it references the correct PVC, see [Configuring the registry for vSphere](#).

### 20.2.14. Backing up VMware vSphere volumes

OpenShift Container Platform provisions new volumes as independent persistent disks to freely attach and detach the volume on any node in the cluster. As a consequence, it is not possible to back up
volumes that use snapshots, or to restore volumes from snapshots. See Snapshot Limitations for more information.

**Procedure**

To create a backup of persistent volumes:

1. Stop the application that is using the persistent volume.
2. Clone the persistent volume.
3. Restart the application.
4. Create a backup of the cloned volume.
5. Delete the cloned volume.

20.2.15. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.10, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- See About remote health monitoring for more information about the Telemetry service

20.2.16. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- Set up your registry and configure registry storage.
- Optional: View the events from the vSphere Problem Detector Operator to determine if the cluster has permission or storage configuration issues.

20.3. INSTALLING A CLUSTER ON VMC WITH CUSTOMIZATIONS

In OpenShift Container Platform version 4.10, you can install a cluster on your VMware vSphere instance using installer-provisioned infrastructure by deploying it to VMware Cloud (VMC) on AWS.

Once you configure your VMC environment for OpenShift Container Platform deployment, you use the OpenShift Container Platform installation program from the bastion management host, co-located in the VMC environment. The installation program and control plane automates the process of deploying and managing the resources needed for the OpenShift Container Platform cluster.

To customize the OpenShift Container Platform installation, you modify parameters in the install-config.yaml file before you install the cluster.
20.3.1. Setting up VMC for vSphere

You can install OpenShift Container Platform on VMware Cloud (VMC) on AWS hosted vSphere clusters to enable applications to be deployed and managed both on-premise and off-premise, across the hybrid cloud.

You must configure several options in your VMC environment prior to installing OpenShift Container Platform on VMware vSphere. Ensure your VMC environment has the following prerequisites:

- Create a non-exclusive, DHCP-enabled, NSX-T network segment and subnet. Other virtual machines (VMs) can be hosted on the subnet, but at least eight IP addresses must be available for the OpenShift Container Platform deployment.

- Allocate two IP addresses, outside the DHCP range, and configure them with reverse DNS records.
  - A DNS record for `api.<cluster_name>.<base_domain>` pointing to the allocated IP address.
  - A DNS record for `*.apps.<cluster_name>.<base_domain>` pointing to the allocated IP address.

- Configure the following firewall rules:
  - An ANY:ANY firewall rule between the OpenShift Container Platform compute network and the internet. This is used by nodes and applications to download container images.
  - An ANY:ANY firewall rule between the installation host and the software-defined data center (SDDC) management network on port 443. This allows you to upload the Red Hat Enterprise Linux CoreOS (RHCOS) OVA during deployment.
  - An HTTPS firewall rule between the OpenShift Container Platform compute network and vCenter. This connection allows OpenShift Container Platform to communicate with vCenter for provisioning and managing nodes, persistent volume claims (PVCs), and other resources.

- You must have the following information to deploy OpenShift Container Platform:
  - The OpenShift Container Platform cluster name, such as `vmc-prod-1`.
  - The base DNS name, such as `companyname.com`.
  - If not using the default, the pod network CIDR and services network CIDR must be identified, which are set by default to `10.128.0.0/14` and `172.30.0.0/16`, respectively. These CIDRs are used for pod-to-pod and pod-to-service communication and are not accessible externally; however, they must not overlap with existing subnets in your organization.
The following vCenter information:
- vCenter hostname, username, and password
- Datacenter name, such as **SDDC-Datacenter**
- Cluster name, such as **Cluster-1**
- Network name
- Datastore name, such as **WorkloadDatastore**

**NOTE**
It is recommended to move your vSphere cluster to the VMC **Compute-ResourcePool** resource pool after your cluster installation is finished.

- A Linux-based host deployed to VMC as a bastion.
  - The bastion host can be Red Hat Enterprise Linux (RHEL) or any another Linux-based host; it must have internet connectivity and the ability to upload an OVA to the ESXi hosts.
  - Download and install the OpenShift CLI tools to the bastion host.
    - The `openshift-install` installation program
    - The OpenShift CLI (**oc**) tool

**NOTE**
You cannot use the VMware NSX Container Plug-in for Kubernetes (NCP), and NSX is not used as the OpenShift SDN. The version of NSX currently available with VMC is incompatible with the version of NCP certified with OpenShift Container Platform.

However, the NSX DHCP service is used for virtual machine IP management with the full-stack automated OpenShift Container Platform deployment and with nodes provisioned, either manually or automatically, by the Machine API integration with vSphere. Additionally, NSX firewall rules are created to enable access with the OpenShift Container Platform cluster and between the bastion host and the VMC vSphere hosts.

### 20.3.1.1. VMC Sizer tool

VMware Cloud on AWS is built on top of AWS bare metal infrastructure; this is the same bare metal infrastructure which runs AWS native services. When a VMware cloud on AWS software-defined data center (SDDC) is deployed, you consume these physical server nodes and run the VMware ESXi hypervisor in a single tenant fashion. This means the physical infrastructure is not accessible to anyone else using VMC. It is important to consider how many physical hosts you will need to host your virtual infrastructure.

To determine this, VMware provides the **VMC on AWS Sizer**. With this tool, you can define the resources you intend to host on VMC:
- Types of workloads
- Total number of virtual machines
• Specification information such as:
  o Storage requirements
  o vCPUs
  o vRAM
  o Overcommit ratios

With these details, the sizer tool can generate a report, based on VMware best practices, and recommend your cluster configuration and the number of hosts you will need.

20.3.2. vSphere prerequisites

• You reviewed details about the OpenShift Container Platform installation and update processes.

• You read the documentation on selecting a cluster installation method and preparing it for users.

• You provisioned block registry storage. For more information on persistent storage, see Understanding persistent storage.

• If you use a firewall, you configured it to allow the sites that your cluster requires access to.

  **NOTE**

  Be sure to also review this site list if you are configuring a proxy.

20.3.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.10, you require access to the internet to install your cluster.

You must have internet access to:

• Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

• Access Quay.io to obtain the packages that are required to install your cluster.

• Obtain the packages that are required to perform cluster updates.

  **IMPORTANT**

  If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

20.3.4. VMware vSphere infrastructure requirements
You must install the OpenShift Container Platform cluster on a VMware vSphere version 6 or 7 instance that meets the requirements for the components that you use.

Table 20.6. Version requirements for vSphere virtual environments

<table>
<thead>
<tr>
<th>Virtual environment product</th>
<th>Required version</th>
</tr>
</thead>
<tbody>
<tr>
<td>VM hardware version</td>
<td>13 or later</td>
</tr>
<tr>
<td>vSphere ESXi hosts</td>
<td>6.5 or later</td>
</tr>
<tr>
<td>vCenter host</td>
<td>6.5 or later</td>
</tr>
</tbody>
</table>

**IMPORTANT**

Installing a cluster on VMware vSphere version 6.7U3 or earlier and virtual hardware version 13 is now deprecated. These versions are still fully supported, but version 4.11 of OpenShift Container Platform will require vSphere virtual hardware version 15 or later. Hardware version 15 is now the default for vSphere virtual machines in OpenShift Container Platform. To update the hardware version for your vSphere nodes, see the "Updating hardware on nodes running in vSphere" article.

If your vSphere nodes are below hardware version 15 or your VMware vSphere version is earlier than 6.7U3, upgrading from OpenShift Container Platform 4.10 to OpenShift Container Platform 4.11 is not available.

Table 20.7. Minimum supported vSphere version for VMware components

<table>
<thead>
<tr>
<th>Component</th>
<th>Minimum supported versions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hypervisor</td>
<td>vSphere 6.5 and later with HW version 13</td>
<td>This version is the minimum version that Red Hat Enterprise Linux CoreOS (RHCOS) supports. See the Red Hat Enterprise Linux 8 supported hypervisors list.</td>
</tr>
<tr>
<td>Storage with in-tree drivers</td>
<td>vSphere 6.5 and later</td>
<td>This plug-in creates vSphere storage by using the in-tree storage drivers for vSphere included in OpenShift Container Platform.</td>
</tr>
</tbody>
</table>

If you use a vSphere version 6.5 instance, consider upgrading to 6.7U3 or 7.0 before you install OpenShift Container Platform.

**IMPORTANT**

You must ensure that the time on your ESXi hosts is synchronized before you install OpenShift Container Platform. See Edit Time Configuration for a Host in the VMware documentation.
20.3.5. VMware vSphere CSI Driver Operator requirements

The following requirements must be met in order to install the CSI Driver Operator:

- VMware vSphere version 6.7U3 or later
- Virtual machines of hardware version 15 or later
- No third-party CSI driver already installed in the cluster

If a third-party CSI driver is present in the cluster, OpenShift Container Platform does not overwrite it. The presence of a third-party CSI driver prevents OpenShift Container Platform from upgrading to 4.11.

Additional resources

- To remove a third-party CSI driver, see Removing a third-party vSphere CSI Driver.
- To update the hardware version for your vSphere nodes, see Updating hardware on nodes running in vSphere.

20.3.6. vCenter requirements

Before you install an OpenShift Container Platform cluster on your vCenter that uses infrastructure that the installer provisions, you must prepare your environment.

Required vCenter account privileges

To install an OpenShift Container Platform cluster in a vCenter, the installation program requires access to an account with privileges to read and create the required resources. Using an account that has global administrative privileges is the simplest way to access all of the necessary permissions.

If you cannot use an account with global administrative privileges, you must create roles to grant the privileges necessary for OpenShift Container Platform cluster installation. While most of the privileges are always required, some are required only if you plan for the installation program to provision a folder to contain the OpenShift Container Platform cluster on your vCenter instance, which is the default behavior. You must create or amend vSphere roles for the specified objects to grant the required privileges.

An additional role is required if the installation program is to create a vSphere virtual machine folder.

Example 20.3. Roles and privileges required for installation

<table>
<thead>
<tr>
<th>vSphere object for role</th>
<th>When required</th>
<th>Required privileges</th>
</tr>
</thead>
</table>

CHAPTER 20. INSTALLING ON VMC
<table>
<thead>
<tr>
<th>vSphere object for role</th>
<th>When required</th>
<th>Required privileges</th>
</tr>
</thead>
<tbody>
<tr>
<td>vSphere vCenter</td>
<td>Always</td>
<td>Cns.Searchable</td>

<td>Required privileges</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>-------------------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
Additionally, the user requires some **ReadOnly** permissions, and some of the roles require permission to propagate the permissions to child objects. These settings vary depending on whether or not you install the cluster into an existing folder.

### Example 20.4. Required permissions and propagation settings

<table>
<thead>

<td>Existing folder</td>
<td>True</td>
<td>Listed required privileges</td>
</tr>
<tr>
<td>Virtual Machine Folder</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

For more information about creating an account with only the required privileges, see **vSphere Permissions and User Management Tasks** in the vSphere documentation.

### Using OpenShift Container Platform with vMotion

**IMPORTANT**

OpenShift Container Platform generally supports compute-only vMotion. Using Storage vMotion can cause issues and is not supported.

If you are using vSphere volumes in your pods, migrating a VM across datastores either manually or through Storage vMotion causes invalid references within OpenShift Container Platform persistent volume (PV) objects. These references prevent affected pods from starting up and can result in data loss.
Similarly, OpenShift Container Platform does not support selective migration of VMDKs across datastores, using datastore clusters for VM provisioning or for dynamic or static provisioning of PVs, or using a datastore that is part of a datastore cluster for dynamic or static provisioning of PVs.

**Cluster resources**

When you deploy an OpenShift Container Platform cluster that uses installer-provisioned infrastructure, the installation program must be able to create several resources in your vCenter instance.

A standard OpenShift Container Platform installation creates the following vCenter resources:

- 1 Folder
- 1 Tag category
- 1 Tag
- Virtual machines:
  - 1 template
  - 1 temporary bootstrap node
  - 3 control plane nodes
  - 3 compute machines

Although these resources use 856 GB of storage, the bootstrap node is destroyed during the cluster installation process. A minimum of 800 GB of storage is required to use a standard cluster.

If you deploy more compute machines, the OpenShift Container Platform cluster will use more storage.

**Cluster limits**

Available resources vary between clusters. The number of possible clusters within a vCenter is limited primarily by available storage space and any limitations on the number of required resources. Be sure to consider both limitations to the vCenter resources that the cluster creates and the resources that you require to deploy a cluster, such as IP addresses and networks.

**Networking requirements**

You must use DHCP for the network and ensure that the DHCP server is configured to provide persistent IP addresses to the cluster machines. All nodes must be in the same VLAN. You cannot scale the cluster using a second VLAN as a Day 2 operation. Additionally, you must create the following networking resources before you install the OpenShift Container Platform cluster:

**NOTE**

It is recommended that each OpenShift Container Platform node in the cluster must have access to a Network Time Protocol (NTP) server that is discoverable via DHCP. Installation is possible without an NTP server. However, asynchronous server clocks will cause errors, which NTP server prevents.

**Required IP Addresses**

An installer-provisioned vSphere installation requires two static IP addresses:

- The **API** address is used to access the cluster API.
- The **Ingress** address is used for cluster ingress traffic.
You must provide these IP addresses to the installation program when you install the OpenShift Container Platform cluster.

DNS records
You must create DNS records for two static IP addresses in the appropriate DNS server for the vCenter instance that hosts your OpenShift Container Platform cluster. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the cluster base domain that you specify when you install the cluster. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>`.

Table 20.8. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>API VIP</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>This DNS A/AAAA or CNAME record must point to the load balancer for the control plane machines. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Ingress VIP</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A wildcard DNS A/AAAA or CNAME record that points to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>

20.3.7. Generating a key pair for cluster node SSH access
During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the `core` user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user `core`. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.
Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N " -f <path>/<file_name>
   1
   ```

   Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the `ed25519` algorithm. Instead, create a key that uses the `rsa` or `ecdsa` algorithm.

2. View the public SSH key:

   ```bash
   $ cat <path>/<file_name>.pub
   ```

   For example, run the following to view the `~/.ssh/id_rsa.pub` public key:

   ```bash
   $ cat ~/.ssh/id_rsa.pub
   ```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

   **NOTE**

   On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

   a. If the `ssh-agent` process is not already running for your local user, start it as a background task:

   ```bash
   $ eval "$(ssh-agent -s)"
   ```

   **Example output**

   ```bash
   Agent pid 31874
   ```

   **NOTE**

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the `ssh-agent`:

```bash
```
$ ssh-add <path>/<file_name>  
Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

Example output

Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

20.3.8. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on your provisioning machine.

Prerequisites

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

**IMPORTANT**

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

$ tar -xvf openshift-install-linux.tar.gz
5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 20.3.9. Adding vCenter root CA certificates to your system trust

Because the installation program requires access to your vCenter’s API, you must add your vCenter’s trusted root CA certificates to your system trust before you install an OpenShift Container Platform cluster.

#### Procedure

1. From the vCenter home page, download the vCenter’s root CA certificates. Click Download trusted root CA certificates in the vSphere Web Services SDK section. The `<vCenter>/certs/download.zip` file downloads.

2. Extract the compressed file that contains the vCenter root CA certificates. The contents of the compressed file resemble the following file structure:

   ```
   certs
   ├── lin
   │   ├── 108f4d17.0
   │   ├── 108f4d17.r1
   │   ├── 7e757f6a.0
   │   │   ├── 8e4f8471.0
   │   │   └── 8e4f8471.r0
   │   └── 8e4f8471.r0
   │   └── mac
   │       ├── 108f4d17.0
   │       ├── 108f4d17.r1
   │       ├── 7e757f6a.0
   │       │   ├── 8e4f8471.0
   │       │   └── 8e4f8471.r0
   │       └── win
   │           ├── 108f4d17.0.crt
   │           ├── 108f4d17.r1.crl
   │           ├── 7e757f6a.0.crt
   │           └── 8e4f8471.0.crt
   │               └── 8e4f8471.r0.crt
   └── win
   3 directories, 15 files
   ```

3. Add the files for your operating system to the system trust. For example, on a Fedora operating system, run the following command:

   ```
   # cp certs/lin/* /etc/pki/ca-trust/source/anchors
   ```

4. Update your system trust. For example, on a Fedora operating system, run the following command:

   ```
   # update-ca-trust extract
   ```

### 20.3.10. Creating the installation configuration file

2844
You can customize the OpenShift Container Platform cluster you install on VMware vSphere.

**Prerequisites**

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.
- Obtain service principal permissions at the subscription level.

**Procedure**

1. Create the `install-config.yaml` file.
   
   a. Change to the directory that contains the installation program and run the following command:

   ```bash
   $ ./openshift-install create install-config --dir <installation_directory>
   ``

   **IMPORTANT**
   
   Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

   b. At the prompts, provide the configuration details for your cloud:

   i. Optional: Select an SSH key to use to access your cluster machines.

   **NOTE**
   
   For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

   ii. Select `vsphere` as the platform to target.

   iii. Specify the name of your vCenter instance.

   iv. Specify the user name and password for the vCenter account that has the required permissions to create the cluster.
   
   The installation program connects to your vCenter instance.

   v. Select the datacenter in your vCenter instance to connect to.

   vi. Select the default vCenter datastore to use.
vii. Select the vCenter cluster to install the OpenShift Container Platform cluster in. The installation program uses the root resource pool of the vSphere cluster as the default resource pool.

viii. Select the network in the vCenter instance that contains the virtual IP addresses and DNS records that you configured.

ix. Enter the virtual IP address that you configured for control plane API access.

x. Enter the virtual IP address that you configured for cluster ingress.

xi. Enter the base domain. This base domain must be the same one that you used in the DNS records that you configured.

xii. Enter a descriptive name for your cluster. The cluster name must be the same one that you used in the DNS records that you configured.

xiii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

2. Modify the `install-config.yaml` file. You can find more information about the available parameters in the "Installation configuration parameters" section.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>apiVersion</code></td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is <code>v1</code>. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------</td>
</tr>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the baseDomain and metadata.name parameter values that uses the &lt;metadata.name&gt;.&lt;baseDomain&gt; format.</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
</tr>
<tr>
<td>metadata</td>
<td>Kubernetes resource ObjectMeta, from which only the name parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of {{.metadata.name}}.{{.baseDomain}}.</td>
<td>String of lowercase letters, hyphens (-), and periods (.), such as dev.</td>
</tr>
<tr>
<td>platform</td>
<td>The configuration for the specific platform upon which to perform the installation: alibabacloud, aws, baremetal, azure, ibmcloud, openstack, ovirt, vsphere, or {}. For additional information about platform.&lt;platform&gt; parameters, consult the table for your specific platform that follows.</td>
<td>Object</td>
</tr>
</tbody>
</table>
Get a `<pullSecret>` from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.

```json
{
  "auths":{
    "cloud.openshift.com":{
      "auth":"b3Blb=",
      "email":"you@example.com"
    },
    "quay.io":{
      "auth":"b3Blb=",
      "email":"you@example.com"
    }
  }
}
```

### 20.3.10.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

**Table 20.10. Network parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>networking</strong></td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td><strong>networking.network</strong></td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either <strong>OpenShiftSDN</strong> or <strong>OVNKubernetes</strong>. The default value is <strong>OpenShiftSDN</strong>.</td>
</tr>
<tr>
<td><strong>networking.clusterNetwork</strong></td>
<td>The IP address blocks for pods.</td>
<td>An array of objects. For example: networking: clusterNetwork: - cidr: 10.128.0.0/14 hostPrefix: 23</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The default value is <strong>10.128.0.0/14</strong> with a host prefix of <strong>/23</strong>.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>If you specify multiple IP address blocks, the blocks must not overlap.</td>
</tr>
</tbody>
</table>
### Parameter Description Values

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking.clusterNetwork.cidr</td>
<td>Required if you use networking.clusterNetwork. An IP address block. An IPv4 network.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td>networking.clusterNetwork.hostPrefix</td>
<td>The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given cidr. A hostPrefix value of 23 provides 510 ((2^{32} - 23) - 2) pod IP addresses.</td>
<td>A subnet prefix. The default value is 23.</td>
</tr>
<tr>
<td>networking.serviceNetwork</td>
<td>The IP address block for services. The default value is 172.30.0.0/16. The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.</td>
<td>An array with an IP address block in CIDR format. For example:</td>
</tr>
<tr>
<td>networking:serviceNetwork: -</td>
<td>networking: serviceNetwork: - 172.30.0.0/16</td>
<td></td>
</tr>
<tr>
<td>networking.machineNetwork</td>
<td>The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap. If you specify multiple IP kernel arguments, the machineNetwork.cidr value must be the CIDR of the primary network.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td>networking:machineNetwork: -</td>
<td>networking: machineNetwork: - cidr: 10.0.0.0/16</td>
<td></td>
</tr>
<tr>
<td>networking.machineNetwork.cidr</td>
<td>Required if you use networking.machineNetwork. An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24.</td>
<td>An IP network block in CIDR notation. For example, 10.0.0.0/16.</td>
</tr>
</tbody>
</table>

#### NOTE
Set the networking.machineNetwork to match the CIDR that the preferred NIC resides in.

20.3.10.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>cgroupsV2</td>
<td>Enables [Linux control groups version 2 (cgroups v2)] on specific nodes in your cluster. The OpenShift Container Platform process for enabling cgroups v2 disables all cgroup version 1 controllers and hierarchies. The OpenShift Container Platform cgroups version 2 feature is in Developer Preview and is not supported by Red Hat at this time.</td>
<td>true</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of <strong>MachinePool</strong> objects.</td>
</tr>
<tr>
<td>compute.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <strong>s390x</strong> (the default).</td>
<td>String</td>
</tr>
<tr>
<td>compute.hyperthreading</td>
<td>Whether to enable or disable simultaneous multithreading, or <strong>hyperthreading</strong>, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td>Enabled or Disabled</td>
</tr>
</tbody>
</table>

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.

<p>| compute.name        | Required if you use <strong>compute</strong>. The name of the machine pool.                                                                                                                                               | worker              |</p>
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>compute.platform</strong></td>
<td>Required if you use <code>compute</code>. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <code>controlPlane.platform</code> parameter value.</td>
<td><code>alibaba, aws, azure, gcp, ibmcloud, openstack, ovirt, vsphere, or {}</code></td>
</tr>
<tr>
<td><strong>compute.replicas</strong></td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td><strong>controlPlane</strong></td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of <code>MachinePool</code> objects.</td>
</tr>
<tr>
<td><strong>controlPlane.architecture</strong></td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>s390x</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td><strong>controlPlane.hypertreading</strong></td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td><strong>controlPlane.name</strong></td>
<td>Required if you use <code>controlPlane</code>. The name of the machine pool.</td>
<td><code>master</code></td>
</tr>
<tr>
<td><strong>controlPlane.platform</strong></td>
<td>Required if you use <code>controlPlane</code>. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the <code>compute.platform</code> parameter value.</td>
<td><code>alibaba, aws, azure, gcp, ibmcloud, openstack, ovirt, vsphere, or {}</code></td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>----------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------</td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is <strong>3</strong>, which is the default value.</td>
</tr>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO</td>
<td><strong>Mint</strong>, <strong>Passthrough</strong>, <strong>Manual</strong>, or an empty string (&quot;&quot;).</td>
</tr>
<tr>
<td></td>
<td>dynamically tries to determine the capabilities of the provided credentials,</td>
<td></td>
</tr>
<tr>
<td></td>
<td>with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td></td>
</tr>
</tbody>
</table>

**NOTE**

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Platform Operators reference content.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>fips</td>
<td>Enable or disable FIPS mode. The default is <strong>false</strong> (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</td>
<td><strong>false</strong> or <strong>true</strong></td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the <strong>x86_64</strong> architecture.</td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you are using Azure File storage, you cannot enable FIPS mode.</td>
<td></td>
</tr>
<tr>
<td>imageContentSources</td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects. Includes a <strong>source</strong> and, optionally, <strong>mirrors</strong>, as described in the following rows of this table.</td>
</tr>
<tr>
<td>imageContentSources.source</td>
<td>Required if you use <strong>imageContentSources</strong>. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td>imageContentSources.mirrors</td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
</tbody>
</table>
How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.

Setting this field to **Internal** is not supported on non-cloud platforms and IBM Cloud.

**IMPORTANT**

If the value of the field is set to **Internal**, the cluster will become non-functional. For more information, refer to [BZ#1953035](#).

The SSH key or keys to authenticate access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

One or more keys. For example:

```
sshKey: <key1>
<key2>
<key3>
```

### 20.3.10.1.4. Additional VMware vSphere configuration parameters

Additional VMware vSphere configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>platform.vsphere.vCenter</code></td>
<td>The fully-qualified hostname or IP address of the vCenter server.</td>
<td>String</td>
</tr>
<tr>
<td><code>platform.vsphere.username</code></td>
<td>The user name to use to connect to the vCenter instance with. This user must have at least the roles and privileges that are required for static or dynamic persistent volume provisioning in vSphere.</td>
<td>String</td>
</tr>
</tbody>
</table>

---

2854
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>platform.vsphere.password</code></td>
<td>The password for the vCenter user name.</td>
<td>String</td>
</tr>
<tr>
<td><code>platform.vsphere.datacenter</code></td>
<td>The name of the datacenter to use in the vCenter instance.</td>
<td>String</td>
</tr>
<tr>
<td><code>platform.vsphere.defaultDatastore</code></td>
<td>The name of the default datastore to use for provisioning volumes.</td>
<td>String</td>
</tr>
<tr>
<td><code>platform.vsphere.folder</code></td>
<td>Optional. The absolute path of an existing folder where the installation program creates the virtual machines. If you do not provide this value, the installation program creates a folder that is named with the infrastructure ID in the datacenter virtual machine folder.</td>
<td>String, for example, <code>/&lt;datacenter_name&gt;/vm/&lt;folder_name&gt;/&lt;subfolder_name&gt;</code></td>
</tr>
<tr>
<td><code>platform.vsphere.network</code></td>
<td>The network in the vCenter instance that contains the virtual IP addresses and DNS records that you configured.</td>
<td>String</td>
</tr>
<tr>
<td><code>platform.vsphere.cluster</code></td>
<td>The vCenter cluster to install the OpenShift Container Platform cluster in.</td>
<td>String</td>
</tr>
<tr>
<td><code>platform.vsphere.apiVIP</code></td>
<td>The virtual IP (VIP) address that you configured for control plane API access.</td>
<td>An IP address, for example 128.0.0.1.</td>
</tr>
<tr>
<td><code>platform.vsphere.ingressVIP</code></td>
<td>The virtual IP (VIP) address that you configured for cluster ingress.</td>
<td>An IP address, for example 128.0.0.1.</td>
</tr>
<tr>
<td><code>platform.vsphere.diskType</code></td>
<td>Optional. The disk provisioning method. This value defaults to the vSphere default storage policy if not set.</td>
<td>Valid values are thin, thick, or eagerZeroedThick.</td>
</tr>
</tbody>
</table>

20.3.10.1.5. Optional VMware vSphere machine pool configuration parameters

Optional VMware vSphere machine pool configuration parameters are described in the following table:

Table 20.13. Optional VMware vSphere machine pool parameters
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>platform.vsphere.clusterOSImage</code></td>
<td>The location from which the installer downloads the RHCOS image. You must set this parameter to perform an installation in a restricted network.</td>
<td>An HTTP or HTTPS URL, optionally with a SHA-256 checksum. For example, <a href="https://mirror.openshift.com/images/rhcos-">https://mirror.openshift.com/images/rhcos-</a>&lt;version&gt;-vmware.&lt;architecture&gt;.ova.</td>
</tr>
<tr>
<td><code>platform.vsphere.osDisk.diskSizeGB</code></td>
<td>The size of the disk in gigabytes.</td>
<td>Integer</td>
</tr>
<tr>
<td><code>platform.vsphere.cpus</code></td>
<td>The total number of virtual processor cores to assign a virtual machine.</td>
<td>Integer</td>
</tr>
<tr>
<td><code>platform.vsphere.coresPerSocket</code></td>
<td>The number of cores per socket in a virtual machine. The number of virtual sockets on the virtual machine is <code>platform.vsphere.cpus/platform.vsphere.coresPerSocket</code>. The default value is 1.</td>
<td>Integer</td>
</tr>
<tr>
<td><code>platform.vsphere.memoryMB</code></td>
<td>The size of a virtual machine’s memory in megabytes.</td>
<td>Integer</td>
</tr>
</tbody>
</table>

20.3.10.2. Sample `install-config.yaml` file for an installer-provisioned VMware vSphere cluster

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute: 2
  - hyperthreading: Enabled
    name: worker
    replicas: 3
    platform:
      vsphere: 4
        cpus: 2
        coresPerSocket: 2
        memoryMB: 8196
        osDisk:
          diskSizeGB: 120
controlPlane: 5
  hyperthreading: Enabled
  name: master
  replicas: 3
  platform:
```
The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

The **controlPlane** section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, -, and the first line of the controlPlane section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading, or **hyperthreading**. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to Disabled. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Your machines must use at least 8 CPUs and 32 GB of RAM if you disable simultaneous multithreading.

Optional: Provide additional configuration for the machine pool parameters for the compute and control plane machines.

The cluster name that you specified in your DNS records.

The vSphere disk provisioning method.

The vSphere cluster to install the OpenShift Container Platform cluster in. The installation program uses the root resource pool of the vSphere cluster as the default resource pool.
20.3.10.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

Prerequisites

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the Proxy object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The Proxy object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port>  # 1
  httpsProxy: https://<username>:<pswd>@<ip>:<port>  # 2
  noProxy: example.com  # 3
  additionalTrustBundle: |
    -----BEGIN CERTIFICATE-----
    <MY_TRUSTED_CA_CERT>
    -----END CERTIFICATE-----
    ...
```

1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.
2. A proxy URL to use for creating HTTPS connections outside the cluster.
3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, `.y.com` matches `x.y.com`, but not `y.com`. Use * to bypass the proxy for all destinations. You must include vCenter's IP address and the IP range that you use for its machines.
4. If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then
that are required for proxying HTTPS connections. The Cluster Network Operator then creates a **trusted-ca-bundle** config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the **trustedCA** field of the **Proxy** object. The **additionalTrustBundle** field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

**NOTE**

The installation program does not support the proxy **readinessEndpoints** field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

**NOTE**

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

### 20.3.11. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the **create cluster** command of the installation program only once, during initial installation.

#### Prerequisites

- Configure an account with the cloud platform that hosts your cluster.
- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

#### Procedure

1. Change to the directory that contains the installation program and initialize the cluster deployment:

   ```bash
   $ ./openshift-install create cluster --dir <installation_directory> \
   --log-level=info
   ```

   1. For `<installation_directory>`, specify the location of your customized `/install-config.yaml` file.

   2. To view different installation details, specify **warn**, **debug**, or **error** instead of **info**.
IMPORTANT

Use the `openshift-install` command from the bastion hosted in the VMC environment.

NOTE

If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.

When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the `kubeadmin` user, display in your terminal.

Example output

```
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-Wt5AL"
INFO Time elapsed: 36m22s
```

NOTE

The cluster access and credential information also outputs to `<installation_directory>/openshift_install.log` when an installation succeeds.

IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

IMPORTANT

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.
20.3.12. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

IMPORTANT

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.10. Download and install the new version of oc.

Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.10 Linux Client entry and save the file.

4. Unpack the archive:

   $ tar xvzf <file>

5. Place the oc binary in a directory that is on your PATH.
   To check your PATH, execute the following command:

   $ echo $PATH

After you install the OpenShift CLI, it is available using the oc command:

   $ oc <command>

Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.10 Windows Client entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the oc binary to a directory that is on your PATH.
   To check your PATH, open the command prompt and execute the following command:

   C:\> path
After you install the OpenShift CLI, it is available using the `oc` command:

```
C:> oc <command>
```

### Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (`oc`) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.

3. Click **Download Now** next to the **OpenShift v4.10 MacOSX Client** entry and save the file.

4. Unpack and unzip the archive.

5. Move the `oc` binary to a directory on your **PATH**. To check your **PATH**, open a terminal and execute the following command:

```
$ echo $PATH
```

After you install the OpenShift CLI, it is available using the `oc` command:

```
$ oc <command>
```

### 20.3.13. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig
```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

```
$ oc whoami
```
20.3.14. Creating registry storage

After you install the cluster, you must create storage for the Registry Operator.

20.3.14.1. Image registry removed during installation

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as Removed. This allows openshift-installer to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the managementState from Removed to Managed.

NOTE

The Prometheus console provides an ImageRegistryRemoved alert, for example:

"Image Registry has been removed. ImageStreamTags, BuildConfigs and DeploymentConfigs which reference ImageStreamTags may not work as expected. Please configure storage and update the config to Managed state by editing configs.imageregistry.operator.openshift.io."

20.3.14.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the Recreate rollout strategy during upgrades.

20.3.14.2.1. Configuring registry storage for VMware vSphere

As a cluster administrator, following installation you must configure your registry to use storage.

Prerequisites

- Cluster administrator permissions.
- A cluster on VMware vSphere.
- Persistent storage provisioned for your cluster, such as Red Hat OpenShift Data Foundation.
IMPORTANT

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have "100Gi" capacity.

IMPORTANT

Testing shows issues with using the NFS server on RHEL as storage backend for core services. This includes the OpenShift Container Registry and Quay, Prometheus for monitoring storage, and Elasticsearch for logging storage. Therefore, using RHEL NFS to back PVs used by core services is not recommended.

Other NFS implementations on the marketplace might not have these issues. Contact the individual NFS implementation vendor for more information on any testing that was possibly completed against these OpenShift Container Platform core components.

Procedure

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

   **NOTE**

   When using shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

   ```bash
   $ oc get pod -n openshift-image-registry -l docker-registry=default
   ```

   **Example output**

   ```
   No resources found in openshift-image-registry namespace
   ```

   **NOTE**

   If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

   ```bash
   $ oc edit configs.imageregistry.operator.openshift.io
   ```

   **Example output**

   ```yaml
   storage:
   pvc:
     claim: 1
   ```
Leave the claim field blank to allow the automatic creation of an image-registry-storage PVC.

4. Check the clusteroperator status:

   $ oc get clusteroperator image-registry

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
<th>SINCE</th>
<th>MESSAGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>image-registry</td>
<td>4.7</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>6h50m</td>
<td></td>
</tr>
</tbody>
</table>

20.3.14.2.2. Configuring block registry storage for VMware vSphere

To allow the image registry to use block storage types such as vSphere Virtual Machine Disk (VMDK) during upgrades as a cluster administrator, you can use the Recreate rollout strategy.

**IMPORTANT**

Block storage volumes are supported but not recommended for use with image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

**Procedure**

1. To set the image registry storage as a block storage type, patch the registry so that it uses the Recreate rollout strategy and runs with only 1 replica:

   $ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec": {"rolloutStrategy":"Recreate","replicas":1}}'

2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.

   a. Create a pvc.yaml file with the following contents to define a VMware vSphere PersistentVolumeClaim object:

   ```yaml
   kind: PersistentVolumeClaim
   apiVersion: v1
   metadata:
     name: image-registry-storage
     namespace: openshift-image-registry
   spec:
     accessModes:
     - ReadWriteOnce
     resources:
       requests:
         storage: 100Gi
   ```

   A unique name that represents the PersistentVolumeClaim object.
The namespace for the `PersistentVolumeClaim` object, which is `openshift-image-registry`.

The access mode of the persistent volume claim. With `ReadWriteOnce`, the volume can be mounted with read and write permissions by a single node.

The size of the persistent volume claim.

b. Create the `PersistentVolumeClaim` object from the file:

```
$ oc create -f pvc.yaml -n openshift-image-registry
```

3. Edit the registry configuration so that it references the correct PVC:

```
$ oc edit config.imageregistry.operator.openshift.io -o yaml
```

Example output

```
storage:
pvc:
  claim: 1
```

Creating a custom PVC allows you to leave the `claim` field blank for the default automatic creation of an `image-registry-storage` PVC.

For instructions about configuring registry storage so that it references the correct PVC, see Configuring the registry for vSphere.

### 20.3.15. Backing up VMware vSphere volumes

OpenShift Container Platform provisions new volumes as independent persistent disks to freely attach and detach the volume on any node in the cluster. As a consequence, it is not possible to back up volumes that use snapshots, or to restore volumes from snapshots. See Snapshot Limitations for more information.

#### Procedure

To create a backup of persistent volumes:

1. Stop the application that is using the persistent volume.
2. Clone the persistent volume.
3. Restart the application.
4. Create a backup of the cloned volume.
5. Delete the cloned volume.

### 20.3.16. Telemetry access for OpenShift Container Platform
In OpenShift Container Platform 4.10, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources
- See About remote health monitoring for more information about the Telemetry service.

20.3.17. Next steps
- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- Set up your registry and configure registry storage.
- Optional: View the events from the vSphere Problem Detector Operator to determine if the cluster has permission or storage configuration issues.

20.4. INSTALLING A CLUSTER ON VMC WITH NETWORK CUSTOMIZATIONS

In OpenShift Container Platform version 4.10, you can install a cluster on your VMware vSphere instance using installer-provisioned infrastructure with customized network configuration options by deploying it to VMware Cloud (VMC) on AWS.

Once you configure your VMC environment for OpenShift Container Platform deployment, you use the OpenShift Container Platform installation program from the bastion management host, co-located in the VMC environment. The installation program and control plane automates the process of deploying and managing the resources needed for the OpenShift Container Platform cluster.

By customizing your OpenShift Container Platform network configuration, your cluster can coexist with existing IP address allocations in your environment and integrate with existing VXLAN configurations. To customize the installation, you modify parameters in the install-config.yaml file before you install the cluster. You must set most of the network configuration parameters during installation, and you can modify only kubeProxy configuration parameters in a running cluster.

20.4.1. Setting up VMC for vSphere

You can install OpenShift Container Platform on VMware Cloud (VMC) on AWS hosted vSphere clusters to enable applications to be deployed and managed both on-premise and off-premise, across the hybrid cloud.
You must configure several options in your VMC environment prior to installing OpenShift Container Platform on VMware vSphere. Ensure your VMC environment has the following prerequisites:

- Create a non-exclusive, DHCP-enabled, NSX-T network segment and subnet. Other virtual machines (VMs) can be hosted on the subnet, but at least eight IP addresses must be available for the OpenShift Container Platform deployment.

- Allocate two IP addresses, outside the DHCP range, and configure them with reverse DNS records.
  - A DNS record for `api.<cluster_name>.<base_domain>` pointing to the allocated IP address.
  - A DNS record for `*.apps.<cluster_name>.<base_domain>` pointing to the allocated IP address.

- Configure the following firewall rules:
  - An ANY:ANY firewall rule between the OpenShift Container Platform compute network and the internet. This is used by nodes and applications to download container images.
  - An ANY:ANY firewall rule between the installation host and the software-defined data center (SDDC) management network on port 443. This allows you to upload the Red Hat Enterprise Linux CoreOS (RHCOS) OVA during deployment.
  - An HTTPS firewall rule between the OpenShift Container Platform compute network and vCenter. This connection allows OpenShift Container Platform to communicate with vCenter for provisioning and managing nodes, persistent volume claims (PVCs), and other resources.

- You must have the following information to deploy OpenShift Container Platform:
  - The OpenShift Container Platform cluster name, such as `vmc-prod-1`.
  - The base DNS name, such as `companyname.com`.
  - If not using the default, the pod network CIDR and services network CIDR must be identified, which are set by default to `10.128.0.0/14` and `172.30.0.0/16`, respectively. These CIDRs are used for pod-to-pod and pod-to-service communication and are not accessible externally; however, they must not overlap with existing subnets in your organization.
  - The following vCenter information:
    - vCenter hostname, username, and password
    - Datacenter name, such as `SDDC-Datacenter`
Cluster name, such as Cluster-1
Network name
Datastore name, such as WorkloadDatastore

NOTE
It is recommended to move your vSphere cluster to the VMC Compute-ResourcePool resource pool after your cluster installation is finished.

- A Linux-based host deployed to VMC as a bastion.
  - The bastion host can be Red Hat Enterprise Linux (RHEL) or any another Linux-based host; it must have internet connectivity and the ability to upload an OVA to the ESXi hosts.
  - Download and install the OpenShift CLI tools to the bastion host.
    - The openshift-install installation program
    - The OpenShift CLI (oc) tool

NOTE
You cannot use the VMware NSX Container Plug-in for Kubernetes (NCP), and NSX is not used as the OpenShift SDN. The version of NSX currently available with VMC is incompatible with the version of NCP certified with OpenShift Container Platform.

However, the NSX DHCP service is used for virtual machine IP management with the full-stack automated OpenShift Container Platform deployment and with nodes provisioned, either manually or automatically, by the Machine API integration with vSphere. Additionally, NSX firewall rules are created to enable access with the OpenShift Container Platform cluster and between the bastion host and the VMC vSphere hosts.

20.4.1. VMC Sizer tool

VMware Cloud on AWS is built on top of AWS bare metal infrastructure; this is the same bare metal infrastructure which runs AWS native services. When a VMware cloud on AWS software-defined data center (SDDC) is deployed, you consume these physical server nodes and run the VMware ESXi hypervisor in a single tenant fashion. This means the physical infrastructure is not accessible to anyone else using VMC. It is important to consider how many physical hosts you will need to host your virtual infrastructure.

To determine this, VMware provides the VMC on AWS Sizer. With this tool, you can define the resources you intend to host on VMC:

- Types of workloads
- Total number of virtual machines
- Specification information such as:
  - Storage requirements
  - vCPUs
With these details, the sizer tool can generate a report, based on VMware best practices, and recommend your cluster configuration and the number of hosts you will need.

20.4.2. vSphere prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You provisioned block registry storage. For more information on persistent storage, see Understanding persistent storage.
- If you use a firewall, you configured it to allow the sites that your cluster requires access to.

**NOTE**

Be sure to also review this site list if you are configuring a proxy.

20.4.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.10, you require access to the internet to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

20.4.4. VMware vSphere infrastructure requirements

You must install the OpenShift Container Platform cluster on a VMware vSphere version 6 or 7 instance that meets the requirements for the components that you use.

**Table 20.14. Version requirements for vSphere virtual environments**
Virtual environment product | Required version
--- | ---
VM hardware version | 13 or later
vSphere ESXi hosts | 6.5 or later
vCenter host | 6.5 or later

**IMPORTANT**

Installing a cluster on VMware vSphere version 6.7U3 or earlier and virtual hardware version 13 is now deprecated. These versions are still fully supported, but version 4.11 of OpenShift Container Platform will require vSphere virtual hardware version 15 or later. Hardware version 15 is now the default for vSphere virtual machines in OpenShift Container Platform. To update the hardware version for your vSphere nodes, see the “Updating hardware on nodes running in vSphere” article.

If your vSphere nodes are below hardware version 15 or your VMware vSphere version is earlier than 6.7U3, upgrading from OpenShift Container Platform 4.10 to OpenShift Container Platform 4.11 is not available.

| Table 20.15. Minimum supported vSphere version for VMware components |
|---|---|---|
| Component | Minimum supported versions | Description |
| Hypervisor | vSphere 6.5 and later with HW version 13 | This version is the minimum version that Red Hat Enterprise Linux CoreOS (RHCOS) supports. See the Red Hat Enterprise Linux 8 supported hypervisors list. |
| Storage with in-tree drivers | vSphere 6.5 and later | This plug-in creates vSphere storage by using the in-tree storage drivers for vSphere included in OpenShift Container Platform. |

If you use a vSphere version 6.5 instance, consider upgrading to 6.7U3 or 7.0 before you install OpenShift Container Platform.

**IMPORTANT**

You must ensure that the time on your ESXi hosts is synchronized before you install OpenShift Container Platform. See Edit Time Configuration for a Host in the VMware documentation.

**20.4.5. VMware vSphere CSI Driver Operator requirements**

The following requirements must be met in order to install the CSI Driver Operator:
- VMware vSphere version 6.7U3 or later
- Virtual machines of hardware version 15 or later
- No third-party CSI driver already installed in the cluster

If a third-party CSI driver is present in the cluster, OpenShift Container Platform does not overwrite it. The presence of a third-party CSI driver prevents OpenShift Container Platform from upgrading to 4.11.

Additional resources
- To remove a third-party CSI driver, see Removing a third-party vSphere CSI Driver.
- To update the hardware version for your vSphere nodes, see Updating hardware on nodes running in vSphere.

20.4.6. vCenter requirements

Before you install an OpenShift Container Platform cluster on your vCenter that uses infrastructure that the installer provisions, you must prepare your environment.

**Required vCenter account privileges**

To install an OpenShift Container Platform cluster in a vCenter, the installation program requires access to an account with privileges to read and create the required resources. Using an account that has global administrative privileges is the simplest way to access all of the necessary permissions.

If you cannot use an account with global administrative privileges, you must create roles to grant the privileges necessary for OpenShift Container Platform cluster installation. While most of the privileges are always required, some are required only if you plan for the installation program to provision a folder to contain the OpenShift Container Platform cluster on your vCenter instance, which is the default behavior. You must create or amend vSphere roles for the specified objects to grant the required privileges.

An additional role is required if the installation program is to create a vSphere virtual machine folder.

**Example 20.5. Roles and privileges required for installation**

<table>
<thead>
<tr>
<th>vSphere object for role</th>
<th>When required</th>
<th>Required privileges</th>
</tr>
</thead>
</table>

2872
<table>
<thead>
<tr>
<th>vSphere object for role</th>
<th>When required</th>
<th>Required privileges</th>
</tr>
</thead>
<tbody>
<tr>
<td>vSphere Port Group</td>
<td>Always</td>
<td>Network.Assign</td>
</tr>
<tr>
<td>vSphere object for role</td>
<td>When required</td>
<td>Required privileges</td>
</tr>
<tr>
<td>------------------------</td>
<td>---------------</td>
<td>--------------------</td>
</tr>
</tbody>
</table>
| Virtual Machine Folder | Always        | Resource.AssignVMToPool  
|                        |               | VApp.Import            
|                        |               | VirtualMachine.Config.AddExistingDisk  
|                        |               | VirtualMachine.Config.AddNewDisk       
|                        |               | VirtualMachine.Config.AddRemoveDevice  
|                        |               | VirtualMachine.Config.AdvancedConfig   
|                        |               | VirtualMachine.Config.Annotation      
|                        |               | VirtualMachine.Config.CPUCount         
|                        |               | VirtualMachine.Config.DiskExtend       
|                        |               | VirtualMachine.Config.DiskLease         
|                        |               | VirtualMachine.Config.EditDevice       
|                        |               | VirtualMachine.Config.Memory           
|                        |               | VirtualMachine.Config.RemoveDisk       
|                        |               | VirtualMachine.Config.Rename           
|                        |               | VirtualMachine.Config.RestGuestInfo    
|                        |               | VirtualMachine.Config.Restore          
|                        |               | VirtualMachine.Config.RestoreGuestInfo 
|                        |               | VirtualMachine.Config.RestoreResource  
|                        |               | VirtualMachine.Config.RestoreSettings  
|                        |               | VirtualMachine.Config.RestoreVirtualHardware  
|                        |               | VirtualMachine.Interact.GuestControl   
|                        |               | VirtualMachine.Interact.PowerOff      
|                        |               | VirtualMachine.Interact.PowerOn       
|                        |               | VirtualMachine.Interact.Reset          
|                        |               | VirtualMachine.Inventory.Create        
|                        |               | VirtualMachine.Inventory.CreateFromExisting  
|                        |               | VirtualMachine.Inventory.Delete        
|                        |               | VirtualMachine.Provisioning.Clone      
<p>|                        |               | VirtualMachine.Provisioning.Clone      |</p>
<table>
<thead>
<tr>
<th>vSphere object for role</th>
<th>When required</th>
<th>Required privileges</th>
</tr>
</thead>
<tbody>
<tr>
<td>vSphere vCenter Datacenter</td>
<td>If the installation program creates the virtual machine folder</td>
<td>g.MarkAsTemplate, g.DeployTemplate, g.Clone, VApp.Import, VirtualMachine.Provisioning.MTemplate, VirtualMachine.Provisioning.vSphere vCenter Datacenter</td>
</tr>
</tbody>
</table>
Additionally, the user requires some **ReadOnly** permissions, and some of the roles require permission to propagate the permissions to child objects. These settings vary depending on whether or not you install the cluster into an existing folder.

**Example 20.6. Required permissions and propagation settings**

<table>
<thead>
<tr>
<th>vSphere object</th>

For more information about creating an account with only the required privileges, see [vSphere Permissions and User Management Tasks](#) in the vSphere documentation.

**Using OpenShift Container Platform with vMotion**

**IMPORTANT**

OpenShift Container Platform generally supports compute-only vMotion. Using Storage vMotion can cause issues and is not supported.

If you are using vSphere volumes in your pods, migrating a VM across datastores either manually or through Storage vMotion causes invalid references within OpenShift Container Platform persistent volume (PV) objects. These references prevent affected pods from starting up and can result in data loss.
Similarly, OpenShift Container Platform does not support selective migration of VMDKs across datastores, using datastore clusters for VM provisioning or for dynamic or static provisioning of PVs, or using a datastore that is part of a datastore cluster for dynamic or static provisioning of PVs.

**Cluster resources**

When you deploy an OpenShift Container Platform cluster that uses installer-provisioned infrastructure, the installation program must be able to create several resources in your vCenter instance.

A standard OpenShift Container Platform installation creates the following vCenter resources:

- 1 Folder
- 1 Tag category
- 1 Tag
- Virtual machines:
  - 1 template
  - 1 temporary bootstrap node
  - 3 control plane nodes
  - 3 compute machines

Although these resources use 856 GB of storage, the bootstrap node is destroyed during the cluster installation process. A minimum of 800 GB of storage is required to use a standard cluster.

If you deploy more compute machines, the OpenShift Container Platform cluster will use more storage.

**Cluster limits**

Available resources vary between clusters. The number of possible clusters within a vCenter is limited primarily by available storage space and any limitations on the number of required resources. Be sure to consider both limitations to the vCenter resources that the cluster creates and the resources that you require to deploy a cluster, such as IP addresses and networks.

**Networking requirements**

You must use DHCP for the network and ensure that the DHCP server is configured to provide persistent IP addresses to the cluster machines. All nodes must be in the same VLAN. You cannot scale the cluster using a second VLAN as a Day 2 operation. Additionally, you must create the following networking resources before you install the OpenShift Container Platform cluster:

**NOTE**

It is recommended that each OpenShift Container Platform node in the cluster must have access to a Network Time Protocol (NTP) server that is discoverable via DHCP. Installation is possible without an NTP server. However, asynchronous server clocks will cause errors, which NTP server prevents.

**Required IP Addresses**

An installer-provisioned vSphere installation requires two static IP addresses:

- The **API** address is used to access the cluster API.
- The **Ingress** address is used for cluster ingress traffic.
You must provide these IP addresses to the installation program when you install the OpenShift Container Platform cluster.

**DNS records**
You must create DNS records for two static IP addresses in the appropriate DNS server for the vCenter instance that hosts your OpenShift Container Platform cluster. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the cluster base domain that you specify when you install the cluster. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>`.

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>API VIP</td>
<td><code>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</code></td>
<td>This DNS A/AAAA or CNAME record must point to the load balancer for the control plane machines. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Ingress VIP</td>
<td><code>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</code></td>
<td>A wildcard DNS A/AAAA or CNAME record that points to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>

### 20.4.7. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the `core` user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user `core`. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.
Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ ssh-keygen -t ed25519 -N " " -f <path>/<file_name>
   ```

   Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the `ed25519` algorithm. Instead, create a key that uses the `rsa` or `ecdsa` algorithm.

2. View the public SSH key:

   ```
   $ cat <path>/<file_name>.pub
   ```

   For example, run the following to view the `~/.ssh/id_rsa.pub` public key:

   ```
   $ cat ~/.ssh/id_rsa.pub
   ```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

   **NOTE**

   On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

   a. If the `ssh-agent` process is not already running for your local user, start it as a background task:

      ```
      $ eval "$(ssh-agent -s)"
      ```

      **Example output**

      ```
      Agent pid 31874
      ```

      **NOTE**

      If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the `ssh-agent`:

   ```
   ```
Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

Example output

Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

20.4.8. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on your provisioning machine.

Prerequisites

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

   ![](https://example.com/image)

   **IMPORTANT**

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   ![](https://example.com/image)

   **IMPORTANT**

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   $ tar -xvf openshift-install-linux.tar.gz
5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

20.4.9. Adding vCenter root CA certificates to your system trust

Because the installation program requires access to your vCenter’s API, you must add your vCenter’s trusted root CA certificates to your system trust before you install an OpenShift Container Platform cluster.

Procedure

1. From the vCenter home page, download the vCenter’s root CA certificates. Click Download trusted root CA certificates in the vSphere Web Services SDK section. The <vCenter>/certs/download.zip file downloads.

2. Extract the compressed file that contains the vCenter root CA certificates. The contents of the compressed file resemble the following file structure:

```
certs
├── lin
│   ├── 108f4d17.0
│   ├── 108f4d17.r1
│   ├── 7e757f6a.0
│   ├── 8e4f8471.0
│   └── 8e4f8471.r0
├── mac
│   ├── 108f4d17.0
│   ├── 108f4d17.r1
│   ├── 7e757f6a.0
│   ├── 8e4f8471.0
│   └── 8e4f8471.r0
└── win
    ├── 108f4d17.0.crt
    ├── 108f4d17.r1.crl
    ├── 7e757f6a.0.crt
    └── 8e4f8471.0.crt
    └── 8e4f8471.r0.crl
```

3 directories, 15 files

3. Add the files for your operating system to the system trust. For example, on a Fedora operating system, run the following command:

```
# cp certs/lin/* /etc/pki/ca-trust/source/anchors
```

4. Update your system trust. For example, on a Fedora operating system, run the following command:

```
# update-ca-trust extract
```

20.4.10. Creating the installation configuration file
You can customize the OpenShift Container Platform cluster you install on VMware vSphere.

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.
- Obtain service principal permissions at the subscription level.

Procedure

1. Create the `install-config.yaml` file.
   a. Change to the directory that contains the installation program and run the following command:

   ```bash
   $ ./openshift-install create install-config --dir <installation_directory> ①
   ```

   ① For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

   **IMPORTANT**

   Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

   b. At the prompts, provide the configuration details for your cloud:

      i. Optional: Select an SSH key to use to access your cluster machines.

      **NOTE**

      For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

      ii. Select `vsphere` as the platform to target.

      iii. Specify the name of your vCenter instance.

      iv. Specify the user name and password for the vCenter account that has the required permissions to create the cluster.

      The installation program connects to your vCenter instance.

      v. Select the datacenter in your vCenter instance to connect to.

      vi. Select the default vCenter datastore to use.
vii. Select the vCenter cluster to install the OpenShift Container Platform cluster in. The installation program uses the root resource pool of the vSphere cluster as the default resource pool.

viii. Select the network in the vCenter instance that contains the virtual IP addresses and DNS records that you configured.

ix. Enter the virtual IP address that you configured for control plane API access.

x. Enter the virtual IP address that you configured for cluster ingress.

xi. Enter the base domain. This base domain must be the same one that you used in the DNS records that you configured.

xii. Enter a descriptive name for your cluster. The cluster name must be the same one that you used in the DNS records that you configured.

xiii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

2. Modify the `install-config.yaml` file. You can find more information about the available parameters in the "Installation configuration parameters" section.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

    **IMPORTANT**

    The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

20.4.10.1. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide a customized `install-config.yaml` installation configuration file that describes the details for your environment.

    **NOTE**

    After installation, you cannot modify these parameters in the `install-config.yaml` file.

20.4.10.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is <code>v1</code>. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>baseDomain</strong></td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the <code>baseDomain</code> and <code>metadata.name</code> parameter values that uses the <code>&lt;metadata.name&gt;</code>, <code>&lt;baseDomain&gt;</code> format.</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
</tr>
<tr>
<td><strong>metadata</strong></td>
<td>Kubernetes resource <code>ObjectMeta</code>, from which only the <code>name</code> parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td><strong>metadata.name</strong></td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of {{.metadata.name}}. {{.baseDomain}}.</td>
<td>String of lowercase letters, hyphens (–), and periods (.), such as dev.</td>
</tr>
<tr>
<td><strong>platform</strong></td>
<td>The configuration for the specific platform upon which to perform the installation: alibabacloud, aws, baremetal, azure, ibmcloud, openstack, ovirt, vsphere, or {}. For additional information about <code>platform.&lt;platform&gt;</code> parameters, consult the table for your specific platform that follows.</td>
<td>Object</td>
</tr>
</tbody>
</table>
20.4.10.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

Table 20.18. Network parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td>networking.network.networkType</td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN.</td>
</tr>
<tr>
<td>networking.clusterNetwork</td>
<td>The IP address blocks for pods.</td>
<td>An array of objects. For example:</td>
</tr>
</tbody>
</table>
|                            | The default value is **10.128.0.0/14** with a host prefix of **/23**. | networking:
|                            | If you specify multiple IP address blocks, the blocks must not overlap. | clusterNetwork:
|                            |                                      | - cidr: **10.128.0.0/14**               |
|                            |                                      | hostPrefix: **23**                       |
### Parameter Descriptions

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>networking.clusterNetwork.cidr</code></td>
<td>Required if you use <code>networking.clusterNetwork</code>. An IP address block.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td></td>
<td>An IPv4 network.</td>
<td></td>
</tr>
<tr>
<td><code>networking.clusterNetwork.hostPrefix</code></td>
<td>The subnet prefix length to assign to each individual node. For example, if <code>hostPrefix</code> is set to 23 then each node is assigned a /23 subnet out of the given cidr. A <code>hostPrefix</code> value of 23 provides 510 (2^{32-23}-2) pod IP addresses.</td>
<td>A subnet prefix. The default value is 23.</td>
</tr>
<tr>
<td><code>networking.serviceNetwork</code></td>
<td>The IP address block for services. The default value is 172.30.0.0/16.</td>
<td>An array with an IP address block in CIDR format. For example:</td>
</tr>
<tr>
<td></td>
<td>The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.</td>
<td>networking: serviceNetwork: - 172.30.0.0/16</td>
</tr>
<tr>
<td><code>networking.machineNetwork</code></td>
<td>The IP address blocks for machines.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td>If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td>networking: machineNetwork: - cidr: 10.0.0.0/16</td>
</tr>
<tr>
<td></td>
<td>If you specify multiple IP kernel arguments, the <code>machineNetwork.cidr</code> value must be the CIDR of the primary network.</td>
<td></td>
</tr>
<tr>
<td><code>networking.machineNetwork.cidr</code></td>
<td>Required if you use <code>networking.machineNetwork</code>. An IP address block.</td>
<td>An IP network block in CIDR notation. For example, 10.0.0.0/16.</td>
</tr>
<tr>
<td></td>
<td>The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24.</td>
<td></td>
</tr>
</tbody>
</table>

### Optional Installation Configuration Parameters

Optional installation configuration parameters are described in the following table:

---

20.4.10.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>additionalTrustBundle</strong></td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td><strong>cgroupsV2</strong></td>
<td>Enables Linux control groups version 2 (cgroups v2) on specific nodes in your cluster. The OpenShift Container Platform process for enabling cgroups v2 disables all cgroup version 1 controllers and hierarchies. The OpenShift Container Platform cgroups version 2 feature is in Developer Preview and is not supported by Red Hat at this time.</td>
<td><strong>true</strong></td>
</tr>
<tr>
<td><strong>compute</strong></td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of <strong>MachinePool</strong> objects.</td>
</tr>
<tr>
<td><strong>compute.architecture</strong></td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <strong>s390x</strong> (the default).</td>
<td><strong>String</strong></td>
</tr>
<tr>
<td><strong>compute.hyperthreading</strong></td>
<td>Whether to enable or disable simultaneous multithreading, or <strong>hyperthreading</strong>, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td><strong>Enabled</strong> or <strong>Disabled</strong></td>
</tr>
<tr>
<td><strong>compute.name</strong></td>
<td>Required if you use <strong>compute</strong>. The name of the machine pool.</td>
<td><strong>worker</strong></td>
</tr>
</tbody>
</table>

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>compute.platform</td>
<td>Required if you use <code>compute</code>. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <code>controlPlane.platform</code> parameter value.</td>
<td>alibaba, aws, azure, gcp, ibmcloud, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td>compute.replicas</td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td>controlPlane</td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of <code>MachinePool</code> objects.</td>
</tr>
<tr>
<td>controlPlane.architect</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>s390x</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td>controlPlane.hypertreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>controlPlane.name</td>
<td>Required if you use <code>controlPlane</code>. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use <code>controlPlane</code>. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the <code>compute.platform</code> parameter value.</td>
<td>alibaba, aws, azure, gcp, ibmcloud, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>--------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (&quot;&quot;).</td>
</tr>
</tbody>
</table>

**NOTE**

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Platform Operators reference content.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>fips</strong></td>
<td>Enable or disable FIPS mode. The default is <code>false</code> (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</td>
<td><strong>false</strong> or <strong>true</strong></td>
</tr>
<tr>
<td><strong>imageContentSources</strong></td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects. Includes a <strong>source</strong> and, optionally, <strong>mirrors</strong>, as described in the following rows of this table.</td>
</tr>
<tr>
<td><strong>imageContentSources.source</strong></td>
<td>Required if you use <strong>imageContentSources</strong>. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td><strong>String</strong></td>
</tr>
<tr>
<td><strong>imageContentSources.mirrors</strong></td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of <strong>strings</strong></td>
</tr>
</tbody>
</table>

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the **x86_64** architecture.

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.
### publish

How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.

**Internal** or **External**. The default value is **External**.

Setting this field to **Internal** is not supported on non-cloud platforms and IBM Cloud.

**IMPORTANT**

If the value of the field is set to **Internal**, the cluster will become non-functional. For more information, refer to [BZ#1953035](#).

### sshKey

The SSH key or keys to authenticate access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

One or more keys. For example:

```
sshKey:
  <key1>
  <key2>
  <key3>
```

---

**20.4.10.1.4. Additional VMware vSphere configuration parameters**

Additional VMware vSphere configuration parameters are described in the following table:

**Table 20.20. Additional VMware vSphere cluster parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>platform.vsphere.vCenter</code></td>
<td>The fully-qualified hostname or IP address of the vCenter server.</td>
<td>String</td>
</tr>
<tr>
<td><code>platform.vsphere.username</code></td>
<td>The user name to use to connect to the vCenter instance with. This user must have at least the roles and privileges that are required for static or dynamic persistent volume provisioning in vSphere.</td>
<td>String</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------</td>
</tr>
<tr>
<td>platform.vsphere.password</td>
<td>The password for the vCenter user name.</td>
<td>String</td>
</tr>
<tr>
<td>platform.vsphere.datacenter</td>
<td>The name of the datacenter to use in the vCenter instance.</td>
<td>String</td>
</tr>
<tr>
<td>platform.vsphere.defaultDatastore</td>
<td>The name of the default datastore to use for provisioning volumes.</td>
<td>String</td>
</tr>
<tr>
<td>platform.vsphere.folder</td>
<td>Optional. The absolute path of an existing folder where the installation program creates the virtual machines. If you do not provide this value, the installation program creates a folder that is named with the infrastructure ID in the datacenter virtual machine folder.</td>
<td>String, for example, /&lt;datacenter_name&gt;/vm/&lt;folder_name&gt;/&lt;subfolder_name&gt;.</td>
</tr>
<tr>
<td>platform.vsphere.network</td>
<td>The network in the vCenter instance that contains the virtual IP addresses and DNS records that you configured.</td>
<td>String</td>
</tr>
<tr>
<td>platform.vsphere.cluster</td>
<td>The vCenter cluster to install the OpenShift Container Platform cluster in.</td>
<td>String</td>
</tr>
<tr>
<td>platform.vsphere.apiVIP</td>
<td>The virtual IP (VIP) address that you configured for control plane API access.</td>
<td>An IP address, for example 128.0.0.1.</td>
</tr>
<tr>
<td>platform.vsphere.ingressVIP</td>
<td>The virtual IP (VIP) address that you configured for cluster ingress.</td>
<td>An IP address, for example 128.0.0.1.</td>
</tr>
<tr>
<td>platform.vsphere.diskType</td>
<td>Optional. The disk provisioning method. This value defaults to the vSphere default storage policy if not set.</td>
<td>Valid values are thin, thick, or eagerZeroedThick.</td>
</tr>
</tbody>
</table>

20.4.10.1.5. Optional VMware vSphere machine pool configuration parameters

Optional VMware vSphere machine pool configuration parameters are described in the following table:

Table 20.21. Optional VMware vSphere machine pool parameters
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>platform.vsphere.clusterOSImage</strong></td>
<td>The location from which the installer downloads the RHCOS image. You must set this parameter to perform an installation in a restricted network.</td>
<td>An HTTP or HTTPS URL, optionally with a SHA-256 checksum. For example, <a href="https://mirror.openshift.com/images/rhcos-">https://mirror.openshift.com/images/rhcos-</a>&lt;version&gt;-vmware.&lt;architecture&gt;.ova.</td>
</tr>
<tr>
<td><strong>platform.vsphere.osDisk.diskSizeGB</strong></td>
<td>The size of the disk in gigabytes.</td>
<td>Integer</td>
</tr>
<tr>
<td><strong>platform.vsphere.cpus</strong></td>
<td>The total number of virtual processor cores to assign a virtual machine.</td>
<td>Integer</td>
</tr>
<tr>
<td><strong>platform.vsphere.coresPerSocket</strong></td>
<td>The number of cores per socket in a virtual machine. The number of virtual sockets on the virtual machine is <strong>platform.vsphere.cpus</strong>/<strong>platform.vsphere.coresPerSocket</strong>. The default value is 1</td>
<td>Integer</td>
</tr>
<tr>
<td><strong>platform.vsphere.memoryMB</strong></td>
<td>The size of a virtual machine’s memory in megabytes.</td>
<td>Integer</td>
</tr>
</tbody>
</table>

20.4.10.2. Sample install-config.yaml file for an installer-provisioned VMware vSphere cluster

You can customize the **install-config.yaml** file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute:  
  - hyperthreading: Enabled  
    name: worker  
    replicas: 3  
    platform:  
      vsphere:  
        cpus: 2  
        coresPerSocket: 2  
        memoryMB: 8196  
        osDisk:  
          diskSizeGB: 120  
controlPlane:  
  hyperthreading: Enabled  
  name: master  
  replicas: 3  
  platform:  
```
The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

The `controlPlane` section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the `compute` section must begin with a hyphen, `-`, and the first line of the `controlPlane` section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading, or `hyperthreading`. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to `Disabled`. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Your machines must use at least 8 CPUs and 32 GB of RAM if you disable simultaneous multithreading.
Optional: Provide additional configuration for the machine pool parameters for the compute and control plane machines.

The cluster name that you specified in your DNS records.

The vSphere disk provisioning method.

The vSphere cluster to install the OpenShift Container Platform cluster in. The installation program uses the root resource pool of the vSphere cluster as the default resource pool.

20.4.10.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

Prerequisites

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

NOTE

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
     httpProxy: http://<username>:<pswd>@<ip>:<port> 1
     httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
     noProxy: example.com 3
   additionalTrustBundle: |
     -----BEGIN CERTIFICATE-----
     <MY_TRUSTED_CA_CERT>
     -----END CERTIFICATE-----
     ...
   
   1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.```
A proxy URL to use for creating HTTPS connections outside the cluster.

A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations. You must include vCenter’s IP address and the IP range that you use for its machines.

If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the trustedCA field of the Proxy object. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

NOTE
The installation program does not support the proxy readinessEndpoints field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

NOTE
Only the Proxy object named cluster is supported, and no additional proxies can be created.

20.4.11. Network configuration phases

There are two phases prior to OpenShift Container Platform installation where you can customize the network configuration.

Phase 1
You can customize the following network-related fields in the install-config.yaml file before you create the manifest files:

- networking.networkType
- networking.clusterNetwork
- networking.serviceNetwork
- networking.machineNetwork

For more information on these fields, refer to Installation configuration parameters.

NOTE
Set the networking.machineNetwork to match the CIDR that the preferred NIC resides in.
Phase 2

After creating the manifest files by running `openshift-install create manifests`, you can define a customized Cluster Network Operator manifest with only the fields you want to modify. You can use the manifest to specify advanced network configuration.

You cannot override the values specified in phase 1 in the `install-config.yaml` file during phase 2. However, you can further customize the cluster network provider during phase 2.

20.4.12. Specifying advanced network configuration

You can use advanced network configuration for your cluster network provider to integrate your cluster into your existing network environment. You can specify advanced network configuration only before you install the cluster.

**IMPORTANT**

Customizing your network configuration by modifying the OpenShift Container Platform manifest files created by the installation program is not supported. Applying a manifest file that you create, as in the following procedure, is supported.

Prerequisites

- You have created the `install-config.yaml` file and completed any modifications to it.

Procedure

1. Change to the directory that contains the installation program and create the manifests:

   ```shell
   $ ./openshift-install create manifests --dir <installation_directory>
   ```

   `<installation_directory>` specifies the name of the directory that contains the `install-config.yaml` file for your cluster.

2. Create a stub manifest file for the advanced network configuration that is named `cluster-network-03-config.yml` in the `<installation_directory>/manifests/` directory:

   ```yaml
   apiVersion: operator.openshift.io/v1
   kind: Network
   metadata:
     name: cluster
   spec:
   ```

3. Specify the advanced network configuration for your cluster in the `cluster-network-03-config.yml` file, such as in the following examples:

   **Specify a different VXLAN port for the OpenShift SDN network provider**

   ```yaml
   apiVersion: operator.openshift.io/v1
   kind: Network
   metadata:
     name: cluster
   spec:
   ```
Enable IPsec for the OVN-Kubernetes network provider

```yaml
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
  name: cluster
spec:
defaultNetwork:
  ovnKubernetesConfig:
    ipsecConfig: {}
```

4. Optional: Back up the `manifests/cluster-network-03-config.yml` file. The installation program consumes the `manifests/` directory when you create the Ignition config files.

20.4.13. Cluster Network Operator configuration

The configuration for the cluster network is specified as part of the Cluster Network Operator (CNO) configuration and stored in a custom resource (CR) object that is named `cluster`. The CR specifies the fields for the `Network` API in the `operator.openshift.io` API group.

The CNO configuration inherits the following fields during cluster installation from the `Network` API in the `Network.config.openshift.io` API group and these fields cannot be changed:

- **clusterNetwork**
  - IP address pools from which pod IP addresses are allocated.

- **serviceNetwork**
  - IP address pool for services.

- **defaultNetwork.type**
  - Cluster network provider, such as OpenShift SDN or OVN-Kubernetes.

You can specify the cluster network provider configuration for your cluster by setting the fields for the `defaultNetwork` object in the CNO object named `cluster`.

20.4.13.1. Cluster Network Operator configuration object

The fields for the Cluster Network Operator (CNO) are described in the following table:

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>metadata.name</td>
<td>string</td>
<td>The name of the CNO object. This name is always <code>cluster</code>.</td>
</tr>
</tbody>
</table>
### Field | Type | Description
--- | --- | ---
**spec.clusterNetwork** | array | A list specifying the blocks of IP addresses from which pod IP addresses are allocated and the subnet prefix length assigned to each individual node in the cluster. For example:

```yaml
spec:
  clusterNetwork:
    - cidr: 10.128.0.0/19
      hostPrefix: 23
    - cidr: 10.128.32.0/19
      hostPrefix: 23
```

You can customize this field only in the `install-config.yaml` file before you create the manifests. The value is read-only in the manifest file.

**spec.serviceNetwork** | array | A block of IP addresses for services. The OpenShift SDN and OVN-Kubernetes Container Network Interface (CNI) network providers support only a single IP address block for the service network. For example:

```yaml
spec:
  serviceNetwork:
    - 172.30.0.0/14
```

You can customize this field only in the `install-config.yaml` file before you create the manifests. The value is read-only in the manifest file.

**spec.defaultNetwork** | object | Configures the Container Network Interface (CNI) cluster network provider for the cluster network.

**spec.kubeProxy Config** | object | The fields for this object specify the kube-proxy configuration. If you are using the OVN-Kubernetes cluster network provider, the kube-proxy configuration has no effect.

---

**defaultNetwork object configuration**

The values for the `defaultNetwork` object are defined in the following table:

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>

---
Either **OpenShiftSDN** or **OVNKubernetes**. The cluster network provider is selected during installation. This value cannot be changed after cluster installation.

**NOTE**
OpenShift Container Platform uses the OpenShift SDN Container Network Interface (CNI) cluster network provider by default.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>type</strong></td>
<td>string</td>
<td>Either <strong>OpenShiftSDN</strong> or <strong>OVNKubernetes</strong>. The cluster network provider is selected during installation. This value cannot be changed after cluster installation.</td>
</tr>
</tbody>
</table>

This object is only valid for the OpenShift SDN cluster network provider.

This object is only valid for the OVN-Kubernetes cluster network provider.

### Configuration for the OpenShift SDN CNI cluster network provider
The following table describes the configuration fields for the OpenShift SDN Container Network Interface (CNI) cluster network provider.

**Table 20.24. openshiftSDNConfig object**

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>mode</strong></td>
<td>string</td>
<td>Configures the network isolation mode for OpenShift SDN. The default value is <strong>NetworkPolicy</strong>. The values <strong>Multitenant</strong> and <strong>Subnet</strong> are available for backwards compatibility with OpenShift Container Platform 3.x but are not recommended. This value cannot be changed after cluster installation.</td>
</tr>
</tbody>
</table>
The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.

If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.

If your cluster requires different MTU values for different nodes, you must set this value to 50 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1450.

This value cannot be changed after cluster installation.

The port to use for all VXLAN packets. The default value is 4789. This value cannot be changed after cluster installation.

If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number.

On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port 9000 and port 9999.

Example OpenShift SDN configuration

```yaml
defaultNetwork:
  type: OpenShiftSDN
  openshiftSDNConfig:
    mode: NetworkPolicy
    mtu: 1450
    vxlanPort: 4789
```

Configuration for the OVN-Kubernetes CNI cluster network provider

The following table describes the configuration fields for the OVN-Kubernetes CNI cluster network provider.

Table 20.25. ovnKubernetesConfig object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mtu</td>
<td>integer</td>
<td>The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU. If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes. If your cluster requires different MTU values for different nodes, you must set this value to 50 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1450. This value cannot be changed after cluster installation.</td>
</tr>
<tr>
<td>vxlanPort</td>
<td>integer</td>
<td>The port to use for all VXLAN packets. The default value is 4789. This value cannot be changed after cluster installation. If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number. On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port 9000 and port 9999.</td>
</tr>
</tbody>
</table>
The maximum transmission unit (MTU) for the Geneve (Generic Network Virtualization Encapsulation) overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.

If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.

If your cluster requires different MTU values for different nodes, you must set this value to 100 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1400.

The port to use for all Geneve packets. The default value is 6081. This value cannot be changed after cluster installation.

Specify an empty object to enable IPsec encryption. This value cannot be changed after cluster installation.

Specify a configuration object for customizing network policy audit logging. If unset, the defaults audit log settings are used.

Optional: Specify a configuration object for customizing how egress traffic is sent to the node gateway.

While migrating egress traffic, you can expect some disruption to workloads and service traffic until the Cluster Network Operator (CNO) successfully rolls out the changes.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mtu</td>
<td>integer</td>
<td>The maximum transmission unit (MTU) for the Geneve (Generic Network Virtualization Encapsulation) overlay network. <td>object</td>
<td>Specify an empty object to enable IPsec encryption. This value cannot be changed after cluster installation.</td>
</tr>
<tr>
<td>policyAuditConfig</td>
<td>object</td>
<td>Specify a configuration object for customizing network policy audit logging. If unset, the defaults audit log settings are used.</td>
</tr>
<tr>
<td>gatewayConfig</td>
<td>object</td>
<td>Optional: Specify a configuration object for customizing how egress traffic is sent to the node gateway.</td>
</tr>
</tbody>
</table>

Table 20.26. policyAuditConfig object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rateLimit</td>
<td>integer</td>
<td>The maximum number of messages to generate every second per node. The default value is 20 messages per second.</td>
</tr>
<tr>
<td>maxFileSize</td>
<td>integer</td>
<td>The maximum size for the audit log in bytes. The default value is 50000000 or 50 MB.</td>
</tr>
</tbody>
</table>
One of the following additional audit log targets:

- **libc**
  The libc `syslog()` function of the journald process on the host.

- **udp:<host>:<port>**
  A syslog server. Replace `<host>:<port>` with the host and port of the syslog server.

- **unix:<file>**
  A Unix Domain Socket file specified by `<file>`.

- **null**
  Do not send the audit logs to any additional target.

The syslog facility, such as `kern`, as defined by RFC5424. The default value is `local0`.

---

**Table 20.27. gatewayConfig object**

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>routingViaHost</td>
<td>boolean</td>
<td>Set this field to <code>true</code> to send egress traffic from pods to the host networking stack. For highly-specialized installations and applications that rely on manually configured routes in the kernel routing table, you might want to route egress traffic to the host networking stack. By default, egress traffic is processed in OVN to exit the cluster and is not affected by specialized routes in the kernel routing table. The default value is <code>false</code>. This field has an interaction with the Open vSwitch hardware offloading feature. If you set this field to <code>true</code>, you do not receive the performance benefits of the offloading because egress traffic is processed by the host networking stack.</td>
</tr>
</tbody>
</table>

Example OVN-Kubernetes configuration with IPSec enabled

```yaml
defaultNetwork:
  type: OVNKubernetes
  ovnKubernetesConfig:
    mtu: 1400
    genevePort: 6081
    ipsecConfig: {}
```

**kubeProxyConfig object configuration**
The values for the `kubeProxyConfig` object are defined in the following table:

**Table 20.28. kubeProxyConfig object**
<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>iptablesSyncPeriod</code></td>
<td>string</td>
<td>The refresh period for iptables rules. The default value is 30s. Valid suffixes include s, m, and h and are described in the Go time package documentation.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>NOTE</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Because of performance improvements introduced in OpenShift Container Platform 4.3 and greater, adjusting the <code>iptablesSyncPeriod</code> parameter is no longer necessary.</td>
</tr>
</tbody>
</table>
| `proxyArguments.iptables-min-sync-period` | array  | The minimum duration before refreshing iptables rules. This field ensures that the refresh does not happen too frequently. Valid suffixes include s, m, and h and are described in the Go time package. The default value is:  
kubeProxyConfig:  
  proxyArguments:  
  iptables-min-sync-period:  
  - 0s                                                                 |

**20.4.14. Deploying the cluster**

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

**Prerequisites**

- Configure an account with the cloud platform that hosts your cluster.
- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Change to the directory that contains the installation program and initialize the cluster deployment:

   ```
   $ ./openshift-install create cluster --dir <installation_directory> \  
   --log-level=info  
   ```
For `<installation_directory>`, specify the location of your customized `./install-config.yaml` file.

To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

**IMPORTANT**

Use the `openshift-install` command from the bastion hosted in the VMC environment.

**NOTE**

If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.

When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the `kubeadmin` user, display in your terminal.

**Example output**

```
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-Wt5AL"
INFO Time elapsed: 36m22s
```

**NOTE**

The cluster access and credential information also outputs to `<installation_directory>/openshift_install.log` when an installation succeeds.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for `Recovering from expired control plane certificates` for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.
20.4.15. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (\texttt{oc}) to interact with OpenShift Container Platform from a command-line interface. You can install \texttt{oc} on Linux, Windows, or macOS.

\textbf{IMPORTANT}

If you installed an earlier version of \texttt{oc}, you cannot use it to complete all of the commands in OpenShift Container Platform 4.10. Download and install the new version of \texttt{oc}.

Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (\texttt{oc}) binary on Linux by using the following procedure.

\textbf{Procedure}

2. Select the appropriate version in the \texttt{Version} drop-down menu.
3. Click \texttt{Download Now} next to the \texttt{OpenShift v4.10 Linux Client} entry and save the file.
4. Unpack the archive:
   \[
   \texttt{\$ tar xzvf <file>}
   \]
5. Place the \texttt{oc} binary in a directory that is on your \texttt{PATH}.
   To check your \texttt{PATH}, execute the following command:
   \[
   \texttt{\$ echo $PATH}
   \]

After you install the OpenShift CLI, it is available using the \texttt{oc} command:

\[
\texttt{\$ oc <command>}
\]

Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (\texttt{oc}) binary on Windows by using the following procedure.

\textbf{Procedure}

2. Select the appropriate version in the \texttt{Version} drop-down menu.
3. Click \texttt{Download Now} next to the \texttt{OpenShift v4.10 Windows Client} entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the oc binary to a directory that is on your PATH.
   To check your PATH, open the command prompt and execute the following command:
   
   ```
   C:\> path
   ```
   
   After you install the OpenShift CLI, it is available using the oc command:
   
   ```
   C:\> oc <command>
   ```

### Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.

#### Procedure

2. Select the appropriate version in the Version drop-down menu.
3. Click Download Now next to the OpenShift v4.10 MacOSX Client entry and save the file.
4. Unpack and unzip the archive.
5. Move the oc binary to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:
   
   ```
   $ echo $PATH
   ```
   
   After you install the OpenShift CLI, it is available using the oc command:
   
   ```
   $ oc <command>
   ```

#### 20.4.16. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster kubeconfig file. The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

#### Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the oc CLI.

#### Procedure

1. Export the kubeadmin credentials:

   ```
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   1 For <installation_directory>, specify the path to the directory that you stored the installation files in.
2. Verify you can run `oc` commands successfully using the exported configuration:

```bash
$ oc whoami
```

Example output

```
system:admin
```

20.4.17. Creating registry storage

After you install the cluster, you must create storage for the registry Operator.

20.4.17.1. Image registry removed during installation

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as `Removed`. This allows `openshift-installer` to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the `managementState` from `Removed` to `Managed`.

**NOTE**

The Prometheus console provides an `ImageRegistryRemoved` alert, for example:

```
"Image Registry has been removed. ImageStreamTags, BuildConfigs and DeploymentConfigs which reference ImageStreamTags may not work as expected. Please configure storage and update the config to Managed state by editing configs.imageregistry.operator.openshift.io."
```

20.4.17.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the `Recreate` rollout strategy during upgrades.

20.4.17.2.1. Configuring registry storage for VMware vSphere

As a cluster administrator, following installation you must configure your registry to use storage.

**Prerequisites**

- Cluster administrator permissions.
- A cluster on VMware vSphere.
- Persistent storage provisioned for your cluster, such as Red Hat OpenShift Data Foundation.
IMPORTANT

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have "100Gi" capacity.

IMPORTANT

Testing shows issues with using the NFS server on RHEL as storage backend for core services. This includes the OpenShift Container Registry and Quay, Prometheus for monitoring storage, and Elasticsearch for logging storage. Therefore, using RHEL NFS to back PVs used by core services is not recommended.

Other NFS implementations on the marketplace might not have these issues. Contact the individual NFS implementation vendor for more information on any testing that was possibly completed against these OpenShift Container Platform core components.

Procedure

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

   **NOTE**

   When using shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

   ```
   $ oc get pod -n openshift-image-registry -l docker-registry=default
   
   Example output
   
   No resources found in openshift-image-registry namespace
   
   **NOTE**

   If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

   ```
   $ oc edit configs.imageregistry.operator.openshift.io
   
   Example output
   
   storage:
   pvc:
   claim: 1
   ```
1. Leave the claim field blank to allow the automatic creation of an image-registry-storage PVC.

4. Check the clusteroperator status:

   $ oc get clusteroperator image-registry

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
<th>SINCE</th>
<th>MESSAGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>image-registry</td>
<td>4.7</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>6h50m</td>
<td></td>
</tr>
</tbody>
</table>

20.4.17.2.2. Configuring block registry storage for VMware vSphere

To allow the image registry to use block storage types such as vSphere Virtual Machine Disk (VMDK) during upgrades as a cluster administrator, you can use the Recreate rollout strategy.

**IMPORTANT**

Block storage volumes are supported but not recommended for use with image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

**Procedure**

1. To set the image registry storage as a block storage type, patch the registry so that it uses the Recreate rollout strategy and runs with only 1 replica:

   $ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec": "rolloutStrategy": "Recreate","replicas":1}''

2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.

   a. Create a pvc.yaml file with the following contents to define a VMware vSphere PersistentVolumeClaim object:

   ```yaml
   kind: PersistentVolumeClaim
   apiVersion: v1
   metadata:
     name: image-registry-storage
     namespace: openshift-image-registry
   spec:
     accessModes:
     - ReadWriteOnce
     resources:
       requests:
         storage: 100Gi
   ```

   A unique name that represents the PersistentVolumeClaim object.
2. The namespace for the `PersistentVolumeClaim` object, which is `openshift-image-registry`.

3. The access mode of the persistent volume claim. With `ReadWriteOnce`, the volume can be mounted with read and write permissions by a single node.

4. The size of the persistent volume claim.

b. Create the `PersistentVolumeClaim` object from the file:

```
$ oc create -f pvc.yaml -n openshift-image-registry
```

3. Edit the registry configuration so that it references the correct PVC:

```
$ oc edit config.imageregistry.operator.openshift.io -o yaml
```

**Example output**

```yaml
storage:
  pvc:
    claim: 1
```

1. Creating a custom PVC allows you to leave the `claim` field blank for the default automatic creation of an `image-registry-storage` PVC.

For instructions about configuring registry storage so that it references the correct PVC, see [Configuring the registry for vSphere](#).

### 20.4.18. Backing up VMware vSphere volumes

OpenShift Container Platform provisions new volumes as independent persistent disks to freely attach and detach the volume on any node in the cluster. As a consequence, it is not possible to back up volumes that use snapshots, or to restore volumes from snapshots. See [Snapshot Limitations](#) for more information.

**Procedure**

To create a backup of persistent volumes:

1. Stop the application that is using the persistent volume.

2. Clone the persistent volume.

3. Restart the application.

4. Create a backup of the cloned volume.

5. Delete the cloned volume.

### 20.4.19. Telemetry access for OpenShift Container Platform
In OpenShift Container Platform 4.10, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service

20.4.20. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- Set up your registry and configure registry storage.
- Optional: View the events from the vSphere Problem Detector Operator to determine if the cluster has permission or storage configuration issues.

20.5. INSTALLING A CLUSTER ON VMC IN A RESTRICTED NETWORK

In OpenShift Container Platform version 4.10, you can install a cluster on VMware vSphere infrastructure in a restricted network by deploying it to VMware Cloud (VMC) on AWS.

Once you configure your VMC environment for OpenShift Container Platform deployment, you use the OpenShift Container Platform installation program from the bastion management host, co-located in the VMC environment. The installation program and control plane automates the process of deploying and managing the resources needed for the OpenShift Container Platform cluster.

20.5.1. Setting up VMC for vSphere

You can install OpenShift Container Platform on VMware Cloud (VMC) on AWS hosted vSphere clusters to enable applications to be deployed and managed both on-premise and off-premise, across the hybrid cloud.

You must configure several options in your VMC environment prior to installing OpenShift Container Platform on VMware vSphere. Ensure your VMC environment has the following prerequisites:
Create a non-exclusive, DHCP-enabled, NSX-T network segment and subnet. Other virtual machines (VMs) can be hosted on the subnet, but at least eight IP addresses must be available for the OpenShift Container Platform deployment.

Allocate two IP addresses, outside the DHCP range, and configure them with reverse DNS records.

- A DNS record for `api.<cluster_name>.<base_domain>` pointing to the allocated IP address.
- A DNS record for `*.apps.<cluster_name>.<base_domain>` pointing to the allocated IP address.

Configure the following firewall rules:

- An ANY:ANY firewall rule between the installation host and the software-defined data center (SDDC) management network on port 443. This allows you to upload the Red Hat Enterprise Linux CoreOS (RHCOS) OVA during deployment.
- An HTTPS firewall rule between the OpenShift Container Platform compute network and vCenter. This connection allows OpenShift Container Platform to communicate with vCenter for provisioning and managing nodes, persistent volume claims (PVCs), and other resources.

You must have the following information to deploy OpenShift Container Platform:

- The OpenShift Container Platform cluster name, such as `vmc-prod-1`.
- The base DNS name, such as `companyname.com`.
- If not using the default, the pod network CIDR and services network CIDR must be identified, which are set by default to `10.128.0.0/14` and `172.30.0.0/16`, respectively. These CIDRs are used for pod-to-pod and pod-to-service communication and are not accessible externally; however, they must not overlap with existing subnets in your organization.
- The following vCenter information:
  - vCenter hostname, username, and password
  - Datacenter name, such as `SDDC-Datacenter`
  - Cluster name, such as `Cluster-1`
  - Network name
  - Datastore name, such as `WorkloadDatastore`

**NOTE**

It is recommended to move your vSphere cluster to the VMC Compute-ResourcePool resource pool after your cluster installation is finished.

A Linux-based host deployed to VMC as a bastion.

- The bastion host can be Red Hat Enterprise Linux (RHEL) or any another Linux-based host; it must have internet connectivity and the ability to upload an OVA to the ESXi hosts.
- Download and install the OpenShift CLI tools to the bastion host.
The openshift-install installation program

The OpenShift CLI (oc) tool

**NOTE**

You cannot use the VMware NSX Container Plug-in for Kubernetes (NCP), and NSX is not used as the OpenShift SDN. The version of NSX currently available with VMC is incompatible with the version of NCP certified with OpenShift Container Platform.

However, the NSX DHCP service is used for virtual machine IP management with the full-stack automated OpenShift Container Platform deployment and with nodes provisioned, either manually or automatically, by the Machine API integration with vSphere. Additionally, NSX firewall rules are created to enable access with the OpenShift Container Platform cluster and between the bastion host and the VMC vSphere hosts.

20.5.1.1. VMC Sizer tool

VMware Cloud on AWS is built on top of AWS bare metal infrastructure; this is the same bare metal infrastructure which runs AWS native services. When a VMware cloud on AWS software-defined data center (SDDC) is deployed, you consume these physical server nodes and run the VMware ESXi hypervisor in a single tenant fashion. This means the physical infrastructure is not accessible to anyone else using VMC. It is important to consider how many physical hosts you will need to host your virtual infrastructure.

To determine this, VMware provides the VMC on AWS Sizer. With this tool, you can define the resources you intend to host on VMC:

- Types of workloads
- Total number of virtual machines
- Specification information such as:
  - Storage requirements
  - vCPUs
  - vRAM
  - Overcommit ratios

With these details, the sizer tool can generate a report, based on VMware best practices, and recommend your cluster configuration and the number of hosts you will need.

20.5.2. vSphere prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You created a registry on your mirror host and obtained the `imageContentSources` data for your version of OpenShift Container Platform.
IMPORTANT
Because the installation media is on the mirror host, you can use that computer to complete all installation steps.

- You provisioned block registry storage. For more information on persistent storage, see Understanding persistent storage.

- If you use a firewall and plan to use the Telemetry service, you configured the firewall to allow the sites that your cluster requires access to.

NOTE
If you are configuring a proxy, be sure to also review this site list.

20.5.3. About installations in restricted networks

In OpenShift Container Platform 4.10, you can perform an installation that does not require an active connection to the internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service’s IAM service, require internet access, so you might still require internet access. Depending on your network, you might require less internet access for an installation on bare metal hardware or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift Container Platform registry and contains the installation media. You can create this registry on a mirror host, which can access both the internet and your closed network, or by using other methods that meet your restrictions.

20.5.3.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The ClusterVersion status includes an Unable to retrieve available updates error.

- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

20.5.4. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.10, you require access to the internet to obtain the images that are necessary to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- Access Quay.io to obtain the packages that are required to install your cluster.

- Obtain the packages that are required to perform cluster updates.
IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

20.5.5. VMware vSphere infrastructure requirements

You must install the OpenShift Container Platform cluster on a VMware vSphere version 6 or 7 instance that meets the requirements for the components that you use.

Table 20.29. Version requirements for vSphere virtual environments

<table>
<thead>
<tr>
<th>Virtual environment product</th>
<th>Required version</th>
</tr>
</thead>
<tbody>
<tr>
<td>VM hardware version</td>
<td>13 or later</td>
</tr>
<tr>
<td>vSphere ESXi hosts</td>
<td>6.5 or later</td>
</tr>
<tr>
<td>vCenter host</td>
<td>6.5 or later</td>
</tr>
</tbody>
</table>

IMPORTANT

Installing a cluster on VMware vSphere version 6.7U3 or earlier and virtual hardware version 13 is now deprecated. These versions are still fully supported, but version 4.11 of OpenShift Container Platform will require vSphere virtual hardware version 15 or later. Hardware version 15 is now the default for vSphere virtual machines in OpenShift Container Platform. To update the hardware version for your vSphere nodes, see the "Updating hardware on nodes running in vSphere" article.

If your vSphere nodes are below hardware version 15 or your VMware vSphere version is earlier than 6.7U3, upgrading from OpenShift Container Platform 4.10 to OpenShift Container Platform 4.11 is not available.

Table 20.30. Minimum supported vSphere version for VMware components

<table>
<thead>
<tr>
<th>Component</th>
<th>Minimum supported versions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hypervisor</td>
<td>vSphere 6.5 and later with HW version 13</td>
<td>This version is the minimum version that Red Hat Enterprise Linux CoreOS (RHCOS) supports. See the Red Hat Enterprise Linux 8 supported hypervisors list.</td>
</tr>
</tbody>
</table>
If you use a vSphere version 6.5 instance, consider upgrading to 6.7U3 or 7.0 before you install OpenShift Container Platform.

**IMPORTANT**

You must ensure that the time on your ESXi hosts is synchronized before you install OpenShift Container Platform. See [Edit Time Configuration for a Host](VMware documentation) in the VMware documentation.

### 20.5.6. VMware vSphere CSI Driver Operator requirements

The following requirements must be met in order to install the CSI Driver Operator:

- VMware vSphere version 6.7U3 or later
- Virtual machines of hardware version 15 or later
- No third-party CSI driver already installed in the cluster

If a third-party CSI driver is present in the cluster, OpenShift Container Platform does not overwrite it. The presence of a third-party CSI driver prevents OpenShift Container Platform from upgrading to 4.11.

**Additional resources**

- To remove a third-party CSI driver, see [Removing a third-party vSphere CSI Driver](VMware documentation).
- To update the hardware version for your vSphere nodes, see [Updating hardware on nodes running in vSphere](VMware documentation).

### 20.5.7. vCenter requirements

Before you install an OpenShift Container Platform cluster on your vCenter that uses infrastructure that the installer provisions, you must prepare your environment.

#### Required vCenter account privileges

To install an OpenShift Container Platform cluster in a vCenter, the installation program requires access to an account with privileges to read and create the required resources. Using an account that has global administrative privileges is the simplest way to access all of the necessary permissions.

If you cannot use an account with global administrative privileges, you must create roles to grant the privileges necessary for OpenShift Container Platform cluster installation. While most of the privileges are always required, some are required only if you plan for the installation program to provision a folder to contain the OpenShift Container Platform cluster on your vCenter instance, which is the default behavior. You must create or amend vSphere roles for the specified objects to grant the required privileges.
An additional role is required if the installation program is to create a vSphere virtual machine folder.

**Example 20.7. Roles and privileges required for installation**

<table>
<thead>
<tr>
<th>vSphere object for role</th>
<th>When required</th>
<th>Required privileges</th>
</tr>
</thead>
<tbody>
<tr>
<td>vSphere vCenter</td>
<td>Always</td>
<td>Cns.Searchable</td>
</tr>

<td>Existing folder</td>
<td>True</td>
<td>Listed required privileges</td>
</tr>
</tbody>
</table>

For more information about creating an account with only the required privileges, see *vSphere Permissions and User Management Tasks* in the vSphere documentation.

### Using OpenShift Container Platform with vMotion

**IMPORTANT**

OpenShift Container Platform generally supports compute-only vMotion. Using Storage vMotion can cause issues and is not supported.

If you are using vSphere volumes in your pods, migrating a VM across datastores either manually or through Storage vMotion causes invalid references within OpenShift Container Platform persistent volume (PV) objects. These references prevent affected pods from starting up and can result in data loss.
Similarly, OpenShift Container Platform does not support selective migration of VMDKs across datastores, using datastore clusters for VM provisioning or for dynamic or static provisioning of PVs, or using a datastore that is part of a datastore cluster for dynamic or static provisioning of PVs.

Cluster resources
When you deploy an OpenShift Container Platform cluster that uses installer-provisioned infrastructure, the installation program must be able to create several resources in your vCenter instance.

A standard OpenShift Container Platform installation creates the following vCenter resources:

- 1 Folder
- 1 Tag category
- 1 Tag
- Virtual machines:
  - 1 template
  - 1 temporary bootstrap node
  - 3 control plane nodes
  - 3 compute machines

Although these resources use 856 GB of storage, the bootstrap node is destroyed during the cluster installation process. A minimum of 800 GB of storage is required to use a standard cluster.

If you deploy more compute machines, the OpenShift Container Platform cluster will use more storage.

Cluster limits
Available resources vary between clusters. The number of possible clusters within a vCenter is limited primarily by available storage space and any limitations on the number of required resources. Be sure to consider both limitations to the vCenter resources that the cluster creates and the resources that you require to deploy a cluster, such as IP addresses and networks.

Networking requirements
You must use DHCP for the network and ensure that the DHCP server is configured to provide persistent IP addresses to the cluster machines. All nodes must be in the same VLAN. You cannot scale the cluster using a second VLAN as a Day 2 operation. The VM in your restricted network must have access to vCenter so that it can provision and manage nodes, persistent volume claims (PVCs), and other resources. Additionally, you must create the following networking resources before you install the OpenShift Container Platform cluster:

**NOTE**

It is recommended that each OpenShift Container Platform node in the cluster must have access to a Network Time Protocol (NTP) server that is discoverable via DHCP. Installation is possible without an NTP server. However, asynchronous server clocks will cause errors, which NTP server prevents.

Required IP Addresses
An installer-provisioned vSphere installation requires two static IP addresses:

- The API address is used to access the cluster API.
The Ingress address is used for cluster ingress traffic.

You must provide these IP addresses to the installation program when you install the OpenShift Container Platform cluster.

DNS records
You must create DNS records for two static IP addresses in the appropriate DNS server for the vCenter instance that hosts your OpenShift Container Platform cluster. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the cluster base domain that you specify when you install the cluster. A complete DNS record takes the form: `<component>..<cluster_name>..<base_domain>`.

Table 20.31. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>API VIP</td>
<td>api.&lt;cluster_name&gt;..&lt;base_domain&gt;</td>
<td>This DNS A/AAAA or CNAME record must point to the load balancer for the control plane machines. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Ingress VIP</td>
<td>*.apps.&lt;cluster_name&gt;..&lt;base_domain&gt;</td>
<td>A wildcard DNS A/AAAA or CNAME record that points to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>

20.5.8. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the `core` user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user `core`. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.
IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N '' -f <path>/<file_name>
   ```

   Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   ```bash
   $ cat <path>/<file_name>.pub
   ```

   For example, run the following to view the `~/.ssh/id_rsa.pub` public key:

   ```bash
   $ cat ~/.ssh/id_rsa.pub
   ```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

   **NOTE**

   On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

   a. If the ssh-agent process is not already running for your local user, start it as a background task:

   ```bash
   $ eval "$(ssh-agent -s)"
   ```

   **Example output**

   ```bash
   Agent pid 31874
   ```
NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the `sshd-agent`:

```
$ ssh-add /path/to/private_key
```

Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

20.5.9. Adding vCenter root CA certificates to your system trust

Because the installation program requires access to your vCenter’s API, you must add your vCenter’s trusted root CA certificates to your system trust before you install an OpenShift Container Platform cluster.

Procedure

1. From the vCenter home page, download the vCenter’s root CA certificates. Click Download trusted root CA certificates in the vSphere Web Services SDK section. The `<vCenter>/certs/download.zip` file downloads.

2. Extract the compressed file that contains the vCenter root CA certificates. The contents of the compressed file resemble the following file structure:
3. Add the files for your operating system to the system trust. For example, on a Fedora operating system, run the following command:

```bash
# cp certs/lin/* /etc/pki/ca-trust/source/anchors
```

4. Update your system trust. For example, on a Fedora operating system, run the following command:

```bash
# update-ca-trust extract
```

20.5.10. Creating the RHCOS image for restricted network installations

Download the Red Hat Enterprise Linux CoreOS (RHCOS) image to install OpenShift Container Platform on a restricted network VMware vSphere environment.

**Prerequisites**

- Obtain the OpenShift Container Platform installation program. For a restricted network installation, the program is on your mirror registry host.

**Procedure**

2. Under Version, select the most recent release of OpenShift Container Platform 4.10 for RHEL 8.

   **IMPORTANT**

   The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available.

3. Download the Red Hat Enterprise Linux CoreOS (RHCOS) - vSphere image.

4. Upload the image you downloaded to a location that is accessible from the bastion server.

   The image is now available for a restricted installation. Note the image name or location for use in OpenShift Container Platform deployment.

20.5.11. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on VMware vSphere.

**Prerequisites**
Obtain the OpenShift Container Platform installation program and the pull secret for your cluster. For a restricted network installation, these files are on your mirror host.

Have the `imageContentSources` values that were generated during mirror registry creation.

Obtain the contents of the certificate for your mirror registry.

Retrieve a Red Hat Enterprise Linux CoreOS (RHCOS) image and upload it to an accessible location.

Obtain service principal permissions at the subscription level.

Procedure

1. Create the `install-config.yaml` file.
   
a. Change to the directory that contains the installation program and run the following command:

```
$ ./openshift-install create install-config --dir <installation_directory>  
```

   For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

   **IMPORTANT**

   Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

   b. At the prompts, provide the configuration details for your cloud:

      i. Optional: Select an SSH key to use to access your cluster machines.

         **NOTE**

         For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

      ii. Select `vsphere` as the platform to target.

      iii. Specify the name of your vCenter instance.

      iv. Specify the user name and password for the vCenter account that has the required permissions to create the cluster.

         The installation program connects to your vCenter instance.

      v. Select the datacenter in your vCenter instance to connect to.
vi. Select the default vCenter datastore to use.

vii. Select the vCenter cluster to install the OpenShift Container Platform cluster in. The installation program uses the root resource pool of the vSphere cluster as the default resource pool.

viii. Select the network in the vCenter instance that contains the virtual IP addresses and DNS records that you configured.

ix. Enter the virtual IP address that you configured for control plane API access.

x. Enter the virtual IP address that you configured for cluster ingress.

xi. Enter the base domain. This base domain must be the same one that you used in the DNS records that you configured.

xii. Enter a descriptive name for your cluster. The cluster name must be the same one that you used in the DNS records that you configured.

xiii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

2. In the `install-config.yaml` file, set the value of `platform.vsphere.clusterOSImage` to the image location or name. For example:

   ```yaml
   platform:
   vsphere:
   clusterOSImage: http://mirror.example.com/images/rhcos-43.81.201912131630.0-vmware.x86_64.ova?
   sha256=fbeb68e8a1f2a245ca19522c16c86f67f9ac8e4e0c1f0a812b068b16f7265d
   
   pullSecret:
   "auths":{
   "<mirror_host_name>:5000": {"auth": ","credentials"","email": "you@example.com"}}}
   
   For `<mirror_host_name>`, specify the registry domain name that you specified in the certificate for your mirror registry, and for `<credentials>`, specify the base64-encoded user name and password for your mirror registry.

   b. Add the `additionalTrustBundle` parameter and value.

   ```
   additionalTrustBundle:
   -----BEGIN CERTIFICATE-----
   ZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZ

   The value must be the contents of the certificate file that you used for your mirror registry, which can be an existing, trusted certificate authority or the self-signed certificate that you generated for the mirror registry.

   c. Add the image content resources, which look like this excerpt:
imageContentSources:
  - mirrors:
    - <mirror_host_name>:5000/<repo_name>/release
      source: quay.example.com/openshift-release-dev/ocp-release
    - mirrors:
      - <mirror_host_name>:5000/<repo_name>/release
        source: registry.example.com/ocp/release

To complete these values, use the `imageContentSources` that you recorded during mirror registry creation.

4. Make any other modifications to the `install-config.yaml` file that you require. You can find more information about the available parameters in the Installation configuration parameters section.

5. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

**IMPORTANT**

The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

20.5.11.1. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide a customized `install-config.yaml` installation configuration file that describes the details for your environment.

**NOTE**

After installation, you cannot modify these parameters in the `install-config.yaml` file.

20.5.11.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

**Table 20.32. Required parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is v1. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the <code>baseDomain</code> and <code>metadata.name</code> parameter values that uses the <code>&lt;metadata.name&gt;</code>., <code>&lt;baseDomain&gt;</code> format.</td>
<td>A fully-qualified domain or subdomain name, such as <code>example.com</code>.</td>
</tr>
<tr>
<td>metadata</td>
<td>Kubernetes resource <code>ObjectMeta</code>, from which only the <code>name</code> parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of <code>{{.metadata.name}}. {{.baseDomain}}</code>.</td>
<td>String of lowercase letters, hyphens (<code>-</code>), and periods (<code>.</code>), such as <code>dev</code>.</td>
</tr>
<tr>
<td>platform</td>
<td>The configuration for the specific platform upon which to perform the installation: <code>alibabacloud</code>, <code>aws</code>, <code>baremetal</code>, <code>azure</code>, <code>ibmcloud</code>, <code>openstack</code>, <code>ovirt</code>, <code>vsphere</code>, or <code>{}</code>. For additional information about <code>platform.&lt;platform&gt;</code> parameters, consult the table for your specific platform that follows.</td>
<td>Object</td>
</tr>
</tbody>
</table>

OpenShift Container Platform 4.10 Installing
Get a **pull secret** from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.

```json
{
  "auths":{
    "cloud.openshift.com":{
      "auth":"b3Blb=",
      "email":"you@example.com"
    },
    "quay.io":{
      "auth":"b3Blb=",
      "email":"you@example.com"
    }
  }
}
```

### 20.5.11.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

#### Table 20.33. Network parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>networking</strong></td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td><strong>networking.network</strong></td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN.</td>
</tr>
</tbody>
</table>
| **networking.clusterNetwork** | The IP address blocks for pods. The default value is 10.128.0.0/14 with a host prefix of /23. If you specify multiple IP address blocks, the blocks must not overlap. | An array of objects. For example: networking: clusterNetwork: 
- cidr: 10.128.0.0/14
  hostPrefix: 23 |
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking.clusterNetwork.cidr</td>
<td>Required if you use networking.clusterNetwork. An IP address block.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td></td>
<td>An IPv4 network.</td>
<td></td>
</tr>
<tr>
<td>networking.clusterNetwork.hostPrefix</td>
<td>The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given cidr. A hostPrefix value of 23 provides 510 (2^{(32 - 23)} - 2) pod IP addresses.</td>
<td>A subnet prefix. The default value is 23.</td>
</tr>
<tr>
<td>networking.serviceNetwork</td>
<td>The IP address block for services. The default value is 172.30.0.0/16.</td>
<td>An array with an IP address block in CIDR format. For example:</td>
</tr>
<tr>
<td></td>
<td>The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.</td>
<td>networking: serviceNetwork: - 172.30.0.0/16</td>
</tr>
<tr>
<td>networking.machineNetwork</td>
<td>The IP address blocks for machines.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td>If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td>networking: machineNetwork: - cidr: 10.0.0.0/16</td>
</tr>
<tr>
<td></td>
<td>If you specify multiple IP kernel arguments, the machineNetwork.cidr value must be the CIDR of the primary network.</td>
<td></td>
</tr>
<tr>
<td>networking.machineNetwork.cidr</td>
<td>Required if you use networking.machineNetwork. An IP address block.</td>
<td>An IP network block in CIDR notation.</td>
</tr>
<tr>
<td></td>
<td>The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24.</td>
<td>For example, 10.0.0.0/16.</td>
</tr>
<tr>
<td></td>
<td>An IPv4 network.</td>
<td></td>
</tr>
</tbody>
</table>

**20.5.11.1.3. Optional configuration parameters**

Optional installation configuration parameters are described in the following table:
### Table 20.34. Optional parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>cgroupsV2</td>
<td>Enables Linux control groups version 2 (cgroups v2) on specific nodes in your cluster. The OpenShift Container Platform process for enabling cgroups v2 disables all cgroup version 1 controllers and hierarchies. The OpenShift Container Platform cgroups version 2 feature is in Developer Preview and is not supported by Red Hat at this time.</td>
<td>true</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of <strong>MachinePool</strong> objects.</td>
</tr>
<tr>
<td>compute.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <strong>s390x</strong> (the default).</td>
<td>String</td>
</tr>
<tr>
<td>compute.hyperthreading</td>
<td>Whether to enable or disable simultaneous multithreading, or <strong>hyperthreading</strong>, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td>Enabled or <strong>Disabled</strong></td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td></td>
</tr>
<tr>
<td>compute.name</td>
<td>Required if you use <strong>compute</strong>. The name of the machine pool.</td>
<td><strong>worker</strong></td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>---------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>compute.platform</code></td>
<td>Required if you use <code>compute</code>. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <code>controlPlane.platform</code> parameter value.</td>
<td>alibaba, aws, azure, gcp, ibmcloud, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td><code>compute.replicas</code></td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td><code>controlPlane</code></td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of <code>MachinePool</code> objects.</td>
</tr>
<tr>
<td><code>controlPlane.architectu re</code></td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>s390x</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td><code>controlPlane.hypertreading</code></td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td><strong>Enabled</strong> or <strong>Disabled</strong></td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td></td>
</tr>
<tr>
<td><code>controlPlane.name</code></td>
<td>Required if you use <code>controlPlane</code>. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td><code>controlPlane.platform</code></td>
<td>Required if you use <code>controlPlane</code>. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the <code>compute.platform</code> parameter value.</td>
<td>alibaba, aws, azure, gcp, ibmcloud, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>----------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------</td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (“”).</td>
</tr>
</tbody>
</table>

**NOTE**

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Platform Operators reference content.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>fips</td>
<td>Enable or disable FIPS mode. The default is <strong>false</strong> (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</td>
<td><strong>false</strong> or <strong>true</strong></td>
</tr>
<tr>
<td><strong>IMPORTANT</strong></td>
<td>The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the <strong>x86_64</strong> architecture.</td>
<td></td>
</tr>
<tr>
<td><strong>NOTE</strong></td>
<td>If you are using Azure File storage, you cannot enable FIPS mode.</td>
<td></td>
</tr>
<tr>
<td>imageContentSources</td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects. Includes a <strong>source</strong> and, optionally, <strong>mirrors</strong>, as described in the following rows of this table.</td>
</tr>
<tr>
<td>imageContentSources.source</td>
<td>Required if you use imageContentSources. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td>imageContentSources.mirrors</td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
</tbody>
</table>
### publish

How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.

- **Internal** or **External**. The default value is **External**.

  Setting this field to **Internal** is not supported on non-cloud platforms and IBM Cloud.

  **IMPORTANT**

  If the value of the field is set to **Internal**, the cluster will become non-functional. For more information, refer to [BZ#1953035](#).

### sshKey

The SSH key or keys to authenticate access your cluster machines.

- **NOTE**

  For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

  One or more keys. For example:

  ```
  sshKey:
  <key1>
  <key2>
  <key3>
  ```

---

### 20.5.11.4. Additional VMware vSphere configuration parameters

Additional VMware vSphere configuration parameters are described in the following table:

**Table 20.35. Additional VMware vSphere cluster parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>platform.vsphere.vCenter</code></td>
<td>The fully-qualified hostname or IP address of the vCenter server.</td>
<td>String</td>
</tr>
<tr>
<td><code>platform.vsphere.username</code></td>
<td>The user name to use to connect to the vCenter instance with. This user must have at least the roles and privileges that are required for static or dynamic persistent volume provisioning in vSphere.</td>
<td>String</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>---------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>platform.vsphere.password</code></td>
<td>The password for the vCenter user name.</td>
<td>String</td>
</tr>
<tr>
<td><code>platform.vsphere.datacenter</code></td>
<td>The name of the datacenter to use in the vCenter instance.</td>
<td>String</td>
</tr>
<tr>
<td><code>platform.vsphere.defaultDatastore</code></td>
<td>The name of the default datastore to use for provisioning volumes.</td>
<td>String</td>
</tr>
<tr>
<td><code>platform.vsphere.folder</code></td>
<td>Optional. The absolute path of an existing folder where the installation program creates the virtual machines. If you do not provide this value, the installation program creates a folder that is named with the infrastructure ID in the datacenter virtual machine folder.</td>
<td>String, for example, <code>&lt;datacenter_name&gt;/vm/&lt;folder_name&gt;/&lt;subfolder_name&gt;</code>.</td>
</tr>
<tr>
<td><code>platform.vsphere.network</code></td>
<td>The network in the vCenter instance that contains the virtual IP addresses and DNS records that you configured.</td>
<td>String</td>
</tr>
<tr>
<td><code>platform.vsphere.cluster</code></td>
<td>The vCenter cluster to install the OpenShift Container Platform cluster in.</td>
<td>String</td>
</tr>
<tr>
<td><code>platform.vsphere.apiVIP</code></td>
<td>The virtual IP (VIP) address that you configured for control plane API access.</td>
<td>An IP address, for example 128.0.0.1.</td>
</tr>
<tr>
<td><code>platform.vsphere.ingressVIP</code></td>
<td>The virtual IP (VIP) address that you configured for cluster ingress.</td>
<td>An IP address, for example 128.0.0.1.</td>
</tr>
<tr>
<td><code>platform.vsphere.diskType</code></td>
<td>Optional. The disk provisioning method. This value defaults to the vSphere default storage policy if not set.</td>
<td>Valid values are thin, thick, or eagerZeroedThick.</td>
</tr>
</tbody>
</table>

20.5.11.1.5. Optional VMware vSphere machine pool configuration parameters

Optional VMware vSphere machine pool configuration parameters are described in the following table:

Table 20.36. Optional VMware vSphere machine pool parameters
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>platform.vsphere.clusterOSImage</strong></td>
<td>The location from which the installer downloads the RHCOS image. You must set this parameter to perform an installation in a restricted network.</td>
<td>An HTTP or HTTPS URL, optionally with a SHA-256 checksum. For example, <a href="https://mirror.openshift.com/images/rhcos-">https://mirror.openshift.com/images/rhcos-</a>&lt;version&gt;-vmware.&lt;architecture&gt;.ova.</td>
</tr>
<tr>
<td><strong>platform.vsphere.osDisk.diskSizeGB</strong></td>
<td>The size of the disk in gigabytes.</td>
<td>Integer</td>
</tr>
<tr>
<td><strong>platform.vsphere.cpus</strong></td>
<td>The total number of virtual processor cores to assign a virtual machine.</td>
<td>Integer</td>
</tr>
<tr>
<td><strong>platform.vsphere.coresPerSocket</strong></td>
<td>The number of cores per socket in a virtual machine. The number of virtual sockets on the virtual machine is <code>platform.vsphere.cpus/platform.vsphere.coresPerSocket</code>. The default value is 1.</td>
<td>Integer</td>
</tr>
<tr>
<td><strong>platform.vsphere.memoryMB</strong></td>
<td>The size of a virtual machine’s memory in megabytes.</td>
<td>Integer</td>
</tr>
</tbody>
</table>

20.5.11.2 Sample install-config.yaml file for an installer-provisioned VMware vSphere cluster

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute: 2
  - hyperthreading: Enabled
    name: worker
    replicas: 3
    platform:
      vsphere: 4
        cpus: 2
        coresPerSocket: 2
        memoryMB: 8196
        osDisk:
          diskSizeGB: 120
controlPlane: 5
  hyperthreading: Enabled
  name: master
  replicas: 3
  platform:
```
The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

The **controlPlane** section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -, and the first line of the **controlPlane** section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading, or **hyperthreading**. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to **Disabled**. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.
IMPORTANT

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Your machines must use at least 8 CPUs and 32 GB of RAM if you disable simultaneous multithreading.

Optional: Provide additional configuration for the machine pool parameters for the compute and control plane machines.

The cluster name that you specified in your DNS records.

The vSphere disk provisioning method.

The vSphere cluster to install the OpenShift Container Platform cluster in. The installation program uses the root resource pool of the vSphere cluster as the default resource pool.

The location of the Red Hat Enterprise Linux CoreOS (RHCOS) image that is accessible from the bastion server.

For `<local_registry>`, specify the registry domain name, and optionally the port, that your mirror registry uses to serve content. For example `registry.example.com` or `registry.example.com:5000`. For `<credentials>`, specify the base64-encoded user name and password for your mirror registry.

Provide the contents of the certificate file that you used for your mirror registry.

Provide the `imageContentSources` section from the output of the command to mirror the repository.

20.5.11.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

Prerequisites

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

NOTE

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).
Procedure

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
     httpProxy: http://<username>:<pswd>@<ip>:<port>  // 1
     httpsProxy: https://<username>:<pswd>@<ip>:<port>  // 2
     noProxy: example.com  // 3
   additionalTrustBundle: |
     -----BEGIN CERTIFICATE-----
     <MY_TRUSTED_CA_CERT>
     -----END CERTIFICATE-----
     ...
   ```

   - **1** A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.
   - **2** A proxy URL to use for creating HTTPS connections outside the cluster.
   - **3** A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with `.` to match subdomains only. For example, `.y.com` matches `x.y.com`, but not `y.com`. Use `*` to bypass the proxy for all destinations. You must include vCenter’s IP address and the IP range that you use for its machines.
   - **4** If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the `trustedCA` field of the `Proxy` object. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

   **NOTE**

   The installation program does not support the proxy `readinessEndpoints` field.

2. Save the file and reference it when installing OpenShift Container Platform.

   The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

   **NOTE**

   Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

20.5.12. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.
IMPORTANT

You can run the `create cluster` command of the installation program only once, during initial installation.

Prerequisites

- Configure an account with the cloud platform that hosts your cluster.
- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Change to the directory that contains the installation program and initialize the cluster deployment:

   ```bash
   $ ./openshift-install create cluster --dir <installation_directory> \  
   --log-level=info
   
   1 For `<installation_directory>`, specify the location of your customized `install-config.yaml` file.
   2 To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.
   
   IMPORTANT
   
   Use the `openshift-install` command from the bastion hosted in the VMC environment.
   
   NOTE
   
   If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.

   When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the `kubeadm` user, display in your terminal.

Example output

... INFO Install complete! INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig' INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-Wi5AL" INFO Time elapsed: 36m22s
NOTE

The cluster access and credential information also outputs to `<installation_directory>/openshift_install.log` when an installation succeeds.

IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

IMPORTANT

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

20.5.13. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (`oc`) to interact with OpenShift Container Platform from a command-line interface. You can install `oc` on Linux, Windows, or macOS.

IMPORTANT

If you installed an earlier version of `oc`, you cannot use it to complete all of the commands in OpenShift Container Platform 4.10. Download and install the new version of `oc`.

Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (`oc`) binary on Linux by using the following procedure.

**Procedure**

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.10 Linux Client entry and save the file.

4. Unpack the archive:

   ```
   $ tar xzvf <file>
   ```

5. Place the `oc` binary in a directory that is on your PATH.
To check your PATH, execute the following command:

```
$ echo $PATH
```

After you install the OpenShift CLI, it is available using the oc command:

```
$ oc <command>
```

### Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version in the Version drop-down menu.
3. Click Download Now next to the OpenShift v4.10 Windows Client entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the oc binary to a directory that is on your PATH.
   To check your PATH, open the command prompt and execute the following command:

```
C:\> path
```

After you install the OpenShift CLI, it is available using the oc command:

```
C:\> oc <command>
```

### Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version in the Version drop-down menu.
3. Click Download Now next to the OpenShift v4.10 MacOSX Client entry and save the file.
4. Unpack and unzip the archive.
5. Move the oc binary to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:

```
$ echo $PATH
```

After you install the OpenShift CLI, it is available using the oc command:

```
$ oc <command>
```
20.5.14. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster kubeconfig file. The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the oc CLI.

Procedure

1. Export the kubeadmin credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run oc commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   system:admin
   ```

Example output

20.5.15. Disabling the default OperatorHub sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

Procedure

- Disable the sources for the default catalogs by adding disableAllDefaultSources: true to the OperatorHub object:

  ```bash
  $ oc patch OperatorHub cluster --type json \
  -p '[{"op": "add", "path": "/spec/disableAllDefaultSources", "value": true}]'
  ```

TIP

Alternatively, you can use the web console to manage catalog sources. From the Administration → Cluster Settings → Configuration → OperatorHub page, click the Sources tab, where you can create, delete, disable, and enable individual sources.

20.5.16. Creating registry storage
After you install the cluster, you must create storage for the Registry Operator.

20.5.16.1. Image registry removed during installation

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as Removed. This allows openshift-installer to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the managementState from Removed to Managed.

NOTE

The Prometheus console provides an ImageRegistryRemoved alert, for example:

"Image Registry has been removed. ImageStreamTags, BuildConfigs and DeploymentConfigs which reference ImageStreamTags may not work as expected. Please configure storage and update the config to Managed state by editing configs.imageregistry.operator.openshift.io."

20.5.16.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the Recreate rollout strategy during upgrades.

20.5.16.2.1. Configuring registry storage for VMware vSphere

As a cluster administrator, following installation you must configure your registry to use storage.

Prerequisites

- Cluster administrator permissions.
- A cluster on VMware vSphere.
- Persistent storage provisioned for your cluster, such as Red Hat OpenShift Data Foundation.

IMPORTANT

OpenShift Container Platform supports ReadWriteOnce access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, ReadWriteMany access is required.

- Must have "100Gi" capacity.
**IMPORTANT**

Testing shows issues with using the NFS server on RHEL as storage backend for core services. This includes the OpenShift Container Registry and Quay, Prometheus for monitoring storage, and Elasticsearch for logging storage. Therefore, using RHEL NFS to back PVs used by core services is not recommended.

Other NFS implementations on the marketplace might not have these issues. Contact the individual NFS implementation vendor for more information on any testing that was possibly completed against these OpenShift Container Platform core components.

**Procedure**

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

   **NOTE**

   When using shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

   ```bash
   $ oc get pod -n openshift-image-registry -l docker-registry=default
   ```

   **Example output**

   No resources found in openshift-image-registry namespace

   **NOTE**

   If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

   ```bash
   $ oc edit configs.imageregistry.operator.openshift.io
   ```

   **Example output**

   `storage:
   pvc:
   claim:`

   Leave the `claim` field blank to allow the automatic creation of an `image-registry-storage` PVC.

4. Check the `clusteroperator` status:

   ```bash
   $ oc get clusteroperator image-registry
   ```
20.5.17. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.10, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service.

20.5.18. Next steps

- Customize your cluster.
- Configure image streams for the Cluster Samples Operator and the must-gather tool.
- Learn how to use Operator Lifecycle Manager (OLM) on restricted networks.
- If necessary, you can opt out of remote health reporting.
- Set up your registry and configure registry storage.

20.6. INSTALLING A CLUSTER ON VMC WITH USER-PROVISIONED INFRASTRUCTURE

In OpenShift Container Platform version 4.10, you can install a cluster on VMware vSphere infrastructure that you provision by deploying it to VMware Cloud (VMC) on AWS.

Once you configure your VMC environment for OpenShift Container Platform deployment, you use the OpenShift Container Platform installation program from the bastion management host, co-located in the VMC environment. The installation program and control plane automates the process of deploying and managing the resources needed for the OpenShift Container Platform cluster.

20.6.1. Setting up VMC for vSphere

You can install OpenShift Container Platform on VMware Cloud (VMC) on AWS hosted vSphere clusters to enable applications to be deployed and managed both on-premise and off-premise, across the hybrid cloud.
You must configure several options in your VMC environment prior to installing OpenShift Container Platform on VMware vSphere. Ensure your VMC environment has the following prerequisites:

- Create a non-exclusive, DHCP-enabled, NSX-T network segment and subnet. Other virtual machines (VMs) can be hosted on the subnet, but at least eight IP addresses must be available for the OpenShift Container Platform deployment.

- Configure the following firewall rules:
  - An ANY:ANY firewall rule between the OpenShift Container Platform compute network and the internet. This is used by nodes and applications to download container images.
  - An ANY:ANY firewall rule between the installation host and the software-defined data center (SDDC) management network on port 443. This allows you to upload the Red Hat Enterprise Linux CoreOS (RHCOS) OVA during deployment.
  - An HTTPS firewall rule between the OpenShift Container Platform compute network and vCenter. This connection allows OpenShift Container Platform to communicate with vCenter for provisioning and managing nodes, persistent volume claims (PVCs), and other resources.

- You must have the following information to deploy OpenShift Container Platform:
  - The OpenShift Container Platform cluster name, such as **vmc-prod-1**.
  - The base DNS name, such as **companyname.com**.
  - If not using the default, the pod network CIDR and services network CIDR must be identified, which are set by default to **10.128.0.0/14** and **172.30.0.0/16**, respectively. These CIDRs are used for pod-to-pod and pod-to-service communication and are not accessible externally; however, they must not overlap with existing subnets in your organization.
  - The following vCenter information:
    - vCenter hostname, username, and password
    - Datacenter name, such as **SDDC-Datacenter**
    - Cluster name, such as **Cluster-1**
    - Network name
    - Datastore name, such as **WorkloadDatastore**
NOTE

It is recommended to move your vSphere cluster to the VMC Compute-ResourcePool resource pool after your cluster installation is finished.

- A Linux-based host deployed to VMC as a bastion.
  - The bastion host can be Red Hat Enterprise Linux (RHEL) or any another Linux-based host; it must have internet connectivity and the ability to upload an OVA to the ESXi hosts.
  - Download and install the OpenShift CLI tools to the bastion host.
    - The openshift-install installation program
    - The OpenShift CLI (oc) tool

NOTE

You cannot use the VMware NSX Container Plug-in for Kubernetes (NCP), and NSX is not used as the OpenShift SDN. The version of NSX currently available with VMC is incompatible with the version of NCP certified with OpenShift Container Platform.

However, the NSX DHCP service is used for virtual machine IP management with the full-stack automated OpenShift Container Platform deployment and with nodes provisioned, either manually or automatically, by the Machine API integration with vSphere. Additionally, NSX firewall rules are created to enable access with the OpenShift Container Platform cluster and between the bastion host and the VMC vSphere hosts.

20.6.1.1. VMC Sizer tool

VMware Cloud on AWS is built on top of AWS bare metal infrastructure; this is the same bare metal infrastructure which runs AWS native services. When a VMware cloud on AWS software-defined data center (SDDC) is deployed, you consume these physical server nodes and run the VMware ESXi hypervisor in a single tenant fashion. This means the physical infrastructure is not accessible to anyone else using VMC. It is important to consider how many physical hosts you will need to host your virtual infrastructure.

To determine this, VMware provides the VMC on AWS Sizer. With this tool, you can define the resources you intend to host on VMC:

- Types of workloads
- Total number of virtual machines
- Specification information such as:
  - Storage requirements
  - vCPUs
  - vRAM
  - Overcommit ratios

With these details, the sizer tool can generate a report, based on VMware best practices, and recommend your cluster configuration and the number of hosts you will need.
20.6.2. vSphere prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You provisioned block registry storage. For more information on persistent storage, see Understanding persistent storage.
- If you use a firewall, you configured it to allow the sites that your cluster requires access to.

**NOTE**
Be sure to also review this site list if you are configuring a proxy.

20.6.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.10, you require access to the internet to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

20.6.4. VMware vSphere infrastructure requirements

You must install the OpenShift Container Platform cluster on a VMware vSphere version 6 or 7 instance that meets the requirements for the components that you use.

Table 20.37. Version requirements for vSphere virtual environments

<table>
<thead>
<tr>
<th>Virtual environment product</th>
<th>Required version</th>
</tr>
</thead>
<tbody>
<tr>
<td>VM hardware version</td>
<td>13 or later</td>
</tr>
<tr>
<td>vSphere ESXi hosts</td>
<td>6.5 or later</td>
</tr>
</tbody>
</table>
**IMPORTANT**

Installing a cluster on VMware vSphere version 6.7U3 or earlier and virtual hardware version 13 is now deprecated. These versions are still fully supported, but version 4.11 of OpenShift Container Platform will require vSphere virtual hardware version 15 or later. Hardware version 15 is now the default for vSphere virtual machines in OpenShift Container Platform. To update the hardware version for your vSphere nodes, see the “Updating hardware on nodes running in vSphere” article.

If your vSphere nodes are below hardware version 15 or your VMware vSphere version is earlier than 6.7U3, upgrading from OpenShift Container Platform 4.10 to OpenShift Container Platform 4.11 is not available.

<table>
<thead>
<tr>
<th>Component</th>
<th>Minimum supported versions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hypervisor</td>
<td>vSphere 6.5 and later with HW version 13</td>
<td>This version is the minimum version that Red Hat Enterprise Linux CoreOS (RHCOS) supports. See the Red Hat Enterprise Linux 8 supported hypervisors list.</td>
</tr>
<tr>
<td>Storage with in-tree drivers</td>
<td>vSphere 6.5 and later</td>
<td>This plug-in creates vSphere storage by using the in-tree storage drivers for vSphere included in OpenShift Container Platform.</td>
</tr>
</tbody>
</table>

**Table 20.38. Minimum supported vSphere version for VMware components**

If you use a vSphere version 6.5 instance, consider upgrading to 6.7U3 or 7.0 before you install OpenShift Container Platform.

**IMPORTANT**

You must ensure that the time on your ESXi hosts is synchronized before you install OpenShift Container Platform. See Edit Time Configuration for a Host in the VMware documentation.

**20.6.5. VMware vSphere CSI Driver Operator requirements**

The following requirements must be met in order to install the CSI Driver Operator:

- VMware vSphere version 6.7U3 or later
- Virtual machines of hardware version 15 or later
• No third-party CSI driver already installed in the cluster

If a third-party CSI driver is present in the cluster, OpenShift Container Platform does not overwrite it. The presence of a third-party CSI driver prevents OpenShift Container Platform from upgrading to 4.11.

Additional resources

• To remove a third-party CSI driver, see Removing a third-party vSphere CSI Driver.

• To update the hardware version for your vSphere nodes, see Updating hardware on nodes running in vSphere.

20.6.6. Requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines. This section describes the requirements for deploying OpenShift Container Platform on user-provisioned infrastructure.

20.6.6.1. Required machines for cluster installation

The smallest OpenShift Container Platform clusters require the following hosts:

Table 20.39. Minimum required hosts

<table>
<thead>
<tr>
<th>Hosts</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>One temporary bootstrap machine</td>
<td>The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.</td>
</tr>
<tr>
<td>Three control plane machines</td>
<td>The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.</td>
</tr>
<tr>
<td>At least two compute machines, which are also known as worker machines.</td>
<td>The workloads requested by OpenShift Container Platform users run on the compute machines.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

To improve high availability of your cluster, distribute the control plane machines over different z/VM instances on at least two physical machines.

The bootstrap, control plane, and compute machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 8 and inherits all of its hardware certifications and requirements. See Red Hat Enterprise Linux technology capabilities and limits.

20.6.6.2. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:
<table>
<thead>
<tr>
<th>Machine</th>
<th>Operating System</th>
<th>vCPU</th>
<th>Virtual RAM</th>
<th>Storage</th>
<th>IOPS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS</td>
<td>2</td>
<td>8 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
</tbody>
</table>

1. One physical core (IFL) provides two logical cores (threads) when SMT-2 is enabled. The hypervisor can provide two or more vCPUs.

### 20.6.6.3. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The `kube-controller-manager` only approves the kubelet client CSRs. The `machine-approver` cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

### 20.6.6.4. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in `initramfs` during boot to fetch their Ignition config files.

During the initial boot, the machines require an HTTP or HTTPS server to establish a network connection to download their Ignition config files.

The machines are configured with static IP addresses. No DHCP server is required. Ensure that the machines have persistent IP addresses and hostnames.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

#### 20.6.6.4.1. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

**IMPORTANT**

In connected OpenShift Container Platform environments, all nodes are required to have internet access to pull images for platform containers and provide telemetry data to Red Hat.
### Table 20.40. Ports used for all-machine to all-machine communications

</tr>
</tbody>
</table>

### NTP configuration for user-provisioned infrastructure

OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for Configuring chrony time service.

#### 20.6.6.5. User-provisioned DNS requirements

In OpenShift Container Platform deployments, DNS name resolution is required for the following components:

- The Kubernetes API
The OpenShift Container Platform application wildcard
The bootstrap, control plane, and compute machines

Reverse DNS resolution is also required for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the hostnames for all the nodes, unless the hostnames are provided by DHCP. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

The following DNS records are required for a user-provisioned OpenShift Container Platform cluster and they must be in place before installation. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>`.

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the API load balancer. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td></td>
<td>api-int.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to internally identify the API load balancer. These records must be resolvable from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Routes</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A wildcard DNS A/AAAA or CNAME record that refers to the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster. For example, <code>console-openshift-console.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;</code> is used as a wildcard route to the OpenShift Container Platform console.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

The API server must be able to resolve the worker nodes by the hostnames that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.
<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap machine</td>
<td>bootstrap.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Control plane machines</td>
<td>&lt;master&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Compute machines</td>
<td>&lt;worker&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**NOTE**

In OpenShift Container Platform 4.4 and later, you do not need to specify etcd host and SRV records in your DNS configuration.

**TIP**

You can use the `dig` command to verify name and reverse name resolution. See the section on Validating DNS resolution for user-provisioned infrastructure for detailed validation steps.

### 20.6.6.5.1. Example DNS configuration for user-provisioned clusters

This section provides A and PTR record configuration samples that meet the DNS requirements for deploying OpenShift Container Platform on user-provisioned infrastructure. The samples are not meant to provide advice for choosing one DNS solution over another.

In the examples, the cluster name is `ocp4` and the base domain is `example.com`.

#### Example DNS A record configuration for a user-provisioned cluster

The following example is a BIND zone file that shows sample A records for name resolution in a user-provisioned cluster.

**Example 20.9. Sample DNS zone database**

```plaintext
$TTL 1W
@ IN SOA ns1.example.com. root (2019070700 ; serial 3H ; refresh (3 hours) 30M ; retry (30 minutes) 2W ; expiry (2 weeks) 1W ) ; minimum (1 week)
IN NS ns1.example.com.
IN MX 10 smtp.example.com.
```
Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer.

Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer and is used for internal cluster communications.

Provides name resolution for the wildcard routes. The record refers to the IP address of the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

**NOTE**

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

Provides name resolution for the bootstrap machine.

Provides name resolution for the control plane machines.

Provides name resolution for the compute machines.

**Example DNS PTR record configuration for a user-provisioned cluster**

The following example BIND zone file shows sample PTR records for reverse name resolution in a user-provisioned cluster.

```plaintext
ns1.example.com.  IN A 192.168.1.5
smtp.example.com.  IN A 192.168.1.5
helper.example.com.  IN A 192.168.1.5
helper.ocp4.example.com. IN A 192.168.1.5
api.ocp4.example.com. IN A 192.168.1.5
api-int.ocp4.example.com. IN A 192.168.1.5
*.apps.ocp4.example.com. IN A 192.168.1.5
bootstrap.ocp4.example.com. IN A 192.168.1.96
master0.ocp4.example.com. IN A 192.168.1.97
master1.ocp4.example.com. IN A 192.168.1.98
master2.ocp4.example.com. IN A 192.168.1.99
worker0.ocp4.example.com. IN A 192.168.1.11
worker1.ocp4.example.com. IN A 192.168.1.17

; EOF
```
Example 20.10. Sample DNS zone database for reverse records

$TTL 1W
@ IN SOA ns1.example.com. root ( 2019070700 ; serial 3H ; refresh (3 hours) 30M ; retry (30 minutes) 2W ; expiry (2 weeks) 1W ) ; minimum (1 week)
IN NS ns1.example.com.
;
5.1.168.192.in-addr.arpa. IN PTR api.ocp4.example.com. 1
5.1.168.192.in-addr.arpa. IN PTR api-int.ocp4.example.com. 2
;
96.1.168.192.in-addr.arpa. IN PTR bootstrap.ocp4.example.com. 3
;
97.1.168.192.in-addr.arpa. IN PTR master0.ocp4.example.com. 4
98.1.168.192.in-addr.arpa. IN PTR master1.ocp4.example.com. 5
99.1.168.192.in-addr.arpa. IN PTR master2.ocp4.example.com. 6
;
11.1.168.192.in-addr.arpa. IN PTR worker0.ocp4.example.com. 7
7.1.168.192.in-addr.arpa. IN PTR worker1.ocp4.example.com. 8
;
;EOF

1. Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer.

2. Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer and is used for internal cluster communications.

3. Provides reverse DNS resolution for the bootstrap machine.

4 5 6. Provides reverse DNS resolution for the control plane machines.

7 8. Provides reverse DNS resolution for the compute machines.

NOTE

A PTR record is not required for the OpenShift Container Platform application wildcard.

20.6.6.6. Load balancing requirements for user-provisioned infrastructure

Before you install OpenShift Container Platform, you must provision the API and application ingress load balancing infrastructure. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

The load balancing infrastructure must meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
• Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.

• A stateless load balancing algorithm. The options vary based on the load balancer implementation.

**NOTE**

Session persistence is not required for the API load balancer to function properly.

Configure the following ports on both the front and back of the load balancers:

**Table 20.44. API load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the /readyz endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>

**NOTE**

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the /readyz endpoint to the removal of the API server instance from the pool. Within the time frame after /readyz returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application ingress load balancer**

   Provides an ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

   • Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the ingress routes.

   • A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.
TIP

If the true IP address of the client can be seen by the application ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

Configure the following ports on both the front and back of the load balancers:

**Table 20.45. Application ingress load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
<tr>
<td>1936</td>
<td>The worker nodes that run the Ingress Controller pods, by default. You must configure the <code>/healthz/ready</code> endpoint for the ingress health check probe.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>

**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

**NOTE**

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

### 20.6.6.6.1. Example load balancer configuration for user-provisioned clusters

This section provides an example API and application ingress load balancer configuration that meets the load balancing requirements for user-provisioned clusters. The sample is an `/etc/haproxy/haproxy.cfg` configuration for an HAProxy load balancer. The example is not meant to provide advice for choosing one load balancing solution over another.

**NOTE**

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.
Example 20.11. Sample API and application ingress load balancer configuration

global
  log         127.0.0.1 local2
  pidfile     /var/run/haproxy.pid
  maxconn     4000
daemon
defaults
  mode                    http
  log                     global
  option                  dontlognull
  option http-server-close
  option                  redispatch
  retries                 3
  timeout http-request    10s
  timeout queue           1m
  timeout connect         10s
  timeout client          1m
  timeout server          1m
  timeout http-keep-alive 10s
  timeout check           10s
  maxconn                 3000
frontend stats
  bind *:1936
  mode            http
  log             global
  maxconn 10
  stats enable
  stats hide-version
  stats refresh 30s
  stats show-node
  stats show-desc Stats for ocp4 cluster
  stats auth admin:ocp4
  stats uri /stats
listen api-server-6443
  bind *:6443
  mode tcp
  server bootstrap bootstrap.ocp4.example.com:6443 check inter 1s backup
  server master0 master0.ocp4.example.com:6443 check inter 1s
  server master1 master1.ocp4.example.com:6443 check inter 1s
  server master2 master2.ocp4.example.com:6443 check inter 1s
listen machine-config-server-22623
  bind *:22623
  mode tcp
  server bootstrap bootstrap.ocp4.example.com:22623 check inter 1s backup
  server master0 master0.ocp4.example.com:22623 check inter 1s
  server master1 master1.ocp4.example.com:22623 check inter 1s
  server master2 master2.ocp4.example.com:22623 check inter 1s
listen ingress-router-443
  bind *:443
  mode tcp
  balance source
  server worker0 worker0.ocp4.example.com:443 check inter 1s
  server worker1 worker1.ocp4.example.com:443 check inter 1s
listen ingress-router-80
In the example, the cluster name is `ocp4`.

Port 6443 handles the Kubernetes API traffic and points to the control plane machines.

The bootstrap entries must be in place before the OpenShift Container Platform cluster installation and they must be removed after the bootstrap process is complete.

Port 22623 handles the machine config server traffic and points to the control plane machines.

Port 443 handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

Port 80 handles the HTTP traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

**TIP**

If you are using HAProxy as a load balancer, you can check that the `haproxy` process is listening on ports 6443, 22623, 443, and 80 by running `netstat -nltupe` on the HAProxy node.

**NOTE**

If you are using HAProxy as a load balancer and SELinux is set to enforcing, you must ensure that the HAProxy service can bind to the configured TCP port by running `setsebool -P haproxy_connect_any=1`.

20.6.7. Preparing the user-provisioned infrastructure

Before you install OpenShift Container Platform on user-provisioned infrastructure, you must prepare the underlying infrastructure.

This section provides details about the high-level steps required to set up your cluster infrastructure in preparation for an OpenShift Container Platform installation. This includes configuring IP networking and network connectivity for your cluster nodes, preparing a web server for the Ignition files, enabling the required ports through your firewall, and setting up the required DNS and load balancing infrastructure.

After preparation, your cluster infrastructure must meet the requirements outlined in the `Requirements for a cluster with user-provisioned infrastructure` section.
Prerequisites

- You have reviewed the OpenShift Container Platform 4.x Tested Integrations page.
- You have reviewed the infrastructure requirements detailed in the Requirements for a cluster with user-provisioned infrastructure section.

Procedure

1. Set up static IP addresses.
2. Set up an HTTP or HTTPS server to provide Ignition files to the cluster nodes.
3. Ensure that your network infrastructure provides the required network connectivity between the cluster components. See the Networking requirements for user-provisioned infrastructure section for details about the requirements.
4. Configure your firewall to enable the ports required for the OpenShift Container Platform cluster components to communicate. See Networking requirements for user-provisioned infrastructure section for details about the ports that are required.
5. Setup the required DNS infrastructure for your cluster.
   a. Configure DNS name resolution for the Kubernetes API, the application wildcard, the bootstrap machine, the control plane machines, and the compute machines.
   b. Configure reverse DNS resolution for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines. See the User-provisioned DNS requirements section for more information about the OpenShift Container Platform DNS requirements.
6. Validate your DNS configuration.
   a. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses in the responses correspond to the correct components.
   b. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names in the responses correspond to the correct components. See the Validating DNS resolution for user-provisioned infrastructure section for detailed DNS validation steps.
7. Provision the required API and application ingress load balancing infrastructure. See the Load balancing requirements for user-provisioned infrastructure section for more information about the requirements.

**NOTE**

Some load balancing solutions require the DNS name resolution for the cluster nodes to be in place before the load balancing is initialized.

20.6.8. Validating DNS resolution for user-provisioned infrastructure

You can validate your DNS configuration before installing OpenShift Container Platform on user-provisioned infrastructure.
**IMPORTANT**

The validation steps detailed in this section must succeed before you install your cluster.

**Prerequisites**

- You have configured the required DNS records for your user-provisioned infrastructure.

**Procedure**

1. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses contained in the responses correspond to the correct components.

   a. Perform a lookup against the Kubernetes API record name. Check that the result points to the IP address of the API load balancer:

   ```
   $ dig +noall +answer @<nameserver_ip> api.<cluster_name>.<base_domain>  # 1
   ``

   Replace `<nameserver_ip>` with the IP address of the nameserver, `<cluster_name>` with your cluster name, and `<base_domain>` with your base domain name.

   **Example output**

   ```
   api.ocp4.example.com. 0 IN A 192.168.1.5
   ```

   b. Perform a lookup against the Kubernetes internal API record name. Check that the result points to the IP address of the API load balancer:

   ```
   $ dig +noall +answer @<nameserver_ip> api-int.<cluster_name>.<base_domain>
   ``

   **Example output**

   ```
   api-int.ocp4.example.com. 0 IN A 192.168.1.5
   ```

   c. Test an example `*.apps.<cluster_name>.<base_domain>` DNS wildcard lookup. All of the application wildcard lookups must resolve to the IP address of the application ingress load balancer:

   ```
   $ dig +noall +answer @<nameserver_ip> random.apps.<cluster_name>.<base_domain>
   ``

   **Example output**

   ```
   random.apps.ocp4.example.com. 0 IN A 192.168.1.5
   ```

   **NOTE**

   In the example outputs, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.
You can replace random with another wildcard value. For example, you can query the route to the OpenShift Container Platform console:

```
$ dig +noall +answer @<nameserver_ip> console-openshift-console.apps.<cluster_name>.<base_domain>
```

**Example output**

```
console-openshift-console.apps.ocp4.example.com. 0 IN A 192.168.1.5
```

d. Run a lookup against the bootstrap DNS record name. Check that the result points to the IP address of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> bootstrap.<cluster_name>.<base_domain>
```

**Example output**

```
bootstrap.ocp4.example.com. 0 IN A 192.168.1.96
```

e. Use this method to perform lookups against the DNS record names for the control plane and compute nodes. Check that the results correspond to the IP addresses of each node.

2. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names contained in the responses correspond to the correct components.

a. Perform a reverse lookup against the IP address of the API load balancer. Check that the response includes the record names for the Kubernetes API and the Kubernetes internal API:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.5
```

**Example output**

```
5.1.168.192.in-addr.arpa. 0 IN PTR api-int.ocp4.example.com. ①
5.1.168.192.in-addr.arpa. 0 IN PTR api.ocp4.example.com. ②
```

① Provides the record name for the Kubernetes internal API.

② Provides the record name for the Kubernetes API.

**NOTE**

A PTR record is not required for the OpenShift Container Platform application wildcard. No validation step is needed for reverse DNS resolution against the IP address of the application ingress load balancer.

b. Perform a reverse lookup against the IP address of the bootstrap node. Check that the result points to the DNS record name of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.96
```
Example output

96.1.168.192.in-addr.arpa. 0 IN PTR bootstrap.ocp4.example.com.

c. Use this method to perform reverse lookups against the IP addresses for the control plane and compute nodes. Check that the results correspond to the DNS record names of each node.

20.6.9. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the 

~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```bash
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>  
```

Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

**NOTE**

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

```bash
$ cat <path>/<file_name>.pub
```

For example, run the following to view the ~/.ssh/id_rsa.pub public key:
3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `/openshift-install gather` command.

**NOTE**

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```bash
$ eval "$(ssh-agent -s)"
```

**Example output**

Agent pid 31874

**NOTE**

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```bash
$ ssh-add <path>/<file_name>
```

Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

**Example output**

Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program. If you install a cluster on infrastructure that you provision, you must provide the key to the installation program.

**20.6.10. Obtaining the installation program**

Before you install OpenShift Container Platform, download the installation file on your provisioning machine.

**Prerequisites**

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space
Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

   **IMPORTANT**

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   **IMPORTANT**

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   $ tar -xvf openshift-install-linux.tar.gz

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 20.6.11. Manually creating the installation configuration file

For user-provisioned installations of OpenShift Container Platform, you manually generate your installation configuration file.

**Prerequisites**

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.

- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Create an installation directory to store your required installation assets in:

   $ mkdir <installation_directory>
IMPORTANT

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample `install-config.yaml` file template that is provided and save it in the `<installation_directory>`.

NOTE

You must name this configuration file `install-config.yaml`.

NOTE

For some platform types, you can alternatively run `/openshift-install create install-config --dir <installation_directory>` to generate an `install-config.yaml` file. You can provide details about your cluster configuration at the prompts.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

IMPORTANT

The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.

20.6.11.1. Sample `install-config.yaml` file for VMware vSphere

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute:
   - hyperthreading: Enabled
     name: worker
     replicas: 0
controlPlane:
   hyperthreading: Enabled
   name: master
   replicas: 3
metadata:
   name: test
platform:
  vsphere:
    vcenter: your.vcenter.server
    username: username
    password: password
    datacenter: datacenter
```
The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

The **controlPlane** section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, `-`, and the first line of the **controlPlane** section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading, or **hyperthreading**. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to **Disabled**. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Your machines must use at least 8 CPUs and 32 GB of RAM if you disable simultaneous multithreading.

You must set the value of the **replicas** parameter to 0. This parameter controls the number of workers that the cluster creates and manages for you, which are functions that the cluster does not perform when you use user-provisioned infrastructure. You must manually deploy worker machines for the cluster to use before you finish installing OpenShift Container Platform.

The number of control plane machines that you add to the cluster. Because the cluster uses this values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

The cluster name that you specified in your DNS records.

The fully-qualified hostname or IP address of the vCenter server.

The name of the user for accessing the server. This user must have at least the roles and privileges that are required for **static or dynamic persistent volume provisioning** in vSphere.

The password associated with the vSphere user.

The vSphere datacenter.

The default vSphere datastore to use.

Optional: For installer-provisioned infrastructure, the absolute path of an existing folder where the installation program creates the virtual machines, for example, `/<datacenter_name>/vm/<folder_name>/subfolder_name`. If you do not provide this value, the installation program creates a top-level folder in the datacenter virtual machine folder that is named with the infrastructure ID. If you are providing the infrastructure for the cluster, omit this
15. The vSphere disk provisioning method.

16. Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

17. The pull secret that you obtained from OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

18. The public portion of the default SSH key for the core user in Red Hat Enterprise Linux CoreOS (RHCOS).

### 20.6.11.2. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**Prerequisites**

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

**Procedure**

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   ```
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port>
  httpsProxy: https://<username>:<pswd>@<ip>:<port>
  noProxy: example.com
  additionalTrustBundle:

  -----BEGIN CERTIFICATE-----
  <MY_TRUSTED_CA_CERT>
  -----END CERTIFICATE-----

1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.

2. A proxy URL to use for creating HTTPS connections outside the cluster.

3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations. You must include vCenter’s IP address and the IP range that you use for its machines.

4. If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the trustedCA field of the Proxy object. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

NOTE

The installation program does not support the proxy readinessEndpoints field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

NOTE

Only the Proxy object named cluster is supported, and no additional proxies can be created.

20.6.12. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.
**IMPORTANT**

- The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

**NOTE**

The installation program that generates the manifest and Ignition files is architecture specific and can be obtained from the [client image mirror](https://clientimage.openshift.build). The Linux version of the installation program runs on s390x only. This installer program is also available as a Mac OS version.

**Prerequisites**

- You obtained the OpenShift Container Platform installation program.

- You created the `install-config.yaml` installation configuration file.

**Procedure**

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

   ```
   $ ./openshift-install create manifests --dir <installation_directory>
   ```

   **Example output**

   ```
   INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
   INFO Consuming Install Config from target directory
   INFO Manifests created in: install_dir/manifests and install_dir/openshift
   ```

   For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.

2. Remove the Kubernetes manifest files that define the control plane machines and compute machine sets:

   ```
   $ rm -f openshift/99_openshift-cluster-api_master-machines-*.yaml openshift/99_openshift-cluster-api_worker-machineset-*.yaml
   ```

   Because you create and manage these resources yourself, you do not have to initialize them.
You can preserve the machine set files to create compute machines by using the machine API, but you must update references to them to match your environment.

**WARNING**
If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.

**IMPORTANT**
When you configure control plane nodes from the default unschedulable to schedulable, additional subscriptions are required. This is because control plane nodes then become worker nodes.

3. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:
   
   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.
   
   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.
   
   c. Save and exit the file.

4. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

   ```
   $ ./openshift-install create ignition-configs --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the same installation directory.

   Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The `kubeadmin-password` and `kubeconfig` files are created in the `./<installation_directory>/auth` directory:

   ```
   ├── auth
   │    ├── kubeadmin-password
   │    └── kubeconfig
   │         ├── bootstrap.ign
   │         └── master.ign
   │           └── metadata.json
   └── worker.ign
   ```

20.6.13. Extracting the infrastructure name
The Ignition config files contain a unique cluster identifier that you can use to uniquely identify your cluster in VMware Cloud on AWS. If you plan to use the cluster identifier as the name of your virtual machine folder, you must extract it.

**Prerequisites**

- You obtained the OpenShift Container Platform installation program and the pull secret for your cluster.
- You generated the Ignition config files for your cluster.
- You installed the `jq` package.

**Procedure**

To extract and view the infrastructure name from the Ignition config file metadata, run the following command:

```
$ jq -r .infraID <installation_directory>/metadata.json
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

**Example output**

```
openshift-vw9j6
```

The output of this command is your cluster name and a random string.

To install OpenShift Container Platform on user-provisioned infrastructure on VMware vSphere, you must install Red Hat Enterprise Linux CoreOS (RHCOS) on vSphere hosts. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS machines have rebooted.

**Prerequisites**

- You have obtained the Ignition config files for your cluster.
- You have access to an HTTP server that you can access from your computer and that the machines that you create can access.
- You have created a vSphere cluster.

**Procedure**

...
1. Upload the bootstrap Ignition config file, which is named `<installation_directory>/bootstrap.ign`, that the installation program created to your HTTP server. Note the URL of this file.

2. Save the following secondary Ignition config file for your bootstrap node to your computer as `<installation_directory>/merge-bootstrap.ign`:

   ```json
   { 
   "ignition": { 
   "config": { 
   "merge": [ 
   { 
   "source": "<bootstrap_ignition_config_url>", 
   "verification": {} 
   } 
   ], 
   "timeouts": {}, 
   "version": "3.2.0"
   },
   "networkd": {},
   "passwd": {},
   "storage": {},
   "systemd": {}
   }
   }
   ``

   Specify the URL of the bootstrap Ignition config file that you hosted.

   When you create the virtual machine (VM) for the bootstrap machine, you use this Ignition config file.

3. Locate the following Ignition config files that the installation program created:

   - `<installation_directory>/master.ign`
   - `<installation_directory>/worker.ign`
   - `<installation_directory>/merge-bootstrap.ign`

4. Convert the Ignition config files to Base64 encoding. Later in this procedure, you must add these files to the extra configuration parameter `guestinfo.ignition.config.data` in your VM. For example, if you use a Linux operating system, you can use the `base64` command to encode the files.

   ```sh
   $ base64 -w0 <installation_directory>/master.ign > <installation_directory>/master.64
   $ base64 -w0 <installation_directory>/worker.ign > <installation_directory>/worker.64
   $ base64 -w0 <installation_directory>/merge-bootstrap.ign > <installation_directory>/merge-bootstrap.64
   ```
If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

5. Obtain the RHCOS OVA image. Images are available from the RHCOS image mirror page.

   IMPORTANT
   The RHCOS images might not change with every release of OpenShift Container Platform. You must download an image with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image version that matches your OpenShift Container Platform version if it is available.

   The filename contains the OpenShift Container Platform version number in the format `rhcos-vmware.<architecture>.ova`.

6. In the vSphere Client, create a folder in your datacenter to store your VMs.
   a. Click the VMs and Templates view.
   b. Right-click the name of your datacenter.
   c. Click New Folder → New VM and Template Folder.
   d. In the window that is displayed, enter the folder name. If you did not specify an existing folder in the `install-config.yaml` file, then create a folder with the same name as the infrastructure ID. You use this folder name so vCenter dynamically provisions storage in the appropriate location for its Workspace configuration.

7. In the vSphere Client, create a template for the OVA image and then clone the template as needed.

   NOTE
   In the following steps, you create a template and then clone the template for all of your cluster machines. You then provide the location for the Ignition config file for that cloned machine type when you provision the VMs.

   a. From the Hosts and Clusters tab, right-click your cluster name and select Deploy OVF Template.
   b. On the Select an OVF tab, specify the name of the RHCOS OVA file that you downloaded.
   c. On the Select a name and folder tab, set a Virtual machine name for your template, such as Template-RHCOS. Click the name of your vSphere cluster and select the folder you created in the previous step.
   d. On the Select a compute resource tab, click the name of your vSphere cluster.
   e. On the Select storage tab, configure the storage options for your VM.
      - Select Thin Provision or Thick Provision, based on your storage preferences.
• Select the datastore that you specified in your install-config.yaml file.

f. On the Select network tab, specify the network that you configured for the cluster, if available.

g. When creating the OVF template, do not specify values on the Customize template tab or configure the template any further.

**IMPORTANT**

Do not start the original VM template. The VM template must remain off and must be cloned for new RH COS machines. Starting the VM template configures the VM template as a VM on the platform, which prevents it from being used as a template that machine sets can apply configurations to.

8. Optional: Update the configured virtual hardware version in the VM template, if necessary. Follow Upgrading a virtual machine to the latest hardware version in the VMware documentation for more information.

**IMPORTANT**

It is recommended that you update the hardware version of the VM template to version 15 before creating VMs from it, if necessary. Using hardware version 13 for your cluster nodes running on vSphere is now deprecated. If your imported template defaults to hardware version 13, you must ensure that your ESXi host is on 6.7U3 or later before upgrading the VM template to hardware version 15. If your vSphere version is less than 6.7U3, you can skip this upgrade step; however, a future version of OpenShift Container Platform is scheduled to remove support for hardware version 13 and vSphere versions less than 6.7U3.

9. After the template deploys, deploy a VM for a machine in the cluster.

a. Right-click the template name and click Clone → Clone to Virtual Machine

b. On the Select a name and folder tab, specify a name for the VM. You might include the machine type in the name, such as control-plane-0 or compute-1.

**NOTE**

Ensure that all virtual machine names across a vSphere installation are unique.

c. On the Select a name and folder tab, select the name of the folder that you created for the cluster.

d. On the Select a compute resource tab, select the name of a host in your datacenter.

e. Optional: On the Select storage tab, customize the storage options.

f. On the Select clone options, select Customize this virtual machine’s hardware

g. On the Customize hardware tab, click VM Options → Advanced.

  • Optional: Override default DHCP networking in vSphere. To enable static IP networking:
i. Set your static IP configuration:

```bash
$ export IPCFG="ip=<ip>::<gateway>::<netmask>::<hostname>::<iface>::none
nameserver=srv1 [nameserver=srv2 [nameserver=srv3 [...]]]"
```

**Example command**

```bash
$ export IPCFG="ip=192.168.100.101::192.168.100.254:255.255.255.0:::none
nameserver=8.8.8.8"
```

ii. Set the `guestinfo.afterburn.initrd.network-kargs` property before booting a VM from an OVA in vSphere:

```bash
$ govc vm.change -vm "<vm_name>" -e "guestinfo.afterburn.initrd.network-
kargs=${IPCFG}"
```

- Optional: In the event of cluster performance issues, from the **Latency Sensitivity** list, select **High**. Ensure that your VM’s CPU and memory reservation have the following values:
  - Memory reservation value must be equal to its configured memory size.
  - CPU reservation value must be at least the number of low latency virtual CPUs multiplied by the measured physical CPU speed.

- Click **Edit Configuration**, and on the **Configuration Parameters** window, click **Add Configuration Params**. Define the following parameter names and values:
  - `guestinfo.ignition.config.data`: Locate the base-64 encoded files that you created previously in this procedure, and paste the contents of the base64-encoded Ignition config file for this machine type.
  - `guestinfo.ignition.config.data.encoding`: Specify **base64**.
  - `disk.EnableUUID`: Specify **TRUE**.

h. In the **Virtual Hardware** panel of the **Customize hardware** tab, modify the specified values as required. Ensure that the amount of RAM, CPU, and disk storage meets the minimum requirements for the machine type.

i. Complete the configuration and power on the VM.

j. Check the console output to verify that Ignition ran.

**Example command**

```
Ignition: ran on 2022/03/14 14:48:33 UTC (this boot)
Ignition: user-provided config was applied
```

10. Create the rest of the machines for your cluster by following the preceding steps for each machine.
**IMPORTANT**

You must create the bootstrap and control plane machines at this time. Because some pods are deployed on compute machines by default, also create at least two compute machines before you install the cluster.

### 20.6.15. Adding more compute machines to a cluster in vSphere

You can add more compute machines to a user-provisioned OpenShift Container Platform cluster on VMware vSphere.

#### Prerequisites

- Obtain the base64-encoded Ignition file for your compute machines.
- You have access to the vSphere template that you created for your cluster.

#### Procedure

1. After the template deploys, deploy a VM for a machine in the cluster.
   a. Right-click the template’s name and click **Clone → Clone to Virtual Machine**
   b. On the **Select a name and folder** tab, specify a name for the VM. You might include the machine type in the name, such as **compute-1**.

   **NOTE**

   Ensure that all virtual machine names across a vSphere installation are unique.

c. On the **Select a name and folder** tab, select the name of the folder that you created for the cluster.

d. On the **Select a compute resource** tab, select the name of a host in your datacenter.

e. Optional: On the **Select storage** tab, customize the storage options.

f. On the **Select clone options**, select **Customize this virtual machine’s hardware**

g. On the **Customize hardware** tab, click **VM Options → Advanced**.
   
   - From the **Latency Sensitivity** list, select **High**.
   
   - Click **Edit Configuration**, and on the **Configuration Parameters** window, click **Add Configuration Params**. Define the following parameter names and values:
      
      - **guestinfo.ignition.config.data**: Paste the contents of the base64-encoded compute Ignition config file for this machine type.
      
      - **guestinfo.ignition.config.data.encoding**: Specify **base64**.

      - **disk.EnableUUID**: Specify **TRUE**.

   h. In the **Virtual Hardware** panel of the **Customize hardware** tab, modify the specified values as required. Ensure that the amount of RAM, CPU, and disk storage meets the minimum
requirements for the machine type. Also, make sure to select the correct network under Add network adapter if there are multiple networks available.

i. Complete the configuration and power on the VM.

2. Continue to create more compute machines for your cluster.

20.6.16. Disk partitioning

In most cases, data partitions are originally created by installing RHCOS, rather than by installing another operating system. In such cases, the OpenShift Container Platform installer should be allowed to configure your disk partitions.

However, there are two cases where you might want to intervene to override the default partitioning when installing an OpenShift Container Platform node:

- Create separate partitions: For greenfield installations on an empty disk, you might want to add separate storage to a partition. This is officially supported for making /var or a subdirectory of /var, such as /var/lib/etcd, a separate partition, but not both.

**IMPORTANT**

Kubernetes supports only two filesystem partitions. If you add more than one partition to the original configuration, Kubernetes cannot monitor all of them.

- Retain existing partitions: For a brownfield installation where you are reinstalling OpenShift Container Platform on an existing node and want to retain data partitions installed from your previous operating system, there are both boot arguments and options to coreos-installer that allow you to retain existing data partitions.

Creating a separate /var partition

In general, disk partitioning for OpenShift Container Platform should be left to the installer. However, there are cases where you might want to create separate partitions in a part of the filesystem that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the /var partition or a subdirectory of /var. For example:

- /var/lib/containers: Holds container-related content that can grow as more images and containers are added to a system.

- /var/lib/etcd: Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.

- /var: Holds data that you might want to keep separate for purposes such as auditing.

Storing the contents of a /var directory separately makes it easier to grow storage for those areas as needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

Because /var must be in place before a fresh installation of Red Hat Enterprise Linux CoreOS (RHCOS), the following procedure sets up the separate /var partition by creating a machine config manifest that is inserted during the openshift-install preparation phases of an OpenShift Container Platform installation.
Procedure

1. Create a directory to hold the OpenShift Container Platform installation files:

```
$ mkdir $HOME/clusterconfig
```

2. Run `openshift-install` to create a set of files in the `manifest` and `openshift` subdirectories. Answer the system questions as you are prompted:

```
$ openshift-install create manifests --dir $HOME/clusterconfig
? SSH Public Key ...
$ ls $HOME/clusterconfig/openshift/
99_kubeadmin-password-secret.yaml
99_openshift-cluster-api_master-machines-0.yaml
99_openshift-cluster-api_master-machines-1.yaml
99_openshift-cluster-api_master-machines-2.yaml
...
```

3. Create a Butane config that configures the additional partition. For example, name the file `$HOME/clusterconfig/98-var-partition.bu`, change the disk device name to the name of the storage device on the `worker` systems, and set the storage size as appropriate. This example places the `/var` directory on a separate partition:

```
variant: openshift
version: 4.10.0
metadata:
  labels:
    machineconfiguration.openshift.io/role: worker
  name: 98-var-partition
storage:
disks:
  - device: /dev/<device_name>  
    partitions:
      - label: var
        start_mib: <partition_start_offset>  
        size_mib: <partition_size>  
filesystems:
  - device: /dev/disk/by-partlabel/var
    path: /var
    format: xfs
    mount_options: [defaults, prjquota]  
    with_mount_unit: true
```

1. The storage device name of the disk that you want to partition.
2. When adding a data partition to the boot disk, a minimum value of 25000 mebibytes is recommended. The root file system is automatically resized to fill all available space up to the specified offset. If no value is specified, or if the specified value is smaller than the recommended minimum, the resulting root file system will be too small, and future reinstalls of RHCOS might overwrite the beginning of the data partition.
3. The size of the data partition in mebibytes.
4. The `prjquota` mount option must be enabled for filesystems used for container storage.
NOTE

When creating a separate /var partition, you cannot use different instance types for worker nodes, if the different instance types do not have the same device name.

4. Create a manifest from the Butane config and save it to the clusterconfig/openshift directory. For example, run the following command:

$ butane $HOME/clusterconfig/98-var-partition.bu -o $HOME/clusterconfig/openshift/98-var-partition.yaml

5. Run openshift-install again to create Ignition configs from a set of files in the manifest and openshift subdirectories:

$ openshift-install create ignition-configs --dir $HOME/clusterconfig
$ ls $HOME/clusterconfig/
  auth bootstrap.ign master.ign metadata.json worker.ign

Now you can use the Ignition config files as input to the vSphere installation procedures to install Red Hat Enterprise Linux CoreOS (RHCOS) systems.

20.6.17. Updating the bootloader using bootupd

To update the bootloader by using bootupd, you must either install bootupd on RHCOS machines manually or provide a machine config with the enabled systemd unit. Unlike grubby or other bootloader tools, bootupd does not manage kernel space configuration such as passing kernel arguments.

After you have installed bootupd, you can manage it remotely from the OpenShift Container Platform cluster.

NOTE

It is recommended that you use bootupd only on bare metal or virtualized hypervisor installations, such as for protection against the BootHole vulnerability.

Manual install method

You can manually install bootupd by using the bootctl command-line tool.

1. Inspect the system status:

# bootupctl status

Example output for x86_64

Component EFI
  Installed: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
  Update: At latest version

Example output for arm64
2. RHCOS images created without `bootupd` installed on them require an explicit adoption phase. If the system status is **Adoptable**, perform the adoption:

```
# bootupctl adopt-and-update
```

**Example output**

```
Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
```

3. If an update is available, apply the update so that the changes take effect on the next reboot:

```
# bootupctl update
```

**Example output**

```
Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
```

**Machine config method**

Another way to enable `bootupd` is by providing a machine config.

- Provide a machine config file with the enabled `systemd` unit, as shown in the following example:

**Example output**

```
variant: rhcos
version: 1.1.0
systemd:
units:
  - name: custom-bootupd-auto.service
    enabled: true
    contents:
      [Unit]
      Description=Bootupd automatic update

      [Service]
      ExecStart=/usr/bin/bootupctl update
      RemainAfterExit=yes

      [Install]
      WantedBy=multi-user.target
```

**20.6.18. Installing the OpenShift CLI by downloading the binary**

You can install the OpenShift CLI (`oc`) to interact with OpenShift Container Platform from a command-line interface. You can install `oc` on Linux, Windows, or macOS.
IMPORTANT

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.10. Download and install the new version of oc.

Installing the OpenShift CLI on Linux
You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.
3. Click Download Now next to the OpenShift v4.10 Linux Client entry and save the file.
4. Unpack the archive:
   
   ```
   $ tar xvzf <file>
   ```
5. Place the oc binary in a directory that is on your PATH.
   To check your PATH, execute the following command:
   
   ```
   $ echo $PATH
   ```

After you install the OpenShift CLI, it is available using the oc command:

```
$ oc <command>
```

Installing the OpenShift CLI on Windows
You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.
3. Click Download Now next to the OpenShift v4.10 Windows Client entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the oc binary to a directory that is on your PATH.
   To check your PATH, open the command prompt and execute the following command:
   
   ```
   C:\> path
   ```

After you install the OpenShift CLI, it is available using the oc command:

```
C:\> oc <command>
```
Installing the OpenShift CLI on macOS
You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.

Procedure
2. Select the appropriate version in the Version drop-down menu.
3. Click Download Now next to the OpenShift v4.10 MacOSX Client entry and save the file.
4. Unpack and unzip the archive.
5. Move the oc binary to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:

   $ echo $PATH

After you install the OpenShift CLI, it is available using the oc command:

   $ oc <command>

20.6.19. Waiting for the bootstrap process to complete
The OpenShift Container Platform bootstrap process begins after the cluster nodes first boot into the persistent RHCOS environment that has been installed to disk. The configuration information provided through the Ignition config files is used to initialize the bootstrap process and install OpenShift Container Platform on the machines. You must wait for the bootstrap process to complete.

Prerequisites
- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have obtained the installation program and generated the Ignition config files for your cluster.
- You installed RHCOS on your cluster machines and provided the Ignition config files that the OpenShift Container Platform installation program generated.
- Your machines have direct internet access or have an HTTP or HTTPS proxy available.

Procedure
1. Monitor the bootstrap process:

   $ ./openshift-install --dir <installation_directory> wait-for bootstrap-complete \  
   --log-level=info

   1 For <installation_directory>, specify the path to the directory that you stored the installation files in.
To view different installation details, specify warn, debug, or error instead of info.

Example output

```
INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
INFO API v1.23.0 up
INFO Waiting up to 30m0s for bootstrapping to complete...
INFO It is now safe to remove the bootstrap resources
```

The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After bootstrap process is complete, remove the bootstrap machine from the load balancer.

**IMPORTANT**

You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the bootstrap machine itself.

### 20.6.20. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

#### Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

#### Procedure

1. Export the **kubeadmin** credentials:

   ```
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

   ```
   $ oc whoami
   ```

   **Example output**

   ```
   system:admin
   ```

### 20.6.21. Approving the certificate signing requests for your machines
When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

**Prerequisites**

- You added machines to your cluster.

**Procedure**

1. Confirm that the cluster recognizes the machines:

   ```
   $ oc get nodes
   ```

   **Example output**

   ```
   NAME      STATUS    ROLES   AGE  VERSION
   master-0  Ready     master  63m  v1.23.0
   master-1  Ready     master  63m  v1.23.0
   master-2  Ready     master  64m  v1.23.0
   ```

   The output lists all of the machines that you created.

   **NOTE**

   The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

   ```
   $ oc get csr
   ```

   **Example output**

   ```
   NAME        AGE   REQUESTOR                                   CONDITION
   csr-mddf5   20m   system:node:master-01.example.com   Approved,Issued
   csr-z5rln   16m   system:node:worker-21.example.com   Approved,Issued
   ```

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

   **NOTE**

   Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.
NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the `oc exec`, `oc rsh`, and `oc logs` commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the `node-bootstrapper` service account in the `system:node` or `system:admin` groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

  ```
  $ oc adm certificate approve <csr_name>
  ```

  `<csr_name>` is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

  ```
  $ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs --no-run-if-empty oc adm certificate approve
  ```

  NOTE

  Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

  ```
  $ oc get csr
  ```

  **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-c57iv</td>
<td>5m26s</td>
<td>system:node:ip-10-0-95-157.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

  ```
  $ oc adm certificate approve <csr_name>
  ```

  `<csr_name>` is the name of a CSR from the list of current CSRs.
To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs oc adm certificate approve
```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

**Example output**

```
NAME      STATUS    ROLES   AGE   VERSION
master-0  Ready     master  73m   v1.23.0
master-1  Ready     master  73m   v1.23.0
master-2  Ready     master  74m   v1.23.0
worker-0  Ready     worker  11m   v1.23.0
worker-1  Ready     worker  11m   v1.23.0
```

**NOTE**

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

**Additional information**

- For more information on CSRs, see [Certificate Signing Requests](#).

### 20.6.22. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

**Prerequisites**

- Your control plane has initialized.

**Procedure**

1. Watch the cluster components come online:

```
$ watch -n5 oc get clusteroperators
```

**Example output**

```
NAME                                       VERSION   AVAILABLE   PROGRESSING   DEGRADED
SINCE
authentication                             4.10.0    True        False         False      19m
baremetal                                 4.10.0    True        False         False      37m
cloud-credential                          4.10.0    True        False         False      40m
cluster-autoscaler                         4.10.0    True        False         False      37m
config-operator                            4.10.0    True        False         False      38m
```
2. Configure the Operators that are not available.

### 20.6.22.1. Image registry removed during installation

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as **Removed**. This allows `openshift-installer` to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the `managementState` from **Removed** to **Managed**.

#### NOTE

The Prometheus console provides an **ImageRegistryRemoved** alert, for example:

"Image Registry has been removed. **ImageStreamTags**, **BuildConfigs** and **DeploymentConfigs** which reference **ImageStreamTags** may not work as expected. Please configure storage and update the config to **Managed** state by editing `configs.imageregistry.operator.openshift.io`.

### 20.6.22.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.
Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the `Recreate` rollout strategy during upgrades.

### 20.6.22.2.1. Configuring registry storage for VMware vSphere

As a cluster administrator, following installation you must configure your registry to use storage.

**Prerequisites**

- Cluster administrator permissions.
- A cluster on VMware vSphere.
- Persistent storage provisioned for your cluster, such as Red Hat OpenShift Data Foundation.

**IMPORTANT**

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have "100Gi" capacity.

**IMPORTANT**

Testing shows issues with using the NFS server on RHEL as storage backend for core services. This includes the OpenShift Container Registry and Quay, Prometheus for monitoring storage, and Elasticsearch for logging storage. Therefore, using RHEL NFS to back PVs used by core services is not recommended.

Other NFS implementations on the marketplace might not have these issues. Contact the individual NFS implementation vendor for more information on any testing that was possibly completed against these OpenShift Container Platform core components.

**Procedure**

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

   **NOTE**

   When using shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

   ```
   $ oc get pod -n openshift-image-registry -l docker-registry=default
   ```

   **Example output**
No resources found in openshift-image-registry namespace

NOTE
If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

   $ oc edit configs.imageregistry.operator.openshift.io

   Example output

   ```yaml
   storage:
   pvc:
   claim: 1
   ```

   Leave the `claim` field blank to allow the automatic creation of an `image-registry-storage` PVC.

4. Check the `clusteroperator` status:

   $ oc get clusteroperator image-registry

   Example output

   ```none
   NAME             VERSION   AVAILABLE  PROGRESSING DEGRADED SINCE MESSAGE
   image-registry   4.7       True       False      False      6h50m
   ```

20.6.22.2.2. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

Procedure

- To set the image registry storage to an empty directory:

  $ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec": {
  "storage": {
    "emptyDir": {}}}}'

WARNING
Configure this option for only non-production clusters.
If you run this command before the Image Registry Operator initializes its components, the `oc patch` command fails with the following error:

```bash
Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
```

Wait a few minutes and run the command again.

### 20.6.22.2.3. Configuring block registry storage for VMware vSphere

To allow the image registry to use block storage types such as vSphere Virtual Machine Disk (VMDK) during upgrades as a cluster administrator, you can use the **Recreate** rollout strategy.

**IMPORTANT**

Block storage volumes are supported but not recommended for use with image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

**Procedure**

1. To set the image registry storage as a block storage type, patch the registry so that it uses the **Recreate** rollout strategy and runs with only 1 replica:

   ```bash
   $ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec":
   "{rolloutStrategy":"Recreate","replicas":1})}'
   ```

2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.

   a. Create a `pvc.yaml` file with the following contents to define a VMware vSphere `PersistentVolumeClaim` object:

   ```yaml
   kind: PersistentVolumeClaim
   apiVersion: v1
   metadata:
     name: image-registry-storage
     namespace: openshift-image-registry
   spec:
     accessModes:
     - ReadWriteOnce
     resources:
       requests:
         storage: 100Gi
   ```

   **1** A unique name that represents the `PersistentVolumeClaim` object.

   **2** The namespace for the `PersistentVolumeClaim` object, which is `openshift-image-registry`.

   **3** The access mode of the persistent volume claim. With `ReadWriteOnce`, the volume can be mounted with read and write permissions by a single node.

   **4** The size of the persistent volume claim.
b. Create the **PersistentVolumeClaim** object from the file:

```bash
$ oc create -f pvc.yaml -n openshift-image-registry
```

3. Edit the registry configuration so that it references the correct PVC:

```bash
$ oc edit config.imageregistry.operator.openshift.io -o yaml
```

**Example output**

```
storage:
pvc:
  claim: 1
```

Creating a custom PVC allows you to leave the **claim** field blank for the default automatic creation of an **image-registry-storage** PVC.

For instructions about configuring registry storage so that it references the correct PVC, see [Configuring the registry for vSphere](#).

### 20.6.23. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

**Prerequisites**

- Your control plane has initialized.
- You have completed the initial Operator configuration.

**Procedure**

1. Confirm that all the cluster components are online with the following command:

```bash
$ watch -n5 oc get clusteroperators
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
</tr>
</thead>
<tbody>
<tr>
<td>SINCE</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>authentication</td>
<td>4.10.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>baremetal</td>
<td>4.10.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>cloud-credential</td>
<td>4.10.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>cluster-autoscaler</td>
<td>4.10.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>config-operator</td>
<td>4.10.0</td>

</tr>
<tr>
<td>ingress</td>
<td>4.10.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
</tbody>
</table>
Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```bash
$ ./openshift-install --dir <installation_directory> wait-for install-complete
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

### Example output

INFO Waiting up to 30m0s for the cluster to initialize...

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.
2. Confirm that the Kubernetes API server is communicating with the pods.

   a. To view a list of all pods, use the following command:

   ```sh
   $ oc get pods --all-namespaces
   ```

   **Example output**

<table>
<thead>
<tr>
<th>NAMESPACE</th>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>openshift-apiserver-operator</td>
<td>openshift-apiserver-operator-85cb746d55-zqhs8</td>

<td></td>
<td></td>
</tr>
<tr>
<td>Running</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>...</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

   b. View the logs for a pod that is listed in the output of the previous command by using the following command:

   ```sh
   $ oc logs <pod_name> -n <namespace>  
   ```

   1 Specify the pod name and namespace, as shown in the output of the previous command.

   If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation.

   See "Enabling multipathing with kernel arguments on RHCOS" in the Post-installation machine configuration tasks documentation for more information.

You can add extra compute machines after the cluster installation is completed by following Adding compute machines to vSphere.

20.6.24. Backing up VMware vSphere volumes

OpenShift Container Platform provisions new volumes as independent persistent disks to freely attach and detach the volume on any node in the cluster. As a consequence, it is not possible to back up volumes that use snapshots, or to restore volumes from snapshots. See Snapshot Limitations for more information.

**Procedure**

To create a backup of persistent volumes:

1. Stop the application that is using the persistent volume.
2. Clone the persistent volume.
3. Restart the application.
4. Create a backup of the cloned volume.
5. Delete the cloned volume.

20.6.25. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.10, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources
- See About remote health monitoring for more information about the Telemetry service

20.6.26. Next steps
- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- Set up your registry and configure registry storage.
- Optional: View the events from the vSphere Problem Detector Operator to determine if the cluster has permission or storage configuration issues.

20.7. INSTALLING A CLUSTER ON VMC WITH USER-PROVISIONED INFRASTRUCTURE AND NETWORK CUSTOMIZATIONS

In OpenShift Container Platform version 4.10, you can install a cluster on your VMware vSphere instance using infrastructure you provision with customized network configuration options by deploying it to VMware Cloud (VMC) on AWS.

Once you configure your VMC environment for OpenShift Container Platform deployment, you use the OpenShift Container Platform installation program from the bastion management host, co-located in the VMC environment. The installation program and control plane automates the process of deploying and managing the resources needed for the OpenShift Container Platform cluster.

By customizing your network configuration, your cluster can coexist with existing IP address allocations in your environment and integrate with existing VXLAN configurations. You must set most of the network configuration parameters during installation, and you can modify only kubeProxy configuration parameters in a running cluster.

20.7.1. Setting up VMC for vSphere

You can install OpenShift Container Platform on VMware Cloud (VMC) on AWS hosted vSphere clusters to enable applications to be deployed and managed both on-premise and off-premise, across the hybrid cloud.
You must configure several options in your VMC environment prior to installing OpenShift Container Platform on VMware vSphere. Ensure your VMC environment has the following prerequisites:

- Create a non-exclusive, DHCP-enabled, NSX-T network segment and subnet. Other virtual machines (VMs) can be hosted on the subnet, but at least eight IP addresses must be available for the OpenShift Container Platform deployment.

- Configure the following firewall rules:
  - An ANY:ANY firewall rule between the OpenShift Container Platform compute network and the internet. This is used by nodes and applications to download container images.
  - An ANY:ANY firewall rule between the installation host and the software-defined data center (SDDC) management network on port 443. This allows you to upload the Red Hat Enterprise Linux CoreOS (RHCOS) OVA during deployment.
  - An HTTPS firewall rule between the OpenShift Container Platform compute network and vCenter. This connection allows OpenShift Container Platform to communicate with vCenter for provisioning and managing nodes, persistent volume claims (PVCs), and other resources.

- You must have the following information to deploy OpenShift Container Platform:
  - The OpenShift Container Platform cluster name, such as vmc-prod-1.
  - The base DNS name, such as companyname.com.
  - If not using the default, the pod network CIDR and services network CIDR must be identified, which are set by default to 10.128.0.0/14 and 172.30.0.0/16, respectively. These CIDRs are used for pod-to-pod and pod-to-service communication and are not accessible externally; however, they must not overlap with existing subnets in your organization.
  - The following vCenter information:
    - vCenter hostname, username, and password
    - Datacenter name, such as SDDC-Datacenter
    - Cluster name, such as Cluster-1
    - Network name
    - Datastore name, such as WorkloadDatastore
It is recommended to move your vSphere cluster to the VMC Compute-ResourcePool resource pool after your cluster installation is finished.

- A Linux-based host deployed to VMC as a bastion.
  - The bastion host can be Red Hat Enterprise Linux (RHEL) or any another Linux-based host; it must have internet connectivity and the ability to upload an OVA to the ESXi hosts.
  - Download and install the OpenShift CLI tools to the bastion host.
    - The `openshift-install` installation program
    - The OpenShift CLI (`oc`) tool

**NOTE**

You cannot use the VMware NSX Container Plug-in for Kubernetes (NCP), and NSX is not used as the OpenShift SDN. The version of NSX currently available with VMC is incompatible with the version of NCP certified with OpenShift Container Platform.

However, the NSX DHCP service is used for virtual machine IP management with the full-stack automated OpenShift Container Platform deployment and with nodes provisioned, either manually or automatically, by the Machine API integration with vSphere. Additionally, NSX firewall rules are created to enable access with the OpenShift Container Platform cluster and between the bastion host and the VMC vSphere hosts.

### 20.7.1.1. VMC Sizer tool

VMware Cloud on AWS is built on top of AWS bare metal infrastructure; this is the same bare metal infrastructure which runs AWS native services. When a VMware cloud on AWS software-defined data center (SDDC) is deployed, you consume these physical server nodes and run the VMware ESXi hypervisor in a single tenant fashion. This means the physical infrastructure is not accessible to anyone else using VMC. It is important to consider how many physical hosts you will need to host your virtual infrastructure.

To determine this, VMware provides the **VMC on AWS Sizer**. With this tool, you can define the resources you intend to host on VMC:

- Types of workloads
- Total number of virtual machines
- Specification information such as:
  - Storage requirements
  - vCPUs
  - vRAM
  - Overcommit ratios

With these details, the sizer tool can generate a report, based on VMware best practices, and recommend your cluster configuration and the number of hosts you will need.
20.7.2. vSphere prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You provisioned block registry storage. For more information on persistent storage, see Understanding persistent storage.
- If you use a firewall, you configured it to allow the sites that your cluster requires access to.

20.7.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.10, you require access to the internet to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

20.7.4. VMware vSphere infrastructure requirements

You must install the OpenShift Container Platform cluster on a VMware vSphere version 6 or 7 instance that meets the requirements for the components that you use.

**Table 20.46. Version requirements for vSphere virtual environments**

<table>
<thead>
<tr>
<th>Virtual environment product</th>
<th>Required version</th>
</tr>
</thead>
<tbody>
<tr>
<td>VM hardware version</td>
<td>13 or later</td>
</tr>
<tr>
<td>vSphere ESXi hosts</td>
<td>6.5 or later</td>
</tr>
<tr>
<td>vCenter host</td>
<td>6.5 or later</td>
</tr>
</tbody>
</table>
IMPORTANT

Installing a cluster on VMware vSphere version 6.7U3 or earlier and virtual hardware version 13 is now deprecated. These versions are still fully supported, but version 4.11 of OpenShift Container Platform will require vSphere virtual hardware version 15 or later. Hardware version 15 is now the default for vSphere virtual machines in OpenShift Container Platform. To update the hardware version for your vSphere nodes, see the “Updating hardware on nodes running in vSphere” article.

If your vSphere nodes are below hardware version 15 or your VMware vSphere version is earlier than 6.7U3, upgrading from OpenShift Container Platform 4.10 to OpenShift Container Platform 4.11 is not available.

Table 20.47. Minimum supported vSphere version for VMware components

<table>
<thead>
<tr>
<th>Component</th>
<th>Minimum supported versions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hypervisor</td>
<td>vSphere 6.5 and later with HW version 13</td>
<td>This version is the minimum version that Red Hat Enterprise Linux CoreOS (RHCOS) supports. See the Red Hat Enterprise Linux 8 supported hypervisors list.</td>
</tr>
<tr>
<td>Storage with in-tree drivers</td>
<td>vSphere 6.5 and later</td>
<td>This plug-in creates vSphere storage by using the in-tree storage drivers for vSphere included in OpenShift Container Platform.</td>
</tr>
</tbody>
</table>

If you use a vSphere version 6.5 instance, consider upgrading to 6.7U3 or 7.0 before you install OpenShift Container Platform.

IMPORTANT

You must ensure that the time on your ESXi hosts is synchronized before you install OpenShift Container Platform. See Edit Time Configuration for a Host in the VMware documentation.

20.7.5. VMware vSphere CSI Driver Operator requirements

The following requirements must be met in order to install the CSI Driver Operator:

- VMware vSphere version 6.7U3 or later
- Virtual machines of hardware version 15 or later
- No third-party CSI driver already installed in the cluster

If a third-party CSI driver is present in the cluster, OpenShift Container Platform does not overwrite it. The presence of a third-party CSI driver prevents OpenShift Container Platform from upgrading to 4.11.

Additional resources
20.7.6. Requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

This section describes the requirements for deploying OpenShift Container Platform on user-provisioned infrastructure.

20.7.6.1. Required machines for cluster installation

The smallest OpenShift Container Platform clusters require the following hosts:

Table 20.48. Minimum required hosts

<table>
<thead>
<tr>
<th>Hosts</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>One temporary bootstrap machine</td>
<td>The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.</td>
</tr>
<tr>
<td>Three control plane machines</td>
<td>The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.</td>
</tr>
<tr>
<td>At least two compute machines, which are also known as worker machines.</td>
<td>The workloads requested by OpenShift Container Platform users run on the compute machines.</td>
</tr>
</tbody>
</table>

IMPORTANT

To improve high availability of your cluster, distribute the control plane machines over different z/VM instances on at least two physical machines.

The bootstrap, control plane, and compute machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 8 and inherits all of its hardware certifications and requirements. See Red Hat Enterprise Linux technology capabilities and limits.

20.7.6.2. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
</tbody>
</table>
Control plane  | Operating System  | vCPU [1]  | Virtual RAM  | Storage  | IOPS
---|---|---|---|---|---
RHCOS  | 4  | 16 GB  | 100 GB  | N/A

Compute  | Operating System  | vCPU [1]  | Virtual RAM  | Storage  | IOPS
---|---|---|---|---|---
RHCOS  | 2  | 8 GB  | 100 GB  | N/A

1. One physical core (IFL) provides two logical cores (threads) when SMT-2 is enabled. The hypervisor can provide two or more vCPUs.

### 20.7.6.3. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The `kube-controller-manager` only approves the kubelet client CSRs. The `machine-approver` cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

### 20.7.6.4. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in `initramfs` during boot to fetch their Ignition config files.

During the initial boot, the machines require an HTTP or HTTPS server to establish a network connection to download their Ignition config files.

The machines are configured with static IP addresses. No DHCP server is required. Ensure that the machines have persistent IP addresses and hostnames.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

### 20.7.6.4.1. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

**IMPORTANT**

In connected OpenShift Container Platform environments, all nodes are required to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

### Table 20.49. Ports used for all-machine to all-machine communications
### Table 20.50. Ports used for all-machine to control plane communications

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Port</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>6443</td>
<td>Kubernetes API</td>
</tr>
</tbody>
</table>

### Table 20.51. Ports used for control plane machine to control plane machine communications

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Port</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>2379-2380</td>
<td>etcd server and peer ports</td>
</tr>
</tbody>
</table>

**NTP configuration for user-provisioned infrastructure**

OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for *Configuring chrony time service*.

### 20.7.6.5. User-provisioned DNS requirements

In OpenShift Container Platform deployments, DNS name resolution is required for the following components:

- The Kubernetes API
- The OpenShift Container Platform application wildcard
Reverse DNS resolution is also required for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the hostnames for all the nodes, unless the hostnames are provided by DHCP. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

The following DNS records are required for a user-provisioned OpenShift Container Platform cluster and they must be in place before installation. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>`.

### Table 20.52. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes API</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the API load balancer. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td></td>
<td>api-int.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to internally identify the API load balancer. These records must be resolvable from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Routes</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>A wildcard DNS A/AAAA or CNAME record that refers to the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster. For example, <code>console-openshift-console.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;</code> is used as a wildcard route to the OpenShift Container Platform console.</td>
</tr>
<tr>
<td>Bootstrap machine</td>
<td>bootstrap.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

The API server must be able to resolve the worker nodes by the hostnames that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.
### Component  
### Record  
### Description  

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Control plane machines</td>
<td>&lt;master&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Compute machines</td>
<td>&lt;worker&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**NOTE**

In OpenShift Container Platform 4.4 and later, you do not need to specify etcd host and SRV records in your DNS configuration.

**TIP**

You can use the `dig` command to verify name and reverse name resolution. See the section on [Validating DNS resolution for user-provisioned infrastructure](chapter20) for detailed validation steps.

20.7.6.5.1. Example DNS configuration for user-provisioned clusters

This section provides A and PTR record configuration samples that meet the DNS requirements for deploying OpenShift Container Platform on user-provisioned infrastructure. The samples are not meant to provide advice for choosing one DNS solution over another.

In the examples, the cluster name is `ocp4` and the base domain is `example.com`.

**Example DNS A record configuration for a user-provisioned cluster**

The following example is a BIND zone file that shows sample A records for name resolution in a user-provisioned cluster.

```
$TTL 1W
@ IN SOA ns1.example.com. root (2019070700 ; serial
3H ; refresh (3 hours)
30M ; retry (30 minutes)
2W ; expiry (2 weeks)
1W ) ; minimum (1 week)
IN NS ns1.example.com.
IN MX 10 smtp.example.com.
; 
ns1.example.com. IN A 192.168.1.5
smtp.example.com. IN A 192.168.1.5
; 
helper.example.com. IN A 192.168.1.5
```
Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer.

Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer and is used for internal cluster communications.

Provides name resolution for the wildcard routes. The record refers to the IP address of the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

NOTE

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

Provides name resolution for the bootstrap machine.

Provides name resolution for the control plane machines.

Provides name resolution for the compute machines.

Example DNS PTR record configuration for a user-provisioned cluster

The following example BIND zone file shows sample PTR records for reverse name resolution in a user-provisioned cluster.

Example 20.13. Sample DNS zone database for reverse records

```
$TTL 1W
@ IN SOA ns1.example.com. root ( 2019070700 ; serial
```
Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer.

Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer and is used for internal cluster communications.

Provides reverse DNS resolution for the bootstrap machine.

Provides reverse DNS resolution for the control plane machines.

Provides reverse DNS resolution for the compute machines.

NOTE

A PTR record is not required for the OpenShift Container Platform application wildcard.

20.7.6.6. Load balancing requirements for user-provisioned infrastructure

Before you install OpenShift Container Platform, you must provision the API and application ingress load balancing infrastructure. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

The load balancing infrastructure must meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.
   - A stateless load balancing algorithm. The options vary based on the load balancer implementation.
NOTE

Session persistence is not required for the API load balancer to function properly.

Configure the following ports on both the front and back of the load balancers:

Table 20.53. API load balancer

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the /readyz endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>

NOTE

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the /readyz endpoint to the removal of the API server instance from the pool. Within the time frame after /readyz returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. Application ingress load balancer: Provides an ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

TIP

If the true IP address of the client can be seen by the application ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

Configure the following ports on both the front and back of the load balancers:

Table 20.54. Application ingress load balancer
<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
<tr>
<td>1936</td>
<td>The worker nodes that run the Ingress Controller pods, by default. You must configure the <code>/healthz/ready</code> endpoint for the ingress health check probe.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>

**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

**NOTE**

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

### 20.7.6.6.1. Example load balancer configuration for user-provisioned clusters

This section provides an example API and application ingress load balancer configuration that meets the load balancing requirements for user-provisioned clusters. The sample is an `/etc/haproxy/haproxy.cfg` configuration for an HAProxy load balancer. The example is not meant to provide advice for choosing one load balancing solution over another.

**NOTE**

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

**Example 20.14. Sample API and application ingress load balancer configuration**

```
global
log 127.0.0.1 local2
pidfile /var/run/haproxy.pid
maxconn 4000
daemon
defaults
mode http
```
In the example, the cluster name is `ocp4`.

Port 6443 handles the Kubernetes API traffic and points to the control plane machines.
The bootstrap entries must be in place before the OpenShift Container Platform cluster installation and they must be removed after the bootstrap process is complete.

Port 22623 handles the machine config server traffic and points to the control plane machines.

Port 443 handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

Port 80 handles the HTTP traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

NOTE

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

TIP

If you are using HAPerxy as a load balancer, you can check that the haproxy process is listening on ports 6443, 22623, 443, and 80 by running netstat -nltupe on the HAPerxy node.

NOTE

If you are using HAPerxy as a load balancer and SELinux is set to enforcing, you must ensure that the HAPerxy service can bind to the configured TCP port by running setsebool -P haproxy_connect_any=1.

20.7.7. Preparing the user-provisioned infrastructure

Before you install OpenShift Container Platform on user-provisioned infrastructure, you must prepare the underlying infrastructure.

This section provides details about the high-level steps required to set up your cluster infrastructure in preparation for an OpenShift Container Platform installation. This includes configuring IP networking and network connectivity for your cluster nodes, preparing a web server for the Ignition files, enabling the required ports through your firewall, and setting up the required DNS and load balancing infrastructure.

After preparation, your cluster infrastructure must meet the requirements outlined in the Requirements for a cluster with user-provisioned infrastructure section.

Prerequisites

- You have reviewed the OpenShift Container Platform 4.x Tested Integrations page.
- You have reviewed the infrastructure requirements detailed in the Requirements for a cluster with user-provisioned infrastructure section.

Procedure
1. Set up static IP addresses.

2. Set up an HTTP or HTTPS server to provide Ignition files to the cluster nodes.

3. Ensure that your network infrastructure provides the required network connectivity between the cluster components. See the Networking requirements for user-provisioned infrastructure section for details about the requirements.

4. Configure your firewall to enable the ports required for the OpenShift Container Platform cluster components to communicate. See Networking requirements for user-provisioned infrastructure section for details about the ports that are required.

5. Setup the required DNS infrastructure for your cluster.
   a. Configure DNS name resolution for the Kubernetes API, the application wildcard, the bootstrap machine, the control plane machines, and the compute machines.
   b. Configure reverse DNS resolution for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines. See the User-provisioned DNS requirements section for more information about the OpenShift Container Platform DNS requirements.

6. Validate your DNS configuration.
   a. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses in the responses correspond to the correct components.
   b. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names in the responses correspond to the correct components. See the Validating DNS resolution for user-provisioned infrastructure section for detailed DNS validation steps.

7. Provision the required API and application ingress load balancing infrastructure. See the Load balancing requirements for user-provisioned infrastructure section for more information about the requirements.

   **NOTE**

   Some load balancing solutions require the DNS name resolution for the cluster nodes to be in place before the load balancing is initialized.

20.7.8. Validating DNS resolution for user-provisioned infrastructure

You can validate your DNS configuration before installing OpenShift Container Platform on user-provisioned infrastructure.

   **IMPORTANT**

   The validation steps detailed in this section must succeed before you install your cluster.

**Prerequisites**

- You have configured the required DNS records for your user-provisioned infrastructure.
Procedure

1. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses contained in the responses correspond to the correct components.

   a. Perform a lookup against the Kubernetes API record name. Check that the result points to the IP address of the API load balancer:

   ```bash
   $ dig +noall +answer @<nameserver_ip> api.<cluster_name>.<base_domain>
   ```

   Replace `<nameserver_ip>` with the IP address of the nameserver, `<cluster_name>` with your cluster name, and `<base_domain>` with your base domain name.

   **Example output**

   ```
   api.ocp4.example.com.  0 IN A 192.168.1.5
   ```

   b. Perform a lookup against the Kubernetes internal API record name. Check that the result points to the IP address of the API load balancer:

   ```bash
   $ dig +noall +answer @<nameserver_ip> api-int.<cluster_name>.<base_domain>
   ```

   **Example output**

   ```
   api-int.ocp4.example.com.  0 IN A 192.168.1.5
   ```

   c. Test an example `*.apps.<cluster_name>.<base_domain>` DNS wildcard lookup. All of the application wildcard lookups must resolve to the IP address of the application ingress load balancer:

   ```bash
   $ dig +noall +answer @<nameserver_ip> random.apps.<cluster_name>.<base_domain>
   ```

   **Example output**

   ```
   random.apps.ocp4.example.com.  0 IN A 192.168.1.5
   ```

   **NOTE**

   In the example outputs, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

   You can replace `random` with another wildcard value. For example, you can query the route to the OpenShift Container Platform console:

   ```bash
   $ dig +noall +answer @<nameserver_ip> console-openshift-console.apps.<cluster_name>.<base_domain>
   ```

   **Example output**
Run a lookup against the bootstrap DNS record name. Check that the result points to the IP address of the bootstrap node:

```bash
$ dig +noall +answer @<nameserver_ip> bootstrap.<cluster_name>.<base_domain>
```

**Example output**

```
bootstrap.ocp4.example.com. 0 IN A 192.168.1.96
```

e. Use this method to perform lookups against the DNS record names for the control plane and compute nodes. Check that the results correspond to the IP addresses of each node.

2. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names contained in the responses correspond to the correct components.

a. Perform a reverse lookup against the IP address of the API load balancer. Check that the response includes the record names for the Kubernetes API and the Kubernetes internal API:

```bash
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.5
```

**Example output**

```
5.1.168.192.in-addr.arpa. 0 IN PTR api-int.o cp4.example.com.
5.1.168.192.in-addr.arpa. 0 IN PTR api.o cp4.example.com.
```

1. Provides the record name for the Kubernetes internal API.
2. Provides the record name for the Kubernetes API.

**NOTE**

A PTR record is not required for the OpenShift Container Platform application wildcard. No validation step is needed for reverse DNS resolution against the IP address of the application ingress load balancer.

b. Perform a reverse lookup against the IP address of the bootstrap node. Check that the result points to the DNS record name of the bootstrap node:

```bash
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.96
```

**Example output**

```
96.1.168.192.in-addr.arpa. 0 IN PTR bootstrap.o cp4.example.com.
```

c. Use this method to perform reverse lookups against the IP addresses for the control plane and compute nodes. Check that the results correspond to the DNS record names of each node.
20.7.9. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The ./openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>  
   ```

   Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   ```bash
   $ cat <path>/<file_name>.pub
   ```

   For example, run the following to view the ~/.ssh/id_rsa.pub public key:

   ```bash
   $ cat ~/.ssh/id_rsa.pub
   ```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the ./openshift-install gather command.
NOTE

On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.

a. If the ssh-agent process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

Example output

```
Agent pid 31874
```

NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the ssh-agent:

```
$ ssh-add /path/file_name
```

Example output

```
Identity added: /home/<you>/path/file_name (/computer_name)
```

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

20.7.10. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on your provisioning machine.

Prerequisites

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.
3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

**IMPORTANT**

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```bash
$ tar -xvf openshift-install-linux.tar.gz
```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

20.7.11. Manually creating the installation configuration file

For user-provisioned installations of OpenShift Container Platform, you manually generate your installation configuration file.

**Prerequisites**

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.

- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Create an installation directory to store your required installation assets in:

```bash
$ mkdir <installation_directory>
```
IMPORTANT

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample install-config.yaml file template that is provided and save it in the <installation_directory>.

NOTE

You must name this configuration file install-config.yaml.

NOTE

For some platform types, you can alternatively run ./openshift-install create install-config --dir <installation_directory> to generate an install-config.yaml file. You can provide details about your cluster configuration at the prompts.

3. Back up the install-config.yaml file so that you can use it to install multiple clusters.

IMPORTANT

The install-config.yaml file is consumed during the next step of the installation process. You must back it up now.

20.7.11.1. Sample install-config.yaml file for VMware vSphere

You can customize the install-config.yaml file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```
apiVersion: v1
baseDomain: example.com
compute:
  - hyperthreading: Enabled
    name: worker
    replicas: 0
controlPlane:
  hyperthreading: Enabled
  name: master
  replicas: 3
metadata:
  name: test
platform:
  vsphere:
    vcenter: your.vcenter.server
    username: username
    password: password
datacenter: datacenter
```
The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

The **controlPlane** section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, `-`, and the first line of the **controlPlane** section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading, or **hyperthreading**. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to **Disabled**. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Your machines must use at least 8 CPUs and 32 GB of RAM if you disable simultaneous multithreading.

You must set the value of the **replicas** parameter to **0**. This parameter controls the number of workers that the cluster creates and manages for you, which are functions that the cluster does not perform when you use user-provisioned infrastructure. You must manually deploy worker machines for the cluster to use before you finish installing OpenShift Container Platform.

The number of control plane machines that you add to the cluster. Because the cluster uses this value as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

The cluster name that you specified in your DNS records.

The fully-qualified hostname or IP address of the vCenter server.

The name of the user for accessing the server. This user must have at least the roles and privileges that are required for **static or dynamic persistent volume provisioning** in vSphere.

The password associated with the vSphere user.

The vSphere datacenter.

The default vSphere datastore to use.

Optional: For installer-provisioned infrastructure, the absolute path of an existing folder where the installation program creates the virtual machines, for example, `<datacenter_name>/vm/<folder_name>/<subfolder_name>`. If you do not provide this value, the installation program creates a top-level folder in the datacenter virtual machine folder that is named with the infrastructure ID. If you are providing the infrastructure for the cluster, omit this
The vSphere disk provisioning method.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

The pull secret that you obtained from OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

The public portion of the default SSH key for the core user in Red Hat Enterprise Linux CoreOS (RHCOS).

### 20.7.11.2. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the install-config.yaml file.

**Prerequisites**

- You have an existing install-config.yaml file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the Proxy object’s spec.noProxy field to bypass the proxy if necessary.

**NOTE**

The Proxy object status.noProxy field is populated with the values of the networking.machineNetwork[].cidr, networking.clusterNetwork[].cidr, and networking.serviceNetwork[] fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object status.noProxy field is also populated with the instance metadata endpoint (169.254.169.254).

**Procedure**

1. Edit your install-config.yaml file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
```
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port> ①
  httpsProxy: https://<username>:<pswd>@<ip>:<port> ②
  noProxy: example.com ③
  additionalTrustBundle:
    -----BEGIN CERTIFICATE-----
    <MY_TRUSTED_CA_CERT>
    -----END CERTIFICATE-----

① A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.

② A proxy URL to use for creating HTTPS connections outside the cluster.

③ A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations. You must include vCenter’s IP address and the IP range that you use for its machines.

④ If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the trustedCA field of the Proxy object. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

NOTE

The installation program does not support the proxy readinessEndpoints field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

NOTE

Only the Proxy object named cluster is supported, and no additional proxies can be created.

20.7.12. Specifying advanced network configuration

You can use advanced network configuration for your cluster network provider to integrate your cluster into your existing network environment. You can specify advanced network configuration only before you install the cluster.
IMPORTANT

Customizing your network configuration by modifying the OpenShift Container Platform manifest files created by the installation program is not supported. Applying a manifest file that you create, as in the following procedure, is supported.

Prerequisites

- You have created the **install-config.yaml** file and completed any modifications to it.

Procedure

1. Change to the directory that contains the installation program and create the manifests:

   ```
   $ ./openshift-install create manifests --dir <installation_directory>
   ```

   - `<installation_directory>` specifies the name of the directory that contains the **install-config.yaml** file for your cluster.

2. Create a stub manifest file for the advanced network configuration that is named **cluster-network-03-config.yml** in the `<installation_directory>/manifests/` directory:

   ```yaml
   apiVersion: operator.openshift.io/v1
   kind: Network
   metadata:
     name: cluster
   spec:
   ```

3. Specify the advanced network configuration for your cluster in the **cluster-network-03-config.yml** file, such as in the following examples:

   **Specify a different VXLAN port for the OpenShift SDN network provider**

   ```yaml
   apiVersion: operator.openshift.io/v1
   kind: Network
   metadata:
     name: cluster
   spec:
     defaultNetwork:
       openshiftSDNConfig:
         vxlanPort: 4800
   ```

   **Enable IPsec for the OVN-Kubernetes network provider**

   ```yaml
   apiVersion: operator.openshift.io/v1
   kind: Network
   metadata:
     name: cluster
   spec:
     defaultNetwork:
       ovnKubernetesConfig:
         ipsecConfig: {}
   ```
4. Optional: Back up the `manifests/cluster-network-03-config.yml` file. The installation program consumes the `manifests/` directory when you create the Ignition config files.

5. Remove the Kubernetes manifest files that define the control plane machines and compute machineSets:

   ```bash
   $ rm -f openshift/99_openshift-cluster-api_master-machines-*.yaml openshift/99_openshift-cluster-api_worker-machineset-*.yaml
   ``

   Because you create and manage these resources yourself, you do not have to initialize them.
   - You can preserve the MachineSet files to create compute machines by using the machine API, but you must update references to them to match your environment.

**20.7.13. Cluster Network Operator configuration**

The configuration for the cluster network is specified as part of the Cluster Network Operator (CNO) configuration and stored in a custom resource (CR) object that is named `cluster`. The CR specifies the fields for the `Network` API in the `operator.openshift.io` API group.

The CNO configuration inherits the following fields during cluster installation from the `Network` API in the `Network.config.openshift.io` API group and these fields cannot be changed:

- `clusterNetwork`:
  - IP address pools from which pod IP addresses are allocated.

- `serviceNetwork`:
  - IP address pool for services.

- `defaultNetwork.type`:
  - Cluster network provider, such as OpenShift SDN or OVN-Kubernetes.

You can specify the cluster network provider configuration for your cluster by setting the fields for the `defaultNetwork` object in the CNO object named `cluster`.

**20.7.13.1. Cluster Network Operator configuration object**

The fields for the Cluster Network Operator (CNO) are described in the following table:

### Table 20.55. Cluster Network Operator configuration object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>metadata.name</td>
<td>string</td>
<td>The name of the CNO object. This name is always <code>cluster</code>.</td>
</tr>
</tbody>
</table>
spec.clusterNetwork array

A list specifying the blocks of IP addresses from which pod IP addresses are allocated and the subnet prefix length assigned to each individual node in the cluster. For example:

```yaml
spec:
  clusterNetwork:
    - cidr: 10.128.0.0/19
      hostPrefix: 23
    - cidr: 10.128.32.0/19
      hostPrefix: 23
```

You can customize this field only in the `install-config.yaml` file before you create the manifests. The value is read-only in the manifest file.

spec.serviceNetwork array

A block of IP addresses for services. The OpenShift SDN and OVN-Kubernetes Container Network Interface (CNI) network providers support only a single IP address block for the service network. For example:

```yaml
spec:
  serviceNetwork:
    - 172.30.0.0/14
```

You can customize this field only in the `install-config.yaml` file before you create the manifests. The value is read-only in the manifest file.

spec.defaultNetwork object

Configures the Container Network Interface (CNI) cluster network provider for the cluster network.

spec.kubeProxy object

The fields for this object specify the kube-proxy configuration. If you are using the OVN-Kubernetes cluster network provider, the kube-proxy configuration has no effect.

defaultNetwork object configuration

The values for the `defaultNetwork` object are defined in the following table:

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>defaultNetwork</td>
<td>object</td>
<td>Configures the Container Network Interface (CNI) cluster network provider for the cluster network.</td>
</tr>
<tr>
<td>spec</td>
<td>object</td>
<td>The fields for this object specify the kube-proxy configuration. If you are using the OVN-Kubernetes cluster network provider, the kube-proxy configuration has no effect.</td>
</tr>
</tbody>
</table>
Either OpenShiftSDN or OVNKubernetes. The cluster network provider is selected during installation. This value cannot be changed after cluster installation.

**NOTE**
OpenShift Container Platform uses the OpenShift SDN Container Network Interface (CNI) cluster network provider by default.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>string</td>
<td>Either OpenShiftSDN or OVNKubernetes. The cluster network provider is selected during installation. This value cannot be changed after cluster installation.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>openshiftSDNConfig</td>
<td>object</td>
<td>This object is only valid for the OpenShift SDN cluster network provider.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ovnKubernetesConfig</td>
<td>object</td>
<td>This object is only valid for the OVN-Kubernetes cluster network provider.</td>
</tr>
</tbody>
</table>

**Configuration for the OpenShift SDN CNI cluster network provider**
The following table describes the configuration fields for the OpenShift SDN Container Network Interface (CNI) cluster network provider.

**Table 20.57. openshiftSDNConfig object**

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mode</td>
<td>string</td>
<td>Configures the network isolation mode for OpenShift SDN. The default value is <strong>NetworkPolicy</strong>. The values <strong>Multitenant</strong> and <strong>Subnet</strong> are available for backwards compatibility with OpenShift Container Platform 3.x but are not recommended. This value cannot be changed after cluster installation.</td>
</tr>
</tbody>
</table>
The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.

If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.

If your cluster requires different MTU values for different nodes, you must set this value to 50 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1450.

This value cannot be changed after cluster installation.

The port to use for all VXLAN packets. The default value is 4789. This value cannot be changed after cluster installation.

If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number.

On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port 9000 and port 9999.

Example OpenShift SDN configuration

defaultNetwork:
  type: OpenShiftSDN
  openshiftSDNConfig:
    mode: NetworkPolicy
    mtu: 1450
    vxlanPort: 4789

Configuration for the OVN-Kubernetes CNI cluster network provider

The following table describes the configuration fields for the OVN-Kubernetes CNI cluster network provider.

Table 20.58. ovnKubernetesConfig object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mtu</td>
<td>integer</td>
<td>The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU. If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes. If your cluster requires different MTU values for different nodes, you must set this value to 50 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1450. This value cannot be changed after cluster installation.</td>
</tr>
<tr>

For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number. On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port 9000 and port 9999.</td>
</tr>
</tbody>
</table>
The maximum transmission unit (MTU) for the Geneve (Generic Network Virtualization Encapsulation) overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.

If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.

If your cluster requires different MTU values for different nodes, you must set this value to 100 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1400.

The port to use for all Geneve packets. The default value is 6081. This value cannot be changed after cluster installation.

Specify an empty object to enable IPsec encryption. This value cannot be changed after cluster installation.

Specify a configuration object for customizing network policy audit logging. If unset, the defaults audit log settings are used.

Optional: Specify a configuration object for customizing how egress traffic is sent to the node gateway.

### NOTE

While migrating egress traffic, you can expect some disruption to workloads and service traffic until the Cluster Network Operator (CNO) successfully rolls out the changes.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mtu</td>
<td>integer</td>
<td>The maximum transmission unit (MTU) for the Geneve (Generic Network Virtualization Encapsulation) overlay network. <td>Specify a configuration object for customizing network policy audit logging. If unset, the defaults audit log settings are used.</td>
</tr>
<tr>
<td>gatewayConfig</td>
<td>object</td>
<td>Optional: Specify a configuration object for customizing how egress traffic is sent to the node gateway.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rateLimit</td>
<td>integer</td>
<td>The maximum number of messages to generate every second per node. The default value is 20 messages per second.</td>
</tr>
<tr>
<td>maxFileSize</td>
<td>integer</td>
<td>The maximum size for the audit log in bytes. The default value is 50000000 or 50 MB.</td>
</tr>
</tbody>
</table>
### destination

A string representing one of the following additional audit log targets:

- **libc**
  - The libc `syslog()` function of the journald process on the host.

- **udp:<host>:<port>**
  - A syslog server. Replace `<host>:<port>` with the host and port of the syslog server.

- **unix:<file>**
  - A Unix Domain Socket file specified by `<file>`.

- **null**
  - Do not send the audit logs to any additional target.

### syslogFacility

A string representing the syslog facility, such as `kern`, as defined by RFC5424. The default value is `local0`.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>destination</td>
<td>string</td>
<td>One of the following additional audit log targets:</td>
</tr>
<tr>

<td>string</td>
<td>The syslog facility, such as <code>kern</code>, as defined by RFC5424. The default value is <code>local0</code>.</td>
</tr>
</tbody>
</table>

### Table 20.60. gatewayConfig object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>routingViaHost</td>
<td>boolean</td>
<td>Set this field to <code>true</code> to send egress traffic from pods to the host networking stack. For highly-specialized installations and applications that rely on manually configured routes in the kernel routing table, you might want to route egress traffic to the host networking stack. By default, egress traffic is processed in OVN to exit the cluster and is not affected by specialized routes in the kernel routing table. The default value is <code>false</code>. This field has an interaction with the Open vSwitch hardware offloading feature. If you set this field to <code>true</code>, you do not receive the performance benefits of the offloading because egress traffic is processed by the host networking stack.</td>
</tr>
</tbody>
</table>

### Example OVN-Kubernetes configuration with IPSec enabled

```yaml
defaultNetwork:
  type: OVNKubernetes
  ovnKubernetesConfig:
    mtu: 1400
    genevePort: 6081
    ipsecConfig: {}
```

**kubeProxyConfig object configuration**

The values for the `kubeProxyConfig` object are defined in the following table:

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table 20.61. kubeProxyConfig object</td>
<td></td>
<td></td>
</tr>

|                          |          | `iptables-min-sync-period:`
|                          |          | - 0s |

### 20.7.14. Creating the Ignition config files

Because you must manually start the cluster machines, you must generate the Ignition config files that the cluster needs to make its machines.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

**Prerequisites**

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster. For a restricted network installation, these files are on your mirror host.
Obtain the Ignition config files:

```bash
$ ./openshift-install create ignition-configs --dir <installation_directory>
```

For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

### IMPORTANT

If you created an `install-config.yaml` file, specify the directory that contains it. Otherwise, specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

The following files are generated in the directory:

```
├── auth
│   ├── kubeadmin-password
│   └── kubectl
│   └── bootstrap.ign
├── master.ign
└── metadata.json
    └── worker.ign
```

### 20.7.15. Extracting the infrastructure name

The Ignition config files contain a unique cluster identifier that you can use to uniquely identify your cluster in VMware Cloud on AWS. If you plan to use the cluster identifier as the name of your virtual machine folder, you must extract it.

#### Prerequisites

- You obtained the OpenShift Container Platform installation program and the pull secret for your cluster.
- You generated the Ignition config files for your cluster.
- You installed the `jq` package.

#### Procedure

- To extract and view the infrastructure name from the Ignition config file metadata, run the following command:

```bash
$ jq -r .infraID <installation_directory>/metadata.json
```
For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

Example output

```
openshift-vw9j6
```

The output of this command is your cluster name and a random string.

20.7.16. Installing RHCOS and starting the OpenShift Container Platform bootstrap process

To install OpenShift Container Platform on user-provisioned infrastructure on VMware vSphere, you must install Red Hat Enterprise Linux CoreOS (RHCOS) on vSphere hosts. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS machines have rebooted.

Prerequisites

- You have obtained the Ignition config files for your cluster.
- You have access to an HTTP server that you can access from your computer and that the machines that you create can access.
- You have created a vSphere cluster.

Procedure

1. Upload the bootstrap Ignition config file, which is named `<installation_directory>/bootstrap.ign`, that the installation program created to your HTTP server. Note the URL of this file.

2. Save the following secondary Ignition config file for your bootstrap node to your computer as `<installation_directory>/merge-bootstrap.ign`:

```json
{
    "ignition": {
        "config": {
            "merge": [
                {
                    "source": "<bootstrap_ignition_config_url>",  
                    "verification": {}
                }
            ],
            "timeouts": {},
            "version": "3.2.0"
        },
        "networkd": {},
        "passwd": {},
```
1. Specify the URL of the bootstrap Ignition config file that you hosted.

When you create the virtual machine (VM) for the bootstrap machine, you use this Ignition config file.

3. Locate the following Ignition config files that the installation program created:
   - `<installation_directory>/master.ign`
   - `<installation_directory>/worker.ign`
   - `<installation_directory>/merge-bootstrap.ign`

4. Convert the Ignition config files to Base64 encoding. Later in this procedure, you must add these files to the extra configuration parameter `guestinfo.ignition.config.data` in your VM. For example, if you use a Linux operating system, you can use the `base64` command to encode the files.

   ```
   $ base64 -w0 <installation_directory>/master.ign > <installation_directory>/master.64
   $ base64 -w0 <installation_directory>/worker.ign > <installation_directory>/worker.64
   $ base64 -w0 <installation_directory>/merge-bootstrap.ign > <installation_directory>/merge-bootstrap.64
   ```

   **IMPORTANT**
   If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

5. Obtain the RHCOS OVA image. Images are available from the RHCOS image mirror page.

   **IMPORTANT**
   The RHCOS images might not change with every release of OpenShift Container Platform. You must download an image with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image version that matches your OpenShift Container Platform version if it is available.

   The filename contains the OpenShift Container Platform version number in the format `rhcos-vmware.<architecture>.ova`.

6. In the vSphere Client, create a folder in your datacenter to store your VMs.
   a. Click the **VMs and Templates** view.
   b. Right-click the name of your datacenter.
c. Click **New Folder → New VM and Template Folder**.

d. In the window that is displayed, enter the folder name. If you did not specify an existing folder in the `install-config.yaml` file, then create a folder with the same name as the infrastructure ID. You use this folder name so vCenter dynamically provisions storage in the appropriate location for its Workspace configuration.

7. In the vSphere Client, create a template for the OVA image and then clone the template as needed.

   **NOTE**

   In the following steps, you create a template and then clone the template for all of your cluster machines. You then provide the location for the Ignition config file for that cloned machine type when you provision the VMs.

   a. From the **Hosts and Clusters** tab, right-click your cluster name and select **Deploy OVF Template**.

   b. On the **Select an OVF** tab, specify the name of the RHCOS OVA file that you downloaded.

   c. On the **Select a name and folder** tab, set a **Virtual machine name** for your template, such as **Template-RHCOS**. Click the name of your vSphere cluster and select the folder you created in the previous step.

   d. On the **Select a compute resource** tab, click the name of your vSphere cluster.

   e. On the **Select storage** tab, configure the storage options for your VM.

      - Select **Thin Provision** or **Thick Provision**, based on your storage preferences.

      - Select the datastore that you specified in your `install-config.yaml` file.

   f. On the **Select network** tab, specify the network that you configured for the cluster, if available.

   g. When creating the OVF template, do not specify values on the **Customize template** tab or configure the template any further.

   **IMPORTANT**

   Do not start the original VM template. The VM template must remain off and must be cloned for new RHCOS machines. Starting the VM template configures the VM template as a VM on the platform, which prevents it from being used as a template that machine sets can apply configurations to.

8. Optional: Update the configured virtual hardware version in the VM template, if necessary. Follow [Upgrading a virtual machine to the latest hardware version](#) in the VMware documentation for more information.
IMPORTANT

It is recommended that you update the hardware version of the VM template to version 15 before creating VMs from it, if necessary. Using hardware version 13 for your cluster nodes running on vSphere is now deprecated. If your imported template defaults to hardware version 13, you must ensure that your ESXi host is on 6.7U3 or later before upgrading the VM template to hardware version 15. If your vSphere version is less than 6.7U3, you can skip this upgrade step; however, a future version of OpenShift Container Platform is scheduled to remove support for hardware version 13 and vSphere versions less than 6.7U3.

9. After the template deploys, deploy a VM for a machine in the cluster.
   
a. Right-click the template name and click **Clone → Clone to Virtual Machine**

b. On the **Select a name and folder** tab, specify a name for the VM. You might include the machine type in the name, such as **control-plane-0** or **compute-1**.

   **NOTE**
   
   Ensure that all virtual machine names across a vSphere installation are unique.

c. On the **Select a name and folder** tab, select the name of the folder that you created for the cluster.

d. On the **Select a compute resource** tab, select the name of a host in your datacenter.

e. Optional: On the **Select storage** tab, customize the storage options.

f. On the **Select clone options**, select **Customize this virtual machine’s hardware**

   On the **Customize hardware** tab, click **VM Options → Advanced**.
   
   • Optional: Override default DHCP networking in vSphere. To enable static IP networking:

      i. Set your static IP configuration:

      ```
      $ export IPCFG="ip=<ip>::<gateway>::<netmask>::<hostname>::<iface>::none
      nameserver=srv1 [nameserver=srv2 [nameserver=srv3 […]]]"
      ```

      **Example command**

      ```
      $ export IPCFG="ip=192.168.100.101::192.168.100.254:255.255.255.0:::none
      nameserver=8.8.8.8"
      ```

      ii. Set the **guestinfo.afterburn.initrd.network-kargs** property before booting a VM from an OVA in vSphere:

      ```
      $ govc vm.change -vm "<vm_name>" -e "guestinfo.afterburn.initrd.network-kargs=${IPCFG}"
      ```

   • Optional: In the event of cluster performance issues, from the **Latency Sensitivity** list,
Optional: In the event of cluster performance issues, from the **Latency Sensitivity** list, select **High**. Ensure that your VM’s CPU and memory reservation have the following values:

- Memory reservation value must be equal to its configured memory size.
- CPU reservation value must be at least the number of low latency virtual CPUs multiplied by the measured physical CPU speed.

Click **Edit Configuration**, and on the **Configuration Parameters** window, click **Add Configuration Params**. Define the following parameter names and values:

- **guestinfo.ignition.config.data**: Locate the base-64 encoded files that you created previously in this procedure, and paste the contents of the base64-encoded Ignition config file for this machine type.

- **guestinfo.ignition.config.data.encoding**: Specify **base64**.

- **disk.EnableUUID**: Specify **TRUE**.

In the **Virtual Hardware** panel of the **Customize hardware** tab, modify the specified values as required. Ensure that the amount of RAM, CPU, and disk storage meets the minimum requirements for the machine type.

Complete the configuration and power on the VM.

Check the console output to verify that Ignition ran.

**Example command**

```
Ignition: ran on 2022/03/14 14:48:33 UTC (this boot)
Ignition: user-provided config was applied
```

10. Create the rest of the machines for your cluster by following the preceding steps for each machine.

**IMPORTANT**

You must create the bootstrap and control plane machines at this time. Because some pods are deployed on compute machines by default, also create at least two compute machines before you install the cluster.

### 20.7.17. Adding more compute machines to a cluster in vSphere

You can add more compute machines to a user-provisioned OpenShift Container Platform cluster on VMware vSphere.

**Prerequisites**

- Obtain the base64-encoded Ignition file for your compute machines.
- You have access to the vSphere template that you created for your cluster.

**Procedure**

1. After the template deploys, deploy a VM for a machine in the cluster.
a. Right-click the template's name and click **Clone → Clone to Virtual Machine**

b. On the **Select a name and folder** tab, specify a name for the VM. You might include the machine type in the name, such as **compute-1**.

   **NOTE**

   Ensure that all virtual machine names across a vSphere installation are unique.

c. On the **Select a name and folder** tab, select the name of the folder that you created for the cluster.

d. On the **Select a compute resource** tab, select the name of a host in your datacenter.

e. Optional: On the **Select storage** tab, customize the storage options.

f. On the **Select clone options**, select **Customize this virtual machine’s hardware**

g. On the **Customize hardware** tab, click **VM Options → Advanced**.
   - From the **Latency Sensitivity** list, select **High**.
   - Click **Edit Configuration**, and on the **Configuration Parameters** window, click **Add Configuration Params**. Define the following parameter names and values:
      - guestinfo.ignition.config.data: Paste the contents of the base64-encoded compute Ignition config file for this machine type.
      - guestinfo.ignition.config.data.encoding: Specify **base64**.
      - disk.EnableUUID: Specify **TRUE**.

h. In the **Virtual Hardware** panel of the **Customize hardware** tab, modify the specified values as required. Ensure that the amount of RAM, CPU, and disk storage meets the minimum requirements for the machine type. Also, make sure to select the correct network under **Add network adapter** if there are multiple networks available.

i. Complete the configuration and power on the VM.

2. Continue to create more compute machines for your cluster.

### 20.7.18. Disk partitioning

In most cases, data partitions are originally created by installing RHCOS, rather than by installing another operating system. In such cases, the OpenShift Container Platform installer should be allowed to configure your disk partitions.

However, there are two cases where you might want to intervene to override the default partitioning when installing an OpenShift Container Platform node:

- Create separate partitions: For greenfield installations on an empty disk, you might want to add separate storage to a partition. This is officially supported for making **/var** or a subdirectory of **/var**, such as **/var/lib/etcd**, a separate partition, but not both.
IMPORTANT

Kubernetes supports only two filesystem partitions. If you add more than one partition to the original configuration, Kubernetes cannot monitor all of them.

- Retain existing partitions: For a brownfield installation where you are reinstalling OpenShift Container Platform on an existing node and want to retain data partitions installed from your previous operating system, there are both boot arguments and options to `coreos-installer` that allow you to retain existing data partitions.

Creating a separate `/var` partition

In general, disk partitioning for OpenShift Container Platform should be left to the installer. However, there are cases where you might want to create separate partitions in a part of the filesystem that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the `/var` partition or a subdirectory of `/var`. For example:

- `/var/lib/containers`: Holds container-related content that can grow as more images and containers are added to a system.
- `/var/lib/etcd`: Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.
- `/var`: Holds data that you might want to keep separate for purposes such as auditing.

Storing the contents of a `/var` directory separately makes it easier to grow storage for those areas as needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

Because `/var` must be in place before a fresh installation of Red Hat Enterprise Linux CoreOS (RHCOS), the following procedure sets up the separate `/var` partition by creating a machine config manifest that is inserted during the `openshift-install` preparation phases of an OpenShift Container Platform installation.

Procedure

1. Create a directory to hold the OpenShift Container Platform installation files:

   ```
   $ mkdir $HOME/clusterconfig
   ```

2. Run `openshift-install` to create a set of files in the `manifest` and `openshift` subdirectories.

   ```
   $ openshift-install create manifests --dir $HOME/clusterconfig
   ? SSH Public Key ...
   $ ls $HOME/clusterconfig/openshift/
   99_kubeadmin-password-secret.yaml
   99_openshift-cluster-api_master-machines-0.yaml
   99_openshift-cluster-api_master-machines-1.yaml
   99_openshift-cluster-api_master-machines-2.yaml
   ...
   ```

3. Create a Butane config that configures the additional partition. For example, name the file
$HOME/clusterconfig/98-var-partition.bu, change the disk device name to the name of the storage device on the worker systems, and set the storage size as appropriate. This example places the /var directory on a separate partition:

```yaml
variant: openshift
version: 4.10.0
metadata:
  machineconfiguration.openshift.io/role: worker
name: 98-var-partition
storage:
disks:
  - device: '/dev/<device_name>'
    partitions:
      - label: var
        start_mib: <partition_start_offset>
        size_mib: <partition_size>
    filesystems:
      - device: '/dev/disk/by-partlabel/var'
        path: '/var'
        format: xfs
        mount_options: [defaults, prjquota]
        with_mount_unit: true
```

1. The storage device name of the disk that you want to partition.
2. When adding a data partition to the boot disk, a minimum value of 25000 mebibytes is recommended. The root file system is automatically resized to fill all available space up to the specified offset. If no value is specified, or if the specified value is smaller than the recommended minimum, the resulting root file system will be too small, and future reinstalls of RHCOS might overwrite the beginning of the data partition.
3. The size of the data partition in mebibytes.
4. The prjquota mount option must be enabled for filesystems used for container storage.

**NOTE**

When creating a separate /var partition, you cannot use different instance types for worker nodes, if the different instance types do not have the same device name.

4. Create a manifest from the Butane config and save it to the clusterconfig/openshift directory. For example, run the following command:

```
$ butane $HOME/clusterconfig/98-var-partition.bu -o $HOME/clusterconfig/openshift/98-var-partition.yaml
```

5. Run openshift-install again to create Ignition configs from a set of files in the manifest and openshift subdirectories:
Now you can use the Ignition config files as input to the vSphere installation procedures to install Red Hat Enterprise Linux CoreOS (RHCOS) systems.

20.7.19. Updating the bootloader using bootupd

To update the bootloader by using **bootupd**, you must either install **bootupd** on RHCOS machines manually or provide a machine config with the enabled **systemd** unit. Unlike **grubby** or other bootloader tools, **bootupd** does not manage kernel space configuration such as passing kernel arguments.

After you have installed **bootupd**, you can manage it remotely from the OpenShift Container Platform cluster.

**NOTE**

It is recommended that you use **bootupd** only on bare metal or virtualized hypervisor installations, such as for protection against the BootHole vulnerability.

**Manual install method**

You can manually install **bootupd** by using the **bootctl** command-line tool.

1. Inspect the system status:

```
# bootupctl status
```

**Example output for x86_64**

```
Component EFI
Installed: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
Update: At latest version
```

**Example output for arm64**

```
Component EFI
Installed: grub2-efi-aa64-1:2.02-99.el8_4.1.aarch64,shim-aa64-15.4-2.el8_1.aarch64
Update: At latest version
```

2. RHCOS images created without **bootupd** installed on them require an explicit adoption phase. If the system status is **Adoptable**, perform the adoption:

```
# bootupctl adopt-and-update
```

**Example output**

```
Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
```

3. If an update is available, apply the update so that the changes take effect on the next reboot:
Machine config method

Another way to enable **bootupd** is by providing a machine config.

- Provide a machine config file with the enabled **systemd** unit, as shown in the following example:

```
Example output

variant: rhcos
version: 1.1.0
systemd:
  units:
    - name: custom-bootupd-auto.service
      enabled: true
      contents:
        [Unit]
        Description=Bootupd automatic update
        [Service]
        ExecStart=/usr/bin/bootupctl update
        RemainAfterExit=yes
        [Install]
        WantedBy=multi-user.target
```

### 20.7.20. Waiting for the bootstrap process to complete

The OpenShift Container Platform bootstrap process begins after the cluster nodes first boot into the persistent RHCOS environment that has been installed to disk. The configuration information provided through the Ignition config files is used to initialize the bootstrap process and install OpenShift Container Platform on the machines. You must wait for the bootstrap process to complete.

**Prerequisites**

- You have created the Ignition config files for your cluster.

- You have configured suitable network, DNS and load balancing infrastructure.

- You have obtained the installation program and generated the Ignition config files for your cluster.

- You installed RHCOS on your cluster machines and provided the Ignition config files that the OpenShift Container Platform installation program generated.

- Your machines have direct internet access or have an HTTP or HTTPS proxy available.

**Procedure**

```bash
# bootupctl update
```

Example output

```
Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
```
1. Monitor the bootstrap process:

```
$ ./openshift-install --dir <installation_directory> wait-for bootstrap-complete \  
   --log-level=info
```

1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

**Example output**

```
INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
INFO API v1.23.0 up
INFO Waiting up to 30m0s for bootstrapping to complete...
INFO It is now safe to remove the bootstrap resources
```

The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After bootstrap process is complete, remove the bootstrap machine from the load balancer.

**IMPORTANT**

You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the bootstrap machine itself.

---

### 20.7.21. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig
```

1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

```
$ oc whoami
```
20.7.22. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

Prerequisites

- You added machines to your cluster.

Procedure

1. Confirm that the cluster recognizes the machines:

   `$ oc get nodes`

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.23.0</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.23.0</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>64m</td>
<td>v1.23.0</td>
</tr>
</tbody>
</table>

   The output lists all of the machines that you created.

   **NOTE**

   The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

   `$ oc get csr`

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-mddf5</td>
<td>20m</td>
<td>system:node:master-01.example.com</td>
<td>Approved,Issued</td>
</tr>
<tr>
<td>csr-z5rln</td>
<td>16m</td>
<td>system:node:worker-21.example.com</td>
<td>Approved,Issued</td>
</tr>
</tbody>
</table>

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:
CHAPTER 20. INSTALLING ON VMC

NOTE
Because the CSRs rotate automatically, approve your CSRs within an hour of
adding the machines to the cluster. If you do not approve them within an hour, the
certificates will rotate, and more than two certificates will be present for each
node. You must approve all of these certificates. After the client CSR is
approved, the Kubelet creates a secondary CSR for the serving certificate, which
requires manual approval. Then, subsequent serving certificate renewal requests
are automatically approved by the machine-approver if the Kubelet requests a
new certificate with identical parameters.

NOTE
For clusters running on platforms that are not machine API enabled, such as bare
metal and other user-provisioned infrastructure, you must implement a method
of automatically approving the kubelet serving certificate requests (CSRs). If a
request is not approved, then the oc exec, oc rsh, and oc logs commands
cannot succeed, because a serving certificate is required when the API server
connects to the kubelet. Any operation that contacts the Kubelet endpoint
requires this certificate approval to be in place. The method must watch for new
CSRs, confirm that the CSR was submitted by the node-bootstrapper service
account in the system:node or system:admin groups, and confirm the identity
of the node.
To approve them individually, run the following command for each valid CSR:
$ oc adm certificate approve <csr_name> 1
1

<csr_name> is the name of a CSR from the list of current CSRs.

To approve all pending CSRs, run the following command:
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}
{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve

NOTE
Some Operators might not become available until some CSRs are approved.
4. Now that your client requests are approved, you must review the server requests for each
machine that you added to the cluster:
$ oc get csr

Example output
NAME
AGE REQUESTOR
CONDITION
csr-bfd72 5m26s system:node:ip-10-0-50-126.us-east-2.compute.internal
Pending
csr-c57lv 5m26s system:node:ip-10-0-95-157.us-east-2.compute.internal
Pending
...

3047


5. If the remaining CSRs are not approved, and are in the Pending status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

  ```
  $ oc adm certificate approve <csr_name>
  ```

  `<csr_name>` is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

  ```
  $ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs oc adm certificate approve
  ```

6. After all client and server CSRs have been approved, the machines have the Ready status. Verify this by running the following command:

```
$ oc get nodes
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.23.0</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.23.0</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>74m</td>
<td>v1.23.0</td>
</tr>
<tr>
<td>worker-0</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.23.0</td>
</tr>
<tr>
<td>worker-1</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.23.0</td>
</tr>
</tbody>
</table>

**NOTE**

It can take a few minutes after approval of the server CSRs for the machines to transition to the Ready status.

**Additional information**

- For more information on CSRs, see [Certificate Signing Requests](#).

---

**20.7.23. Initial Operator configuration**

After the control plane initializes, you must immediately configure some Operators so that they all become available.

**Prerequisites**

- Your control plane has initialized.

**Procedure**

1. Watch the cluster components come online:

```
$ watch -n5 oc get clusteroperators
```

2. Configure the Operators that are not available.

20.7.23.1. Image registry removed during installation

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as Removed. This allows openshift-installer to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the managementState from Removed to Managed.

NOTE

The Prometheus console provides an ImageRegistryRemoved alert, for example:

"Image Registry has been removed. ImageStreamTags, BuildConfigs and DeploymentConfigs which reference ImageStreamTags may not work as expected. Please configure storage and update the config to Managed state by editing configs.imageregistry.operator.openshift.io."
20.7.23.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the `Recreate` rollout strategy during upgrades.

20.7.23.2.1. Configuring block registry storage for VMware vSphere

To allow the image registry to use block storage types such as vSphere Virtual Machine Disk (VMDK) during upgrades as a cluster administrator, you can use the `Recreate` rollout strategy.

**IMPORTANT**

Block storage volumes are supported but not recommended for use with image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

Procedure

1. To set the image registry storage as a block storage type, patch the registry so that it uses the `Recreate` rollout strategy and runs with only 1 replica:

   ```bash
   $ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec":
   {"rolloutStrategy":"Recreate","replicas":1}}'
   ``

2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.

   a. Create a `pvc.yaml` file with the following contents to define a VMware vSphere `PersistentVolumeClaim` object:

   ```yaml
   kind: PersistentVolumeClaim
   apiVersion: v1
   metadata:
     name: image-registry-storage
     namespace: openshift-image-registry
   spec:
     accessModes:
     - ReadWriteOnce
     resources:
       requests:
         storage: 100Gi
   ```

   1 A unique name that represents the `PersistentVolumeClaim` object.
   2 The namespace for the `PersistentVolumeClaim` object, which is `openshift-image-registry`. 
The access mode of the persistent volume claim. With ReadWriteOnce, the volume can be mounted with read and write permissions by a single node.

The size of the persistent volume claim.

b. Create the PersistentVolumeClaim object from the file:

```
$ oc create -f pvc.yaml -n openshift-image-registry
```

3. Edit the registry configuration so that it references the correct PVC:

```
$ oc edit config.imageregistry.operator.openshift.io -o yaml
```

Example output

```
storage:
pvc:
  claim: 1
```

Creating a custom PVC allows you to leave the claim field blank for the default automatic creation of an image-registry-storage PVC.

For instructions about configuring registry storage so that it references the correct PVC, see Configuring the registry for vSphere.

20.7.24. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

Prerequisites

- Your control plane has initialized.
- You have completed the initial Operator configuration.

Procedure

1. Confirm that all the cluster components are online with the following command:

```
$ watch -n5 oc get clusteroperators
```

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
<th>SINCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>authentication</td>
<td>4.10.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>19m</td>
</tr>
<tr>
<td>baremetal</td>
<td>4.10.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>37m</td>
</tr>
<tr>
<td>cloud-credential</td>
<td>4.10.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>40m</td>
</tr>
<tr>
<td>cluster-autoscaler</td>
<td>4.10.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>37m</td>
</tr>
<tr>
<td>config-operator</td>
<td>4.10.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>38m</td>
</tr>
</tbody>
</table>
Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```bash
$ ./openshift-install --dir <installation_directory> wait-for install-complete
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

### Example output

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.
IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

2. Confirm that the Kubernetes API server is communicating with the pods.

a. To view a list of all pods, use the following command:

   ```bash
   $ oc get pods --all-namespaces
   ```

   **Example output**

<table>
<thead>
<tr>
<th>NAMESPACE</th>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>openshift-apiserver-operator</td>
<td>openshift-apiserver-operator-85cb746d55-zqhs8</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td></td>
<td>Running 1 9m</td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>openshift-apiserver-67b9g</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td></td>
<td>Running 1 3m</td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>openshift-apiserver-ljcmx</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td></td>
<td>Running 1 1m</td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>openshift-apiserver-z25h4</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td></td>
<td>Running 2 2m</td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-authentication-operator</td>
<td>openshift-authentication-operator-69d5d8bf84-vh2n8</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td></td>
<td>Running 0 5m</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>...</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

b. View the logs for a pod that is listed in the output of the previous command by using the following command:

   ```bash
   $ oc logs <pod_name> -n <namespace>
   ```

   Specify the pod name and namespace, as shown in the output of the previous command.

   If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation.

   See "Enabling multipathing with kernel arguments on RHCOS" in the Post-installation machine configuration tasks documentation for more information.
You can add extra compute machines after the cluster installation is completed by following Adding compute machines to vSphere.

20.7.25. Backing up VMware vSphere volumes

OpenShift Container Platform provisions new volumes as independent persistent disks to freely attach and detach the volume on any node in the cluster. As a consequence, it is not possible to back up volumes that use snapshots, or to restore volumes from snapshots. See Snapshot Limitations for more information.

Procedure

To create a backup of persistent volumes:

1. Stop the application that is using the persistent volume.
2. Clone the persistent volume.
3. Restart the application.
4. Create a backup of the cloned volume.
5. Delete the cloned volume.

20.7.26. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.10, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service

20.7.27. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- Set up your registry and configure registry storage.
- Optional: View the events from the vSphere Problem Detector Operator to determine if the cluster has permission or storage configuration issues.

20.8. INSTALLING A CLUSTER ON VMC IN A RESTRICTED NETWORK WITH USER-PROVISIONED INFRASTRUCTURE

In OpenShift Container Platform version 4.10, you can install a cluster on VMware vSphere infrastructure that you provision in a restricted network by deploying it to VMware Cloud (VMC) on AWS.
Once you configure your VMC environment for OpenShift Container Platform deployment, you use the OpenShift Container Platform installation program from the bastion management host, co-located in the VMC environment. The installation program and control plane automates the process of deploying and managing the resources needed for the OpenShift Container Platform cluster.

### 20.8.1. Setting up VMC for vSphere

You can install OpenShift Container Platform on VMware Cloud (VMC) on AWS hosted vSphere clusters to enable applications to be deployed and managed both on-premise and off-premise, across the hybrid cloud.

You must configure several options in your VMC environment prior to installing OpenShift Container Platform on VMware vSphere. Ensure your VMC environment has the following prerequisites:

- Create a non-exclusive, DHCP-enabled, NSX-T network segment and subnet. Other virtual machines (VMs) can be hosted on the subnet, but at least eight IP addresses must be available for the OpenShift Container Platform deployment.

- Configure the following firewall rules:
  - An ANY:ANY firewall rule between the installation host and the software-defined data center (SDDC) management network on port 443. This allows you to upload the Red Hat Enterprise Linux CoreOS (RHCOS) OVA during deployment.
  - An HTTPS firewall rule between the OpenShift Container Platform compute network and vCenter. This connection allows OpenShift Container Platform to communicate with vCenter for provisioning and managing nodes, persistent volume claims (PVCs), and other resources.

- You must have the following information to deploy OpenShift Container Platform:
  - The OpenShift Container Platform cluster name, such as `vmc-prod-1`.
  - The base DNS name, such as `companyname.com`.
  - If not using the default, the pod network CIDR and services network CIDR must be identified, which are set by default to `10.128.0.0/14` and `172.30.0.0/16`, respectively. These CIDRs are used for pod-to-pod and pod-to-service communication and are not accessible externally; however, they must not overlap with existing subnets in your organization.
  - The following vCenter information:
    - vCenter hostname, username, and password
    - Datacenter name, such as `SDDC-Datacenter`
- Cluster name, such as **Cluster-1**
- Network name
- Datastore name, such as **WorkloadDatastore**

**NOTE**

It is recommended to move your vSphere cluster to the VMC **Compute-ResourcePool** resource pool after your cluster installation is finished.

- A Linux-based host deployed to VMC as a bastion.
  - The bastion host can be Red Hat Enterprise Linux (RHEL) or any another Linux-based host; it must have internet connectivity and the ability to upload an OVA to the ESXi hosts.
  - Download and install the OpenShift CLI tools to the bastion host.
    - The **openshift-install** installation program
    - The OpenShift CLI (**oc**) tool

**NOTE**

You cannot use the VMware NSX Container Plug-in for Kubernetes (NCP), and NSX is not used as the OpenShift SDN. The version of NSX currently available with VMC is incompatible with the version of NCP certified with OpenShift Container Platform.

However, the NSX DHCP service is used for virtual machine IP management with the full-stack automated OpenShift Container Platform deployment and with nodes provisioned, either manually or automatically, by the Machine API integration with vSphere. Additionally, NSX firewall rules are created to enable access with the OpenShift Container Platform cluster and between the bastion host and the VMC vSphere hosts.

### 20.8.1.1. VMC Sizer tool

VMware Cloud on AWS is built on top of AWS bare metal infrastructure; this is the same bare metal infrastructure which runs AWS native services. When a VMware cloud on AWS software-defined data center (SDDC) is deployed, you consume these physical server nodes and run the VMware ESXi hypervisor in a single tenant fashion. This means the physical infrastructure is not accessible to anyone else using VMC. It is important to consider how many physical hosts you will need to host your virtual infrastructure.

To determine this, VMware provides the **VMC on AWS Sizer**. With this tool, you can define the resources you intend to host on VMC:

- Types of workloads
- Total number of virtual machines
- Specification information such as:
  - Storage requirements
  - vCPUs
vRAM

- Overcommit ratios

With these details, the sizer tool can generate a report, based on VMware best practices, and recommend your cluster configuration and the number of hosts you will need.

### 20.8.2. vSphere prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You created a registry on your mirror host and obtain the `imageContentSources` data for your version of OpenShift Container Platform.

**IMPORTANT**

Because the installation media is on the mirror host, you can use that computer to complete all installation steps.

- You provisioned block registry storage. For more information on persistent storage, see Understanding persistent storage.

- If you use a firewall and plan to use the Telemetry service, you configured the firewall to allow the sites that your cluster requires access to.

**NOTE**

Be sure to also review this site list if you are configuring a proxy.

### 20.8.3. About installations in restricted networks

In OpenShift Container Platform 4.10, you can perform an installation that does not require an active connection to the internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service’s IAM service, require internet access, so you might still require internet access. Depending on your network, you might require less internet access for an installation on bare metal hardware or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift Container Platform registry and contains the installation media. You can create this registry on a mirror host, which can access both the internet and your closed network, or by using other methods that meet your restrictions.
IMPORTANT

Because of the complexity of the configuration for user-provisioned installations, consider completing a standard user-provisioned infrastructure installation before you attempt a restricted network installation using user-provisioned infrastructure. Completing this test installation might make it easier to isolate and troubleshoot any issues that might arise during your installation in a restricted network.

20.8.3.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The ClusterVersion status includes an Unable to retrieve available updates error.
- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

20.8.4. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.10, you require access to the internet to obtain the images that are necessary to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

20.8.5. VMware vSphere infrastructure requirements

You must install the OpenShift Container Platform cluster on a VMware vSphere version 6 or 7 instance that meets the requirements for the components that you use.

Table 20.62. Version requirements for vSphere virtual environments

<table>
<thead>
<tr>
<th>Virtual environment product</th>
<th>Required version</th>
</tr>
</thead>
<tbody>
<tr>
<td>VM hardware version</td>
<td>13 or later</td>
</tr>
<tr>
<td>vSphere ESXi hosts</td>
<td>6.5 or later</td>
</tr>
</tbody>
</table>
VCenter host | 6.5 or later

**IMPORTANT**

Installing a cluster on VMware vSphere version 6.7U3 or earlier and virtual hardware version 13 is now deprecated. These versions are still fully supported, but version 4.11 of OpenShift Container Platform will require vSphere virtual hardware version 15 or later. Hardware version 15 is now the default for vSphere virtual machines in OpenShift Container Platform. To update the hardware version for your vSphere nodes, see the "Updating hardware on nodes running in vSphere" article.

If your vSphere nodes are below hardware version 15 or your VMware vSphere version is earlier than 6.7U3, upgrading from OpenShift Container Platform 4.10 to OpenShift Container Platform 4.11 is not available.

**Table 20.63. Minimum supported vSphere version for VMware components**

<table>
<thead>
<tr>
<th>Component</th>
<th>Minimum supported versions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hypervisor</td>
<td>vSphere 6.5 and later with HW version 13</td>
<td>This version is the minimum version that Red Hat Enterprise Linux CoreOS (RHCOS) supports. See the Red Hat Enterprise Linux 8 supported hypervisors list.</td>
</tr>
<tr>
<td>Storage with in-tree drivers</td>
<td>vSphere 6.5 and later</td>
<td>This plug-in creates vSphere storage by using the in-tree storage drivers for vSphere included in OpenShift Container Platform.</td>
</tr>
</tbody>
</table>

If you use a vSphere version 6.5 instance, consider upgrading to 6.7U3 or 7.0 before you install OpenShift Container Platform.

**IMPORTANT**

You must ensure that the time on your ESXi hosts is synchronized before you install OpenShift Container Platform. See Edit Time Configuration for a Host in the VMware documentation.

**20.8.6. VMware vSphere CSI Driver Operator requirements**

The following requirements must be met in order to install the CSI Driver Operator:

- VMware vSphere version 6.7U3 or later
- Virtual machines of hardware version 15 or later
• No third-party CSI driver already installed in the cluster

If a third-party CSI driver is present in the cluster, OpenShift Container Platform does not overwrite it. The presence of a third-party CSI driver prevents OpenShift Container Platform from upgrading to 4.11.

Additional resources

• To remove a third-party CSI driver, see Removing a third-party vSphere CSI Driver.
• To update the hardware version for your vSphere nodes, see Updating hardware on nodes running in vSphere.

20.8.7. Requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines. This section describes the requirements for deploying OpenShift Container Platform on user-provisioned infrastructure.

20.8.7.1. Required machines for cluster installation

The smallest OpenShift Container Platform clusters require the following hosts:

Table 20.64. Minimum required hosts

<table>
<thead>
<tr>
<th>Hosts</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>One temporary bootstrap machine</td>
<td>The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.</td>
</tr>
<tr>
<td>Three control plane machines</td>
<td>The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.</td>
</tr>
<tr>
<td>At least two compute machines, which are also known as worker machines.</td>
<td>The workloads requested by OpenShift Container Platform users run on the compute machines.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

To improve high availability of your cluster, distribute the control plane machines over different z/VM instances on at least two physical machines.

The bootstrap, control plane, and compute machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 8 and inherits all of its hardware certifications and requirements. See Red Hat Enterprise Linux technology capabilities and limits.

20.8.7.2. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:
<table>
<thead>
<tr>
<th>Machine</th>
<th>Operating System</th>
<th>vCPU</th>
<th>Virtual RAM</th>
<th>Storage</th>
<th>IOPS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS</td>
<td>2</td>
<td>8 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
</tbody>
</table>

1. One physical core (IFL) provides two logical cores (threads) when SMT-2 is enabled. The hypervisor can provide two or more vCPUs.

20.8.7.3. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The `kube-controller-manager` only approves the kubelet client CSRs. The `machine-approver` cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

20.8.7.4. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in `initramfs` during boot to fetch their Ignition config files.

During the initial boot, the machines require an HTTP or HTTPS server to establish a network connection to download their Ignition config files.

The machines are configured with static IP addresses. No DHCP server is required. Ensure that the machines have persistent IP addresses and hostnames.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

20.8.7.4.1. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

**IMPORTANT**

In connected OpenShift Container Platform environments, all nodes are required to have internet access to pull images for platform containers and provide telemetry data to Red Hat.
Table 20.65. Ports used for all-machine to all-machine communications

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Port</th>

**NTP configuration for user-provisioned infrastructure**

OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for *Configuring chrony time service*.

**20.8.7.5. User-provisioned DNS requirements**

In OpenShift Container Platform deployments, DNS name resolution is required for the following components:

- The Kubernetes API
The OpenShift Container Platform application wildcard
The bootstrap, control plane, and compute machines

Reverse DNS resolution is also required for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the hostnames for all the nodes, unless the hostnames are provided by DHCP. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

The following DNS records are required for a user-provisioned OpenShift Container Platform cluster and they must be in place before installation. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>`.

Table 20.68. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the API load balancer. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td></td>
<td>api-int.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to internally identify the API load balancer. These records must be resolvable from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Routes</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A wildcard DNS A/AAAA or CNAME record that refers to the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster. For example, <code>console-openshift-console.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;</code> is used as a wildcard route to the OpenShift Container Platform console.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

The API server must be able to resolve the worker nodes by the hostnames that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.
<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap machine</td>
<td><code>bootstrap.&lt;cluster_name&gt;..&lt;base_domain&gt;</code></td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Control plane</td>
<td><code>&lt;master&gt;&lt;n&gt;..&lt;cluster_name&gt;..&lt;base_domain&gt;</code></td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Compute machines</td>
<td><code>&lt;worker&gt;&lt;n&gt;..&lt;cluster_name&gt;..&lt;base_domain&gt;</code></td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**NOTE**

In OpenShift Container Platform 4.4 and later, you do not need to specify etcd host and SRV records in your DNS configuration.

**TIP**

You can use the `dig` command to verify name and reverse name resolution. See the section on Validating DNS resolution for user-provisioned infrastructure for detailed validation steps.

### 20.8.7.5.1. Example DNS configuration for user-provisioned clusters

This section provides A and PTR record configuration samples that meet the DNS requirements for deploying OpenShift Container Platform on user-provisioned infrastructure. The samples are not meant to provide advice for choosing one DNS solution over another.

In the examples, the cluster name is `ocp4` and the base domain is `example.com`.

**Example DNS A record configuration for a user-provisioned cluster**

The following example is a BIND zone file that shows sample A records for name resolution in a user-provisioned cluster.

Example 20.15. Sample DNS zone database

```text
$TTL 1W
@ IN SOA ns1.example.com. root ( 2019070700 ; serial 3H ; refresh (3 hours) 30M ; retry (30 minutes) 2W ; expiry (2 weeks) 1W ) ; minimum (1 week)
IN NS ns1.example.com.
IN MX 10 smtp.example.com.
```
Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer. The record refers to the IP address of the API load balancer and is used for internal cluster communications.

Provides name resolution for the wildcard routes. The record refers to the IP address of the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

NOTE

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

Provides name resolution for the bootstrap machine.

Provides name resolution for the control plane machines.

Provides name resolution for the compute machines.

Example DNS PTR record configuration for a user-provisioned cluster

The following example BIND zone file shows sample PTR records for reverse name resolution in a user-provisioned cluster.

```
# Example DNS PTR record configuration for a user-provisioned cluster

ns1.example.com. IN A 192.168.1.5
smtp.example.com. IN A 192.168.1.5
helper.example.com. IN A 192.168.1.5
helper.ocp4.example.com. IN A 192.168.1.5
api.ocp4.example.com. IN A 192.168.1.5
api-int.ocp4.example.com. IN A 192.168.1.5
*.apps.ocp4.example.com. IN A 192.168.1.5
bootstrap.ocp4.example.com. IN A 192.168.1.96
master0.ocp4.example.com. IN A 192.168.1.97
master1.ocp4.example.com. IN A 192.168.1.98
master2.ocp4.example.com. IN A 192.168.1.99
worker0.ocp4.example.com. IN A 192.168.1.11
worker1.ocp4.example.com. IN A 192.168.1.7

; EOF
```
Example 20.16. Sample DNS zone database for reverse records

```plaintext
$TTL 1W  
@ IN SOA ns1.example.com. root (  
2019070700 ; serial  
3H ; refresh (3 hours)  
30M ; retry (30 minutes)  
2W ; expiry (2 weeks)  
1W ) ; minimum (1 week)  
IN NS ns1.example.com.  
; 5.1.168.192.in-addr.arpa. IN PTR api.ocp4.example.com.  
; 96.1.168.192.in-addr.arpa. IN PTR bootstrap.ocp4.example.com.  
; 97.1.168.192.in-addr.arpa. IN PTR master0.ocp4.example.com.  
; 11.1.168.192.in-addr.arpa. IN PTR worker0.ocp4.example.com.  
; EOF
```

1. Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer.
2. Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer and is used for internal cluster communications.
3. Provides reverse DNS resolution for the bootstrap machine.
4. 5. 6. Provides reverse DNS resolution for the control plane machines.
7. 8. Provides reverse DNS resolution for the compute machines.

**NOTE**

A PTR record is not required for the OpenShift Container Platform application wildcard.

### 20.8.7.6. Load balancing requirements for user-provisioned infrastructure

Before you install OpenShift Container Platform, you must provision the API and application ingress load balancing infrastructure. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

The load balancing infrastructure must meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.

A stateless load balancing algorithm. The options vary based on the load balancer implementation.

**NOTE**
Session persistence is not required for the API load balancer to function properly.

Configure the following ports on both the front and back of the load balancers:

**Table 20.69. API load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the <code>/readyz</code> endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
</tbody>
</table>

**NOTE**

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the `/readyz` endpoint to the removal of the API server instance from the pool. Within the time frame after `/readyz` returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application ingress load balancer**: Provides an ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.
TIP

If the true IP address of the client can be seen by the application ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

Configure the following ports on both the front and back of the load balancers:

**Table 20.70. Application ingress load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
<tr>
<td>1936</td>
<td>The worker nodes that run the Ingress Controller pods, by default. You must configure the /healthz/ready endpoint for the ingress health check probe.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>

**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

**NOTE**

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

### 20.8.7.6.1. Example load balancer configuration for user-provisioned clusters

This section provides an example API and application ingress load balancer configuration that meets the load balancing requirements for user-provisioned clusters. The sample is an `/etc/haproxy/haproxy.cfg` configuration for an HAPProxy load balancer. The example is not meant to provide advice for choosing one load balancing solution over another.

**NOTE**

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.
Example 20.17. Sample API and application ingress load balancer configuration

```
# global
log 127.0.0.1 local2
pidfile /var/run/haproxy.pid
maxconn 4000
daemon
defaults
  mode  http
  log  global
  option  dontlognull
  option http-server-close
  option  redispatch
  retries 3
  timeout http-request 10s
  timeout queue 1m
  timeout connect 10s
  timeout client 1m
  timeout server 1m
  timeout http-keep-alive 10s
  timeout check 10s
  maxconn 3000

# frontend stats
bind *:1936
  mode http
  log  global
  maxconn 10
  stats enable
  stats hide-version
  stats refresh 30s
  stats show-node
  stats show-desc Stats for ocp4 cluster
  stats auth admin:ocp4
  stats uri /stats

listen api-server-6443
  bind *:6443
  mode tcp
  server bootstrap bootstrap.ocp4.example.com:6443 check inter 1s backup
  server master0 master0.ocp4.example.com:6443 check inter 1s
  server master1 master1.ocp4.example.com:6443 check inter 1s
  server master2 master2.ocp4.example.com:6443 check inter 1s

listen machine-config-server-22623
  bind *:22623
  mode tcp
  server bootstrap bootstrap.ocp4.example.com:22623 check inter 1s backup
  server master0 master0.ocp4.example.com:22623 check inter 1s
  server master1 master1.ocp4.example.com:22623 check inter 1s
  server master2 master2.ocp4.example.com:22623 check inter 1s

listen ingress-router-443
  bind *:443
  mode tcp
  balance source
  server worker0 worker0.ocp4.example.com:443 check inter 1s
  server worker1 worker1.ocp4.example.com:443 check inter 1s

listen ingress-router-80
```

In the example, the cluster name is `ocp4`.

Port `6443` handles the Kubernetes API traffic and points to the control plane machines.

The bootstrap entries must be in place before the OpenShift Container Platform cluster installation and they must be removed after the bootstrap process is complete.

Port `22623` handles the machine config server traffic and points to the control plane machines.

Port `443` handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

Port `80` handles the HTTP traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

**TIP**

If you are using HAProxy as a load balancer, you can check that the `haproxy` process is listening on ports `6443`, `22623`, `443`, and `80` by running `netstat -nltupe` on the HAProxy node.

**NOTE**

If you are using HAProxy as a load balancer and SELinux is set to `enforcing`, you must ensure that the HAProxy service can bind to the configured TCP port by running `setsebool -P haproxy_connect_any=1`.

### 20.8.8. Preparing the user-provisioned infrastructure

Before you install OpenShift Container Platform on user-provisioned infrastructure, you must prepare the underlying infrastructure.

This section provides details about the high-level steps required to set up your cluster infrastructure in preparation for an OpenShift Container Platform installation. This includes configuring IP networking and network connectivity for your cluster nodes, preparing a web server for the Ignition files, enabling the required ports through your firewall, and setting up the required DNS and load balancing infrastructure.

After preparation, your cluster infrastructure must meet the requirements outlined in the *Requirements for a cluster with user-provisioned infrastructure* section.
Prerequisites

- You have reviewed the OpenShift Container Platform 4.x Tested Integrations page.
- You have reviewed the infrastructure requirements detailed in the Requirements for a cluster with user-provisioned infrastructure section.

Procedure

1. Set up static IP addresses.

2. Set up an HTTP or HTTPS server to provide Ignition files to the cluster nodes.

3. Ensure that your network infrastructure provides the required network connectivity between the cluster components. See the Networking requirements for user-provisioned infrastructure section for details about the requirements.

4. Configure your firewall to enable the ports required for the OpenShift Container Platform cluster components to communicate. See Networking requirements for user-provisioned infrastructure section for details about the ports that are required.

5. Setup the required DNS infrastructure for your cluster.
   - a. Configure DNS name resolution for the Kubernetes API, the application wildcard, the bootstrap machine, the control plane machines, and the compute machines.
   - b. Configure reverse DNS resolution for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines. See the User-provisioned DNS requirements section for more information about the OpenShift Container Platform DNS requirements.

6. Validate your DNS configuration.
   - a. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses in the responses correspond to the correct components.
   - b. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names in the responses correspond to the correct components. See the Validating DNS resolution for user-provisioned infrastructure section for detailed DNS validation steps.

7. Provision the required API and application ingress load balancing infrastructure. See the Load balancing requirements for user-provisioned infrastructure section for more information about the requirements.

NOTE

Some load balancing solutions require the DNS name resolution for the cluster nodes to be in place before the load balancing is initialized.

20.8.9. Validating DNS resolution for user-provisioned infrastructure

You can validate your DNS configuration before installing OpenShift Container Platform on user-provisioned infrastructure.
IMPORTANT

The validation steps detailed in this section must succeed before you install your cluster.

Prerequisites

- You have configured the required DNS records for your user-provisioned infrastructure.

Procedure

1. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses contained in the responses correspond to the correct components.

   a. Perform a lookup against the Kubernetes API record name. Check that the result points to the IP address of the API load balancer:

      ```
      $ dig +noall +answer @<nameserver_ip> api.<cluster_name>.<base_domain>
      ```

      Replace `<nameserver_ip>` with the IP address of the nameserver, `<cluster_name>` with your cluster name, and `<base_domain>` with your base domain name.

      Example output

      ```
      api.o cp4.example.com. 0 IN A 192.168.1.5
      ```

   b. Perform a lookup against the Kubernetes internal API record name. Check that the result points to the IP address of the API load balancer:

      ```
      $ dig +noall +answer @<nameserver_ip> api-int.<cluster_name>.<base_domain>
      ```

      Example output

      ```
      api-int.o cp4.example.com. 0 IN A 192.168.1.5
      ```

   c. Test an example `*.apps.<cluster_name>.<base_domain>` DNS wildcard lookup. All of the application wildcard lookups must resolve to the IP address of the application ingress load balancer:

      ```
      $ dig +noall +answer @<nameserver_ip> random.apps.<cluster_name>.<base_domain>
      ```

      Example output

      ```
      random.apps.o cp4.example.com. 0 IN A 192.168.1.5
      ```

NOTE

In the example outputs, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.
You can replace random with another wildcard value. For example, you can query the route to the OpenShift Container Platform console:

```
$ dig +noall +answer @<nameserver_ip> console-openshift-console.apps.<cluster_name>.<base_domain>
```

**Example output**

```
console-openshift-console.apps.ocp4.example.com. 0 IN A 192.168.1.5
```

d. Run a lookup against the bootstrap DNS record name. Check that the result points to the IP address of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> bootstrap.<cluster_name>.<base_domain>
```

**Example output**

```
bootstrap.ocp4.example.com. 0 IN A 192.168.1.96
```

e. Use this method to perform lookups against the DNS record names for the control plane and compute nodes. Check that the results correspond to the IP addresses of each node.

2. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names contained in the responses correspond to the correct components.

a. Perform a reverse lookup against the IP address of the API load balancer. Check that the response includes the record names for the Kubernetes API and the Kubernetes internal API:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.5
```

**Example output**

```
5.1.168.192.in-addr.arpa. 0 IN PTR api-int.ocp4.example.com. 1
5.1.168.192.in-addr.arpa. 0 IN PTR api.ocp4.example.com. 2
```

1 Provides the record name for the Kubernetes internal API.

2 Provides the record name for the Kubernetes API.

**NOTE**

A PTR record is not required for the OpenShift Container Platform application wildcard. No validation step is needed for reverse DNS resolution against the IP address of the application ingress load balancer.

b. Perform a reverse lookup against the IP address of the bootstrap node. Check that the result points to the DNS record name of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.96
```
Example output

96.1.168.192.in-addr.arpa. 0 IN PTR bootstrap.ocp4.example.com.

c. Use this method to perform reverse lookups against the IP addresses for the control plane and compute nodes. Check that the results correspond to the DNS record names of each node.

20.8.10. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The ./openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N '' -f <path>/<file_name>
   ```

   **NOTE**

   Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

2. View the public SSH key:

   ```bash
   $ cat <path>/<file_name>.pub
   ```

   For example, run the following to view the ~/.ssh/id_rsa.pub public key:
Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the ./openshift-install gather command.

**NOTE**

On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.

a. If the `ssh-agent` process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

**Example output**

```
Agent pid 31874
```

**NOTE**

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the `ssh-agent`:

```
$ ssh-add <path>/<file_name>
```

Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

**Example output**

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program. If you install a cluster on infrastructure that you provision, you must provide the key to the installation program.

**20.8.11. Manually creating the installation configuration file**

For user-provisioned installations of OpenShift Container Platform, you manually generate your installation configuration file.

**Prerequisites**

```
$ cat ~/.ssh/id_rsa.pub
```
- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.

- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

- Obtain the `imageContentSources` section from the output of the command to mirror the repository.

- Obtain the contents of the certificate for your mirror registry.

**Procedure**

1. Create an installation directory to store your required installation assets in:

   ```bash
   $ mkdir <installation_directory>
   ```

   **IMPORTANT**

   You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample `install-config.yaml` file template that is provided and save it in the `<installation_directory>`.

   **NOTE**

   You must name this configuration file `install-config.yaml`.

   - Unless you use a registry that RHCOS trusts by default, such as `docker.io`, you must provide the contents of the certificate for your mirror repository in the `additionalTrustBundle` section. In most cases, you must provide the certificate for your mirror.

   - You must include the `imageContentSources` section from the output of the command to mirror the repository.

   **NOTE**

   For some platform types, you can alternatively run `./openshift-install create install-config --dir <installation_directory>` to generate an `install-config.yaml` file. You can provide details about your cluster configuration at the prompts.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.
IMPORTANT

The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.

20.8.11.1. Sample install-config.yaml file for VMware vSphere

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute:
  - hyperthreading: Enabled
    name: worker
    replicas: 0
controlPlane:
  hyperthreading: Enabled
  name: master
  replicas: 3
metadata:
  name: test
platform:
  vsphere:
    vcenter: your.vcenter.server
    username: username
    password: password
datacenter: datacenter
defaultDatastore: datastore
  folder: "/<datacenter_name>/vm/<folder_name>/<subfolder_name>
diskType: thin
fips: false
pullSecret: '{"auths":{"<local_registry>":{"auth": "<credentials>"}},"email": "you@example.com"}}'
sshKey: 'ssh-ed25519 AAAA...'
additionalTrustBundle: |-----BEGIN CERTIFICATE-----
ZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZ
-----END CERTIFICATE-----
imageContentSources:
  - mirrors:
    source: quay.io/openshift-release-dev/ocp-release
  - mirrors:
    source: quay.io/openshift-release-dev/ocp-v4.0-art-dev
```

1. The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

2, 5. The `controlPlane` section is a single mapping, but the `compute` section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the `compute` section must begin with a hyphen, `-`, and the first line of the `controlPlane` section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift
Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading, or **hyperthreading**. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores. You can disable it by setting the parameter value to **Disabled**. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Your machines must use at least 8 CPUs and 32 GB of RAM if you disable simultaneous multithreading.

You must set the value of the `replicas` parameter to 0. This parameter controls the number of workers that the cluster creates and manages for you, which are functions that the cluster does not perform when you use user-provisioned infrastructure. You must manually deploy worker machines for the cluster to use before you finish installing OpenShift Container Platform.

The number of control plane machines that you add to the cluster. Because the cluster uses this values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

The cluster name that you specified in your DNS records.

The fully-qualified hostname or IP address of the vCenter server.

The name of the user for accessing the server. This user must have at least the roles and privileges that are required for **static or dynamic persistent volume provisioning** in vSphere.

The password associated with the vSphere user.

The vSphere datacenter.

The default vSphere datastore to use.

Optional: For installer-provisioned infrastructure, the absolute path of an existing folder where the installation program creates the virtual machines, for example, `/<datacenter_name>/vm/<folder_name>/<subfolder_name>`. If you do not provide this value, the installation program creates a top-level folder in the datacenter virtual machine folder that is named with the infrastructure ID. If you are providing the infrastructure for the cluster, omit this parameter.

The vSphere disk provisioning method.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the **x86_64** architecture.
For `<local_registry>`, specify the registry domain name, and optionally the port, that your mirror registry uses to serve content. For example `registry.example.com` or `registry.example.com:5000`.

The public portion of the default SSH key for the `core` user in Red Hat Enterprise Linux CoreOS (RHCOS).

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

Provide the contents of the certificate file that you used for your mirror registry.

Provide the `imageContentSources` section from the output of the command to mirror the repository.

### 20.8.11.2. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**Prerequisites**

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

**Procedure**

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
     httpProxy: http://<username>:<pswd>@<ip>:<port> 1
     httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
   noProxy: example.com 3
   ```
A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.

A proxy URL to use for creating HTTPS connections outside the cluster.

A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with `.` to match subdomains only. For example, `.y.com` matches `x.y.com`, but not `y.com`. Use `*` to bypass the proxy for all destinations. You must include vCenter’s IP address and the IP range that you use for its machines.

If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the `trustedCA` field of the `Proxy` object. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

**NOTE**

The installation program does not support the proxy `readinessEndpoints` field.

Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

**NOTE**

Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

### 20.8.12. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.
**IMPORTANT**

- The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

**NOTE**

The installation program that generates the manifest and Ignition files is architecture specific and can be obtained from the client image mirror. The Linux version of the installation program runs on s390x only. This installer program is also available as a Mac OS version.

**Prerequisites**

- You obtained the OpenShift Container Platform installation program. For a restricted network installation, these files are on your mirror host.

- You created the `install-config.yaml` installation configuration file.

**Procedure**

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

   ```bash
   $ ./openshift-install create manifests --dir <installation_directory>
   ```

   **Example output**

   ```plaintext
   INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
   INFO Consuming Install Config from target directory
   INFO Manifests created in: install_dir/manifests and install_dir/openshift
   ```

   For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.

2. Remove the Kubernetes manifest files that define the control plane machines and compute machine sets:

   ```bash
   $ rm -f openshift/99_openshift-cluster-api_master-machines-*.yaml
   ```

   ```bash
   $ rm -f openshift/99_openshift-cluster-api_worker-machineset-*.yaml
   ```

   Because you create and manage these resources yourself, you do not have to initialize them.
You can preserve the machine set files to create compute machines by using the machine API, but you must update references to them to match your environment.

**WARNING**

If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.

**IMPORTANT**

When you configure control plane nodes from the default unschedulable to schedulable, additional subscriptions are required. This is because control plane nodes then become worker nodes.

3. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:

   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.
   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.
   c. Save and exit the file.

4. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

   ```
   $ ./openshift-install create ignition-configs --dir <installation_directory>
   ```

   1. For `<installation_directory>`, specify the same installation directory.

   Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The `kubeadmin-password` and `kubeconfig` files are created in the `./<installation_directory>/auth` directory:

   ```
   ├── auth
   │   └── kubeadmin-password
   │   └── kubeconfig
   │       ├── bootstrap.ign
   │       └── master.ign
   │       └── metadata.json
   │       └── worker.ign
   ```

   20.8.13. Extracting the infrastructure name
The Ignition config files contain a unique cluster identifier that you can use to uniquely identify your cluster in VMware Cloud on AWS. If you plan to use the cluster identifier as the name of your virtual machine folder, you must extract it.

**Prerequisites**

- You obtained the OpenShift Container Platform installation program and the pull secret for your cluster.
- You generated the Ignition config files for your cluster.
- You installed the **jq** package.

**Procedure**

To extract and view the infrastructure name from the Ignition config file metadata, run the following command:

```
$ jq -r .infraID <installation_directory>/metadata.json
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

**Example output**

```
openshift-vw9j6
```

The output of this command is your cluster name and a random string.

To install OpenShift Container Platform on user-provisioned infrastructure on VMware vSphere, you must install Red Hat Enterprise Linux CoreOS (RHCOS) on vSphere hosts. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS machines have rebooted.

**Prerequisites**

- You have obtained the Ignition config files for your cluster.
- You have access to an HTTP server that you can access from your computer and that the machines that you create can access.
- You have created a **vSphere cluster**.
1. Upload the bootstrap Ignition config file, which is named 
<installation_directory>/bootstrap.ign, that the installation program created to your HTTP server. Note the URL of this file.

2. Save the following secondary Ignition config file for your bootstrap node to your computer as <installation_directory>/merge-bootstrap.ign:

   ```json
   {
   "ignition": {
   "config": {
   "merge": [
   {
   "source": "<bootstrap_ignition_config_url>",
   "verification": {}
   }
   ],
   "timeouts": {},
   "version": "3.2.0"
   },
   "networkd": {},
   "passwd": {},
   "storage": {},
   "systemd": {}
   }
   }
   
   Specify the URL of the bootstrap Ignition config file that you hosted.
   
   When you create the virtual machine (VM) for the bootstrap machine, you use this Ignition config file.

3. Locate the following Ignition config files that the installation program created:

   - <installation_directory>/master.ign
   - <installation_directory>/worker.ign
   - <installation_directory>/merge-bootstrap.ign

4. Convert the Ignition config files to Base64 encoding. Later in this procedure, you must add these files to the extra configuration parameter guestinfo.ignition.config.data in your VM. For example, if you use a Linux operating system, you can use the `base64` command to encode the files.

   ```bash
   $ base64 -w0 <installation_directory>/master.ign > <installation_directory>/master.64
   $ base64 -w0 <installation_directory>/worker.ign > <installation_directory>/worker.64
   $ base64 -w0 <installation_directory>/merge-bootstrap.ign > <installation_directory>/merge-bootstrap.64
   ```
5. Obtain the RHCOS OVA image. Images are available from the [RHCOS image mirror](#) page.

### IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must download an image with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image version that matches your OpenShift Container Platform version if it is available.

The filename contains the OpenShift Container Platform version number in the format `rhcos-vmware.<architecture>.ova`.

6. In the vSphere Client, create a folder in your datacenter to store your VMs.
   a. Click the **VMs and Templates** view.
   b. Right-click the name of your datacenter.
   c. Click **New Folder → New VM and Template Folder**.
   d. In the window that is displayed, enter the folder name. If you did not specify an existing folder in the `install-config.yaml` file, then create a folder with the same name as the infrastructure ID. You use this folder name so vCenter dynamically provisions storage in the appropriate location for its Workspace configuration.

7. In the vSphere Client, create a template for the OVA image and then clone the template as needed.

### NOTE

In the following steps, you create a template and then clone the template for all of your cluster machines. You then provide the location for the Ignition config file for that cloned machine type when you provision the VMs.

   a. From the **Hosts and Clusters** tab, right-click your cluster name and select **Deploy OVF Template**.
   b. On the **Select an OVF** tab, specify the name of the RHCOS OVA file that you downloaded.
   c. On the **Select a name and folder** tab, set a **Virtual machine name** for your template, such as **Template-RHCOS**. Click the name of your vSphere cluster and select the folder you created in the previous step.
   d. On the **Select a compute resource** tab, click the name of your vSphere cluster.
   e. On the **Select storage** tab, configure the storage options for your VM.

   - Select **Thin Provision** or **Thick Provision**, based on your storage preferences.
• Select the datastore that you specified in your `install-config.yaml` file.

f. On the Select network tab, specify the network that you configured for the cluster, if available.

g. When creating the OVF template, do not specify values on the Customize template tab or configure the template any further.

**IMPORTANT**

Do not start the original VM template. The VM template must remain off and must be cloned for new RHCOs machines. Starting the VM template configures the VM template as a VM on the platform, which prevents it from being used as a template that machine sets can apply configurations to.

8. Optional: Update the configured virtual hardware version in the VM template, if necessary. Follow Upgrading a virtual machine to the latest hardware version in the VMware documentation for more information.

**IMPORTANT**

It is recommended that you update the hardware version of the VM template to version 15 before creating VMs from it, if necessary. Using hardware version 13 for your cluster nodes running on vSphere is now deprecated. If you imported template defaults to hardware version 13, you must ensure that your ESXi host is on 6.7U3 or later before upgrading the VM template to hardware version 15. If your vSphere version is less than 6.7U3, you can skip this upgrade step; however, a future version of OpenShift Container Platform is scheduled to remove support for hardware version 13 and vSphere versions less than 6.7U3.

9. After the template deploys, deploy a VM for a machine in the cluster.

   a. Right-click the template name and click Clone → Clone to Virtual Machine

   b. On the Select a name and folder tab, specify a name for the VM. You might include the machine type in the name, such as `control-plane-0` or `compute-1`.

   **NOTE**

   Ensure that all virtual machine names across a vSphere installation are unique.

   c. On the Select a name and folder tab, select the name of the folder that you created for the cluster.

   d. On the Select a compute resource tab, select the name of a host in your datacenter.

   e. Optional: On the Select storage tab, customize the storage options.

   f. On the Select clone options, select Customize this virtual machine’s hardware

   g. On the Customize hardware tab, click VM Options → Advanced.

      • Optional: Override default DHCP networking in vSphere. To enable static IP networking:
i. Set your static IP configuration:

```
$ export IPCFG="ip=<ip>::<gateway>::<netmask>::<hostname>::<iface>::none
    nameserver=srv1 [nameserver=srv2 [nameserver=srv3 [...]]]"
```

**Example command**

```
$ export IPCFG="ip=192.168.100.101::192.168.100.254:255.255.255.0:::none
    nameserver=8.8.8.8"
```

ii. Set the `guestinfo.afterburn.initrd.network-kargs` property before booting a VM from an OVA in vSphere:

```
$ govc vm.change -vm "<vm_name>" -e "guestinfo.afterburn.initrd.network-
    kargs=${IPCFG}"
```

- Optional: In the event of cluster performance issues, from the **Latency Sensitivity** list, select **High**. Ensure that your VM's CPU and memory reservation have the following values:
  - Memory reservation value must be equal to its configured memory size.
  - CPU reservation value must be at least the number of low latency virtual CPUs multiplied by the measured physical CPU speed.

- Click **Edit Configuration**, and on the **Configuration Parameters** window, click **Add Configuration Params**. Define the following parameter names and values:
  - `guestinfo.ignition.config.data`: Locate the base-64 encoded files that you created previously in this procedure, and paste the contents of the base64-encoded Ignition config file for this machine type.
  - `guestinfo.ignition.config.data.encoding`: Specify **base64**.
  - `disk.EnableUUID`: Specify **TRUE**.

h. In the **Virtual Hardware** panel of the **Customize hardware** tab, modify the specified values as required. Ensure that the amount of RAM, CPU, and disk storage meets the minimum requirements for the machine type.

i. Complete the configuration and power on the VM.

j. Check the console output to verify that Ignition ran.

**Example command**

```
Ignition: ran on 2022/03/14 14:48:33 UTC (this boot)
Ignition: user-provided config was applied
```

10. Create the rest of the machines for your cluster by following the preceding steps for each machine.
IMPORTANT

You must create the bootstrap and control plane machines at this time. Because some pods are deployed on compute machines by default, also create at least two compute machines before you install the cluster.

20.8.15. Adding more compute machines to a cluster in vSphere

You can add more compute machines to a user-provisioned OpenShift Container Platform cluster on VMware vSphere.

Prerequisites

- Obtain the base64-encoded Ignition file for your compute machines.
- You have access to the vSphere template that you created for your cluster.

Procedure

1. After the template deploys, deploy a VM for a machine in the cluster.
   a. Right-click the template’s name and click **Clone → Clone to Virtual Machine**
   b. On the **Select a name and folder** tab, specify a name for the VM. You might include the machine type in the name, such as **compute-1**.

   **NOTE**

   Ensure that all virtual machine names across a vSphere installation are unique.

   c. On the **Select a name and folder** tab, select the name of the folder that you created for the cluster.
   d. On the **Select a compute resource** tab, select the name of a host in your datacenter.
   e. Optional: On the **Select storage** tab, customize the storage options.
   f. On the **Select clone options**, select **Customize this virtual machine’s hardware**
   g. On the **Customize hardware** tab, click **VM Options → Advanced**.
      - From the **Latency Sensitivity** list, select **High**.
      - Click **Edit Configuration**, and on the **Configuration Parameters** window, click **Add Configuration Params**. Define the following parameter names and values:
        - **guestinfo.ignition.config.data**: Paste the contents of the base64-encoded compute Ignition config file for this machine type.
        - **guestinfo.ignition.config.data.encoding**: Specify **base64**.
        - **disk.EnableUUID**: Specify **TRUE**.
   h. In the **Virtual Hardware** panel of the **Customize hardware** tab, modify the specified values as required. Ensure that the amount of RAM, CPU, and disk storage meets the minimum
requirements for the machine type. Also, make sure to select the correct network under Add network adapter if there are multiple networks available.

i. Complete the configuration and power on the VM.

2. Continue to create more compute machines for your cluster.

20.8.16. Disk partitioning

In most cases, data partitions are originally created by installing RHCOS, rather than by installing another operating system. In such cases, the OpenShift Container Platform installer should be allowed to configure your disk partitions.

However, there are two cases where you might want to intervene to override the default partitioning when installing an OpenShift Container Platform node:

- Create separate partitions: For greenfield installations on an empty disk, you might want to add separate storage to a partition. This is officially supported for making /var or a subdirectory of /var, such as /var/lib/etcd, a separate partition, but not both.

  **IMPORTANT**

  Kubernetes supports only two filesystem partitions. If you add more than one partition to the original configuration, Kubernetes cannot monitor all of them.

- Retain existing partitions: For a brownfield installation where you are reinstalling OpenShift Container Platform on an existing node and want to retain data partitions installed from your previous operating system, there are both boot arguments and options to coreos-installer that allow you to retain existing data partitions.

Creating a separate /var partition

In general, disk partitioning for OpenShift Container Platform should be left to the installer. However, there are cases where you might want to create separate partitions in a part of the filesystem that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the /var partition or a subdirectory of /var. For example:

- **/var/lib/containers**: Holds container-related content that can grow as more images and containers are added to a system.

- **/var/lib/etcd**: Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.

- **/var**: Holds data that you might want to keep separate for purposes such as auditing.

Storing the contents of a /var directory separately makes it easier to grow storage for those areas as needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

Because /var must be in place before a fresh installation of Red Hat Enterprise Linux CoreOS (RHCOS), the following procedure sets up the separate /var partition by creating a machine config manifest that is inserted during the openshift-install preparation phases of an OpenShift Container Platform installation.
Procedure

1. Create a directory to hold the OpenShift Container Platform installation files:

   ```bash
   $ mkdir $HOME/clusterconfig
   ```

2. Run `openshift-install` to create a set of files in the `manifest` and `openshift` subdirectories. Answer the system questions as you are prompted:

   ```bash
   $ openshift-install create manifests --dir $HOME/clusterconfig
   ? SSH Public Key ...
   $ ls $HOME/clusterconfig/openshift/
   99_kubeadmin-password-secret.yaml
   99_openshift-cluster-api_master-machines-0.yaml
   99_openshift-cluster-api_master-machines-1.yaml
   99_openshift-cluster-api_master-machines-2.yaml
   ...
   ```

3. Create a Butane config that configures the additional partition. For example, name the file `$HOME/clusterconfig/98-var-partition.bu`, change the disk device name to the name of the storage device on the `worker` systems, and set the storage size as appropriate. This example places the `/var` directory on a separate partition:

   ```yaml
   variant: openshift
   version: 4.10.0
   metadata:
     labels:
       machineconfiguration.openshift.io/role: worker
     name: 98-var-partition
   storage:
     disks:
       - device: /dev/<device_name> 1
         partitions:
           - label: var
             start_mib: <partition_start_offset> 2
             size_mib: <partition_size> 3
       filesystems:
         - device: /dev/disk/by-partlabel/var
           path: /var
           format: xfs
           mount_options: [defaults, prjquota] 4
           with_mount_unit: true
   ```

   1. The storage device name of the disk that you want to partition.
   2. When adding a data partition to the boot disk, a minimum value of 25000 mebibytes is recommended. The root file system is automatically resized to fill all available space up to the specified offset. If no value is specified, or if the specified value is smaller than the recommended minimum, the resulting root file system will be too small, and future reinstalls of RHCOS might overwrite the beginning of the data partition.
   3. The size of the data partition in mebibytes.
   4. The `prjquota` mount option must be enabled for filesystems used for container storage.
4. Create a manifest from the Butane config and save it to the `clusterconfig/openshift` directory. For example, run the following command:

```bash
$ butane $HOME/clusterconfig/98-var-partition.bu -o $HOME/clusterconfig/openshift/98-var-partition.yaml
```

5. Run `openshift-install` again to create Ignition configs from a set of files in the `manifest` and `openshift` subdirectories:

```bash
$ openshift-install create ignition-configs --dir $HOME/clusterconfig
$ ls $HOME/clusterconfig/
auth  bootstrap.ign  master.ign  metadata.json  worker.ign
```

Now you can use the Ignition config files as input to the vSphere installation procedures to install Red Hat Enterprise Linux CoreOS (RHCOS) systems.

### 20.8.17. Updating the bootloader using `bootupd`

To update the bootloader by using `bootupd`, you must either install `bootupd` on RHCOS machines manually or provide a machine config with the enabled `systemd` unit. Unlike `grubby` or other bootloader tools, `bootupd` does not manage kernel space configuration such as passing kernel arguments.

After you have installed `bootupd`, you can manage it remotely from the OpenShift Container Platform cluster.

#### NOTE

It is recommended that you use `bootupd` only on bare metal or virtualized hypervisor installations, such as for protection against the BootHole vulnerability.

### Manual install method

You can manually install `bootupd` by using the `bootctl` command-line tool.

1. Inspect the system status:

```bash
# bootupctl status
```

**Example output for x86_64**

Component EFI

- Installed: grub2-efi-x64-1:2.04-31.fc33.x86_64, shim-x64-15-8.x86_64
- Update: At latest version

**Example output for arm64**

...
Component EFI

Installed: grub2-efi-aa64-1:2.02-99.el8_4.1.aarch64, shim-aa64-15.4-2.el8_1.aarch64
Update: At latest version

2. RHCOS images created without `bootupd` installed on them require an explicit adoption phase. If the system status is `Adoptable`, perform the adoption:

```
# bootupctl adopt-and-update
```

**Example output**

Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64, shim-x64-15-8.x86_64

3. If an update is available, apply the update so that the changes take effect on the next reboot:

```
# bootupctl update
```

**Example output**

Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64, shim-x64-15-8.x86_64

**Machine config method**

Another way to enable `bootupd` is by providing a machine config.

- Provide a machine config file with the enabled `systemd` unit, as shown in the following example:

**Example output**

```
variant: rhcos
version: 1.1.0
systemd:
  units:
    - name: custom-bootupd-auto.service
      enabled: true
      contents:
        [Unit]
        Description=Bootupd automatic update

        [Service]
        ExecStart=/usr/bin/bootupctl update
        RemainAfterExit=yes

        [Install]
        WantedBy=multi-user.target
```

**20.8.18. Waiting for the bootstrap process to complete**

The OpenShift Container Platform bootstrap process begins after the cluster nodes first boot into the persistent RHCOS environment that has been installed to disk. The configuration information provided through the Ignition config files is used to initialize the bootstrap process and install OpenShift Container Platform on the machines. You must wait for the bootstrap process to complete.
Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have obtained the installation program and generated the Ignition config files for your cluster.
- You installed RHCOS on your cluster machines and provided the Ignition config files that the OpenShift Container Platform installation program generated.

Procedure

1. Monitor the bootstrap process:

   `$ ./openshift-install --dir <installation_directory> wait-for bootstrap-complete \  
   --log-level=info` 

   1 For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   2 To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

Example output

```
INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
INFO API v1.23.0 up
INFO Waiting up to 30m0s for bootstrapping to complete...
INFO It is now safe to remove the bootstrap resources
```

The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After bootstrap process is complete, remove the bootstrap machine from the load balancer.

   **IMPORTANT**
   
   You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the bootstrap machine itself.

20.8.19. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.
Procedure

1. Export the **kubeadmin** credentials:

   ```sh
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

   ```sh
   $ oc whoami
   ```

   **Example output**

   ```
   system:admin
   ```

20.8.20. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

**Prerequisites**

- You added machines to your cluster.

**Procedure**

1. Confirm that the cluster recognizes the machines:

   ```sh
   $ oc get nodes
   ```

   **Example output**

   ```
   NAME      STATUS    ROLES    AGE     VERSION
   master-0  Ready     master   63m     v1.23.0
   master-1  Ready     master   63m     v1.23.0
   master-2  Ready     master   64m     v1.23.0
   ```

   The output lists all of the machines that you created.

   **NOTE**

   The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

   ```sh
   $ oc get csr
   ```
Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-mddf5</td>
<td>20m</td>
<td>system:node:master-01.example.com</td>
<td>Approved,Issued</td>
</tr>
<tr>
<td>csr-z5rln</td>
<td>16m</td>
<td>system:node:worker-21.example.com</td>
<td>Approved,Issued</td>
</tr>
</tbody>
</table>

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in Pending status, approve the CSRs for your cluster machines:

NOTE
Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the machine-approver if the Kubelet requests a new certificate with identical parameters.

NOTE
For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the oc exec, oc rsh, and oc logs commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the node-bootstrapper service account in the system:node or system:admin groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

  $ oc adm certificate approve <csr_name> 1

  <csr_name> is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

  $ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve

  NOTE
  Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

  $ oc get csr
Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-c57lv</td>
<td>5m26s</td>
<td>system:node:ip-10-0-95-157.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

  $$\text{"$ oc adm certificate approve <csr_name>"}$$

  `<csr_name>` is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

  $$\text{"$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{\"\n\"}}{{end}}{{end}}\r\n| xargs oc adm certificate approve"}$$

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

$$\text{"$ oc get nodes"}$$

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.23.0</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.23.0</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>74m</td>
<td>v1.23.0</td>
</tr>
<tr>
<td>worker-0</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.23.0</td>
</tr>
<tr>
<td>worker-1</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.23.0</td>
</tr>
</tbody>
</table>

**NOTE**

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

**Additional information**

- For more information on CSRs, see Certificate Signing Requests.

**20.8.21. Initial Operator configuration**

After the control plane initializes, you must immediately configure some Operators so that they all become available.
Prerequisites

- Your control plane has initialized.

Procedure

1. Watch the cluster components come online:

   ```
   $ watch -n5 oc get clusteroperators
   ```

   **Example output**

<table>

2. Configure the Operators that are not available.

20.8.21.1. Disabling the default OperatorHub sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.
Procedure

- Disable the sources for the default catalogs by adding `disableAllDefaultSources: true` to the `OperatorHub` object:

  ```bash
  $ oc patch OperatorHub cluster --type json \
   -p '[{"op": "add", "path": "/spec/disableAllDefaultSources", "value": true}]'
  ```

TIP

Alternatively, you can use the web console to manage catalog sources. From the Administration → Cluster Settings → Configuration → OperatorHub page, click the Sources tab, where you can create, delete, disable, and enable individual sources.

20.8.21.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the `Recreate` rollout strategy during upgrades.

20.8.21.2.1. Configuring registry storage for VMware vSphere

As a cluster administrator, following installation you must configure your registry to use storage.

Prerequisites

- Cluster administrator permissions.
- A cluster on VMware vSphere.
- Persistent storage provisioned for your cluster, such as Red Hat OpenShift Data Foundation.

IMPORTANT

OpenShift Container Platform supports `ReadWriteOnce` access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, `ReadWriteMany` access is required.

- Must have "100Gi" capacity.
IMPORTANT

Testing shows issues with using the NFS server on RHEL as storage backend for core services. This includes the OpenShift Container Registry and Quay, Prometheus for monitoring storage, and Elasticsearch for logging storage. Therefore, using RHEL NFS to back PVs used by core services is not recommended.

Other NFS implementations on the marketplace might not have these issues. Contact the individual NFS implementation vendor for more information on any testing that was possibly completed against these OpenShift Container Platform core components.

Procedure

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

   **NOTE**
   
   When using shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

   ```
   $ oc get pod -n openshift-image-registry -l docker-registry=default
   
   Example output
   
   No resources found in openshift-image-registry namespace
   
   **NOTE**
   
   If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

   ```
   $ oc edit configs.imageregistry.operator.openshift.io
   
   Example output
   
   storage:
   pvc:
     claim: 

   Leave the `claim` field blank to allow the automatic creation of an `image-registry-storage` PVC.

4. Check the `clusteroperator` status:

   ```
   $ oc get clusteroperator image-registry
   ```
20.8.21.2.2. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

Procedure

- To set the image registry storage to an empty directory:

```bash
$ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec": {"storage": {"emptyDir":{}}}}'
```

**WARNING**

Configure this option for only non-production clusters.

If you run this command before the Image Registry Operator initializes its components, the `oc patch` command fails with the following error:

```
Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
```

Wait a few minutes and run the command again.

20.8.21.2.3. Configuring block registry storage for VMware vSphere

To allow the image registry to use block storage types such as vSphere Virtual Machine Disk (VMDK) during upgrades as a cluster administrator, you can use the **Recreate** rollout strategy.

**IMPORTANT**

Block storage volumes are supported but not recommended for use with image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

Procedure

1. To set the image registry storage as a block storage type, patch the registry so that it uses the **Recreate** rollout strategy and runs with only 1 replica:

```bash
$ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec": {"rolloutStrategy": "Recreate","replicas":1}}'
```
2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.

a. Create a `pvc.yaml` file with the following contents to define a VMware vSphere PersistentVolumeClaim object:

```yaml
kind: PersistentVolumeClaim
apiVersion: v1
metadata:
  name: image-registry-storage
  namespace: openshift-image-registry
spec:
  accessModes:
    - ReadWriteOnce
  resources:
    requests:
      storage: 100Gi
```

1. A unique name that represents the PersistentVolumeClaim object.
2. The namespace for the PersistentVolumeClaim object, which is `openshift-image-registry`.
3. The access mode of the persistent volume claim. With ReadWriteOnce, the volume can be mounted with read and write permissions by a single node.
4. The size of the persistent volume claim.

b. Create the PersistentVolumeClaim object from the file:

```bash
$ oc create -f pvc.yaml -n openshift-image-registry
```

3. Edit the registry configuration so that it references the correct PVC:

```bash
$ oc edit config.imageregistry.operator.openshift.io -o yaml
```

**Example output**

```yaml
storage:
  pvc:
    claim: image-registry-storage
```

1. Creating a custom PVC allows you to leave the claim field blank for the default automatic creation of an image-registry-storage PVC.

For instructions about configuring registry storage so that it references the correct PVC, see [Configuring registry storage for VMware vSphere](#).

### 20.8.22. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.
Prerequisites

- Your control plane has initialized.
- You have completed the initial Operator configuration.

Procedure

1. Confirm that all the cluster components are online with the following command:

   ```
   $ watch -n5 oc get clusteroperators
   ```

Example output

</tbody>
</table>

Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```
$ ./openshift-install --dir <installation_directory> wait-for install-complete
```

1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.
Example output

INFO Waiting up to 30m0s for the cluster to initialize...

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

2. Confirm that the Kubernetes API server is communicating with the pods.

   a. To view a list of all pods, use the following command:

   ```
   $ oc get pods --all-namespaces
   ```

   **Example output**

<table>
<thead>
<tr>
<th>NAMESPACE</th>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>openshift-apiserver-operator</td>
<td>openshift-apiserver-operator-85cb746d55-zqhs8</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apiserver-67b9g</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apiserver-ljcmx</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apiserver-z25h4</td>
<td>1/1</td>

<td>authentication-operator-69d5d8bf84-vh2n8</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

   b. View the logs for a pod that is listed in the output of the previous command by using the following command:

   ```
   $ oc logs <pod_name> -n <namespace>
   ```

   Specify the pod name and namespace, as shown in the output of the previous command.
If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation. See "Enabling multipathing with kernel arguments on RHCOS" in the Post-installation machine configuration tasks documentation for more information.

4. Register your cluster on the Cluster registration page.

You can add extra compute machines after the cluster installation is completed by following Adding compute machines to vSphere.

20.8.23. Backing up VMware vSphere volumes

OpenShift Container Platform provisions new volumes as independent persistent disks to freely attach and detach the volume on any node in the cluster. As a consequence, it is not possible to back up volumes that use snapshots, or to restore volumes from snapshots. See Snapshot Limitations for more information.

Procedure

To create a backup of persistent volumes:

1. Stop the application that is using the persistent volume.
2. Clone the persistent volume.
3. Restart the application.
4. Create a backup of the cloned volume.
5. Delete the cloned volume.

20.8.24. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.10, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service

20.8.25. Next steps

- Customize your cluster.
- Configure image streams for the Cluster Samples Operator and the must-gather tool.
- Learn how to use Operator Lifecycle Manager (OLM) on restricted networks.
If the mirror registry that you used to install your cluster has a trusted CA, add it to the cluster by configuring additional trust stores.

If necessary, you can opt out of remote health reporting.

Optional: View the events from the vSphere Problem Detector Operator to determine if the cluster has permission or storage configuration issues.

20.9. UNINSTALLING A CLUSTER ON VMC

You can remove a cluster installed on VMware vSphere infrastructure that you deployed to VMware Cloud (VMC) on AWS by using installer-provisioned infrastructure.

20.9.1. Removing a cluster that uses installer-provisioned infrastructure

You can remove a cluster that uses installer-provisioned infrastructure from your cloud.

NOTE

After uninstallation, check your cloud provider for any resources not removed properly, especially with User Provisioned Infrastructure (UPI) clusters. There might be resources that the installer did not create or that the installer is unable to access.

Prerequisites

- Have a copy of the installation program that you used to deploy the cluster.
- Have the files that the installation program generated when you created your cluster.

Procedure

1. From the directory that contains the installation program on the computer that you used to install the cluster, run the following command:

```bash
$ ./openshift-install destroy cluster
--dir <installation_directory> --log-level info
```

   1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.
   2. To view different details, specify `warn`, `debug`, or `error` instead of `info`.

   NOTE

   You must specify the directory that contains the cluster definition files for your cluster. The installation program requires the `metadata.json` file in this directory to delete the cluster.

1. Optional: Delete the `<installation_directory>` directory and the OpenShift Container Platform installation program.
CHAPTER 21. INSTALLING ON ANY PLATFORM

21.1. INSTALLING A CLUSTER ON ANY PLATFORM

In OpenShift Container Platform version 4.10, you can install a cluster on any infrastructure that you provision, including virtualization and cloud environments.

IMPORTANT

Review the information in the guidelines for deploying OpenShift Container Platform on non-tested platforms before you attempt to install an OpenShift Container Platform cluster in virtualized or cloud environments.

21.1.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- If you use a firewall, you configured it to allow the sites that your cluster requires access to.

NOTE

Be sure to also review this site list if you are configuring a proxy.

21.1.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.10, you require access to the internet to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

21.1.3. Requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.
This section describes the requirements for deploying OpenShift Container Platform on user-provisioned infrastructure.

21.1.3.1. Required machines for cluster installation

The smallest OpenShift Container Platform clusters require the following hosts:

Table 21.1. Minimum required hosts

<table>
<thead>
<tr>
<th>Hosts</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>One temporary bootstrap machine</td>
<td>The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.</td>
</tr>
<tr>
<td>Three control plane machines</td>
<td>The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.</td>
</tr>
<tr>
<td>At least two compute machines, which are also known as worker machines.</td>
<td>The workloads requested by OpenShift Container Platform users run on the compute machines.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

To improve high availability of your cluster, distribute the control plane machines over different z/VM instances on at least two physical machines.

The bootstrap, control plane, and compute machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 8 and inherits all of its hardware certifications and requirements. See [Red Hat Enterprise Linux technology capabilities and limits](#) .

21.1.3.2. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

<table>
<thead>
<tr>
<th>Machine</th>
<th>Operating System</th>
<th>vCPU</th>
<th>Virtual RAM</th>
<th>Storage</th>
<th>IOPS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS</td>
<td>2</td>
<td>8 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
</tbody>
</table>

1. One physical core (IFL) provides two logical cores (threads) when SMT-2 is enabled. The hypervisor can provide two or more vCPUs.
21.1.3.3. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The `kube-controller-manager` only approves the kubelet client CSRs. The `machine-approver` cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

21.1.3.4. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in `initramfs` during boot to fetch their Ignition config files.

During the initial boot, the machines require an HTTP or HTTPS server to establish a network connection to download their Ignition config files.

The machines are configured with static IP addresses. No DHCP server is required. Ensure that the machines have persistent IP addresses and hostnames.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

21.1.3.4.1. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

**IMPORTANT**

In connected OpenShift Container Platform environments, all nodes are required to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Port</th>

</tbody>
</table>

NTP configuration for user-provisioned infrastructure

OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for Configuring chrony time service.

Additional resources
- Configuring chrony time service

21.1.3.5. User-provisioned DNS requirements

In OpenShift Container Platform deployments, DNS name resolution is required for the following components:

- The Kubernetes API
- The OpenShift Container Platform application wildcard
- The bootstrap, control plane, and compute machines

Reverse DNS resolution is also required for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse
name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the hostnames for all the nodes, unless the hostnames are provided by DHCP. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

The following DNS records are required for a user-provisioned OpenShift Container Platform cluster and they must be in place before installation. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>`.

### Table 21.5. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes API</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the API load balancer. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td></td>
<td>api-int.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to internally identify the API load balancer. These records must be resolvable from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Routes</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A wildcard DNS A/AAAA or CNAME record that refers to the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster. For example, console-openshift-console.apps.&lt;cluster_name&gt;.&lt;base_domain&gt; is used as a wildcard route to the OpenShift Container Platform console.</td>
</tr>
<tr>
<td>Bootstrap machine</td>
<td>bootstrap.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Control plane</td>
<td>&lt;master&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

The API server must be able to resolve the worker nodes by the hostnames that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.
NOTE

In OpenShift Container Platform 4.4 and later, you do not need to specify etcd host and SRV records in your DNS configuration.

TIP

You can use the `dig` command to verify name and reverse name resolution. See the section on Validating DNS resolution for user-provisioned infrastructure for detailed validation steps.

21.1.3.5.1. Example DNS configuration for user-provisioned clusters

This section provides A and PTR record configuration samples that meet the DNS requirements for deploying OpenShift Container Platform on user-provisioned infrastructure. The samples are not meant to provide advice for choosing one DNS solution over another.

In the examples, the cluster name is `ocp4` and the base domain is `example.com`.

Example DNS A record configuration for a user-provisioned cluster

The following example is a BIND zone file that shows sample A records for name resolution in a user-provisioned cluster.

```
$TTL 1W
@ IN SOA ns1.example.com. root (2019070700 ; serial 3H ; refresh (3 hours) 30M ; retry (30 minutes) 2W ; expiry (2 weeks) 1W ) ; minimum (1 week)
IN NS ns1.example.com.
IN MX 10 smtp.example.com.
; ;
ns1.example.com. IN A 192.168.1.5
smtp.example.com. IN A 192.168.1.5
; ;
helper.example.com. IN A 192.168.1.5
helper.ocp4.example.com. IN A 192.168.1.5
; ;
api.ocp4.example.com. IN A 192.168.1.5
api-int.ocp4.example.com. IN A 192.168.1.5 1
; ;
```
Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer.

Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer and is used for internal cluster communications.

Provides name resolution for the wildcard routes. The record refers to the IP address of the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

**NOTE**

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

Provides name resolution for the bootstrap machine.

Provides name resolution for the control plane machines.

Provides name resolution for the compute machines.

**Example DNS PTR record configuration for a user-provisioned cluster**

The following example BIND zone file shows sample PTR records for reverse name resolution in a user-provisioned cluster.

**Example 21.2. Sample DNS zone database for reverse records**

```
$.apps.ocp4.example.com. IN A 192.168.1.15
; bootstrap.ocp4.example.com. IN A 192.168.1.96
; master0.ocp4.example.com. IN A 192.168.1.97
master1.ocp4.example.com. IN A 192.168.1.98
master2.ocp4.example.com. IN A 192.168.1.99
; worker0.ocp4.example.com. IN A 192.168.1.11
worker1.ocp4.example.com. IN A 192.168.1.17
; EOF
```

```bash
$TTL 1W
@ IN SOA ns1.example.com. root ( 2019070700 ; serial 3H ; refresh (3 hours) 30M ; retry (30 minutes) 2W ; expiry (2 weeks) 1W ) ; minimum (1 week)
IN NS ns1.example.com.
```
Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer.

Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer and is used for internal cluster communications.

Provides reverse DNS resolution for the bootstrap machine.

Provides reverse DNS resolution for the control plane machines.

Provides reverse DNS resolution for the compute machines.

NOTE
A PTR record is not required for the OpenShift Container Platform application wildcard.

21.1.3.6. Load balancing requirements for user-provisioned infrastructure

Before you install OpenShift Container Platform, you must provision the API and application ingress load balancing infrastructure. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

The load balancing infrastructure must meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.
   - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

   NOTE
   Session persistence is not required for the API load balancer to function properly.
Configure the following ports on both the front and back of the load balancers:

### Table 21.6. API load balancer

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the <code>/readyz</code> endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>

**NOTE**

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the `/readyz` endpoint to the removal of the API server instance from the pool. Within the time frame after `/readyz` returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application ingress load balancer** Provides an ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

**TIP**

If the true IP address of the client can be seen by the application ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

Configure the following ports on both the front and back of the load balancers:

### Table 21.7. Application ingress load balancer

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
</table>
The machines that run the Ingress Controller pods, compute, or worker, by default.

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
<tr>
<td>1936</td>
<td>The worker nodes that run the Ingress Controller pods, by default. You must configure the /healthz/ready endpoint for the ingress health check probe.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>

**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

**NOTE**

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

### 21.1.3.6.1. Example load balancer configuration for user-provisioned clusters

This section provides an example API and application ingress load balancer configuration that meets the load balancing requirements for user-provisioned clusters. The sample is an `/etc/haproxy/haproxy.cfg` configuration for an HAProxy load balancer. The example is not meant to provide advice for choosing one load balancing solution over another.

**NOTE**

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

#### Example 21.3. Sample API and application ingress load balancer configuration

```
global
log 127.0.0.1 local2
pidfile /var/run/haproxy.pid
maxconn 4000
daemon
```
In the example, the cluster name is **ocp4**.
Port **6443** handles the Kubernetes API traffic and points to the control plane machines.

The bootstrap entries must be in place before the OpenShift Container Platform cluster installation and they must be removed after the bootstrap process is complete.

Port **22623** handles the machine config server traffic and points to the control plane machines.

Port **443** handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

Port **80** handles the HTTP traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

**TIP**

If you are using HAProxy as a load balancer, you can check that the **haproxy** process is listening on ports **6443, 22623, 443**, and **80** by running `netstat -nltupe` on the HAProxy node.

**NOTE**

If you are using HAProxy as a load balancer and SELinux is set to **enforcing**, you must ensure that the HAProxy service can bind to the configured TCP port by running `setsebool -P haproxy_connect_any=1`.

### 21.1.4. Preparing the user-provisioned infrastructure

Before you install OpenShift Container Platform on user-provisioned infrastructure, you must prepare the underlying infrastructure.

This section provides details about the high-level steps required to set up your cluster infrastructure in preparation for an OpenShift Container Platform installation. This includes configuring IP networking and network connectivity for your cluster nodes, preparing a web server for the Ignition files, enabling the required ports through your firewall, and setting up the required DNS and load balancing infrastructure.

After preparation, your cluster infrastructure must meet the requirements outlined in the *Requirements for a cluster with user-provisioned infrastructure* section.

**Prerequisites**

- You have reviewed the [OpenShift Container Platform 4.x Tested Integrations](#) page.
- You have reviewed the infrastructure requirements detailed in the *Requirements for a cluster with user-provisioned infrastructure* section.
Procedure

1. Set up static IP addresses.

2. Set up an HTTP or HTTPS server to provide Ignition files to the cluster nodes.

3. Ensure that your network infrastructure provides the required network connectivity between the cluster components. See the Networking requirements for user-provisioned infrastructure section for details about the requirements.

4. Configure your firewall to enable the ports required for the OpenShift Container Platform cluster components to communicate. See Networking requirements for user-provisioned infrastructure section for details about the ports that are required.

5. Setup the required DNS infrastructure for your cluster.
   a. Configure DNS name resolution for the Kubernetes API, the application wildcard, the bootstrap machine, the control plane machines, and the compute machines.
   b. Configure reverse DNS resolution for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines. See the User-provisioned DNS requirements section for more information about the OpenShift Container Platform DNS requirements.

6. Validate your DNS configuration.
   a. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses in the responses correspond to the correct components.
   b. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names in the responses correspond to the correct components. See the Validating DNS resolution for user-provisioned infrastructure section for detailed DNS validation steps.

7. Provision the required API and application ingress load balancing infrastructure. See the Load balancing requirements for user-provisioned infrastructure section for more information about the requirements.

NOTE

Some load balancing solutions require the DNS name resolution for the cluster nodes to be in place before the load balancing is initialized.

21.1.5. Validating DNS resolution for user-provisioned infrastructure

You can validate your DNS configuration before installing OpenShift Container Platform on user-provisioned infrastructure.

IMPORTANT

The validation steps detailed in this section must succeed before you install your cluster.

Prerequisites
You have configured the required DNS records for your user-provisioned infrastructure.

**Procedure**

1. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses contained in the responses correspond to the correct components.

   a. Perform a lookup against the Kubernetes API record name. Check that the result points to the IP address of the API load balancer:

   ```
   $ dig +noall +answer @<nameserver_ip> api.<cluster_name>.<base_domain> 1
   ```

   Replace `<nameserver_ip>` with the IP address of the nameserver, `<cluster_name>` with your cluster name, and `<base_domain>` with your base domain name.

   **Example output**

   ```
   api.ocp4.example.com. 0 IN A 192.168.1.5
   ```

   b. Perform a lookup against the Kubernetes internal API record name. Check that the result points to the IP address of the API load balancer:

   ```
   $ dig +noall +answer @<nameserver_ip> api-int.<cluster_name>.<base_domain>
   ```

   **Example output**

   ```
   api-int.ocp4.example.com. 0 IN A 192.168.1.5
   ```

   c. Test an example `*.apps.<cluster_name>.<base_domain>` DNS wildcard lookup. All of the application wildcard lookups must resolve to the IP address of the application ingress load balancer:

   ```
   $ dig +noall +answer @<nameserver_ip> random.apps.<cluster_name>.<base_domain>
   ```

   **Example output**

   ```
   random.apps.ocp4.example.com. 0 IN A 192.168.1.5
   ```

   **NOTE**

   In the example outputs, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

   You can replace `random` with another wildcard value. For example, you can query the route to the OpenShift Container Platform console:

   ```
   $ dig +noall +answer @<nameserver_ip> console-openshift-console.apps.<cluster_name>.<base_domain>
   ```
Example output

```
console-openshift-console.apps.ocp4.example.com. 0 IN A 192.168.1.5
```

d. Run a lookup against the bootstrap DNS record name. Check that the result points to the IP address of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> bootstrap.<cluster_name>.<base_domain>
```

Example output

```
bootstrap.ocp4.example.com. 0 IN A 192.168.1.96
```

e. Use this method to perform lookups against the DNS record names for the control plane and compute nodes. Check that the results correspond to the IP addresses of each node.

2. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names contained in the responses correspond to the correct components.

a. Perform a reverse lookup against the IP address of the API load balancer. Check that the response includes the record names for the Kubernetes API and the Kubernetes internal API:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.5
```

Example output

```
5.1.168.192.in-addr.arpa. 0 IN PTR api-int.ocp4.example.com. 1
5.1.168.192.in-addr.arpa. 0 IN PTR api.ocp4.example.com. 2
```

1. Provides the record name for the Kubernetes internal API.

2. Provides the record name for the Kubernetes API.

**NOTE**

A PTR record is not required for the OpenShift Container Platform application wildcard. No validation step is needed for reverse DNS resolution against the IP address of the application ingress load balancer.

b. Perform a reverse lookup against the IP address of the bootstrap node. Check that the result points to the DNS record name of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.96
```

Example output

```
96.1.168.192.in-addr.arpa. 0 IN PTR bootstrap.ocp4.example.com.
```
c. Use this method to perform reverse lookups against the IP addresses for the control plane and compute nodes. Check that the results correspond to the DNS record names of each node.

21.1.6. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The /openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>  
   ```

   Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   NOTE

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   ```bash
   $ cat <path>/<file_name>.pub
   ```

   For example, run the following to view the ~/.ssh/id_rsa.pub public key:

   ```bash
   $ cat ~/.ssh/id_rsa.pub
   ```
3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the ./openshift-install gather command.

   NOTE
   On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.

   a. If the ssh-agent process is not already running for your local user, start it as a background task:

   ```
   $ eval "$(ssh-agent -s)"
   ```

   Example output

   ```
   Agent pid 31874
   ```

   NOTE
   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the ssh-agent:

   ```
   $ ssh-add <path>/<file_name>  
   ```

   Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

   Example output

   ```
   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
   ```

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program. If you install a cluster on infrastructure that you provision, you must provide the key to the installation program.

21.1.7. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on your provisioning machine.

Prerequisites

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space

Procedure
1. Access the **Infrastructure Provider** page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

   **IMPORTANT**
   
   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   **IMPORTANT**
   
   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ tar -xvf openshift-install-linux.tar.gz
   ```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

21.1.8. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

   **IMPORTANT**
   
   If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.10. Download and install the new version of **oc**.

**Installing the OpenShift CLI on Linux**

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.

3. Click **Download Now** next to the **OpenShift v4.10 Linux Client** entry and save the file.
4. Unpack the archive:

   ```
   $ tar xzvf <file>
   ```

5. Place the `oc` binary in a directory that is on your PATH.
   To check your PATH, execute the following command:

   ```
   $ echo $PATH
   ```

After you install the OpenShift CLI, it is available using the `oc` command:

   ```
   $ oc <command>
   ```

**Installing the OpenShift CLI on Windows**

You can install the OpenShift CLI (`oc`) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.10 Windows Client entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the `oc` binary to a directory that is on your PATH.
   To check your PATH, open the command prompt and execute the following command:

   ```
   C:\> path
   ```

After you install the OpenShift CLI, it is available using the `oc` command:

   ```
   C:\> oc <command>
   ```

**Installing the OpenShift CLI on macOS**

You can install the OpenShift CLI (`oc`) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.10 MacOSX Client entry and save the file.

4. Unpack and unzip the archive.

5. Move the `oc` binary to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:
After you install the OpenShift CLI, it is available using the `oc` command:

```bash
$ echo $PATH
```

```bash
$ oc <command>
```

### 21.1.9. Manually creating the installation configuration file

For user-provisioned installations of OpenShift Container Platform, you manually generate your installation configuration file.

#### Prerequisites

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.

- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

#### Procedure

1. Create an installation directory to store your required installation assets in:

   ```bash
   $ mkdir <installation_directory>
   ```

   **IMPORTANT**

   You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample `install-config.yaml` file template that is provided and save it in the `<installation_directory>`.

   **NOTE**

   You must name this configuration file `install-config.yaml`.

   **NOTE**

   For some platform types, you can alternatively run `./openshift-install create install-config --dir <installation_directory>` to generate an `install-config.yaml` file. You can provide details about your cluster configuration at the prompts.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.
IMPORTANT

The **install-config.yaml** file is consumed during the next step of the installation process. You must back it up now.

21.1.9.1. Sample install-config.yaml file for IBM Z

21.1.9.2. Sample install-config.yaml file for other platforms

You can customize the **install-config.yaml** file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute:
  - hyperthreading: Enabled
    name: worker
    replicas: 0
controlPlane:
  hyperthreading: Enabled
  name: master
  replicas: 3
metadata:
  name: test
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
  hostPrefix: 23
  networkType: OpenShiftSDN
  serviceNetwork:
    - 172.30.0.0/16
platform:
  none: {}
fips: false
pullSecret: '{"auths": ...}"
sshKey: 'ssh-ed25519 AAAA...'
```

1. The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.
2. The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -, and the first line of the **controlPlane** section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.
3. Specifies whether to enable or disable simultaneous multithreading (SMT), or hyperthreading. By default, SMT is enabled to increase the performance of the cores in your machines. You can disable it by setting the parameter value to **Disabled**. If you disable SMT, you must disable it in all cluster machines; this includes both control plane and compute machines.
Simultaneous multithreading (SMT) is enabled by default. If SMT is not available on your OpenShift Container Platform nodes, the `hyperthreading` parameter has no effect.

**IMPORTANT**

If you disable `hyperthreading`, whether on your OpenShift Container Platform nodes or in the `install-config.yaml` file, ensure that your capacity planning accounts for the dramatically decreased machine performance.

You must set this value to 0 when you install OpenShift Container Platform on user-provisioned infrastructure. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. In user-provisioned installations, you must manually deploy the compute machines before you finish installing the cluster.

If you are installing a three-node cluster, do not deploy any compute machines when you install the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

The cluster name that you specified in your DNS records.

A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to access the pods from an external network, you must configure load balancers and routers to manage the traffic.

The subnet prefix length to assign to each individual node. For example, if `hostPrefix` is set to 23, then each node is assigned a /23 subnet out of the given `cidr`, which allows for 510 \(2^{32 - 23} - 2\) pod IP addresses. If you are required to provide access to nodes from an external network, configure load balancers and routers to manage the traffic.

The IP address pool to use for service IP addresses. You can enter only one IP address pool. This block must not overlap with existing physical networks. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.

You must set the platform to `none`. You cannot provide additional platform configuration variables for IBM Z infrastructure.
WARNING

Red Hat Virtualization does not currently support installation with user-provisioned infrastructure on the oVirt platform. Therefore, you must set the platform to **none**, allowing OpenShift Container Platform to identify each node as a bare-metal node and the cluster as a bare-metal cluster. This is the same as **installing a cluster on any platform**, and has the following limitations:

1. There will be no cluster provider so you must manually add each machine and there will be no node scaling capabilities.

2. The oVirt CSI driver will not be installed and there will be no CSI capabilities.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the **x86_64** architecture.

The **pull secret from the Red Hat OpenShift Cluster Manager**. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

The SSH public key for the **core** user in Red Hat Enterprise Linux CoreOS (RHCOS).

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

### 21.1.9.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

**Prerequisites**

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to
hosting cloud provider APIs. You added sites to the **Proxy** object’s **spec.noProxy** field to bypass the proxy if necessary.

**NOTE**

The **Proxy** object **status.noProxy** field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (169.254.169.254).

**Procedure**

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port> 1
  httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
  noProxy: example.com 3
additionalTrustBundle: |
  -----BEGIN CERTIFICATE-----
  <MY_TRUSTED_CA_CERT>
  -----END CERTIFICATE-----
...
```

   1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.
   2 A proxy URL to use for creating HTTPS connections outside the cluster.
   3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, `.y.com` matches `x.y.com`, but not `y.com`. Use `*` to bypass the proxy for all destinations.
   4 If provided, the installation program generates a config map that is named `user-ca-bundle` in the **openshift-config** namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the `trustedCA` field of the **Proxy** object. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

**NOTE**

The installation program does not support the proxy **readinessEndpoints** field.

2. Save the file and reference it when installing OpenShift Container Platform.
The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

**NOTE**

Only the Proxy object named cluster is supported, and no additional proxies can be created.

21.1.9.4. Configuring a three-node cluster

Optionally, you can deploy zero compute machines in a minimal three node cluster that consists of three control plane machines only. This provides smaller, more resource efficient clusters for cluster administrators and developers to use for testing, development, and production.

In three-node OpenShift Container Platform environments, the three control plane machines are schedulable, which means that your application workloads are scheduled to run on them.

**Prerequisites**

- You have an existing install-config.yaml file.

**Procedure**

- Ensure that the number of compute replicas is set to 0 in your install-config.yaml file, as shown in the following compute stanza:

```
compute:
  - name: worker
    platform: {}
    replicas: 0
```

**NOTE**

You must set the value of the replicas parameter for the compute machines to 0 when you install OpenShift Container Platform on user-provisioned infrastructure, regardless of the number of compute machines you are deploying. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. This does not apply to user-provisioned installations, where the compute machines are deployed manually.

**NOTE**

The preferred resource for control plane nodes is six vCPUs and 21 GB. For three control plane nodes this is the memory + vCPU equivalent of a minimum five-node cluster. You should back the three nodes, each installed on a 120 GB disk, with three IFLs that are SMT2 enabled. The minimum tested setup is three vCPUs and 10 GB on a 120 GB disk for each control plane node.

For three-node cluster installations, follow these next steps:

- If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your
application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes. See the Load balancing requirements for user-provisioned infrastructure section for more information.

- When you create the Kubernetes manifest files in the following procedure, ensure that the mastersSchedulable parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file is set to true. This enables your application workloads to run on the control plane nodes.

- Do not deploy any compute nodes when you create the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

21.1.10. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

**IMPORTANT**

- The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

**NOTE**

The installation program that generates the manifest and Ignition files is architecture specific and can be obtained from the client image mirror. The Linux version of the installation program runs on s390x only. This installer program is also available as a Mac OS version.

**Prerequisites**

- You obtained the OpenShift Container Platform installation program.

- You created the `install-config.yaml` installation configuration file.

**Procedure**

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:
$ ./openshift-install create manifests --dir <installation_directory>

**Example output**

INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
INFO Consuming Install Config from target directory
INFO Manifests created in: install_dir/manifests and install_dir/openshift

For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.

**WARNING**

If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.

**IMPORTANT**

When you configure control plane nodes from the default unschedulable to schedulable, additional subscriptions are required. This is because control plane nodes then become worker nodes.

2. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:
   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.
   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.
   c. Save and exit the file.

3. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

```
$ ./openshift-install create ignition-configs --dir <installation_directory>
```

For `<installation_directory>`, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The `kubeadmin-password` and `kubeconfig` files are created in the `./<installation_directory>/auth` directory:

```
├── auth
│   ├── kubeadmin-password
```
21.1.11. Installing RHCOS and starting the OpenShift Container Platform bootstrap process

To install OpenShift Container Platform on bare metal infrastructure that you provision, you must install Red Hat Enterprise Linux CoreOS (RHCOS) on the machines. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS machines have rebooted.

To install RHCOS on the machines, follow either the steps to use an ISO image or network PXE booting.

**NOTE**

The compute node deployment steps included in this installation document are RHCOS-specific. If you choose instead to deploy RHEL-based compute nodes, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Only RHEL 8 compute machines are supported.

You can configure RHCOS during ISO and PXE installations by using the following methods:

- **Kernel arguments:** You can use kernel arguments to provide installation-specific information. For example, you can specify the locations of the RHCOS installation files that you uploaded to your HTTP server and the location of the Ignition config file for the type of node you are installing. For a PXE installation, you can use the `APPEND` parameter to pass the arguments to the kernel of the live installer. For an ISO installation, you can interrupt the live installation boot process to add the kernel arguments. In both installation cases, you can use special `coreos.inst.*` arguments to direct the live installer, as well as standard installation boot arguments for turning standard kernel services on or off.

- **Ignition configs:** OpenShift Container Platform Ignition config files (*.ign) are specific to the type of node you are installing. You pass the location of a bootstrap, control plane, or compute node Ignition config file during the RHCOS installation so that it takes effect on first boot. In special cases, you can create a separate, limited Ignition config to pass to the live system. That Ignition config could do a certain set of tasks, such as reporting success to a provisioning system after completing installation. This special Ignition confg is consumed by the `coreos-installer` to be applied on first boot of the installed system. Do not provide the standard control plane and compute node Ignition configs to the live ISO directly.

- **coreos-installer:** You can boot the live ISO installer to a shell prompt, which allows you to prepare the permanent system in a variety of ways before first boot. In particular, you can run the `coreos-installer` command to identify various artifacts to include, work with disk partitions, and set up networking. In some cases, you can configure features on the live system and copy them to the installed system.

Whether to use an ISO or PXE install depends on your situation. A PXE install requires an available DHCP service and more preparation, but can make the installation process more automated. An ISO install is a more manual process and can be inconvenient if you are setting up more than a few machines.
NOTE

As of OpenShift Container Platform 4.6, the RHCOS ISO and other installation artifacts provide support for installation on disks with 4K sectors.

21.1.11.1. Installing RHCOS by using an ISO image

You can use an ISO image to install RHCOS on the machines.

Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have an HTTP server that can be accessed from your computer, and from the machines that you create.
- You have reviewed the Advanced RHCOS installation configuration section for different ways to configure features, such as networking and disk partitioning.

Procedure

1. Obtain the SHA512 digest for each of your Ignition config files. For example, you can use the following on a system running Linux to get the SHA512 digest for your bootstrap.ign Ignition config file:

   ```
   $ sha512sum <installation_directory>/bootstrap.ign
   a5a2d43879223273c9b60af66b44202a1d1248fc01cf156c46d4a79f552b6bad47bc8cc78dd011
   6e80c59d2ea9e32ba53bc807afbca581aa059311def2c3e3b
   installation_directory/bootstrap.ign
   ```

   The digests are provided to the coreos-installer in a later step to validate the authenticity of the Ignition config files on the cluster nodes.

2. Upload the bootstrap, control plane, and compute node Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

   IMPORTANT

   You can add or change configuration settings in your Ignition configs before saving them to your HTTP server. If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

3. From the installation host, validate that the Ignition config files are available on the URLs. The following example gets the Ignition config file for the bootstrap node:

   ```
   $ curl -k http://<HTTP_server>/bootstrap.ign
   ```

   Example output
Replace `bootstrap.ign` with `master.ign` or `worker.ign` in the command to validate that the Ignition config files for the control plane and compute nodes are also available.

4. Obtain the RHCOS images that are required for your preferred method of installing operating system instances for your target cluster architecture from the RHCOS (x86_64) image mirror or RHCOS (aarch64) image mirror pages.

   **IMPORTANT**

   The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available. Use only ISO images for this procedure. RHCOS qcow2 images are not supported for this installation type.

   ISO file names resemble the following example:

   `rhcos-<version>-live.<architecture>.iso`

5. Use the ISO to start the RHCOS installation. Use one of the following installation options:

   - Burn the ISO image to a disk and boot it directly.
   - Use ISO redirection by using a lights-out management (LOM) interface.

6. Boot the RHCOS ISO image without specifying any options or interrupting the live boot sequence. Wait for the installer to boot into a shell prompt in the RHCOS live environment.

   **NOTE**

   It is possible to interrupt the RHCOS installation boot process to add kernel arguments. However, for this ISO procedure you should use the `coreos-installer` command as outlined in the following steps, instead of adding kernel arguments.

7. Run the `coreos-installer` command and specify the options that meet your installation requirements. At a minimum, you must specify the URL that points to the Ignition config file for the node type, and the device that you are installing to:

   `sudo coreos-installer install --ignition-url=http://<HTTP_server>/<node_type>.ign <device> --ignition-hash=SHA512-<digest>`

   **1** You must run the `coreos-installer` command by using `sudo`, because the `core` user does not have the required root privileges to perform the installation.

   **2** The `--ignition-hash` option is required when the Ignition config file is obtained through an HTTP URL to validate the authenticity of the Ignition config file on the cluster node. `<digest>` is the Ignition config file SHA512 digest obtained in a preceding step.
NOTE

If you want to provide your Ignition config files through an HTTPS server that uses TLS, you can add the internal certificate authority (CA) to the system trust store before running `coreos-installer`.

The following example initializes a bootstrap node installation to the `/dev/sda` device. The Ignition config file for the bootstrap node is obtained from an HTTP web server with the IP address 192.168.1.2:

```
$ sudo coreos-installer install --ignition-url=http://192.168.1.2:80/installation_directory/bootstrap.ign /dev/sda --ignition-hash=SHA512-a5a2d43879223273c9b60af66b44202a1d1248fc01cf156c46d4a79f552b6bad47bc8cc78ddf0116e80c59d2ea9e32ba53bc807afbeca581aa059311def2c3e3b
```

### 8. Monitor the progress of the RHCOS installation on the console of the machine.

**IMPORTANT**

Be sure that the installation is successful on each node before commencing with the OpenShift Container Platform installation. Observing the installation process can also help to determine the cause of RHCOS installation issues that might arise.

### 9. After RHCOS installs, the system reboots. During the system reboot, it applies the Ignition config file that you specified.

### 10. Check the console output to verify that Ignition ran.

**Example command**

```
Ignition: ran on 2022/03/14 14:48:33 UTC (this boot)
Ignition: user-provided config was applied
```

### 11. Continue to create the other machines for your cluster.

**IMPORTANT**

You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, also create at least two compute machines before you install OpenShift Container Platform.

If the required network, DNS, and load balancer infrastructure are in place, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS nodes have rebooted.
NOTE

RHCOS nodes do not include a default password for the core user. You can access the nodes by running `ssh core@<node>.<cluster_name>.<base_domain>` as a user with access to the SSH private key that is paired to the public key that you specified in your `install_config.yaml` file. OpenShift Container Platform 4 cluster nodes running RHCOS are immutable and rely on Operators to apply cluster changes. Accessing cluster nodes by using SSH is not recommended. However, when investigating installation issues, if the OpenShift Container Platform API is not available, or the kubelet is not properly functioning on a target node, SSH access might be required for debugging or disaster recovery.

21.11.2. Installing RHCOS by using PXE or iPXE booting

You can use PXE or iPXE booting to install RHCOS on the machines.

Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have configured suitable PXE or iPXE infrastructure.
- You have an HTTP server that can be accessed from your computer, and from the machines that you create.
- You have reviewed the Advanced RHCOS installation configuration section for different ways to configure features, such as networking and disk partitioning.

Procedure

1. Upload the bootstrap, control plane, and compute node Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

   IMPORTANT

   You can add or change configuration settings in your Ignition configs before saving them to your HTTP server. If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

2. From the installation host, validate that the Ignition config files are available on the URLs. The following example gets the Ignition config file for the bootstrap node:

   ```sh
   $ curl -k http://<HTTP_server>/bootstrap.ign
   ```

   Example output

   ```
   {'ignition':
   {'version':"3.2.0"},
   'passwd':
   {'users':
   [{'name':"core"},
   {'sshAuthorizedKeys':"ssh-rsa..."}]
   }
   ```
Replace `bootstrap.ign` with `master.ign` or `worker.ign` in the command to validate that the Ignition config files for the control plane and compute nodes are also available.

3. Obtain the RHCOS **kernel**, **initramfs**, and **rootfs** files from the RHCOS image mirror page.

**IMPORTANT**

The RHCOS artifacts might not change with every release of OpenShift Container Platform. You must download artifacts with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate **kernel**, **initramfs**, and **rootfs** artifacts described below for this procedure. RHCOS QCOW2 images are not supported for this installation type.

The file names contain the OpenShift Container Platform version number. They resemble the following examples:

- **kernel**: `rhcos-<version>-live-kernel-<architecture>`
- **initramfs**: `rhcos-<version>-live-initramfs.<architecture>.img`
- **rootfs**: `rhcos-<version>-live-rootfs.<architecture>.img`

4. Upload the **rootfs**, **kernel**, and **initramfs** files to your HTTP server.

**IMPORTANT**

If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

5. Configure the network boot infrastructure so that the machines boot from their local disks after RHCOS is installed on them.

6. Configure PXE or iPXE installation for the RHCOS images and begin the installation. Modify one of the following example menu entries for your environment and verify that the image and Ignition files are properly accessible:

   - For PXE (**x86_64**):

     ```
     DEFAULT pxeboot
     TIMEOUT 20
     PROMPT 0
     LABEL pxeboot
     KERNAL http://<HTTP_server>/rhcos-<version>-live-kernel-<architecture>  # 1
     ```

     1 Specify the location of the live **kernel** file that you uploaded to your HTTP server. The URL must be HTTP, TFTP, or FTP; HTTPS and NFS are not supported.

     2 If you use multiple NICs, specify a single interface in the `ip` option. For example, to use DHCP on a NIC that is named `eno1`, set `ip=eno1:dhcp`. 
Specify the locations of the RHCOS files that you uploaded to your HTTP server. The `initrd` parameter value is the location of the `initramfs` file, the `coreos.live.rootfs_url` parameter value is the location of the `rootfs` file, and the `coreos.inst.ignition_url` parameter value is the location of the bootstrap Ignition config file.

**NOTE**

This configuration does not enable serial console access on machines with a graphical console. To configure a different console, add one or more `console=` arguments to the `APPEND` line. For example, add `console=tty0 console=ttyS0` to set the first PC serial port as the primary console and the graphical console as a secondary console. For more information, see How does one set up a serial terminal and/or console in Red Hat Enterprise Linux?

- For iPXE (`x86_64` + `arm64`):

  initrd=main
  coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign
  coreos.inst.install_dev=/dev/sda
  initrd --name main http://<HTTP_server>/rhcos-<version>-live-initramfs.<architecture>.img
  boot

  1. Specify the locations of the RHCOS files that you uploaded to your HTTP server. The `kernel` parameter value is the location of the `kernel` file, the `initrd=main` argument is needed for booting on UEFI systems, the `coreos.live.rootfs_url` parameter value is the location of the `rootfs` file, and the `coreos.inst.ignition_url` parameter value is the location of the bootstrap Ignition config file.

  2. If you use multiple NICs, specify a single interface in the `ip` option. For example, to use DHCP on a NIC that is named `eno1`, set `ip=eno1:dhcp`.

  3. Specify the location of the `initramfs` file that you uploaded to your HTTP server.

**NOTE**

To network boot the CoreOS `kernel` on `arm64` architecture, you need to use a version of iPXE build with the `IMAGE_GZIP` option enabled. See `IMAGE_GZIP` option in iPXE.

- For PXE (with UEFI and Grub as second stage) on `arm64`:
menuentry 'Install CoreOS' {
    linux rhcos-<version>-live-kernel-<architecture>
    coreos.inst.install_dev=/dev/sda
coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign
    initrd rhcos-<version>-live-initramfs.<architecture>.img
}

1 Specify the locations of the RHCOS files that you uploaded to your HTTP/TFTP server. The kernel parameter value is the location of the kernel file on your TFTP server. The coreos.live.rootsfs_url parameter value is the location of the rootfs file, and the coreos.inst.ignition_url parameter value is the location of the bootstrap Ignition config file on your HTTP Server.

2 If you use multiple NICs, specify a single interface in the ip option. For example, to use DHCP on a NIC that is named eno1, set ip=eno1:dhcp.

3 Specify the location of the initramfs file that you uploaded to your TFTP server.

7. Monitor the progress of the RHCOS installation on the console of the machine.

   IMPORTANT

   Be sure that the installation is successful on each node before commencing with the OpenShift Container Platform installation. Observing the installation process can also help to determine the cause of RHCOS installation issues that might arise.

8. After RHCOS installs, the system reboots. During reboot, the system applies the Ignition config file that you specified.

9. Check the console output to verify that Ignition ran.

   Example command

   Ignition: ran on 2022/03/14 14:48:33 UTC (this boot)
   Ignition: user-provided config was applied

10. Continue to create the machines for your cluster.

   IMPORTANT

   You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, also create at least two compute machines before you install the cluster.

   If the required network, DNS, and load balancer infrastructure are in place, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS nodes have rebooted.
NOTE

RHCOS nodes do not include a default password for the core user. You can access the nodes by running `ssh core@<node>_<cluster_name>._<base_domain>` as a user with access to the SSH private key that is paired to the public key that you specified in your `install_config.yaml` file. OpenShift Container Platform 4 cluster nodes running RHCOS are immutable and rely on Operators to apply cluster changes. Accessing cluster nodes by using SSH is not recommended. However, when investigating installation issues, if the OpenShift Container Platform API is not available, or the kubelet is not properly functioning on a target node, SSH access might be required for debugging or disaster recovery.

21.11.3. Advanced RHCOS installation configuration

A key benefit for manually provisioning the Red Hat Enterprise Linux CoreOS (RHCOS) nodes for OpenShift Container Platform is to be able to do configuration that is not available through default OpenShift Container Platform installation methods. This section describes some of the configurations that you can do using techniques that include:

- Passing kernel arguments to the live installer
- Running `coreos-installer` manually from the live system
- Customizing a live ISO or PXE boot image

The advanced configuration topics for manual Red Hat Enterprise Linux CoreOS (RHCOS) installations detailed in this section relate to disk partitioning, networking, and using Ignition configs in different ways.

21.11.3.1. Using advanced networking options for PXE and ISO installations

Networking for OpenShift Container Platform nodes uses DHCP by default to gather all necessary configuration settings. To set up static IP addresses or configure special settings, such as bonding, you can do one of the following:

- Pass special kernel parameters when you boot the live installer.
- Use a machine config to copy networking files to the installed system.
- Configure networking from a live installer shell prompt, then copy those settings to the installed system so that they take effect when the installed system first boots.

To configure a PXE or iPXE installation, use one of the following options:

- See the "Advanced RHCOS installation reference" tables.
- Use a machine config to copy networking files to the installed system.

To configure an ISO installation, use the following procedure.

Procedure

1. Boot the ISO installer.

2. From the live system shell prompt, configure networking for the live system using available RHEL tools, such as `nmcli` or `nmtui`.
3. Run the `coreos-installer` command to install the system, adding the `--copy-network` option to copy networking configuration. For example:

```bash
$ coreos-installer install --copy-network \
   --ignition-url=http://host/worker.ign /dev/sda
```

**IMPORTANT**

The `--copy-network` option only copies networking configuration found under `/etc/NetworkManager/system-connections`. In particular, it does not copy the system hostname.

4. Reboot into the installed system.

Additional resources

- See [Getting started with nmcli](https://docs.openshift.com/container-platform/4.10/installing/coreos-installer/index.html) and [Getting started with nmtui](https://docs.openshift.com/container-platform/4.10/installing/coreos-installer/index.html) in the RHEL 8 documentation for more information about the `nmcli` and `nmtui` tools.

21.11.3.2. Disk partitioning

The disk partitions are created on OpenShift Container Platform cluster nodes during the Red Hat Enterprise Linux CoreOS (RHCOS) installation. Each RHCOS node of a particular architecture uses the same partition layout, unless the default partitioning configuration is overridden. During the RHCOS installation, the size of the root file system is increased to use the remaining available space on the target device.

There are two cases where you might want to override the default partitioning when installing RHCOS on an OpenShift Container Platform cluster node:

- Creating separate partitions: For greenfield installations on an empty disk, you might want to add separate storage to a partition. This is officially supported for mounting `/var` or a subdirectory of `/var`, such as `/var/lib/etcd`, on a separate partition, but not both.

  **IMPORTANT**

  Kubernetes supports only two file system partitions. If you add more than one partition to the original configuration, Kubernetes cannot monitor all of them.

- Retaining existing partitions: For a brownfield installation where you are reinstalling OpenShift Container Platform on an existing node and want to retain data partitions installed from your previous operating system, there are both boot arguments and options to `coreos-installer` that allow you to retain existing data partitions.
21.1.11.3.2.1. Creating a separate /var partition

In general, you should use the default disk partitioning that is created during the RHCOS installation. However, there are cases where you might want to create a separate partition for a directory that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the /var directory or a subdirectory of /var. For example:

- **/var/lib/containers**: Holds container-related content that can grow as more images and containers are added to a system.

- **/var/lib/etcd**: Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.

- **/var**: Holds data that you might want to keep separate for purposes such as auditing.

Storing the contents of a /var directory separately makes it easier to grow storage for those areas as needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

The use of a separate partition for the /var directory or a subdirectory of /var also prevents data growth in the partitioned directory from filling up the root file system.

The following procedure sets up a separate /var partition by adding a machine config manifest that is wrapped into the Ignition config file for a node type during the preparation phase of an installation.

**Procedure**

1. On your installation host, change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

   ```
   $ openshift-install create manifests --dir <installation_directory>
   ```

2. Create a Butane config that configures the additional partition. For example, name the file
   `$HOME/clusterconfig/98-var-partition.bu`, change the disk device name to the name of the storage device on the **worker** systems, and set the storage size as appropriate. This example places the /var directory on a separate partition:

   ```
   variant: openshift
   version: 4.10.0
   metadata:
   ```
labels:
  machineconfiguration.openshift.io/role: worker
name: 98-var-partition
storage:
disks:
  - device: /dev/<device_name> 1
partitions:
  - label: var
    start_mib: <partition_start_offset> 2
    size_mib: <partition_size> 3
filesystems:
  - device: /dev/disk/by-partlabel/var
    path: /var
    format: xfs
    mount_options: [defaults, prjquota] 4
    with_mount_unit: true

1. The storage device name of the disk that you want to partition.
2. When adding a data partition to the boot disk, a minimum offset value of 25000 mebibytes is recommended. The root file system is automatically resized to fill all available space up to the specified offset. If no offset value is specified, or if the specified value is smaller than the recommended minimum, the resulting root file system will be too small, and future reinstalls of RHCOS might overwrite the beginning of the data partition.
3. The size of the data partition in mebibytes.
4. The prjquota mount option must be enabled for filesystems used for container storage.

NOTE
When creating a separate /var partition, you cannot use different instance types for compute nodes, if the different instance types do not have the same device name.

3. Create a manifest from the Butane config and save it to the clusterconfig/openshift directory. For example, run the following command:

   $ butane $HOME/clusterconfig/98-var-partition.bu -o $HOME/clusterconfig/openshift/98-var-partition.yaml

4. Create the Ignition config files:

   $ openshift-install create ignition-configs --dir <installation_directory> 1

1. For <installation_directory>, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory:

   . auth
The files in the `<installation_directory>/manifest` and `<installation_directory>/openshift` directories are wrapped into the Ignition config files, including the file that contains the `98-var-partition` custom MachineConfig object.

Next steps

- You can apply the custom disk partitioning by referencing the Ignition config files during the RHCOS installations.

21.11.3.2.2. Retaining existing partitions

For an ISO installation, you can add options to the `coreos-installer` command that cause the installer to maintain one or more existing partitions. For a PXE installation, you can add `coreos.inst.*` options to the `APPEND` parameter to preserve partitions.

Saved partitions might be data partitions from an existing OpenShift Container Platform system. You can identify the disk partitions you want to keep either by partition label or by number.

**NOTE**

If you save existing partitions, and those partitions do not leave enough space for RHCOS, the installation will fail without damaging the saved partitions.

Retaining existing partitions during an ISO installation

This example preserves any partition in which the partition label begins with `data` (`data*`):

```bash
# coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign \   --save-partlabel 'data*' /dev/sda
```

The following example illustrates running the `coreos-installer` in a way that preserves the sixth (6) partition on the disk:

```bash
# coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign \   --save-partindex 6 /dev/sda
```

This example preserves partitions 5 and higher:

```bash
# coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign \   --save-partindex 5- /dev/sda
```

In the previous examples where partition saving is used, `coreos-installer` recreates the partition immediately.

Retaining existing partitions during a PXE installation

This `APPEND` option preserves any partition in which the partition label begins with `data` (`'data*'`):
This APPEND option preserves partitions 5 and higher:

```
coreos.inst.save_partindex=5-
```

This APPEND option preserves partition 6:

```
coreos.inst.save_partindex=6
```

### 21.1.11.3.3. Identifying Ignition configs

When doing an RHCOS manual installation, there are two types of Ignition configs that you can provide, with different reasons for providing each one:

- **Permanent install Ignition config** Every manual RHCOS installation needs to pass one of the Ignition config files generated by `openshift-installer`, such as `bootstrap.ign`, `master.ign` and `worker.ign`, to carry out the installation.

  **IMPORTANT**

  It is not recommended to modify these Ignition config files directly. You can update the manifest files that are wrapped into the Ignition config files, as outlined in examples in the preceding sections.

  For PXE installations, you pass the Ignition configs on the APPEND line using the `coreos.inst.ignition_url=` option. For ISO installations, after the ISO boots to the shell prompt, you identify the Ignition config on the `coreos-installer` command line with the `--ignition-url=` option. In both cases, only HTTP and HTTPS protocols are supported.

- **Live install Ignition config**: This type can be created by using the `coreos-installer customize` subcommand and its various options. With this method, the Ignition config passes to the live install medium, runs immediately upon booting, and performs setup tasks before or after the RHCOS system installs to disk. This method should only be used for performing tasks that must be done once and not applied again later, such as with advanced partitioning that cannot be done using a machine config.

  For PXE or ISO boots, you can create the Ignition config and APPEND the `ignition.config.url=` option to identify the location of the Ignition config. You also need to append `ignition.firstboot` `ignition.platform.id=metal` or the `ignition.config.url` option will be ignored.

### 21.1.11.3.4. Advanced RHCOS installation reference

This section illustrates the networking configuration and other advanced options that allow you to modify the Red Hat Enterprise Linux CoreOS (RHCOS) manual installation process. The following tables describe the kernel arguments and command-line options you can use with the RHCOS live installer and the `coreos-installer` command.

#### 21.1.11.3.4.1. Networking and bonding options for ISO installations

If you install RHCOS from an ISO image, you can add kernel arguments manually when you boot the image to configure networking for a node. If no networking arguments are specified, DHCP is activated in the initramfs when RHCOS detects that networking is required to fetch the Ignition config file.
IMPORTANT

When adding networking arguments manually, you must also add the `rd.neednet=1` kernel argument to bring the network up in the initramfs.

The following table provides examples for configuring networking and bonding on your RHCOS nodes for ISO installations. The examples describe how to use the `ip=`, `nameserver=`, and `bond=` kernel arguments.

### NOTE

Ordering is important when adding the kernel arguments: `ip=`, `nameserver=`, and then `bond=`.

The networking options are passed to the `dracut` tool during system boot. For more information about the networking options supported by `dracut`, see the `dracut.cmdline` manual page.

<table>
<thead>
<tr>
<th>Table 21.8. Networking and bonding options for ISO installations</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>To configure an IP address, either use DHCP (<code>ip=dhcp</code>) or set an individual static IP address (<code>ip=&lt;host_ip&gt;</code>). If setting a static IP, you must then identify the DNS server IP address (<code>nameserver=&lt;dns_ip&gt;</code>) on each node. This example sets:</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>• The node’s IP address to <strong>10.10.10.2</strong></td>
</tr>
<tr>
<td>• The gateway address to <strong>10.10.10.254</strong></td>
</tr>
<tr>
<td>• The netmask to <strong>255.255.255.0</strong></td>
</tr>
<tr>
<td>• The hostname to <strong>core0.example.com</strong></td>
</tr>
<tr>
<td>• The DNS server address to <strong>4.4.4.41</strong></td>
</tr>
<tr>
<td>• The auto-configuration value to <strong>none</strong>. No auto-configuration is required when IP networking is configured statically.</td>
</tr>
</tbody>
</table>

### NOTE

When you use DHCP to configure IP addressing for the RHCOS machines, the machines also obtain the DNS server information through DHCP. For DHCP-based deployments, you can define the DNS server address that is used by the RHCOS nodes through your DHCP server configuration.
You can configure an IP address without assigning a static hostname. If a static hostname is not set by the user, it will be picked up and automatically set by a reverse DNS lookup. To configure an IP address without a static hostname:

- The node's IP address to **10.10.10.2**
- The gateway address to **10.10.10.254**
- The netmask to **255.255.255.0**
- The DNS server address to **4.4.4.41**
- The auto-configuration value to **none**. No auto-configuration is required when IP networking is configured statically.

Specify multiple network interfaces by specifying multiple `ip=` entries.

<table>
<thead>
<tr>
<th>Description</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional: You can configure routes to additional networks by setting an <code>rd.route=</code> value.</td>
<td>Examples</td>
</tr>
<tr>
<td>When you configure one or multiple networks, one default gateway is required. If the additional network gateway is different from the primary network gateway, the default gateway must be the primary network gateway.</td>
<td>Examples</td>
</tr>
<tr>
<td>Disable DHCP on a single interface, such as when there are two or more network interfaces and only one interface is being used. In the example, the <code>enp1s0</code> interface has a static networking configuration and DHCP is disabled for <code>enp2s0</code>, which is not used.</td>
<td>Examples</td>
</tr>
<tr>
<td>You can combine DHCP and static IP configurations on systems with multiple network interfaces.</td>
<td>Examples</td>
</tr>
</tbody>
</table>

Disable DHCP on a single interface, such as when there are two or more network interfaces and only one interface is being used. In the example, the `enp1s0` interface has a static networking configuration and DHCP is disabled for `enp2s0`, which is not used.

You can combine DHCP and static IP configurations on systems with multiple network interfaces.
### Description
Optional: You can configure VLANs on individual interfaces by using the `vlan=` parameter.

You can provide multiple DNS servers by adding a `nameserver=` entry for each server.

Optional: Bonding multiple network interfaces to a single interface is supported using the `bond=` option. In these two examples:

- The syntax for configuring a bonded interface is:

  \[
  \text{bond} = \text{name}[:, \text{network\_interfaces}] [:\text{options}]
  \]

  name is the bonding device name (bond0), `network\_interfaces` represents a comma-separated list of physical (ethernet) interfaces (em1,em2), and options is a comma-separated list of bonding options. Enter `modinfo bonding` to see available options.

- When you create a bonded interface using `bond=`, you must specify how the IP address is assigned and other information for the bonded interface.

### Examples
To configure a VLAN on a network interface and use a static IP address:

- `ip=10.10.10.2::10.10.254.255.255.255.0:core0.example.com:enp2s0.100:enp2s0`
- `vlan=enp2s0.100:enp2s0`

To configure a VLAN on a network interface and to use DHCP:

- `ip=enp2s0.100:dhcp`
- `vlan=enp2s0.100:enp2s0`

You can provide multiple DNS servers by adding a `nameserver=` entry for each server:

- `nameserver=1.1.1.1`
- `nameserver=8.8.8.8`

To configure the bonded interface to use DHCP, set the bond's IP address to `dhcp`. For example:

- `bond=bond0:em1,em2:mode=active-backup`
- `ip=bond0:dhcp`

To configure the bonded interface to use a static IP address, enter the specific IP address you want and related information. For example:

- `bond=bond0:em1,em2:mode=active-backup`
- `ip=10.10.10.2::10.10.254.255.255.255.0:core0.example.com:bond0:none`
21.1.11.4. Updating the bootloader using bootupd

To update the bootloader by using `bootupd`, you must either install `bootupd` on RHCOS machines manually or provide a machine config with the enabled `systemd` unit. Unlike `grubby` or other bootloader tools, `bootupd` does not manage kernel space configuration such as passing kernel arguments.

After you have installed `bootupd`, you can manage it remotely from the OpenShift Container Platform cluster.
NOTE
It is recommended that you use **bootupd** only on bare metal or virtualized hypervisor installations, such as for protection against the BootHole vulnerability.

Manual install method
You can manually install **bootupd** by using the **bootctl** command-line tool.

1. Inspect the system status:

   ```
   # bootupctl status
   ```

   **Example output for x86_64**

   Component EFI
   Installed: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
   Update: At latest version

   **Example output for arm64**

   Component EFI
   Installed: grub2-efi-aa64-1:2.02-99.el8_4.1.aarch64,shim-aa64-15.4-2.el8_1.aarch64
   Update: At latest version

2. RHCOS images created without **bootupd** installed on them require an explicit adoption phase. If the system status is **Adoptable**, perform the adoption:

   ```
   # bootupctl adopt-and-update
   ```

   **Example output**

   Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64

3. If an update is available, apply the update so that the changes take effect on the next reboot:

   ```
   # bootupctl update
   ```

   **Example output**

   Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64

Machine config method
Another way to enable **bootupd** is by providing a machine config.

- Provide a machine config file with the enabled **systemd** unit, as shown in the following example:

  **Example output**

  ```
  variant: rhcos
  version: 1.1.0
  ```
21.1.12. Waiting for the bootstrap process to complete

The OpenShift Container Platform bootstrap process begins after the cluster nodes first boot into the persistent RH COS environment that has been installed to disk. The configuration information provided through the Ignition config files is used to initialize the bootstrap process and install OpenShift Container Platform on the machines. You must wait for the bootstrap process to complete.

Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have obtained the installation program and generated the Ignition config files for your cluster.
- You installed RH COS on your cluster machines and provided the Ignition config files that the OpenShift Container Platform installation program generated.
- Your machines have direct internet access or have an HTTP or HTTPS proxy available.

Procedure

1. Monitor the bootstrap process:

   ```bash
   $ ./openshift-install --dir <installation_directory> wait-for bootstrap-complete \
   --log-level=info
   ```

   **1** For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   **2** To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

Example output

INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
INFO API v1.23.0 up
INFO Waiting up to 30m0s for bootstrapping to complete...
INFO It is now safe to remove the bootstrap resources
The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After bootstrap process is complete, remove the bootstrap machine from the load balancer.

IMPORTANT
You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the bootstrap machine itself.

21.1.13. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**
- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   ```

   **Example output**

   ```
   system:admin
   ```

21.1.14. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

**Prerequisites**
- You added machines to your cluster.

**Procedure**
1. Confirm that the cluster recognizes the machines:

```
$ oc get nodes
```

**Example output**

```
NAME      STATUS    ROLES   AGE  VERSION
master-0  Ready     master  63m  v1.23.0
master-1  Ready     master  63m  v1.23.0
master-2  Ready     master  64m  v1.23.0
```

The output lists all of the machines that you created.

**NOTE**

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```
$ oc get csr
```

**Example output**

```
NAME        AGE   REQUESTOR                                   CONDITION
csr-mddf5   20m   system:node:master-01.example.com   Approved,Issued
csr-z5rln   16m   system:node:worker-21.example.com   Approved,Issued
```

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

**NOTE**

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.
CHAPTER 21. INSTALLING ON ANY PLATFORM

NOTE
For clusters running on platforms that are not machine API enabled, such as bare
metal and other user-provisioned infrastructure, you must implement a method
of automatically approving the kubelet serving certificate requests (CSRs). If a
request is not approved, then the oc exec, oc rsh, and oc logs commands
cannot succeed, because a serving certificate is required when the API server
connects to the kubelet. Any operation that contacts the Kubelet endpoint
requires this certificate approval to be in place. The method must watch for new
CSRs, confirm that the CSR was submitted by the node-bootstrapper service
account in the system:node or system:admin groups, and confirm the identity
of the node.
To approve them individually, run the following command for each valid CSR:
$ oc adm certificate approve <csr_name> 1
1

<csr_name> is the name of a CSR from the list of current CSRs.

To approve all pending CSRs, run the following command:
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}
{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve

NOTE
Some Operators might not become available until some CSRs are approved.
4. Now that your client requests are approved, you must review the server requests for each
machine that you added to the cluster:
$ oc get csr

Example output
NAME
AGE REQUESTOR
CONDITION
csr-bfd72 5m26s system:node:ip-10-0-50-126.us-east-2.compute.internal
Pending
csr-c57lv 5m26s system:node:ip-10-0-95-157.us-east-2.compute.internal
Pending
...
5. If the remaining CSRs are not approved, and are in the Pending status, approve the CSRs for
your cluster machines:
To approve them individually, run the following command for each valid CSR:
$ oc adm certificate approve <csr_name> 1
1

<csr_name> is the name of a CSR from the list of current CSRs.

3155


• To approve all pending CSRs, run the following command:

```bash
$ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs oc adm certificate approve
```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```bash
$ oc get nodes
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.23.0</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.23.0</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>74m</td>
<td>v1.23.0</td>
</tr>
<tr>
<td>worker-0</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.23.0</td>
</tr>
<tr>
<td>worker-1</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.23.0</td>
</tr>
</tbody>
</table>

**NOTE**

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

**Additional information**

• For more information on CSRs, see [Certificate Signing Requests](#).

### 21.1.15. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

**Prerequisites**

• Your control plane has initialized.

**Procedure**

1. Watch the cluster components come online:

```bash
$ watch -n5 oc get clusteroperators
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
</tr>
</thead>
<tbody>
<tr>
<td>authentication</td>
<td>4.10.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>baremetal</td>
<td>4.10.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>cloud-credential</td>
<td>4.10.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>cluster-autoscaler</td>
<td>4.10.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>config-operator</td>
<td>4.10.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
</tbody>
</table>
### 21.1.15.1. Disabling the default OperatorHub sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

**Procedure**

- Disable the sources for the default catalogs by adding `disableAllDefaultSources: true` to the `OperatorHub` object:

  ```
  $ oc patch OperatorHub cluster --type json
  -p '[[{"op": "add", "path": "/spec/disableAllDefaultSources", "value": true}]]
  ```

**TIP**

Alternatively, you can use the web console to manage catalog sources. From the Administration → Cluster Settings → Configuration → OperatorHub page, click the Sources tab, where you can create, delete, disable, and enable individual sources.

### 21.1.15.2. Image registry removed during installation

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as Removed. This allows openshift-installer to complete installations on these platform types.
After installation, you must edit the Image Registry Operator configuration to switch the managementState from Removed to Managed.

**NOTE**

The Prometheus console provides an ImageRegistryRemoved alert, for example:

"Image Registry has been removed. ImageStreamTags, BuildConfigs and DeploymentConfigs which reference ImageStreamTags may not work as expected. Please configure storage and update the config to Managed state by editing configs.imageregistry.operator.openshift.io."

21.1.15.3. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the Recreate rollout strategy during upgrades.

21.1.15.3.1. Configuring registry storage for IBM Z

As a cluster administrator, following installation you must configure your registry to use storage.

**Prerequisites**

- You have access to the cluster as a user with the cluster-admin role.
- You have a cluster on IBM Z.
- You have provisioned persistent storage for your cluster.

**IMPORTANT**

OpenShift Container Platform supports ReadWriteOnce access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, ReadWriteMany access is required.

- Must have 100Gi capacity.

**Procedure**

1. To configure your registry to use storage, change the spec.storage.pvc in the configs.imageregistry/cluster resource.
2. Verify that you do not have a registry pod:

   `$ oc get pod -n openshift-image-registry -l docker-registry=default`

   **Example output**
   
   No resources found in openshift-image-registry namespace

3. Check the registry configuration:

   `$ oc edit configs.imageregistry.operator.openshift.io`

   **Example output**
   
   ```
   storage:
   pvc:
   claim:
   ```
   
   Leave the **claim** field blank to allow the automatic creation of an **image-registry-storage** PVC.

4. Check the **clusteroperator** status:

   `$ oc get clusteroperator image-registry`

   **Example output**
   
   ```
   NAME             VERSION                              AVAILABLE   PROGRESSING   DEGRADED
   SINCE   MESSAGE
   image-registry   4.7                                  True        False         False      6h50m
   ```

5. Ensure that your registry is set to managed to enable building and pushing of images.

   - Run:
     
     `$ oc edit configs.imageregistry/cluster`
     
     Then, change the line
     
     ```
     managementState: Removed
     ```
     
     to
21.1.15.3.2. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

Procedure

- To set the image registry storage to an empty directory:

  ```
  $ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec":
  {"storage":{"emptyDir":{}}}}'
  ```

  **WARNING**

  Configure this option for only non-production clusters.

  If you run this command before the Image Registry Operator initializes its components, the `oc patch` command fails with the following error:

  ```
  Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
  ```

  Wait a few minutes and run the command again.

21.1.15.3.3. Configuring block registry storage

To allow the image registry to use block storage types during upgrades as a cluster administrator, you can use the `Recreate` rollout strategy.

**IMPORTANT**

Block storage volumes are supported but not recommended for use with the image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

Procedure

1. To set the image registry storage as a block storage type, patch the registry so that it uses the `Recreate` rollout strategy and runs with only one (1) replica:

   ```
   $ oc patch config.imageregistry.operator.openshift.io/cluster --type merge -p '{"spec":
   {"rolloutStrategy":"Recreate","replicas":1}}'
   ```

2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.

3. Edit the registry configuration so that it references the correct PVC.
21.1.16. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

Prerequisites

- Your control plane has initialized.
- You have completed the initial Operator configuration.

Procedure

1. Confirm that all the cluster components are online with the following command:

```
$ watch -n5 oc get clusteroperators
```

Example output

```
NAME                        VERSION   AVAILABLE   PROGRESSING   DEGRADED   SINCE
authentication              4.10.0    True        False         False      19m
baremetal                   4.10.0    True        False         False      37m
cloud-credential            4.10.0    True        False         False      40m
cluster-autoscaler          4.10.0    True        False         False      37m
config-operator              4.10.0    True        False         False      38m
console                     4.10.0    True        False         False      26m
csi-snapshot-controller     4.10.0    True        False         False      37m

etcd                        4.10.0    True        False         False      36m
image-registry               4.10.0    True        False         False      31m
ingress                     4.10.0    True        False         False      30m
insights                    4.10.0    True        False         False      31m
kube-apiserver               4.10.0    True        False         False      32m
kube-controller-manager     4.10.0    True        False         False      30m
kube-scheduler              4.10.0    True        False         False      32m
kube-storage-version-migrator 4.10.0   True        False         False      32m
machine-api                 4.10.0    True        False         False      29m
machine-approver            4.10.0    True        False         False      37m
machine-config              4.10.0    True        False         False      36m
marketplace                 4.10.0    True        False         False      37m
monitoring                  4.10.0    True        False         False      29m
network                     4.10.0    True        False         False      38m
node-tuning                 4.10.0    True        False         False      37m
openshift-apiserver        4.10.0    True        False         False      32m
openshift-controller-manager 4.10.0   True        False         False      32m
openshift-samples           4.10.0    True        False         False      32m
operator-lifecycle-manager  4.10.0    True        False         False      37m
operator-lifecycle-manager-catalog 4.10.0 True        False         False      37m
operator-lifecycle-manager-packageserver 4.10.0 True        False         False      32m
service-ca                  4.10.0    True        False         False      38m
storage                     4.10.0    True        False         False      37m
```

Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:
$ ./openshift-install --dir <installation_directory> wait-for install-complete

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

**Example output**

INFO Waiting up to 30m0s for the cluster to initialize...

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

2. Confirm that the Kubernetes API server is communicating with the pods.

   a. To view a list of all pods, use the following command:

   ```bash
   $ oc get pods --all-namespaces
   ```

   **Example output**

<table>
<thead>
<tr>
<th>NAMESPACE</th>

b. View the logs for a pod that is listed in the output of the previous command by using the following command:

```
$ oc logs <pod_name> -n <namespace>
```

1 Specify the pod name and namespace, as shown in the output of the previous command.

If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation. See “Enabling multipathing with kernel arguments on RHCOS” in the Post-installation machine configuration tasks documentation for more information.

### 21.1.17. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.10, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- See About remote health monitoring for more information about the Telemetry service

### 21.1.18. Next steps

- Customize your cluster.

- If necessary, you can opt out of remote health reporting.

- Set up your registry and configure registry storage.
CHAPTER 22. INSTALLATION CONFIGURATION

22.1. CUSTOMIZING NODES

Although directly making changes to OpenShift Container Platform nodes is discouraged, there are times when it is necessary to implement a required low-level security, redundancy, networking, or performance feature. Direct changes to OpenShift Container Platform nodes can be done by:

- Creating machine configs that are included in manifest files to start up a cluster during `openshift-install`.
- Creating machine configs that are passed to running OpenShift Container Platform nodes via the Machine Config Operator.
- Creating an Ignition config that is passed to `coreos-installer` when installing bare-metal nodes.

The following sections describe features that you might want to configure on your nodes in this way.

22.1.1. Creating machine configs with Butane

Machine configs are used to configure control plane and worker machines by instructing machines how to create users and file systems, set up the network, install systemd units, and more.

Because modifying machine configs can be difficult, you can use Butane configs to create machine configs for you, thereby making node configuration much easier.

22.1.1.1. About Butane

Butane is a command-line utility that OpenShift Container Platform uses to provide convenient, short-hand syntax for writing machine configs, as well as for performing additional validation of machine configs. The format of the Butane config file that Butane accepts is defined in the OpenShift Butane config spec.

22.1.1.2. Installing Butane

You can install the Butane tool (`butane`) to create OpenShift Container Platform machine configs from a command-line interface. You can install `butane` on Linux, Windows, or macOS by downloading the corresponding binary file.

**TIP**

Butane releases are backwards-compatible with older releases and with the Fedora CoreOS Config Transpiler (FCCT).

**Procedure**

2. Get the `butane` binary:
   a. For the newest version of Butane, save the latest `butane` image to your current directory:
b. Optional: For a specific type of architecture you are installing Butane on, such as aarch64 or ppc64le, indicate the appropriate URL. For example:

```
$ curl https://mirror.openshift.com/pub/openshift-v4/clients/butane/latest/butane-aarch64
```

3. Make the downloaded binary file executable:

```
$ chmod +x butane
```

4. Move the butane binary file to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:

```
$ echo $PATH
```

**Verification steps**

- You can now use the Butane tool by running the butane command:

```
$ butane <butane_file>
```

**22.1.1.3. Creating a MachineConfig object by using Butane**

You can use Butane to produce a MachineConfig object so that you can configure worker or control plane nodes at installation time or via the Machine Config Operator.

**Prerequisites**

- You have installed the butane utility.

**Procedure**

1. Create a Butane config file. The following example creates a file named 99-worker-custom.bu that configures the system console to show kernel debug messages and specifies custom settings for the chrony time service:

```
variant: openshift
version: 4.10.0
metadata:
  name: 99-worker-custom
  labels:
    machineconfiguration.openshift.io/role: worker
  openshift:
    kernel_arguments:
      - loglevel=7
storage:
  files:
    - path: /etc/chrony.conf
      mode: 0644
```
2. Create a `MachineConfig` object by giving Butane the file that you created in the previous step:

```bash
$ butane 99-worker-custom.bu -o ./99-worker-custom.yaml
```

A `MachineConfig` object YAML file is created for you to finish configuring your machines.

3. Save the Butane config in case you need to update the `MachineConfig` object in the future.

4. If the cluster is not running yet, generate manifest files and add the `MachineConfig` object YAML file to the `openshift` directory. If the cluster is already running, apply the file as follows:

```bash
$ oc create -f 99-worker-custom.yaml
```

Additional resources

- Adding kernel modules to nodes
- Encrypting and mirroring disks during installation

### 22.1.2. Adding day-1 kernel arguments

Although it is often preferable to modify kernel arguments as a day-2 activity, you might want to add kernel arguments to all master or worker nodes during initial cluster installation. Here are some reasons you might want to add kernel arguments during cluster installation so they take effect before the systems first boot up:

- You want to disable a feature, such as SELinux, so it has no impact on the systems when they first come up.
- You need to do some low-level network configuration before the systems start.

To add kernel arguments to master or worker nodes, you can create a `MachineConfig` object and inject that object into the set of manifest files used by Ignition during cluster setup.

For a listing of arguments you can pass to a RHEL 8 kernel at boot time, see Kernel.org kernel parameters. It is best to only add kernel arguments with this procedure if they are needed to complete the initial OpenShift Container Platform installation.
Procedure

1. Change to the directory that contains the installation program and generate the Kubernetes manifests for the cluster:

   $ ./openshift-install create manifests --dir <installation_directory>

2. Decide if you want to add kernel arguments to worker or control plane nodes.

3. In the openshift directory, create a file (for example, 99-openshift-machineconfig-master-kargs.yaml) to define a MachineConfig object to add the kernel settings. This example adds a loglevel=7 kernel argument to control plane nodes:

   $ cat << EOF > 99-openshift-machineconfig-master-kargs.yaml
   apiVersion: machineconfiguration.openshift.io/v1
   kind: MachineConfig
   metadata:
     labels:
       machineconfiguration.openshift.io/role: master
     name: 99-openshift-machineconfig-master-kargs
   spec:
     kernelArguments:
     - loglevel=7
   EOF

You can change master to worker to add kernel arguments to worker nodes instead. Create a separate YAML file to add to both master and worker nodes.

You can now continue on to create the cluster.

22.1.3. Adding kernel modules to nodes

For most common hardware, the Linux kernel includes the device driver modules needed to use that hardware when the computer starts up. For some hardware, however, modules are not available in Linux. Therefore, you must find a way to provide those modules to each host computer. This procedure describes how to do that for nodes in an OpenShift Container Platform cluster.

When a kernel module is first deployed by following these instructions, the module is made available for the current kernel. If a new kernel is installed, the kmods-via-containers software will rebuild and deploy the module so a compatible version of that module is available with the new kernel.

The way that this feature is able to keep the module up to date on each node is by:

- Adding a systemd service to each node that starts at boot time to detect if a new kernel has been installed and
- If a new kernel is detected, the service rebuilds the module and installs it to the kernel

For information on the software needed for this procedure, see the kmods-via-containers github site.

A few important issues to keep in mind:

- This procedure is Technology Preview.
- Software tools and examples are not yet available in official RPM form and can only be obtained for now from unofficial github.com sites noted in the procedure.
- Third-party kernel modules you might add through these procedures are not supported by Red Hat.

- In this procedure, the software needed to build your kernel modules is deployed in a RHEL 8 container. Keep in mind that modules are rebuilt automatically on each node when that node gets a new kernel. For that reason, each node needs access to a yum repository that contains the kernel and related packages needed to rebuild the module. That content is best provided with a valid RHEL subscription.

22.1.3.1. Building and testing the kernel module container

Before deploying kernel modules to your OpenShift Container Platform cluster, you can test the process on a separate RHEL system. Gather the kernel module’s source code, the KVC framework, and the kmod-via-containers software. Then build and test the module. To do that on a RHEL 8 system, do the following:

Procedure

1. Register a RHEL 8 system:
   ```
   # subscription-manager register
   ```

2. Attach a subscription to the RHEL 8 system:
   ```
   # subscription-manager attach --auto
   ```

3. Install software that is required to build the software and container:
   ```
   # yum install podman make git -y
   ```

4. Clone the kmod-via-containers repository:
   a. Create a folder for the repository:
      ```
      $ mkdir kmods; cd kmods
      ```
   b. Clone the repository:
      ```
      $ git clone https://github.com/kmods-via-containers/kmods-via-containers
      ```

5. Install a KVC framework instance on your RHEL 8 build host to test the module. This adds a kmods-via-container systemd service and loads it:
   a. Change to the kmod-via-containers directory:
      ```
      $ cd kmods-via-containers/
      ```
   b. Install the KVC framework instance:
      ```
      $ sudo make install
      ```
   c. Reload the systemd manager configuration:
6. Get the kernel module source code. The source code might be used to build a third-party module that you do not have control over, but is supplied by others. You will need content similar to the content shown in the `kvc-simple-kmod` example that can be cloned to your system as follows:

```
$ cd .. ; git clone https://github.com/kmods-via-containers/kvc-simple-kmod
```

7. Edit the configuration file, `simple-kmod.conf` file, in this example, and change the name of the Dockerfile to `Dockerfile.rhel`:

   a. Change to the `kvc-simple-kmod` directory:

```
$ cd kvc-simple-kmod
```

   b. Rename the Dockerfile:

```
$ cat simple-kmod.conf
```

### Example Dockerfile

```
KMOD_CONTAINER_BUILD_CONTEXT="https://github.com/kmods-via-containers/kvc-
simple-kmod.git"
KMOD_CONTAINER_BUILD_FILE=Dockerfile.rhel
KMOD_SOFTWARE_VERSION=dd1a7d4
KMOD_NAMES="simple-kmod simple-procfs-kmod"
```

8. Create an instance of `kmods-via-containers@.service` for your kernel module, `simple-kmod` in this example:

```
$ sudo make install
```

9. Enable the `kmods-via-containers@.service` instance:

```
$ sudo kmods-via-containers build simple-kmod $(uname -r)
```

10. Enable and start the systemd service:

```
$ sudo systemctl enable kmods-via-containers@simple-kmod.service --now
```

   a. Review the service status:

```
$ sudo systemctl status kmods-via-containers@simple-kmod.service
```

### Example output

```
● kmods-via-containers@simple-kmod.service - Kmods Via Containers - simple-kmod
   Loaded: loaded (/etc/systemd/system/kmods-via-containers@.service; enabled; vendor preset: disabled)
   Active: active (exited) since Sun 2020-01-12 23:49:49 EST; 5s ago...
```
11. To confirm that the kernel modules are loaded, use the `lsmod` command to list the modules:

   ```bash
   $ lsmod | grep simple_
   
   Example output
   ```

   ```bash
   simple_procs_kmod     16384  0
   simple_kmod            16384  0
   ```

12. Optional. Use other methods to check that the `simple-kmod` example is working:

   - Look for a "Hello world" message in the kernel ring buffer with `dmesg`:

     ```bash
     $ dmesg | grep 'Hello world'
     
     Example output
     ```

     ```bash
     [ 6420.761332] Hello world from simple_kmod.
     ```

   - Check the value of `simple-procfs-kmod` in `/proc`:

     ```bash
     $ sudo cat /proc/simple-procfs-kmod
     
     Example output
     ```

     ```bash
     simple-procfs-kmod number = 0
     ```

   - Run the `spkut` command to get more information from the module:

     ```bash
     $ sudo spkut 44
     
     Example output
     ```

     ```bash
     KVC: wrapper simple-kmod for 4.18.0-147.3.1.el8_1.x86_64
     Running userspace wrapper using the kernel module container...
     + podman run -i --rm --privileged
     simple-kmod-dd1a7d4:4.18.0-147.3.1.el8_1.x86_64 spkut 44
     simple-procfs-kmod number = 0
     simple-procfs-kmod number = 44
     ```

Going forward, when the system boots this service will check if a new kernel is running. If there is a new kernel, the service builds a new version of the kernel module and then loads it. If the module is already built, it will just load it.

### 22.1.3.2. Provisioning a kernel module to OpenShift Container Platform

Depending on whether or not you must have the kernel module in place when OpenShift Container Platform cluster first boots, you can set up the kernel modules to be deployed in one of two ways:

- **Provision kernel modules at cluster install time (day-1)** You can create the content as a `MachineConfig` object and provide it to `openshift-install` by including it with a set of manifest files.
• **Provision kernel modules via Machine Config Operator (day-2)** If you can wait until the cluster is up and running to add your kernel module, you can deploy the kernel module software via the Machine Config Operator (MCO).

In either case, each node needs to be able to get the kernel packages and related software packages at the time that a new kernel is detected. There are a few ways you can set up each node to be able to obtain that content.

• Provide RHEL entitlements to each node.

• Get RHEL entitlements from an existing RHEL host, from the `/etc/pki/entitlement` directory and copy them to the same location as the other files you provide when you build your Ignition config.

• Inside the Dockerfile, add pointers to a `yum` repository containing the kernel and other packages. This must include new kernel packages as they are needed to match newly installed kernels.

22.1.3.2.1. **Provision kernel modules via a MachineConfig object**

By packaging kernel module software with a MachineConfig object, you can deliver that software to worker or control plane nodes at installation time or via the Machine Config Operator.

**Procedure**

1. Register a RHEL 8 system:
   ```bash
   # subscription-manager register
   ```

2. Attach a subscription to the RHEL 8 system:
   ```bash
   # subscription-manager attach --auto
   ```

3. Install software needed to build the software:
   ```bash
   # yum install podman make git -y
   ```

4. Create a directory to host the kernel module and tooling:
   ```bash
   $ mkdir kmods; cd kmods
   ```

5. Get the `kmods-via-containers` software:
   a. Clone the `kmods-via-containers` repository:
      ```bash
      $ git clone https://github.com/kmods-via-containers/kmods-via-containers
      ```
   b. Clone the `kvc-simple-kmod` repository:
      ```bash
      $ git clone https://github.com/kmods-via-containers/kvc-simple-kmod
      ```

6. Get your module software. In this example, `kvc-simple-kmod` is used.
7. Create a fakeroot directory and populate it with files that you want to deliver via Ignition, using the repositories cloned earlier:

   a. Create the directory:

   ```
   $ FAKEROOT=$(mktemp -d)
   ```

   b. Change to the `kmod-via-containers` directory:

   ```
   $ cd kmods-via-containers
   ```

   c. Install the KVC framework instance:

   ```
   $ make install DESTDIR=${FAKEROOT}/usr/local CONFDIR=${FAKEROOT}/etc/
   ```

   d. Change to the `kvc-simple-kmod` directory:

   ```
   $ cd ../kvc-simple-kmod
   ```

   e. Create the instance:

   ```
   $ make install DESTDIR=${FAKEROOT}/usr/local CONFDIR=${FAKEROOT}/etc/
   ```

8. Clone the fakeroot directory, replacing any symbolic links with copies of their targets, by running the following command:

   ```
   $ cd .. && rm -rf kmod-tree && cp -Lpr ${FAKEROOT} kmod-tree
   ```

9. Create a Butane config file, `99-simple-kmod.bu`, that embeds the kernel module tree and enables the systemd service.

   **NOTE**

   See “Creating machine configs with Butane” for information about Butane.

   ```
   variant: openshift
   version: 4.10.0
   metadata:
   name: 99-simple-kmod
   labels:
   machineconfiguration.openshift.io/role: worker
   storage:
   trees:
   - local: kmod-tree
   systemd:
   units:
   - name: kmods-via-containers@simple-kmod.service
     enabled: true
   ```

   To deploy on control plane nodes, change `worker` to `master`. To deploy on both control plane and worker nodes, perform the remainder of these instructions once for each node type.
Use Butane to generate a machine config YAML file, 99-simple-kmod.yaml, containing the files and configuration to be delivered:

```sh
$ butane 99-simple-kmod.bu --files-dir . -o 99-simple-kmod.yaml
```

If the cluster is not up yet, generate manifest files and add this file to the openshift directory. If the cluster is already running, apply the file as follows:

```sh
$ oc create -f 99-simple-kmod.yaml
```

Your nodes will start the kmods-via-containers@simple-kmod.service service and the kernel modules will be loaded.

To confirm that the kernel modules are loaded, you can log in to a node (using oc debug node/<openshift-node>, then chroot /host). To list the modules, use the lsmod command:

```sh
$ lsmod | grep simple_
```

**Example output**

```
simple_procfs_kmod     16384  0
simple_kmod            16384  0
```

### 22.1.4. Encrypting and mirroring disks during installation

During an OpenShift Container Platform installation, you can enable boot disk encryption and mirroring on the cluster nodes.

#### 22.1.4.1. About disk encryption

You can enable encryption for the boot disks on the control plane and compute nodes at installation time. OpenShift Container Platform supports the Trusted Platform Module (TPM) v2 and Tang encryption modes.

- **TPM v2:** This is the preferred mode. TPM v2 stores passphrases in a secure cryptoprocessor contained within a server. You can use this mode to prevent the boot disk data on a cluster node from being decrypted if the disk is removed from the server.

- **Tang:** Tang and Clevis are server and client components that enable network-bound disk encryption (NBDE). You can bind the boot disk data on your cluster nodes to one or more Tang servers. This prevents the data from being decrypted unless the nodes are on a secure network where the Tang servers can be accessed. Clevis is an automated decryption framework that is used to implement the decryption on the client side.

**IMPORTANT**

The use of the Tang encryption mode to encrypt your disks is only supported for bare metal and vSphere installations on user-provisioned infrastructure.
NOTE

On previous versions of Red Hat Enterprise Linux CoreOS (RHCOS), disk encryption was configured by specifying `/etc/clevis.json` in the Ignition config. That file is not supported in clusters created with OpenShift Container Platform 4.7 or above, and disk encryption should be configured by using the following procedure.

When the TPM v2 or Tang encryption modes are enabled, the RHCOS boot disks are encrypted using the LUKS2 format.

This feature:

- Is available for installer-provisioned infrastructure and user-provisioned infrastructure deployments
- Is supported on Red Hat Enterprise Linux CoreOS (RHCOS) systems only
- Sets up disk encryption during the manifest installation phase so all data written to disk, from first boot forward, is encrypted
- Requires no user intervention for providing passphrases
- Uses AES-256-XTS encryption, or AES-256-CBC if FIPS mode is enabled

22.1.4.1.1. Configuring an encryption threshold

In OpenShift Container Platform, you can specify a requirement for more than one Tang server. You can also configure the TPM v2 and Tang encryption modes simultaneously, so that the boot disk data can be decrypted only if the TPM secure cryptoprocessor is present and the Tang servers can be accessed over a secure network.

You can use the `threshold` attribute in your Butane configuration to define the minimum number of TPM v2 and Tang encryption conditions that must be met for decryption to occur. The threshold is met when the stated value is reached through any combination of the declared conditions. For example, the `threshold` value of 2 in the following configuration can be reached by accessing the two Tang servers, or by accessing the TPM secure cryptoprocessor and one of the Tang servers:

Example Butane configuration for disk encryption

```
variant: openshift
version: 4.10.0
metadata:
  name: worker-storage
  labels:
    machineconfiguration.openshift.io/role: worker
boot_device:
layout: x86_64
luks:
tpm2: true
  tang: 2
  - url: http://tang1.example.com:7500
    thumbprint: jwGN5tRFK-kF6piX89ssF3khxxX
  - url: http://tang2.example.com:7500
    thumbprint: VCJsvZFjBSIH5ldw78rOqr7h2ZF
```
1 Include this field if you want to use a Trusted Platform Module (TPM) to encrypt the root file system.

2 Include this section if you want to use one or more Tang servers.

3 Specify the minimum number of TPM v2 and Tang encryption conditions that must be met for decryption to occur.

IMPORTANT
The default threshold value is 1. If you include multiple encryption conditions in your configuration but do not specify a threshold, decryption can occur if any of the conditions are met.

NOTE
If you require both TPM v2 and Tang for decryption, the value of the threshold attribute must equal the total number of stated Tang servers plus one. If the threshold value is lower, it is possible for the threshold to be reached by using one of the encryption modes only. For example, if tpm2 is set to true and you specify two Tang servers, a threshold of 2 can be met by accessing the two Tang servers even if the TPM secure cryptoprocessor is not available.

22.1.4.2. About disk mirroring

During OpenShift Container Platform installation on control plane and worker nodes, you can enable mirroring of the boot and other disks to two or more redundant storage devices. A node continues to function after storage device failure as long as one device remains available.

Mirroring does not support replacement of a failed disk. To restore the mirror to a pristine, non-degraded state, reprovision the node.

NOTE
Mirroring is available only for user-provisioned infrastructure deployments on RHCOS systems. Mirroring support is available on x86_64 nodes booted with BIOS or UEFI and on ppc64le nodes.

22.1.4.3. Configuring disk encryption and mirroring

You can enable and configure encryption and mirroring during an OpenShift Container Platform installation.

Prerequisites

- You have downloaded the OpenShift Container Platform installation program on your installation node.
- You installed Butane on your installation node.
NOTE

Butane is a command-line utility that OpenShift Container Platform uses to provide convenient, short-hand syntax for writing machine configs, as well as for performing additional validation of machine configs. For more information, see the Creating machine configs with Butane section.

- You have access to a Red Hat Enterprise Linux (RHEL) 8 machine that can be used to generate a thumbprint of the Tang exchange key.

Procedure

1. If you want to use TPM v2 to encrypt your cluster, check to see if TPM v2 encryption needs to be enabled in the BIOS on each node. This is required on most Dell systems. Check the manual for your computer.

2. If you want to use Tang to encrypt your cluster, follow these preparatory steps:
   a. Set up a Tang server or access an existing one. See Network-bound disk encryption for instructions.
   b. Install the clevis package on a RHEL 8 machine, if it is not already installed:
      ```bash
      $ sudo yum install clevis
      ```
   c. On the RHEL 8 machine, run the following command to generate a thumbprint of the exchange key. Replace `http://tang.example.com:7500` with the URL of your Tang server:
      ```bash
      $ clevis-encrypt-tang '{"url":"http://tang.example.com:7500"}'} < /dev/null > /dev/null
      ```
      In this example, `tangd.socket` is listening on port 7500 on the Tang server.

   NOTE

   The `clevis-encrypt-tang` command is used in this step only to generate a thumbprint of the exchange key. No data is being passed to the command for encryption at this point, so `/dev/null` is provided as an input instead of plain text. The encrypted output is also sent to `/dev/null`, because it is not required for this procedure.

Example output

The advertisement contains the following signing keys:

PLJ NyRdGw03zI RoGjQYMahSZGu9

The thumbprint of the exchange key.

When the Do you wish to trust these keys? [ynYN] prompt displays, type Y.
NOTE

RHEL 8 provides Clevis version 15, which uses the SHA-1 hash algorithm to generate thumbprints. Some other distributions provide Clevis version 17 or later, which use the SHA-256 hash algorithm for thumbprints. You must use a Clevis version that uses SHA-1 to create the thumbprint, to prevent Clevis binding issues when you install Red Hat Enterprise Linux CoreOS (RHCOS) on your OpenShift Container Platform cluster nodes.

d. If the nodes are configured with static IP addressing, run `coreos-installer iso customize --dest-karg-append` or use the `coreos-installer --append-karg` option when installing RHCOS nodes to set the IP address of the installed system. Append the `ip=` and other arguments needed for your network.

IMPORTANT

Some methods for configuring static IPs do not affect the initramfs after the first boot and will not work with Tang encryption. These include the `coreos-installer --copy-network` option, the `coreos-installer iso customize --network-keyfile` option, and the `coreos-installer pxe customize --network-keyfile` option, as well as adding `ip=` arguments to the kernel command line of the live ISO or PXE image during installation. Incorrect static IP configuration causes the second boot of the node to fail.

3. On your installation node, change to the directory that contains the installation program and generate the Kubernetes manifests for the cluster:

   ```bash
   $ ./openshift-install create manifests --dir <installation_directory>  
   ```

   Replace `<installation_directory>` with the path to the directory that you want to store the installation files in.

4. Create a Butane config that configures disk encryption, mirroring, or both. For example, to configure storage for compute nodes, create a `$HOME/clusterconfig/worker-storage.bu` file.

   **Butane config example for a boot device**

   ```yaml
   variant: openshift
   version: 4.10.0
   metadata:
     name: worker-storage
     labels:
       machineconfiguration.openshift.io/role: worker
   boot_device:
     layout: x86_64
     luks:
     tpm2: true
     tang:
       - url: http://tang.example.com:7500
       thumbprint: PLjNyRdGw03zlRoGjQYMahSZGu
     threshold: 1
     mirror: 1
   ```
For control plane configurations, replace worker with master in both of these locations.

On ppc64le nodes, set this field to ppc64le. On all other nodes, this field can be omitted.

Include this section if you want to encrypt the root file system. For more details, see the About disk encryption section.

Include this field if you want to use a Trusted Platform Module (TPM) to encrypt the root file system.

Include this section if you want to use one or more Tang servers.

Specify the URL of a Tang server. In this example, tangd.socket is listening on port 7500 on the Tang server.

Specify the exchange key thumbprint, which was generated in a preceding step.

Specify the minimum number of TPM v2 and Tang encryption conditions that must be met for decryption to occur. The default value is 1. For more information on this topic, see the Configuring an encryption threshold section.

Include this section if you want to mirror the boot disk. For more details, see About disk mirroring.

List all disk devices that should be included in the boot disk mirror, including the disk that RHCOS will be installed onto.

Include this directive to enable FIPS mode on your cluster.

IMPORTANT

If you are configuring nodes to use both disk encryption and mirroring, both features must be configured in the same Butane config. In addition, if you are configuring disk encryption on a node with FIPS mode enabled, you must include the fips directive in the same Butane config, even if FIPS mode is also enabled in a separate manifest.

5. Create a control plane or compute node manifest from the corresponding Butane config and save it to the `<installation_directory>/openshift` directory. For example, to create a manifest for the compute nodes, run the following command:

   $ butane $HOME/clusterconfig/worker-storage.bu -o <installation_directory>/openshift/99-worker-storage.yaml

   Repeat this step for each node type that requires disk encryption or mirroring.

6. Save the Butane configs in case you need to update the manifests in the future.
7. Continue with the remainder of the OpenShift Container Platform installation.

**TIP**

You can monitor the console log on the RHCOS nodes during installation for error messages relating to disk encryption or mirroring.

**IMPORTANT**

If you configure additional data partitions, they will not be encrypted unless encryption is explicitly requested.

**Verification**

After installing OpenShift Container Platform, you can verify if boot disk encryption or mirroring is enabled on the cluster nodes.

1. From the installation host, access a cluster node by using a debug pod:
   
   a. Start a debug pod for the node. The following example starts a debug pod for the `compute-1` node:

   ```bash
   $ oc debug node/compute-1
   ```

   b. Set `/host` as the root directory within the debug shell. The debug pod mounts the root file system of the node in `/host` within the pod. By changing the root directory to `/host`, you can run binaries contained in the executable paths on the node:

   ```bash
   # chroot /host
   ```

   **NOTE**

   OpenShift Container Platform cluster nodes running Red Hat Enterprise Linux CoreOS (RHCOS) are immutable and rely on Operators to apply cluster changes. Accessing cluster nodes using SSH is not recommended. However, if the OpenShift Container Platform API is not available, or `kubelet` is not properly functioning on the target node, `oc` operations will be impacted. In such situations, it is possible to access nodes using `ssh core@<node>.<cluster_name>.<base_domain>` instead.

2. If you configured boot disk encryption, verify if it is enabled:

   a. From the debug shell, review the status of the root mapping on the node:

   ```bash
   # cryptsetup status root
   ```

   **Example output**

   ```bash
   /dev/mapper/root is active and is in use.
   type:     LUKS2
   cipher:   aes-xts-plain64
   keysize:  512 bits
   key location: keyring
   ```
The encryption format. When the TPM v2 or Tang encryption modes are enabled, the RHCOS boot disks are encrypted using the LUKS2 format.

The encryption algorithm used to encrypt the LUKS2 volume. The **aes-cbc-essiv:sha256** cipher is used if FIPS mode is enabled.

The device that contains the encrypted LUKS2 volume. If mirroring is enabled, the value will represent a software mirror device, for example `/dev/md126`.

b. List the Clevis plug-ins that are bound to the encrypted device:

```
# clevis luks list -d /dev/sda4
```

Specify the device that is listed in the `device` field in the output of the preceding step.

**Example output**

```
1: sss {'t':1,'pins':{'tang':[{'url':'http://tang.example.com:7500'}]}}
```

In the example output, the Tang plug-in is used by the Shamir’s Secret Sharing (SSS) Clevis plug-in for the `/dev/sda4` device.

3. If you configured mirroring, verify if it is enabled:
   a. From the debug shell, list the software RAID devices on the node:

```
# cat /proc/mdstat
```

**Example output**

```
Personalities : [raid1]
md126 : active raid1 sdb3[1] sda3[0] 393152 blocks super 1.0 [2/2] [UU]

md127 : active raid1 sda4[0] sdb4[1] 51869632 blocks super 1.2 [2/2] [UU]

unused devices: <none>
```

In the example, the `/dev/md126` software RAID mirror device uses the `/dev/sda3` and `/dev/sdb3` disk devices on the cluster node.

In the example, the `/dev/md127` software RAID mirror device uses the `/dev/sda4` and `/dev/sdb4` disk devices on the cluster node.
b. Review the details of each of the software RAID devices listed in the output of the preceding command. The following example lists the details of the `/dev/md126` device:

```
# mdadm --detail /dev/md126
```

**Example output**

```
/dev/md126:
   Version : 1.0
   Creation Time : Wed Jul  7 11:07:36 2021
   Raid Level : raid1
   Array Size : 393152 (383.94 MiB 402.59 MB)
   Used Dev Size : 393152 (383.94 MiB 402.59 MB)
   Raid Devices : 2
   Total Devices : 2
   Persistence : Superblock is persistent
   State : clean
   Active Devices : 2
   Working Devices : 2
   Failed Devices : 0
   Spare Devices : 0
   Consistency Policy : resync
   Name : any:md-boot
   UUID : ccfa3801:c520e0b5:2bee2755:69043055
   Events : 19

   Number  Major  Minor  RaidDevice State
   0     252      3        0    active sync   /dev/sda3
   1     252      19        1    active sync   /dev/sdb3
```

1. Specifies the RAID level of the device. `raid1` indicates RAID 1 disk mirroring.
2. Specifies the state of the RAID device.
3. States the number of underlying disk devices that are active and working.
4. States the number of underlying disk devices that are in a failed state.
5. The name of the software RAID device.
6. Provides information about the underlying disk devices that are used by the software RAID device.
7. Provides information about the underlying disk devices that are used by the software RAID device.

---

c. List the file systems that are mounted on the software RAID devices:

```
# mount | grep /dev/md
```

**Example output**
In the example output, the /boot file system is mounted on the /dev/md126 software RAID device and the root file system is mounted on /dev/md127.

4. Repeat the verification steps for each OpenShift Container Platform node type.

Additional resources

- For more information about the TPM v2 and Tang encryption modes, see Configuring automated unlocking of encrypted volumes using policy-based decryption.

22.1.4.4. Configuring a RAID-enabled data volume

You can enable software RAID partitioning to provide an external data volume. OpenShift Container Platform supports RAID 0, RAID 1, RAID 4, RAID 5, RAID 6, and RAID 10 for data protection and fault tolerance. See “About disk mirroring” for more details.

Prerequisites

- You have downloaded the OpenShift Container Platform installation program on your installation node.

- You have installed Butane on your installation node.
NOTE

Butane is a command-line utility that OpenShift Container Platform uses to provide convenient, short-hand syntax for writing machine configs, as well as for performing additional validation of machine configs. For more information, see the Creating machine configs with Butane section.

Procedure

1. Create a Butane config that configures a data volume by using software RAID.

   - To configure a data volume with RAID 1 on the same disks that are used for a mirrored boot disk, create a `$HOME/clusterconfig/raid1-storage.bu` file, for example:

```
RAID 1 on mirrored boot disk

variant: openshift
version: 4.10.0
metadata:
  name: raid1-storage
  labels:
    machineconfiguration.openshift.io/role: worker
boot_device:
  mirror:
    devices:
      - /dev/sda
      - /dev/sdb
storage:
  disks:
    - device: /dev/sda
      partitions:
        - label: root-1
          size_mib: 25000
        - label: var-1
        - device: /dev/sdb
      partitions:
        - label: root-2
          size_mib: 25000
        - label: var-2
    raid:
      - name: md-var
        level: raid1
        devices:
          - /dev/disk/by-partlabel/var-1
          - /dev/disk/by-partlabel/var-2
    filesystems:
      - device: /dev/md/md-var
        path: /var
        format: xfs
        wipe_filesystem: true
        with_mount_unit: true
```

When adding a data partition to the boot disk, a minimum value of 25000 mebibytes is recommended. If no value is specified, or if the specified value is smaller than the recommended minimum, the resulting root file system will be too small, and future
reinstalls of RHCOS might overwrite the beginning of the data partition.

- To configure a data volume with RAID 1 on secondary disks, create a
  `$HOME/clusterconfig/raid1-alt-storage.bu` file, for example:

RAID 1 on secondary disks

```yaml
variant: openshift
version: 4.10.0
metadata:
  name: raid1-alt-storage
  labels:
    machineconfiguration.openshift.io/role: worker
storage:
  disks:
    - device: /dev/sdc
      wipe_table: true
      partitions:
        - label: data-1
        - device: /dev/sdd
          wipe_table: true
          partitions:
            - label: data-2
  raid:
    - name: md-var-lib-containers
      level: raid1
      devices:
        - /dev/disk/by-partlabel/data-1
        - /dev/disk/by-partlabel/data-2
  filesystems:
    - device: /dev/md/md-var-lib-containers
      path: /var/lib/containers
      format: xfs
      wipe_filesystem: true
      with_mount_unit: true
```

2. Create a RAID manifest from the Butane config you created in the previous step and save it to the `<installation_directory>/openshift` directory. For example, to create a manifest for the compute nodes, run the following command:

```bash
$ butane $HOME/clusterconfig/<butane_config>.bu -o <installation_directory>/openshift/<manifest_name>.yaml
```

   1 Replace `<butane_config>` and `<manifest_name>` with the file names from the previous step. For example, `raid1-alt-storage.bu` and `raid1-alt-storage.yaml` for secondary disks.

3. Save the Butane config in case you need to update the manifest in the future.

4. Continue with the remainder of the OpenShift Container Platform installation.

22.1.5. Configuring chrony time service
You can set the time server and related settings used by the chrony time service (chronyd) by modifying the contents of the `chrony.conf` file and passing those contents to your nodes as a machine config.

**Procedure**

1. Create a Butane config including the contents of the `chrony.conf` file. For example, to configure chrony on worker nodes, create a `99-worker-chrony.bu` file.

   **NOTE**

   See “Creating machine configs with Butane” for information about Butane.

   ```yaml
   variant: openshift
   version: 4.10.0
   metadata:
     name: 99-worker-chrony
     labels:
       machineconfiguration.openshift.io/role: worker
   storage:
     files:
     - path: /etc/chrony.conf
       mode: 0644
       overwrite: true
       inline: |
         pool 0.rhel.pool.ntp.org iburst
         driftfile /var/lib/chrony/drift
         makestep 1.0 3
         rtsync
         logdir /var/log/chrony
   
   On control plane nodes, substitute `master` for `worker` in both of these locations.

   Specify an octal value mode for the `mode` field in the machine config file. After creating the file and applying the changes, the `mode` is converted to a decimal value. You can check the YAML file with the command `oc get mc <mc-name> -o yaml`.

   Specify any valid, reachable time source, such as the one provided by your DHCP server. Alternately, you can specify any of the following NTP servers: `1.rhel.pool.ntp.org`, `2.rhel.pool.ntp.org`, or `3.rhel.pool.ntp.org`.

2. Use Butane to generate a `MachineConfig` object file, `99-worker-chrony.yaml`, containing the configuration to be delivered to the nodes:

   ```bash
   $ butane 99-worker-chrony.bu -o 99-worker-chrony.yaml
   ```

3. Apply the configurations in one of two ways:

   - If the cluster is not running yet, after you generate manifest files, add the `MachineConfig` object file to the `<installation_directory>/openshift` directory, and then continue to create the cluster.
If the cluster is already running, apply the file:
```
$ oc apply -f ./99-worker-chrony.yaml
```

22.1.6. Additional resources
- For information on Butane, see Creating machine configs with Butane.
- For information on FIPS support, see Support for FIPS cryptography.

22.2. CONFIGURING YOUR FIREWALL

If you use a firewall, you must configure it so that OpenShift Container Platform can access the sites that it requires to function. You must always grant access to some sites, and you grant access to more if you use Red Hat Insights, the Telemetry service, a cloud to host your cluster, and certain build strategies.

22.2.1. Configuring your firewall for OpenShift Container Platform

Before you install OpenShift Container Platform, you must configure your firewall to grant access to the sites that OpenShift Container Platform requires.

There are no special configuration considerations for services running on only controller nodes versus worker nodes.

**Procedure**

1. Allowlist the following registry URLs:

<table>
<thead>
<tr>
<th>URL</th>
<th>Port</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>registry.redhat.io</td>
<td>443, 80</td>
<td>Provides core container images</td>
</tr>
<tr>
<td>quay.io</td>
<td>443, 80</td>
<td>Provides core container images</td>
</tr>
<tr>
<td>cdn.quay.io</td>
<td>443, 80</td>
<td>Provides core container images</td>
</tr>
<tr>
<td>cdn01.quay.io</td>
<td>443, 80</td>
<td>Provides core container images</td>
</tr>
<tr>
<td>cdn02.quay.io</td>
<td>443, 80</td>
<td>Provides core container images</td>
</tr>
<tr>
<td>cdn03.quay.io</td>
<td>443, 80</td>
<td>Provides core container images</td>
</tr>
<tr>
<td>sso.redhat.com</td>
<td>443, 80</td>
<td>The <a href="https://console.redhat.com/openshift">https://console.redhat.com/openshift</a> site uses authentication from sso.redhat.com</td>
</tr>
<tr>
<td>rhcos-redirector.apps.art.xq1c.p1.openshiftapps.com</td>
<td>443, 80</td>
<td>Provides Red Hat Enterprise Linux CoreOS (RHCOS) images</td>
</tr>
</tbody>
</table>
You can use the wildcards *.quay.io and *.openshiftapps.com instead of cdn0[1-3].quay.io and rhcos-redirector.apps.art.xq1c.p1.openshiftapps.com in your allowlist. When you add a site, such as quay.io, to your allowlist, do not add a wildcard entry, such as *.quay.io, to your denylist. In most cases, image registries use a content delivery network (CDN) to serve images. If a firewall blocks access, then image downloads are denied when the initial download request is redirected to a hostname such as cdn01.quay.io.

2. Allowlist any site that provides resources for a language or framework that your builds require.

3. If you do not disable Telemetry, you must grant access to the following URLs to access Red Hat Insights:

<table>
<thead>
<tr>
<th>URL</th>
<th>Port</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>cert-api.access.redhat.com</td>
<td>443, 80</td>
<td>Required for Telemetry</td>
</tr>
<tr>
<td>api.access.redhat.com</td>
<td>443, 80</td>
<td>Required for Telemetry</td>
</tr>
<tr>
<td>infogw.api.openshift.com</td>
<td>443, 80</td>
<td>Required for Telemetry</td>
</tr>
<tr>
<td>console.redhat.com/api/ingress,</td>
<td>443, 80</td>
<td>Required for Telemetry</td>
</tr>
<tr>
<td>cloud.redhat.com/api/ingress</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

4. If you use Alibaba Cloud, Amazon Web Services (AWS), Microsoft Azure, or Google Cloud Platform (GCP) to host your cluster, you must grant access to the URLs that provide the cloud provider API and DNS for that cloud:

<table>
<thead>
<tr>
<th>Cloud</th>
<th>URL</th>
<th>Port</th>
<th>Function</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alibaba</td>
<td>*.aliyuncs.com</td>
<td>443, 80</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>Required to access Alibaba Cloud services and resources. Review the Alibaba endpoints_config.go file to determine the exact endpoints to allow for the regions that you use.</td>
</tr>
<tr>
<td>AWS</td>
<td>*.amazonaws.com</td>
<td>443, 80</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>Required to access AWS services and resources. Review the AWS Service Endpoints in the AWS documentation to determine the exact endpoints to allow for the regions that you use.</td>
</tr>
<tr>
<td>GCP</td>
<td>*.googleapis.com</td>
<td>443, 80</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>Required to access GCP services and resources. Review Cloud Endpoints in the GCP documentation to determine the endpoints to allow for your APIs.</td>
</tr>
<tr>
<td></td>
<td>accounts.google.com</td>
<td>443, 80</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td>Required to access your GCP account.</td>
</tr>
<tr>
<td>Cloud</td>
<td>URL</td>
<td>Port</td>
<td>Function</td>
<td></td>
</tr>
<tr>
<td>------------</td>
<td>----------------------------</td>
<td>----------</td>
<td>---------------------------------------------------------------------------------------------------</td>
<td></td>
</tr>
<tr>
<td>Azure</td>
<td>management.azure.com</td>
<td>443, 80</td>
<td>Required to access Azure services and resources. Review the Azure REST API reference in the Azure documentation to determine the endpoints to allow for your APIs.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>*.blob.core.windows.net</td>
<td>443, 80</td>
<td>Required to download Ignition files.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>login.microsoftonline.com</td>
<td>443, 80</td>
<td>Required to access Azure services and resources. Review the Azure REST API reference in the Azure documentation to determine the endpoints to allow for your APIs.</td>
<td></td>
</tr>
</tbody>
</table>

5. Allowlist the following URLs:

<table>
<thead>
<tr>
<th>URL</th>
<th>Port</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>mirror.openshift.com</td>
<td>443, 80</td>
<td>Required to access mirrored installation content and images. This site is also a source of release image signatures, although the Cluster Version Operator needs only a single functioning source.</td>
</tr>
<tr>
<td>storage.googleapis.com/openshift-release</td>
<td>443, 80</td>
<td>A source of release image signatures, although the Cluster Version Operator needs only a single functioning source.</td>
</tr>
<tr>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>443, 80</td>
<td>Required to access the default cluster routes unless you set an ingress wildcard during installation.</td>
</tr>
<tr>
<td>quayio-production-s3.s3.amazonaws.com</td>
<td>443, 80</td>
<td>Required to access Quay image content in AWS.</td>
</tr>
<tr>
<td>api.openshift.com</td>
<td>443, 80</td>
<td>Required both for your cluster token and to check if updates are available for the cluster.</td>
</tr>
<tr>
<td>art-rhcos-ci.s3.amazonaws.com</td>
<td>443, 80</td>
<td>Required to download Red Hat Enterprise Linux CoreOS (RHCOS) images.</td>
</tr>
<tr>
<td>console.redhat.com/openshift</td>
<td>443, 80</td>
<td>Required for your cluster token.</td>
</tr>
</tbody>
</table>
Operators require route access to perform health checks. Specifically, the authentication and web console Operators connect to two routes to verify that the routes work. If you are the cluster administrator and do not want to allow `*.apps.<cluster_name>.<base_domain>`, then allow these routes:

- `oauth-openshift.apps.<cluster_name>.<base_domain>`
- `console-openshift-console.apps.<cluster_name>.<base_domain>`, or the hostname that is specified in the `spec.route.hostname` field of the `consoles.operator/cluster` object if the field is not empty.

6. Allowlist the following URLs for optional third-party content:

<table>
<thead>
<tr>
<th>URL</th>
<th>Port</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>registry.connect.redhat.com</code></td>
<td>443, 80</td>
<td>Required for all third-party images and certified operators.</td>
</tr>
<tr>
<td><code>rhc4tp-prod-z8cxfl-image-registry-us-east-1-evenkylefocxqvorfk.s3.dualstack.us-east-1.amazonaws.com</code></td>
<td>443, 80</td>
<td>Provides access to container images hosted on <code>registry.connect.redhat.com</code></td>
</tr>
<tr>
<td><code>oso-rhc4tp-docker-registry.s3-us-west-2.amazonaws.com</code></td>
<td>443, 80</td>
<td>Required for Sonatype Nexus, F5 Big IP operators.</td>
</tr>
</tbody>
</table>

7. If you use a default Red Hat Network Time Protocol (NTP) server allow the following URLs:

- `1.rhel.pool.ntp.org`
- `2.rhel.pool.ntp.org`
- `3.rhel.pool.ntp.org`

NOTE

If you do not use a default Red Hat NTP server, verify the NTP server for your platform and allow it in your firewall.
CHAPTER 23. VALIDATING AN INSTALLATION

You can check the status of an OpenShift Container Platform cluster after an installation by following the procedures in this document.

23.1. REVIEWING THE INSTALLATION LOG

You can review a summary of an installation in the OpenShift Container Platform installation log. If an installation succeeds, the information required to access the cluster is included in the log.

Prerequisites

- You have access to the installation host.

Procedure

Review the .openshift_install.log log file in the installation directory on your installation host:

```
$ cat <install_dir>/openshift_install.log
```

Example output

Cluster credentials are included at the end of the log if the installation is successful, as outlined in the following example:

```
... time="2020-12-03T09:50:47Z" level=info msg="Install complete!"
    time="2020-12-03T09:50:47Z" level=info msg="To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'"
    time="2020-12-03T09:50:47Z" level=info msg="Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com"
    time="2020-12-03T09:50:47Z" level=info msg="Login to the console with user: \"kubeadmin\", and password: \"6zYIx-ckbW3-4d2Ne-IWvDF\""
    time="2020-12-03T09:50:47Z" level=debug msg="Time elapsed per stage:"
    time="2020-12-03T09:50:47Z" level=debug msg="Infrastructure: 6m45s"
    time="2020-12-03T09:50:47Z" level=debug msg="Bootstrap Complete: 11m30s"
    time="2020-12-03T09:50:47Z" level=debug msg="Bootstrap Destroy: 1m5s"
    time="2020-12-03T09:50:47Z" level=debug msg="Cluster Operators: 17m31s"
    time="2020-12-03T09:50:47Z" level=info msg="Time elapsed: 37m26s"
```

23.2. VIEWING THE IMAGE PULL SOURCE

For clusters with unrestricted network connectivity, you can view the source of your pulled images by using a command on a node, such as `crictl images`.

However, for disconnected installations, to view the source of pulled images, you must review the CRI-O logs to locate the `Trying to access` log entry, as shown in the following procedure. Other methods to view the image pull source, such as the `crictl images` command, show the non-mirrored image name, even though the image is pulled from the mirrored location.

Prerequisites

- You have access to the cluster as a user with the `cluster-admin` role.
Procedure

- Review the CRI-O logs for a master or worker node:

  ```
  $ oc adm node-logs <node_name> -u crio
  ```

Example output

The **Trying to access** log entry indicates where the image is being pulled from.

```markdown
... Mar 17 02:52:50 ip-10-0-138-140.ec2.internal crio[1366]: time="2021-08-05 10:33:21.594930907Z" level=info msg="Pulling image: quay.io/openshift-release-dev/ocp-release:4.10.0-ppc64le" id=abcd713b-d0e1-4844-ac1c-474c5b60c07c name=/runtime.v1alpha2.ImageService/PullImage
Mar 17 02:52:50 ip-10-0-138-140.ec2.internal crio[1484]: time="2021-03-17 02:52:50.194341109Z" level=info msg="Trying to access \"li0317gcp1.mirror-registry.qe.gcp.devcluster.openshift.com:5000/ocp/release@sha256:1926eae7cacb9c00f142ec9b00628970e974284b6ddaf9a6a086cb9a7a6c31\""
Mar 17 02:52:50 ip-10-0-138-140.ec2.internal crio[1484]: time="2021-03-17 02:52:50.226788351Z" level=info msg="Trying to access \"li0317gcp1.mirror-registry.qe.gcp.devcluster.openshift.com:5000/ocp/release@sha256:1926eae7cacb9c00f142ec9b00628970e974284b6ddaf9a6a086cb9a7a6c31\"
...```

The log might show the image pull source twice, as shown in the preceding example.

If your **ImageContentSourcePolicy** object lists multiple mirrors, OpenShift Container Platform attempts to pull the images in the order listed in the configuration, for example:

```markdown
Trying to access \"li0317gcp1.mirror-registry.qe.gcp.devcluster.openshift.com:5000/ocp/release@sha256:1926eae7cacb9c00f142ec9b00628970e974284b6ddaf9a6a086cb9a7a6c31\"
Trying to access \"li0317gcp2.mirror-registry.qe.gcp.devcluster.openshift.com:5000/ocp/release@sha256:1926eae7cacb9c00f142ec9b00628970e974284b6ddaf9a6a086cb9a7a6c31\"
```

23.3. GETTING CLUSTER VERSION, STATUS, AND UPDATE DETAILS

You can view the cluster version and status by running the `oc get clusterversion` command. If the status shows that the installation is still progressing, you can review the status of the Operators for more information.

You can also list the current update channel and review the available cluster updates.

Prerequisites

- You have access to the cluster as a user with the `cluster-admin` role.
- You have installed the OpenShift CLI (`oc`).

Procedure

1. Obtain the cluster version and overall status:
$ oc get clusterversion

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>SINCE</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>4.6.4</td>
<td>True</td>
<td>False</td>
<td>6m25s</td>
<td>Cluster version is 4.6.4</td>
</tr>
</tbody>
</table>

The example output indicates that the cluster has been installed successfully.

2. If the cluster status indicates that the installation is still progressing, you can obtain more detailed progress information by checking the status of the Operators:

   $ oc get clusteroperators.config.openshift.io

3. View a detailed summary of cluster specifications, update availability, and update history:

   $ oc describe clusterversion

4. List the current update channel:

   $ oc get clusterversion -o jsonpath='{.items[0].spec}{"\n"}'

   **Example output**

   ```json
   {"channel":"stable-4.6","clusterID":"245539c1-72a3-41aa-9cec-72ed8cf25c5c"}
   ```

5. Review the available cluster updates:

   $ oc adm upgrade

   **Example output**

   Cluster version is 4.6.4
   Updates:
   VERSION IMAGE
   4.6.6 quay.io/openshift-release-dev/ocp-release@sha256:c7e8f18e8116356701bd23ae3a23fb9892dd5ea66c8300662ef30563d7104f3

**Additional resources**

- See [Querying Operator status after installation](#) for more information about querying Operator status if your installation is still progressing.
- See [Troubleshooting Operator issues](#) for information about investigating issues with Operators.
- See [Updating a cluster between minor versions](#) for more information on updating your cluster.
- See [OpenShift Container Platform upgrade channels and releases](#) for an overview about upgrade release channels.
23.4. QUERYING THE STATUS OF THE CLUSTER NODES BY USING THE CLI

You can verify the status of the cluster nodes after an installation.

Prerequisites

- You have access to the cluster as a user with the `cluster-admin` role.
- You have installed the OpenShift CLI (`oc`).

Procedure

1. List the status of the cluster nodes. Verify that the output lists all of the expected control plane and compute nodes and that each node has a `Ready` status:

   ```bash
   $ oc get nodes
   NAME                          STATUS   ROLES    AGE   VERSION
   compute-1.example.com         Ready    worker   33m   v1.23.0
   control-plane-1.example.com   Ready    master   41m   v1.23.0
   control-plane-2.example.com   Ready    master   45m   v1.23.0
   compute-2.example.com         Ready    worker   38m   v1.23.0
   compute-3.example.com         Ready    worker   33m   v1.23.0
   control-plane-3.example.com   Ready    master   41m   v1.23.0
   ```

2. Review CPU and memory resource availability for each cluster node:

   ```bash
   $ oc adm top nodes
   NAME                          CPU(cores)   CPU%   MEMORY(bytes)   MEMORY%
   compute-1.example.com         128m         8%     1132Mi          16%
   control-plane-1.example.com   801m         22%    3471Mi          23%
   control-plane-2.example.com   1718m        49%    6085Mi          40%
   compute-2.example.com         935m         62%    5178Mi          75%
   compute-3.example.com         111m         7%     1131Mi          16%
   control-plane-3.example.com   942m         26%    4100Mi          27%
   ```

Additional resources

- See [Verifying node health](#) for more details about reviewing node health and investigating node issues.

23.5. REVIEWING THE CLUSTER STATUS FROM THE OPENSHIFT CONTAINER PLATFORM WEB CONSOLE

You can review the following information in the **Overview** page in the OpenShift Container Platform web console:
- The general status of your cluster
- The status of the control plane, cluster Operators, and storage
- CPU, memory, file system, network transfer, and pod availability
- The API address of the cluster, the cluster ID, and the name of the provider
- Cluster version information
- Cluster update status, including details of the current update channel and available updates
- A cluster inventory detailing node, pod, storage class, and persistent volume claim (PVC) information
- A list of ongoing cluster activities and recent events

**Prerequisites**

- You have access to the cluster as a user with the `cluster-admin` role.

**Procedure**

1. In the Administrator perspective, navigate to Home → Overview.

**23.6. REVIEWING THE CLUSTER STATUS FROM RED HAT OPENSFHT CLUSTER MANAGER**

You can review detailed information about the status of your cluster in the OpenShift Cluster Manager.

**Prerequisites**

- You have access to the cluster as a user with the `cluster-admin` role.

**Procedure**

1. In the Administrator perspective, navigate to Home → Overview → Details → OpenShift Cluster Manager to open the Overview page for the cluster in OpenShift Cluster Manager.

    **NOTE**

    Alternatively, you can navigate to OpenShift Cluster Manager directly and select your cluster ID from the list of available clusters.

2. In the Overview page, review the following information about your cluster:

    - vCPU and memory availability and resource usage
    - The cluster ID, status, type, location, and the provider name
    - Node counts by node type
    - Cluster version details, the creation date of the cluster, and the name of the cluster owner
    - The life cycle support status of the cluster
• Subscription information, including the service level agreement (SLA) status, the subscription unit type, the production status of the cluster, the subscription obligation, and the service level

• A cluster history

3. Navigate to the **Observe** page to review the following information:

• A list of any issues that have been detected

• A list of alerts that are firing

• The cluster Operator status and version

• Cluster resource usage

4. Navigate to the **Insights** page to review the following information provided by Red Hat Insights:

• Potential issues that your cluster might be exposed to, categorized by risk level

• Health-check status by category

**Additional resources**

• See [Using Insights to identify issues with your cluster](#) for more information about reviewing potential issues with your cluster.

### 23.7. CHECKING CLUSTER RESOURCE AVAILABILITY AND UTILIZATION

OpenShift Container Platform provides a comprehensive set of monitoring dashboards that help you understand the state of cluster components.

In the **Administrator** perspective, you can access dashboards for core OpenShift Container Platform components, including:

• etcd

• Kubernetes compute resources

• Kubernetes network resources

• Prometheus

• Dashboards relating to cluster and node performance
Prerequisites

- You have access to the cluster as a user with the `cluster-admin` role.

Procedure

1. In the Administrator perspective in the OpenShift Container Platform web console, navigate to **Observe → Dashboards**.

2. Choose a dashboard in the **Dashboard** list. Some dashboards, such as the **etcd** dashboard, produce additional sub-menus when selected.

3. Optional: Select a time range for the graphs in the **Time Range** list.
   - Select a pre-defined time period.
   - Set a custom time range by selecting **Custom time range** in the **Time Range** list.
     a. Input or select the **From** and **To** dates and times.
     b. Click **Save** to save the custom time range.

4. Optional: Select a **Refresh Interval**

5. Hover over each of the graphs within a dashboard to display detailed information about specific items.

Additional resources

- See **Monitoring overview** for more information about the OpenShift Container Platform monitoring stack.
23.8. LISTING ALERTS THAT ARE FIRING

Alerts provide notifications when a set of defined conditions are true in an OpenShift Container Platform cluster. You can review the alerts that are firing in your cluster by using the Alerting UI in the OpenShift Container Platform web console.

Prerequisites

- You have access to the cluster as a user with the cluster-admin role.

Procedure

1. In the Administrator perspective, navigate to the Observe → Alerting → Alerts page.
2. Review the alerts that are firing, including their Severity, State, and Source.
3. Select an alert to view more detailed information in the Alert Details page.

Additional resources

- See Managing alerts for further details about alerting in OpenShift Container Platform.

23.9. NEXT STEPS

- See Troubleshooting installations if you experience issues when installing your cluster.
- After installing OpenShift Container Platform, you can further expand and customize your cluster.
CHAPTER 24. TROUBLESHOOTING INSTALLATION ISSUES

To assist in troubleshooting a failed OpenShift Container Platform installation, you can gather logs from the bootstrap and control plane, or master, machines. You can also get debug information from the installation program.

24.1. PREREQUISITES

- You attempted to install an OpenShift Container Platform cluster and the installation failed.

24.2. GATHERING LOGS FROM A FAILED INSTALLATION

If you gave an SSH key to your installation program, you can gather data about your failed installation.

NOTE

You use a different command to gather logs about an unsuccessful installation than to gather logs from a running cluster. If you must gather logs from a running cluster, use the `oc adm must-gather` command.

Prerequisites

- Your OpenShift Container Platform installation failed before the bootstrap process finished. The bootstrap node is running and accessible through SSH.
- The `sshd` process is active on your computer, and you provided the same SSH key to both the `sshd` process and the installation program.
- If you tried to install a cluster on infrastructure that you provisioned, you must have the fully qualified domain names of the bootstrap and control plane nodes.

Procedure

1. Generate the commands that are required to obtain the installation logs from the bootstrap and control plane machines:

   - If you used installer-provisioned infrastructure, change to the directory that contains the installation program and run the following command:

     ```
     ./openshift-install gather bootstrap --dir <installation_directory>  
     installation_directory is the directory you specified when you ran ./openshift-install create cluster. This directory contains the OpenShift Container Platform definition files that the installation program creates.
     ```

   - If you used infrastructure that you provisioned yourself, change to the directory that contains the installation program and run the following command:

     ```
     ./openshift-install gather bootstrap --dir <installation_directory> \  
     --bootstrap <bootstrap_address>  
     ```
For `installation_directory`, specify the same directory you specified when you ran 
`.openshift-install create cluster`. This directory contains the OpenShift Container
Platform definition files that the installation program creates.

<bootstrap_address> is the fully qualified domain name or IP address of the cluster’s bootstrap machine.

For each control plane, or master, machine in your cluster, replace
<master_*_address> with its fully qualified domain name or IP address.

NOTE
A default cluster contains three control plane machines. List all of your control plane machines as shown, no matter how many your cluster uses.

Example output
INFO Pulling debug logs from the bootstrap machine
INFO Bootstrap gather logs captured here "<installation_directory>/log-bundle-
<timestamp>.tar.gz"

If you open a Red Hat support case about your installation failure, include the compressed logs in the case.

24.3. MANUALLY GATHERING LOGS WITH SSH ACCESS TO YOUR HOST(S)

Manually gather logs in situations where must-gather or automated collection methods do not work.

IMPORTANT
By default, SSH access to the OpenShift Container Platform nodes is disabled on the Red Hat OpenStack Platform (RHOSP) based installations.

Prerequisites
- You must have SSH access to your host(s).

Procedure
1. Collect the `bootkube.service` service logs from the bootstrap host using the `journalctl`
command by running:

   $ journalctl -b -f -u bootkube.service

2. Collect the bootstrap host’s container logs using the podman logs. This is shown as a loop to get all of the container logs from the host:
$ for pod in $(sudo podman ps -a -q); do sudo podman logs $pod; done

3. Alternatively, collect the host’s container logs using the tail command by running:

   # tail -f /var/lib/containers/storage/overlay-containers/*/userdata/ctr.log

4. Collect the kubelet.service and crio.service service logs from the master and worker hosts using the journalctl command by running:

   $ journalctl -b -f -u kubelet.service -u crio.service

5. Collect the master and worker host container logs using the tail command by running:

   $ sudo tail -f /var/log/containers/*

**24.4. MANUALLY GATHERING LOGS WITHOUT SSH ACCESS TO YOUR HOST(S)**

Manually gather logs in situations where must-gather or automated collection methods do not work.

If you do not have SSH access to your node, you can access the systems journal to investigate what is happening on your host.

**Prerequisites**

- Your OpenShift Container Platform installation must be complete.
- Your API service is still functional.
- You have system administrator privileges.

**Procedure**

1. Access journald unit logs under /var/log by running:

   $ oc adm node-logs --role=master -u kubelet

2. Access host file paths under /var/log by running:

   $ oc adm node-logs --role=master --path=openshift-apiserver

**24.5. GETTING DEBUG INFORMATION FROM THE INSTALLATION PROGRAM**

You can use any of the following actions to get debug information from the installation program.

- Look at debug messages from a past installation in the hidden .openshift_install.log file. For example, enter:

  $ cat ~/<installation_directory>/openshift_install.log
For **installation_directory**, specify the same directory you specified when you ran `./openshift-install create cluster`.

- Change to the directory that contains the installation program and re-run it with `--log-level=debug`:
  
  ```
  $ ./openshift-install create cluster --dir <installation_directory> --log-level debug
  ```

  For **installation_directory**, specify the same directory you specified when you ran `./openshift-install create cluster`.

### 24.6. REINSTALLING THE OPENSHIFT CONTAINER PLATFORM CLUSTER

If you are unable to debug and resolve issues in the failed OpenShift Container Platform installation, consider installing a new OpenShift Container Platform cluster. Before starting the installation process again, you must complete thorough cleanup. For a user-provisioned infrastructure (UPI) installation, you must manually destroy the cluster and delete all associated resources. The following procedure is for an installer-provisioned infrastructure (IPI) installation.

**Procedure**

1. Destroy the cluster and remove all the resources associated with the cluster, including the hidden installer state files in the installation directory:

   ```
   $ ./openshift-install destroy cluster --dir <installation_directory>
   ```

   * **installation_directory** is the directory you specified when you ran `./openshift-install create cluster`. This directory contains the OpenShift Container Platform definition files that the installation program creates.

2. Before reinstalling the cluster, delete the installation directory:

   ```
   $ rm -rf <installation_directory>
   ```

3. Follow the procedure for installing a new OpenShift Container Platform cluster.

**Additional resources**

- [Installing an OpenShift Container Platform cluster](#)
CHAPTER 25. SUPPORT FOR FIPS CRYPTOGRAPHY

You can install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture.

For the Red Hat Enterprise Linux CoreOS (RHCOS) machines in your cluster, this change is applied when the machines are deployed based on the status of an option in the install-config.yaml file, which governs the cluster options that a user can change during cluster deployment. With Red Hat Enterprise Linux (RHEL) machines, you must enable FIPS mode when you install the operating system on the machines that you plan to use as worker machines. These configuration methods ensure that your cluster meet the requirements of a FIPS compliance audit: only FIPS Validated / Modules in Process cryptography packages are enabled before the initial system boot.

Because FIPS must be enabled before the operating system that your cluster uses boots for the first time, you cannot enable FIPS after you deploy a cluster.

25.1. FIPS VALIDATION IN OPENSIFT CONTAINER PLATFORM

OpenShift Container Platform uses certain FIPS Validated / Modules in Process modules within RHEL and RHCOS for the operating system components that it uses. See RHEL8 core crypto components. For example, when users SSH into OpenShift Container Platform clusters and containers, those connections are properly encrypted.

OpenShift Container Platform components are written in Go and built with Red Hat’s golang compiler. When you enable FIPS mode for your cluster, all OpenShift Container Platform components that require cryptographic signing call RHEL and RHCOS cryptographic libraries.

Table 25.1. FIPS mode attributes and limitations in OpenShift Container Platform 4.10

<table>
<thead>
<tr>
<th>Attributes</th>
<th>Limitations</th>
</tr>
</thead>
<tbody>
<tr>
<td>FIPS support in RHEL 8 and RHCOS operating systems.</td>
<td>The FIPS implementation does not offer a single function that both computes hash functions and validates the keys that are based on that hash. This limitation will continue to be evaluated and improved in future OpenShift Container Platform releases.</td>
</tr>
<tr>
<td>FIPS support in CRI-O runtimes.</td>
<td></td>
</tr>
<tr>
<td>FIPS support in OpenShift Container Platform services.</td>
<td></td>
</tr>
<tr>
<td>FIPS Validated / Modules in Process cryptographic module and algorithms that are obtained from RHEL 8 and RHCOS binaries and images.</td>
<td></td>
</tr>
<tr>
<td>Use of FIPS compatible golang compiler.</td>
<td>TLS FIPS support is not complete but is planned for future OpenShift Container Platform releases.</td>
</tr>
<tr>
<td>FIPS support across multiple architectures.</td>
<td>FIPS is currently only supported on OpenShift Container Platform deployments using the x86_64 architecture.</td>
</tr>
</tbody>
</table>

25.2. FIPS SUPPORT IN COMPONENTS THAT THE CLUSTER USES
Although the OpenShift Container Platform cluster itself uses FIPS Validated / Modules in Process modules, ensure that the systems that support your OpenShift Container Platform cluster use FIPS Validated / Modules in Process modules for cryptography.

25.2.1. etcd

To ensure that the secrets that are stored in etcd use FIPS Validated / Modules in Process encryption, boot the node in FIPS mode. After you install the cluster in FIPS mode, you can encrypt the etcd data by using the FIPS-approved aes cbc cryptographic algorithm.

25.2.2. Storage

For local storage, use RHEL-provided disk encryption or Container Native Storage that uses RHEL-provided disk encryption. By storing all data in volumes that use RHEL-provided disk encryption and enabling FIPS mode for your cluster, both data at rest and data in motion, or network data, are protected by FIPS Validated / Modules in Process encryption. You can configure your cluster to encrypt the root filesystem of each node, as described in Customizing nodes.

25.2.3. Runtimes

To ensure that containers know that they are running on a host that is using FIPS Validated / Modules in Process cryptography modules, use CRI-O to manage your runtimes. CRI-O supports FIPS mode, in that it configures the containers to know that they are running in FIPS mode.

25.3. INSTALLING A CLUSTER IN FIPS MODE

To install a cluster in FIPS mode, follow the instructions to install a customized cluster on your preferred infrastructure. Ensure that you set fips: true in the install-config.yaml file before you deploy your cluster.

- Amazon Web Services
- Microsoft Azure
- Bare metal
- Google Cloud Platform
- Red Hat OpenStack Platform (RHOSP)
- VMware vSphere

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.

To apply AES CBC encryption to your etcd data store, follow the Encrypting etcd data process after you install your cluster.

If you add RHEL nodes to your cluster, ensure that you enable FIPS mode on the machines before their initial boot. See Adding RHEL compute machines to an OpenShift Container Platform cluster and Enabling FIPS Mode in the RHEL 8 documentation.
