1. The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

2. The `controlPlane` section is a single mapping, but the `compute` section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the `compute` section must begin with a hyphen, `-`, and the first line of the `controlPlane` section must not. Only one control plane pool is used.
Specifies whether to enable or disable simultaneous multithreading (SMT), or hyperthreading. By default, SMT is enabled to increase the performance of the cores in your machines. You can

NOTE
Simultaneous multithreading (SMT) is enabled by default. If SMT is not enabled in your BIOS settings, the hyperthreading parameter has no effect.

IMPORTANT
If you disable hyperthreading, whether in the BIOS or in the install-config.yaml file, ensure that your capacity planning accounts for the dramatically decreased machine performance.

You must set this value to 0 when you install OpenShift Container Platform on user-provisioned infrastructure. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. In user-provisioned installations, you must manually deploy the compute machines before you finish installing the cluster.

NOTE
If you are installing a three-node cluster, do not deploy any compute machines when you install the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

The cluster name that you specified in your DNS records.

A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to access the pods from an external network, you must configure load balancers and routers to manage the traffic.

NOTE
Class E CIDR range is reserved for a future use. To use the Class E CIDR range, you must ensure your networking environment accepts the IP addresses within the Class E CIDR range.

The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23, then each node is assigned a /23 subnet out of the given cidr, which allows for 510 \(2^{(32 - 23)} - 2\) pod IP addresses. If you are required to provide access to nodes from an external network, configure load balancers and routers to manage the traffic.

The cluster network plugin to install. The supported values are OVNKubernetes and OpenShiftSDN. The default value is OVNKubernetes.

The IP address pool to use for service IP addresses. You can enter only one IP address pool. This block must not overlap with existing physical networks. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.

You must set the platform to none. You cannot provide additional platform configuration variables.
Clusters that are installed with the platform type none are unable to use some features, such as managing compute machines with the Machine API. This limitation applies even if the compute machines that are attached to the cluster are installed on a platform that would normally support the feature. This parameter cannot be changed after installation.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see Installing the system in FIPS mode. When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures.

For <local_registry>, specify the registry domain name, and optionally the port, that your mirror registry uses to serve content. For example, registry.example.com or registry.example.com:5000. For <credentials>, specify the base64-encoded user name and password for your mirror registry.

The SSH public key for the core user in Red Hat Enterprise Linux CoreOS (RHCOS).

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

Provide the contents of the certificate file that you used for your mirror registry.

Provide the imageContentSources section according to the output of the command that you used to mirror the repository.

- When using the oc adm release mirror command, use the output from the imageContentSources section.
- When using oc mirror command, use the repositoryDigestMirrors section of the ImageContentSourcePolicy file that results from running the command.
- ImageContentSourcePolicy is deprecated. For more information see Configuring image registry repository mirroring.
Additional resources

- See Load balancing requirements for user-provisioned infrastructure for more information on the API and application ingress load balancing requirements.

12.4.8.2. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the install-config.yaml file.

NOTE

For bare metal installations, if you do not assign node IP addresses from the range that is specified in the networking.machineNetwork[].cidr field in the install-config.yaml file, you must include them in the proxy.noProxy field.

Prerequisites

- You have an existing install-config.yaml file.

- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the Proxy object’s spec.noProxy field to bypass the proxy if necessary.

NOTE

The Proxy object status.noProxy field is populated with the values of the networking.machineNetwork[].cidr, networking.clusterNetwork[].cidr, and networking.serviceNetwork[] fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object status.noProxy field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your install-config.yaml file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port> 1
  httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
  noProxy: example.com 3
additionalTrustBundle:
  -----BEGIN CERTIFICATE-----
  <MY_TRUSTED_CA_CERT>
  -----END CERTIFICATE-----
additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> 4
```
A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.

A proxy URL to use for creating HTTPS connections outside the cluster.

A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.

If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the trustedCA field of the Proxy object. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

Optional: The policy to determine the configuration of the Proxy object to reference the user-ca-bundle config map in the trustedCA field. The allowed values are Proxyonly and Always. Use Proxyonly to reference the user-ca-bundle config map only when http/https proxy is configured. Use Always to always reference the user-ca-bundle config map. The default value is Proxyonly.

NOTE
The installation program does not support the proxy readinessEndpoints field.

NOTE
If the installer times out, restart and then complete the deployment by using the wait-for command of the installer. For example:

$ ./openshift-install wait-for install-complete --log-level debug

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

NOTE
Only the Proxy object named cluster is supported, and no additional proxies can be created.

12.4.8.3. Configuring a three-node cluster

Optionally, you can deploy zero compute machines in a bare metal cluster that consists of three control plane machines only. This provides smaller, more resource efficient clusters for cluster administrators and developers to use for testing, development, and production.
In three-node OpenShift Container Platform environments, the three control plane machines are schedulable, which means that your application workloads are scheduled to run on them.

Prerequisites

- You have an existing `install-config.yaml` file.

Procedure

- Ensure that the number of compute replicas is set to 0 in your `install-config.yaml` file, as shown in the following `compute` stanza:

```yaml
compute:
  - name: worker
    platform: {}
    replicas: 0
```

**NOTE**

You must set the value of the `replicas` parameter for the compute machines to 0 when you install OpenShift Container Platform on user-provisioned infrastructure, regardless of the number of compute machines you are deploying. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. This does not apply to user-provisioned installations, where the compute machines are deployed manually.

For three-node cluster installations, follow these next steps:

- If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes. See the `Load balancing requirements for user-provisioned infrastructure` section for more information.

- When you create the Kubernetes manifest files in the following procedure, ensure that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file is set to `true`. This enables your application workloads to run on the control plane nodes.

- Do not deploy any compute nodes when you create the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

### 12.4.9. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.
The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

### Prerequisites

- You obtained the OpenShift Container Platform installation program. For a restricted network installation, these files are on your mirror host.
- You created the `install-config.yaml` installation configuration file.

### Procedure

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

   ```bash
   $ ./openshift-install create manifests --dir <installation_directory>  
   ``

   For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.

### WARNING

If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.

### IMPORTANT

When you configure control plane nodes from the default unschedulable to schedulable, additional subscriptions are required. This is because control plane nodes then become compute nodes.

2. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yaml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:
a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.

b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.

c. Save and exit the file.

3. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

   ```bash
   $ ./openshift-install create ignition-configs --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the same installation directory.

   Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The `kubeadmin-password` and `kubeconfig` files are created in the `./<installation_directory>/auth` directory:

   ```
   ├── auth
   │   ├── kubeadmin-password
   │   └── kubeconfig
   │       ├── bootstrap.ign
   │       └── master.ign
   │           └── metadata.json
   └── worker.ign
   ```

   Additional resources

   - See [Recovering from expired control plane certificates](#) for more information about recovering kubelet certificates.

### 12.4.10. Configuring chrony time service

You must set the time server and related settings used by the chrony time service (`chronyd`) by modifying the contents of the `chrony.conf` file and passing those contents to your nodes as a machine config.

**Procedure**

1. Create a Butane config including the contents of the `chrony.conf` file. For example, to configure chrony on worker nodes, create a `99-worker-chrony.bu` file.

   ```yaml
   variant: openshift
   version: 4.14.0
   metadata:
     name: 99-worker-chrony
   labels:
     machineconfiguration.openshift.io/role: worker
   ```

   **NOTE**

   See "Creating machine configs with Butane" for information about Butane.
1. On control plane nodes, substitute master for worker in both of these locations.

2. Specify an octal value mode for the mode field in the machine config file. After creating the file and applying the changes, the mode is converted to a decimal value. You can check the YAML file with the command `oc get mc <mc-name> -o yaml`.

3. Specify any valid, reachable time source, such as the one provided by your DHCP server.

4. Use Butane to generate a MachineConfig object file, 99-worker-chrony.yaml, containing the configuration to be delivered to the nodes:

   ```bash
   $ butane 99-worker-chrony.bu -o 99-worker-chrony.yaml
   ``

3. Apply the configurations in one of two ways:

   - If the cluster is not running yet, after you generate manifest files, add the MachineConfig object file to the `<installation_directory>/openshift` directory, and then continue to create the cluster.

   - If the cluster is already running, apply the file:

     ```bash
     $ oc apply -f ./99-worker-chrony.yaml
     ```

### 12.4.11. Installing RHCOS and starting the OpenShift Container Platform bootstrap process

To install OpenShift Container Platform on bare metal infrastructure that you provision, you must install Red Hat Enterprise Linux CoreOS (RHCOS) on the machines. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS machines have rebooted.

To install RHCOS on the machines, follow either the steps to use an ISO image or network PXE booting.
NOTE
The compute node deployment steps included in this installation document are RHCOS-specific. If you choose instead to deploy RHEL-based compute nodes, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Only RHEL 8 compute machines are supported.

You can configure RHCOS during ISO and PXE installations by using the following methods:

- Kernel arguments: You can use kernel arguments to provide installation-specific information. For example, you can specify the locations of the RHCOS installation files that you uploaded to your HTTP server and the location of the Ignition config file for the type of node you are installing. For a PXE installation, you can use the APPEND parameter to pass the arguments to the kernel of the live installer. For an ISO installation, you can interrupt the live installation boot process to add the kernel arguments. In both installation cases, you can use special coreos.inst.* arguments to direct the live installer, as well as standard installation boot arguments for turning standard kernel services on or off.

- Ignition configs: OpenShift Container Platform Ignition config files (*.ign) are specific to the type of node you are installing. You pass the location of a bootstrap, control plane, or compute node Ignition config file during the RHCOS installation so that it takes effect on first boot. In special cases, you can create a separate, limited Ignition config to pass to the live system. That Ignition config could do a certain set of tasks, such as reporting success to a provisioning system after completing installation. This special Ignition config is consumed by the coreos-installer to be applied on first boot of the installed system. Do not provide the standard control plane and compute node Ignition configs to the live ISO directly.

- coreos-installer: You can boot the live ISO installer to a shell prompt, which allows you to prepare the permanent system in a variety of ways before first boot. In particular, you can run the coreos-installer command to identify various artifacts to include, work with disk partitions, and set up networking. In some cases, you can configure features on the live system and copy them to the installed system.

Whether to use an ISO or PXE install depends on your situation. A PXE install requires an available DHCP service and more preparation, but can make the installation process more automated. An ISO install is a more manual process and can be inconvenient if you are setting up more than a few machines.

NOTE
As of OpenShift Container Platform 4.6, the RHCOS ISO and other installation artifacts provide support for installation on disks with 4K sectors.

12.4.11.1. Installing RHCOS by using an ISO image

You can use an ISO image to install RHCOS on the machines.

Prerequisites
- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have an HTTP server that can be accessed from your computer, and from the machines that you create.
CHAPTER 12. INSTALLING ON BARE METAL

You have reviewed the Advanced RHCOS installation configuration section for different ways to
configure features, such as networking and disk partitioning.
Procedure
1. Obtain the SHA512 digest for each of your Ignition config files. For example, you can use the
following on a system running Linux to get the SHA512 digest for your bootstrap.ign Ignition
config file:
$ sha512sum <installation_directory>/bootstrap.ign
The digests are provided to the coreos-installer in a later step to validate the authenticity of
the Ignition config files on the cluster nodes.
2. Upload the bootstrap, control plane, and compute node Ignition config files that the installation
program created to your HTTP server. Note the URLs of these files.

IMPORTANT
You can add or change configuration settings in your Ignition configs before
saving them to your HTTP server. If you plan to add more compute machines to
your cluster after you finish installation, do not delete these files.
3. From the installation host, validate that the Ignition config files are available on the URLs. The
following example gets the Ignition config file for the bootstrap node:
$ curl -k http://<HTTP_server>/bootstrap.ign 1

Example output
% Total

% Received % Xferd Average Speed Time Time Time Current
Dload Upload Total Spent Left Speed
0 0 0 0 0 0
0
0 --:--:-- --:--:-- --:--:-- 0{"ignition":
{"version":"3.2.0"},"passwd":{"users":[{"name":"core","sshAuthorizedKeys":["ssh-rsa...
Replace bootstrap.ign with master.ign or worker.ign in the command to validate that the
Ignition config files for the control plane and compute nodes are also available.
4. Although it is possible to obtain the RHCOS images that are required for your preferred method
of installing operating system instances from the RHCOS image mirror page, the recommended
way to obtain the correct version of your RHCOS images are from the output of openshiftinstall command:
$ openshift-install coreos print-stream-json | grep '\.iso[^.]'

Example output
"location": "<url>/art/storage/releases/rhcos-4.14-aarch64/<release>/aarch64/rhcos<release>-live.aarch64.iso",
"location": "<url>/art/storage/releases/rhcos-4.14-ppc64le/<release>/ppc64le/rhcos<release>-live.ppc64le.iso",
"location": "<url>/art/storage/releases/rhcos-4.14-s390x/<release>/s390x/rhcos-<release>-

2167


IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available. Use only ISO images for this procedure. RHCOS qcow2 images are not supported for this installation type.

ISO file names resemble the following example:

rhcos-<version>-live.<architecture>.iso

5. Use the ISO to start the RHCOS installation. Use one of the following installation options:
   - Burn the ISO image to a disk and boot it directly.
   - Use ISO redirection by using a lights-out management (LOM) interface.

6. Boot the RHCOS ISO image without specifying any options or interrupting the live boot sequence. Wait for the installer to boot into a shell prompt in the RHCOS live environment.

NOTE

It is possible to interrupt the RHCOS installation boot process to add kernel arguments. However, for this ISO procedure you should use the `coreos-installer` command as outlined in the following steps, instead of adding kernel arguments.

7. Run the `coreos-installer` command and specify the options that meet your installation requirements. At a minimum, you must specify the URL that points to the Ignition config file for the node type, and the device that you are installing to:

```
$ sudo coreos-installer install --ignition-url=http://<HTTP_server>/<node_type>.ign <device>  
--ignition-hash=sha512-<digest> 1 2
```

1. You must run the `coreos-installer` command by using `sudo`, because the `core` user does not have the required root privileges to perform the installation.

2. The `--ignition-hash` option is required when the Ignition config file is obtained through an HTTP URL to validate the authenticity of the Ignition config file on the cluster node. `<digest>` is the Ignition config file SHA512 digest obtained in a preceding step.

NOTE

If you want to provide your Ignition config files through an HTTPS server that uses TLS, you can add the internal certificate authority (CA) to the system trust store before running `coreos-installer`. 

---

OpenShift Container Platform 4.14 Installing

live.s390x.iso",
"location": "<url>/art/storage/releases/rhc-os-4.14/<release>/x86_64/rhc-os-<release>-live.x86_64.iso",

---

| Page 2168 |
The following example initializes a bootstrap node installation to the `/dev/sda` device. The Ignition config file for the bootstrap node is obtained from an HTTP web server with the IP address 192.168.1.2:

```
$ sudo coreos-installer install --ignition-url=http://192.168.1.2:80/installation_directory/bootstrap.ign /dev/sda --ignition-hash=sha512-a5a2d43879223273c9b60af66b44202a1d1248fc01cf156c46d4a79f552b6bad47bc8c78ddfd0116e80c59d2ea9e32ba53bc807afbca581aa059311defc2c3e3b
```

8. Monitor the progress of the RHCOS installation on the console of the machine.

**IMPORTANT**

Be sure that the installation is successful on each node before commencing with the OpenShift Container Platform installation. Observing the installation process can also help to determine the cause of RHCOS installation issues that might arise.

9. After RHCOS installs, you must reboot the system. During the system reboot, it applies the Ignition config file that you specified.

10. Check the console output to verify that Ignition ran.

**Example command**

```
Ignition: ran on 2022/03/14 14:48:33 UTC (this boot)
Ignition: user-provided config was applied
```

11. Continue to create the other machines for your cluster.

**IMPORTANT**

You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, also create at least two compute machines before you install OpenShift Container Platform.

If the required network, DNS, and load balancer infrastructure are in place, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS nodes have rebooted.

**NOTE**

RHCOS nodes do not include a default password for the core user. You can access the nodes by running `ssh core@<node>.<cluster_name>.<base_domain>` as a user with access to the SSH private key that is paired to the public key that you specified in your `install_config.yaml` file. OpenShift Container Platform 4 cluster nodes running RHCOS are immutable and rely on Operators to apply cluster changes. Accessing cluster nodes by using SSH is not recommended. However, when investigating installation issues, if the OpenShift Container Platform API is not available, or the kubelet is not properly functioning on a target node, SSH access might be required for debugging or disaster recovery.
12.4.11.2. Installing RHCOS by using PXE or iPXE booting

You can use PXE or iPXE booting to install RHCOS on the machines.

Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have configured suitable PXE or iPXE infrastructure.
- You have an HTTP server that can be accessed from your computer, and from the machines that you create.
- You have reviewed the Advanced RHCOS installation configuration section for different ways to configure features, such as networking and disk partitioning.

Procedure

1. Upload the bootstrap, control plane, and compute node Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

   IMPORTANT
   You can add or change configuration settings in your Ignition configs before saving them to your HTTP server. If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

2. From the installation host, validate that the Ignition config files are available on the URLs. The following example gets the Ignition config file for the bootstrap node:

   ```bash
   $ curl -k http://<HTTP_server>/bootstrap.ign
   ````
   
   Example output
   
   Replace `bootstrap.ign` with `master.ign` or `worker.ign` in the command to validate that the Ignition config files for the control plane and compute nodes are also available.

3. Although it is possible to obtain the RHCOS `kernel`, `initramfs` and `rootfs` files that are required for your preferred method of installing operating system instances from the RHCOS image mirror page, the recommended way to obtain the correct version of your RHCOS files are from the output of `openshift-install` command:

   ```bash
   $ openshift-install coreos print-stream-json | grep -Eo "https.*\(kernel-|initramfs.|rootfs.\)\w+\(.\img\)"?
   ````
   
   Example output
   
   ```
The RHCOS artifacts might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate kernel, initramfs, and rootfs artifacts described below for this procedure. RHCOS QCOW2 images are not supported for this installation type.

The file names contain the OpenShift Container Platform version number. They resemble the following examples:

- **kernel**: `rhcos-<version>-live-kernel-<architecture>`
- **initramfs**: `rhcos-<version>-live-initramfs.<architecture>.img`
- **rootfs**: `rhcos-<version>-live-rootfs.<architecture>.img`

4. Upload the rootfs, kernel, and initramfs files to your HTTP server.

**IMPORTANT**

If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

5. Configure the network boot infrastructure so that the machines boot from their local disks after RHCOS is installed on them.

6. Configure PXE or iPXE installation for the RHCOS images and begin the installation.
Modify one of the following example menu entries for your environment and verify that the image and Ignition files are properly accessible:

- For PXE (**x86_64**):

  ```
  DEFAULT pxeboot
  TIMEOUT 20
  PROMPT 0
  LABEL pxeboot
  KERN v/xe://<HTTP_server>/rhcos-<version>-live-kernel-<architecture>
  <architecture>,img coreos.live.roots_url=http://<HTTP_server>/rhcos-<version>-live-
  roots.<architecture>,img coreos.inst.install_dev=/dev/sda
  coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign
  ```

  1. Specify the location of the live kernel file that you uploaded to your HTTP server. The URL must be HTTP, TFTP, or FTP; HTTPS and NFS are not supported.
  2. If you use multiple NICs, specify a single interface in the `ip` option. For example, to use DHCP on a NIC that is named `eno1`, set `ip=eno1:dhcp`.
  3. Specify the locations of the RHCOS files that you uploaded to your HTTP server. The `initrd` parameter value is the location of the initramfs file, the `coreos.live.roots_url` parameter value is the location of the rootfs file, and the `coreos.inst.ignition_url` parameter value is the location of the bootstrap Ignition config file. You can also add more kernel arguments to the `APPEND` line to configure networking or other boot options.

**NOTE**

This configuration does not enable serial console access on machines with a graphical console. To configure a different console, add one or more `console=` arguments to the `APPEND` line. For example, add `console=tty0 console=ttyS0` to set the first PC serial port as the primary console and the graphical console as a secondary console. For more information, see How does one set up a serial terminal and/or console in Red Hat Enterprise Linux? and "Enabling the serial console for PXE and ISO installation" in the "Advanced RHCOS installation configuration" section.

- For iPXE (**x86_64 + aarch64**):

  ```
  kernel http://<HTTP_server>/rhcos-<version>-live-kernel-<architecture> initrd=main
  coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign
  ```

  1. Specify the locations of the RHCOS files that you uploaded to your HTTP server. The `kernel` parameter value is the location of the kernel file, the `initrd=main` argument is needed for booting on UEFI systems, the `coreos.live.roots_url` parameter value is the location of the rootfs file, and the `coreos.inst.ignition_url` parameter value is the location of the bootstrap Ignition config file.
2 If you use multiple NICs, specify a single interface in the ip option. For example, to use DHCP on a NIC that is named eno1, set ip=eno1:dhcp.

3 Specify the location of the initramfs file that you uploaded to your HTTP server.

**NOTE**
This configuration does not enable serial console access on machines with a graphical console. To configure a different console, add one or more console= arguments to the kernel line. For example, add console=tty0 console=ttyS0 to set the first PC serial port as the primary console and the graphical console as a secondary console. For more information, see How does one set up a serial terminal and/or console in Red Hat Enterprise Linux? and “Enabling the serial console for PXE and ISO installation” in the "Advanced RHCOS installation configuration" section.

**NOTE**
To network boot the CoreOS kernel on aarch64 architecture, you need to use a version of iPXE build with the IMAGE_GZIP option enabled. See IMAGE_GZIP option in iPXE.

- For PXE (with UEFI and Grub as second stage) on aarch64:

```plaintext
menuentry 'Install CoreOS' {
    linux rhcos-<version>-live-kernel-<architecture>
    coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign
    initrd rhcos-<version>-live-initramfs.<architecture>.img
}
```

1 Specify the locations of the RHCOS files that you uploaded to your HTTP/TFTP server. The kernel parameter value is the location of the kernel file on your TFTP server. The coreos.live.rootfs_url parameter value is the location of the rootfs file, and the coreos.inst.ignition_url parameter value is the location of the bootstrap Ignition config file on your HTTP Server.

2 If you use multiple NICs, specify a single interface in the ip option. For example, to use DHCP on a NIC that is named eno1, set ip=eno1:dhcp.

3 Specify the location of the initramfs file that you uploaded to your TFTP server.

7. Monitor the progress of the RHCOS installation on the console of the machine.

**IMPORTANT**
Be sure that the installation is successful on each node before commencing with the OpenShift Container Platform installation. Observing the installation process can also help to determine the cause of RHCOS installation issues that might arise.
8. After RHCOS installs, the system reboots. During reboot, the system applies the Ignition config file that you specified.

9. Check the console output to verify that Ignition ran.

**Example command**

```
Ignition: ran on 2022/03/14 14:48:33 UTC (this boot)
Ignition: user-provided config was applied
```

10. Continue to create the machines for your cluster.

**IMPORTANT**

You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, also create at least two compute machines before you install the cluster.

If the required network, DNS, and load balancer infrastructure are in place, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS nodes have rebooted.

**NOTE**

RHCOS nodes do not include a default password for the `core` user. You can access the nodes by running `ssh core@<node>.<cluster_name>.<base_domain>` as a user with access to the SSH private key that is paired to the public key that you specified in your `install_config.yaml` file. OpenShift Container Platform 4 cluster nodes running RHCOS are immutable and rely on Operators to apply cluster changes. Accessing cluster nodes by using SSH is not recommended. However, when investigating installation issues, if the OpenShift Container Platform API is not available, or the kubelet is not properly functioning on a target node, SSH access might be required for debugging or disaster recovery.

**12.4.11.3. Advanced RHCOS installation configuration**

A key benefit for manually provisioning the Red Hat Enterprise Linux CoreOS (RHCOS) nodes for OpenShift Container Platform is to be able to do configuration that is not available through default OpenShift Container Platform installation methods. This section describes some of the configurations that you can do using techniques that include:

- Passing kernel arguments to the live installer
- Running `coreos-installer` manually from the live system
- Customizing a live ISO or PXE boot image

The advanced configuration topics for manual Red Hat Enterprise Linux CoreOS (RHCOS) installations detailed in this section relate to disk partitioning, networking, and using Ignition configs in different ways.

**12.4.11.3.1. Using advanced networking options for PXE and ISO installations**
Networking for OpenShift Container Platform nodes uses DHCP by default to gather all necessary configuration settings. To set up static IP addresses or configure special settings, such as bonding, you can do one of the following:

- Pass special kernel parameters when you boot the live installer.
- Use a machine config to copy networking files to the installed system.
- Configure networking from a live installer shell prompt, then copy those settings to the installed system so that they take effect when the installed system first boots.

To configure a PXE or iPXE installation, use one of the following options:

- See the "Advanced RHCOS installation reference" tables.
- Use a machine config to copy networking files to the installed system.

To configure an ISO installation, use the following procedure.

**Procedure**

1. Boot the ISO installer.

2. From the live system shell prompt, configure networking for the live system using available RHEL tools, such as `nmcli` or `nmtui`.

3. Run the `coreos-installer` command to install the system, adding the `--copy-network` option to copy networking configuration. For example:

   ```bash
   $ sudo coreos-installer install --copy-network
   --ignition-url=http://host/worker.ign /dev/disk/by-id/scsi-<serial_number>
   
   IMPORTANT
   
   The `--copy-network` option only copies networking configuration found under `/etc/NetworkManager/system-connections`. In particular, it does not copy the system hostname.
   
   4. Reboot into the installed system.

**Additional resources**

- See [Getting started with nmcli](#) and [Getting started with nmtui](#) in the RHEL 8 documentation for more information about the `nmcli` and `nmtui` tools.

**12.4.11.3.2. Disk partitioning**

The disk partitions are created on OpenShift Container Platform cluster nodes during the Red Hat Enterprise Linux CoreOS (RHCOS) installation. Each RHCOS node of a particular architecture uses the same partition layout, unless the default partitioning configuration is overridden. During the RHCOS installation, the size of the root file system is increased to use the remaining available space on the target device.

There are two cases where you might want to override the default partitioning when installing RHCOS on an OpenShift Container Platform cluster node:
Creating separate partitions: For greenfield installations on an empty disk, you might want to add separate storage to a partition. This is officially supported for mounting `/var` or a subdirectory of `/var`, such as `/var/lib/etcd`, on a separate partition, but not both.

**IMPORTANT**

For disk sizes larger than 100GB, and especially disk sizes larger than 1TB, create a separate `/var` partition. See "Creating a separate `/var` partition" and this Red Hat Knowledgebase article for more information.

**IMPORTANT**

Kubernetes supports only two file system partitions. If you add more than one partition to the original configuration, Kubernetes cannot monitor all of them.

Retaining existing partitions: For a brownfield installation where you are reinstalling OpenShift Container Platform on an existing node and want to retain data partitions installed from your previous operating system, there are both boot arguments and options to `coreos-installer` that allow you to retain existing data partitions.

**WARNING**

The use of custom partitions could result in those partitions not being monitored by OpenShift Container Platform or alerted on. If you are overriding the default partitioning, see Understanding OpenShift File System Monitoring (eviction conditions) for more information about how OpenShift Container Platform monitors your host file systems.

12.4.11.3.2.1. Creating a separate `/var` partition

In general, you should use the default disk partitioning that is created during the RHCOS installation. However, there are cases where you might want to create a separate partition for a directory that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the `/var` directory or a subdirectory of `/var`. For example:

- `/var/lib/containers`: Holds container-related content that can grow as more images and containers are added to a system.
- `/var/lib/etcd`: Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.
- `/var`: Holds data that you might want to keep separate for purposes such as auditing.

**IMPORTANT**

For disk sizes larger than 100GB, and especially larger than 1TB, create a separate `/var` partition.
Storing the contents of a `/var` directory separately makes it easier to grow storage for those areas as needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

The use of a separate partition for the `/var` directory or a subdirectory of `/var` also prevents data growth in the partitioned directory from filling up the root file system.

The following procedure sets up a separate `/var` partition by adding a machine config manifest that is wrapped into the Ignition config file for a node type during the preparation phase of an installation.

Procedure

1. On your installation host, change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

   ```
   $ openshift-install create manifests --dir <installation_directory>
   ```

2. Create a Butane config that configures the additional partition. For example, name the file `$HOME/clusterconfig/98-var-partition.bu`, change the disk device name to the name of the storage device on the worker systems, and set the storage size as appropriate. This example places the `/var` directory on a separate partition:

   ```yaml
   variant: openshift
   version: 4.14.0
   metadata:
     labels:
       machineconfiguration.openshift.io/role: worker
     name: 98-var-partition
   storage:
     disks:
       - device: /dev/disk/by-id/<device_name> 1
         partitions:
           - label: var
             start_mib: <partition_start_offset> 2
             size_mib: <partition_size> 3
     filesystems:
       - device: /dev/disk/by-partlabel/var
         path: /var
         format: xfs
         mount_options: [defaults, prjquota] 4
         with_mount_unit: true
   ```

1. The storage device name of the disk that you want to partition.

2. When adding a data partition to the boot disk, a minimum offset value of 25000 mebibytes is recommended. The root file system is automatically resized to fill all available space up to the specified offset. If no offset value is specified, or if the specified value is smaller than the recommended minimum, the resulting root file system will be too small, and future reinstalls of RHCOS might overwrite the beginning of the data partition.

3. The size of the data partition in mebibytes.

4. The `prjquota` mount option must be enabled for filesystems used for container storage.
NOTE

When creating a separate /var partition, you cannot use different instance types for compute nodes, if the different instance types do not have the same device name.

3. Create a manifest from the Butane config and save it to the `clusterconfig/openshift` directory. For example, run the following command:

```bash
$ butane $HOME/clusterconfig/98-var-partition.bu -o $HOME/clusterconfig/openshift/98-var-partition.yaml
```

4. Create the Ignition config files:

```bash
$ openshift-install create ignition-configs --dir <installation_directory> ¹
```

¹ For `<installation_directory>`, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory:

```
├── auth
│   ├── kubeadmin-password
│   └── kubeconfig
├── bootstrap.ign
├── master.ign
├── metadata.json
└── worker.ign
```

The files in the `<installation_directory>/manifest` and `<installation_directory>/openshift` directories are wrapped into the Ignition config files, including the file that contains the 98-var-partition custom `MachineConfig` object.

Next steps

- You can apply the custom disk partitioning by referencing the Ignition config files during the RHCOS installations.

12.4.11.3.2.2. Retaining existing partitions

For an ISO installation, you can add options to the `coreos-installer` command that cause the installer to maintain one or more existing partitions. For a PXE installation, you can add `coreos.inst.*` options to the `APPEND` parameter to preserve partitions.

Saved partitions might be data partitions from an existing OpenShift Container Platform system. You can identify the disk partitions you want to keep either by partition label or by number.

NOTE

If you save existing partitions, and those partitions do not leave enough space for RHCOS, the installation will fail without damaging the saved partitions.
Retaining existing partitions during an ISO installation

This example preserves any partition in which the partition label begins with data (data*):

```
# coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign \
  --save-partlabel 'data*' /dev/disk/by-id/scsi-<serial_number>
```

The following example illustrates running the `coreos-installer` in a way that preserves the sixth (6) partition on the disk:

```
# coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign \
  --save-partindex 6 /dev/disk/by-id/scsi-<serial_number>
```

This example preserves partitions 5 and higher:

```
# coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign \%
  --save-partindex 5- /dev/disk/by-id/scsi-<serial_number>
```

In the previous examples where partition saving is used, `coreos-installer` recreates the partition immediately.

Retaining existing partitions during a PXE installation

This `APPEND` option preserves any partition in which the partition label begins with 'data' ('data*'):

```
coreos.inst.save_partlabel=data*
```

This `APPEND` option preserves partitions 5 and higher:

```
coreos.inst.save_partindex=5-
```

This `APPEND` option preserves partition 6:

```
coreos.inst.save_partindex=6
```

12.4.11.3.3. Identifying Ignition configs

When doing an RHCOS manual installation, there are two types of Ignition configs that you can provide, with different reasons for providing each one:

- **Permanent install Ignition config**: Every manual RHCOS installation needs to pass one of the Ignition config files generated by `openshift-installer`, such as `bootstrap.ign`, `master.ign` and `worker.ign`, to carry out the installation.

  **IMPORTANT**

  It is not recommended to modify these Ignition config files directly. You can update the manifest files that are wrapped into the Ignition config files, as outlined in examples in the preceding sections.

For PXE installations, you pass the Ignition configs on the `APPEND` line using the `coreos.inst.ignition_url=` option. For ISO installations, after the ISO boots to the shell prompt, you identify the Ignition config on the `coreos-installer` command line with the `--ignition-url=` option.
option. In both cases, only HTTP and HTTPS protocols are supported.

- **Live install Ignition config**: This type can be created by using the `coreos-installer customize` subcommand and its various options. With this method, the Ignition config passes to the live install medium, runs immediately upon booting, and performs setup tasks before or after the RHCOS system installs to disk. This method should only be used for performing tasks that must be done once and not applied again later, such as with advanced partitioning that cannot be done using a machine config. For PXE or ISO boots, you can create the Ignition config and APPEND the `ignition.config.url=` option to identify the location of the Ignition config. You also need to append `ignition.firstboot` or the `ignition.config.url` option will be ignored.

### 12.4.11.3.4. Default console configuration

Red Hat Enterprise Linux CoreOS (RHCOS) nodes installed from an OpenShift Container Platform 4.14 boot image use a default console that is meant to accommodate most virtualized and bare metal setups. Different cloud and virtualization platforms may use different default settings depending on the chosen architecture. Bare metal installations use the kernel default settings which typically means the graphical console is the primary console and the serial console is disabled.

The default consoles may not match your specific hardware configuration or you might have specific needs that require you to adjust the default console. For example:

- You want to access the emergency shell on the console for debugging purposes.
- Your cloud platform does not provide interactive access to the graphical console, but provides a serial console.
- You want to enable multiple consoles.

Console configuration is inherited from the boot image. This means that new nodes in existing clusters are unaffected by changes to the default console.

You can configure the console for bare metal installations in the following ways:

- Using `coreos-installer` manually on the command line.
- Using the `coreos-installer iso customize` or `coreos-installer pxe customize` subcommands with the `--dest-console` option to create a custom image that automates the process.

**NOTE**

For advanced customization, perform console configuration using the `coreos-installer iso` or `coreos-installer pxe` subcommands, and not kernel arguments.

### 12.4.11.3.5. Enabling the serial console for PXE and ISO installations

By default, the Red Hat Enterprise Linux CoreOS (RHCOS) serial console is disabled and all output is written to the graphical console. You can enable the serial console for an ISO installation and reconfigure the bootloader so that output is sent to both the serial console and the graphical console.

**Procedure**

1. Boot the ISO installer.
2. Run the `coreos-installer` command to install the system, adding the `--console` option once to specify the graphical console, and a second time to specify the serial console:

```
$ coreos-installer install \
   --console=ttv0 \1
   --console=ttvS0,<options> \2
   --ignition-url=http://host/worker.ign /dev/disk/by-id/scsi-<serial_number>
```

1. The desired secondary console. In this case, the graphical console. Omitting this option will disable the graphical console.

2. The desired primary console. In this case the serial console. The `options` field defines the baud rate and other settings. A common value for this field is `11520n8`. If no options are provided, the default kernel value of `9600n8` is used. For more information on the format of this option, see [Linux kernel serial console documentation](#).

3. Reboot into the installed system.

   **NOTE**

   A similar outcome can be obtained by using the `coreos-installer install --append-karg` option, and specifying the console with `console=`. However, this will only set the console for the kernel and not the bootloader.

To configure a PXE installation, make sure the `coreos.inst.install_dev` kernel command line option is omitted, and use the shell prompt to run `coreos-installer` manually using the above ISO installation procedure.

12.4.11.3.6. Customizing a live RHCOS ISO or PXE install

You can use the live ISO image or PXE environment to install RHCOS by injecting an Ignition config file directly into the image. This creates a customized image that you can use to provision your system.

For an ISO image, the mechanism to do this is the `coreos-installer iso customize` subcommand, which modifies the `.iso` file with your configuration. Similarly, the mechanism for a PXE environment is the `coreos-installer pxe customize` subcommand, which creates a new `initramfs` file that includes your customizations.

The `customize` subcommand is a general purpose tool that can embed other types of customizations as well. The following tasks are examples of some of the more common customizations:

- Inject custom CA certificates for when corporate security policy requires their use.
- Configure network settings without the need for kernel arguments.
- Embed arbitrary preinstall and post-install scripts or binaries.

12.4.11.3.7. Customizing a live RHCOS ISO image

You can customize a live RHCOS ISO image directly with the `coreos-installer iso customize` subcommand. When you boot the ISO image, the customizations are applied automatically.

You can use this feature to configure the ISO image to automatically install RHCOS.
Procedure

1. Download the coreos-installer binary from the coreos-installer image mirror page.

2. Retrieve the RHCOS ISO image from the RHCOS image mirror page and the Ignition config file, and then run the following command to inject the Ignition config directly into the ISO image:

   ```bash
   $ coreos-installer iso customize rhcos-<version>-live.x86_64.iso \
   --dest-ignition bootstrap.ign \n   --dest-device /dev/disk/by-id/scsi-<serial_number>
   ```

   1. The Ignition config file that is generated from the openshift-installer installation program.
   2. When you specify this option, the ISO image automatically runs an installation. Otherwise, the image remains configured for installation, but does not install automatically unless you specify the coreos.inst.install_dev kernel argument.

3. Optional: To remove the ISO image customizations and return the image to its pristine state, run:

   ```bash
   $ coreos-installer iso reset rhcos-<version>-live.x86_64.iso
   ```

   You can now re-customize the live ISO image or use it in its pristine state.

Applying your customizations affects every subsequent boot of RHCOS.

12.4.11.3.7.1 Modifying a live install ISO image to enable the serial console

On clusters installed with OpenShift Container Platform 4.12 and above, the serial console is disabled by default and all output is written to the graphical console. You can enable the serial console with the following procedure.

Procedure

1. Download the coreos-installer binary from the coreos-installer image mirror page.

2. Retrieve the RHCOS ISO image from the RHCOS image mirror page and run the following command to customize the ISO image to enable the serial console to receive output:

   ```bash
   $ coreos-installer iso customize rhcos-<version>-live.x86_64.iso \
   --dest-ignition <path> \n   --dest-console tty0 \n   --dest-console ttyS0,<options> \n   --dest-device /dev/disk/by-id/scsi-<serial_number>
   ```

   1. The location of the Ignition config to install.
   2. The desired secondary console. In this case, the graphical console. Omitting this option will disable the graphical console.
   3. The desired primary console. In this case, the serial console. The options field defines the baud rate and other settings. A common value for this field is 115200n8. If no options are provided, the default kernel value of 9600n8 is used. For more information on the format of this option, see the Linux kernel serial console documentation.
4 The specified disk to install to. If you omit this option, the ISO image automatically runs the installation program which will fail unless you also specify the `coreos.inst.install_dev`

**NOTE**

The `--dest-console` option affects the installed system and not the live ISO system. To modify the console for a live ISO system, use the `--live-karg-append` option and specify the console with `console=`.

Your customizations are applied and affect every subsequent boot of the ISO image.

3. Optional: To remove the ISO image customizations and return the image to its original state, run the following command:

```
$ coreos-installer iso reset rhcos-<version>-live.x86_64.iso
```

You can now recustomize the live ISO image or use it in its original state.

12.4.11.3.7.2. Modifying a live install ISO image to use a custom certificate authority

You can provide certificate authority (CA) certificates to Ignition with the `--ignition-ca` flag of the `customize` subcommand. You can use the CA certificates during both the installation boot and when provisioning the installed system.

**NOTE**

Custom CA certificates affect how Ignition fetches remote resources but they do not affect the certificates installed onto the system.

**Procedure**

1. Download the `coreos-installer` binary from the `coreos-installer` image mirror page.

2. Retrieve the RHCOS ISO image from the RHCOS image mirror page and run the following command to customize the ISO image for use with a custom CA:

```
$ coreos-installer iso customize rhcos-<version>-live.x86_64.iso --ignition-ca cert.pem
```

**IMPORTANT**

The `coreos.inst.ignition_url` kernel parameter does not work with the `--ignition-ca` flag. You must use the `--dest-ignition` flag to create a customized image for each cluster.

Applying your custom CA certificate affects every subsequent boot of RHCOS.

12.4.11.3.7.3. Modifying a live install ISO image with customized network settings

You can embed a NetworkManager keyfile into the live ISO image and pass it through to the installed system with the `--network-keyfile` flag of the `customize` subcommand.
WARNING

When creating a connection profile, you must use a `.nmconnection` filename extension in the filename of the connection profile. If you do not use a `.nmconnection` filename extension, the cluster will apply the connection profile to the live environment, but it will not apply the configuration when the cluster first boots up the nodes, resulting in a setup that does not work.

Procedure

1. Download the `coreos-installer` binary from the `coreos-installer` image mirror page.

2. Create a connection profile for a bonded interface. For example, create the `bond0.nmconnection` file in your local directory with the following content:

   ```
   [connection]
   id=bond0
   type=bond
   interface-name=bond0
   multi-connect=1
   permissions=

   [ethernet]
   mac-address-blacklist=

   [bond]
   miimon=100
   mode=active-backup

   [ipv4]
   method=auto

   [ipv6]
   method=auto

   [proxy]
   
   ``

3. Create a connection profile for a secondary interface to add to the bond. For example, create the `bond0-proxy-em1.nmconnection` file in your local directory with the following content:

   ```
   [connection]
   id=em1
   type=ethernet
   interface-name=em1
   master=bond0
   multi-connect=1
   permissions=
   slave-type=bond

   [ethernet]
   mac-address-blacklist=
   ```
4. Create a connection profile for a secondary interface to add to the bond. For example, create the `bond0-proxy-em2.nmconnection` file in your local directory with the following content:

```
[connection]
  id=em2
  type=ethernet
  interface-name=em2
  master=bond0
  multi-connect=1
  permissions=
  slave-type=bond

[ethernet]
  mac-address-blacklist=
```

5. Retrieve the RHCOS ISO image from the RHCOS image mirror page and run the following command to customize the ISO image with your configured networking:

```
$ coreos-installer iso customize rhcos-<version>-live.x86_64.iso \
   --network-keyfile bond0.nmconnection \
   --network-keyfile bond0-proxy-em1.nmconnection \
   --network-keyfile bond0-proxy-em2.nmconnection
```

Network settings are applied to the live system and are carried over to the destination system.

12.4.11.3.8. Customizing a live RHCOS PXE environment

You can customize a live RHCOS PXE environment directly with the `coreos-installer pxe customize` subcommand. When you boot the PXE environment, the customizations are applied automatically.

You can use this feature to configure the PXE environment to automatically install RHCOS.

**Procedure**

1. Download the `coreos-installer` binary from the `coreos-installer` image mirror page.

2. Retrieve the RHCOS kernel, initramfs and rootfs files from the RHCOS image mirror page and the Ignition config file, and then run the following command to create a new initramfs file that contains the customizations from your Ignition config:

```
$ coreos-installer pxe customize rhcos-<version>-live-initramfs.x86_64.img \
   --dest-ignition bootstrap.ign \1
   --dest-device /dev/disk/by-id/scsi-<serial_number> \2
   -o rhcos-<version>-custom-initramfs.x86_64.img 3
```

1. The Ignition config file that is generated from openshift-installer.

2. When you specify this option, the PXE environment automatically runs an install. Otherwise, the image remains configured for installing, but does not do so automatically unless you specify the `coreos.inst.install_dev` kernel argument.

3. Use the customized initramfs file in your PXE configuration. Add the `ignition.firstboot` and `ignition.platform.id=metal` kernel arguments if they are not already present.
Applying your customizations affects every subsequent boot of RHCOS.

12.4.11.3.8.1. Modifying a live install PXE environment to enable the serial console

On clusters installed with OpenShift Container Platform 4.12 and above, the serial console is disabled by default and all output is written to the graphical console. You can enable the serial console with the following procedure.

Procedure

1. Download the `coreos-installer` binary from the `coreos-installer` image mirror page.

2. Retrieve the RHCOS kernel, initramfs and rootfs files from the RHCOS image mirror page and the Ignition config file, and then run the following command to create a new customized initramfs file that enables the serial console to receive output:

   ```bash
   $ coreos-installer pxe customize rhcos-<version>-live-initramfs.x86_64.img 
   --dest-ignition <path> 
   --dest-console tty0 
   --dest-console ttyS0,<options> 
   --dest-device /dev/disk/by-id/scsi-<serial_number> 
   -o rhcos-<version>-custom-initramfs.x86_64.img
   ```

   1. The location of the Ignition config to install.
   2. The desired secondary console. In this case, the graphical console. Omitting this option will disable the graphical console.
   3. The desired primary console. In this case, the serial console. The `options` field defines the baud rate and other settings. A common value for this field is `115200n8`. If no options are provided, the default kernel value of `9600n8` is used. For more information on the format of this option, see the Linux kernel serial console documentation.
   4. The specified disk to install to. If you omit this option, the PXE environment automatically runs the installer which will fail unless you also specify the `coreos.inst.install_dev` kernel argument.
   5. Use the customized initramfs file in your PXE configuration. Add the `ignition.firstboot` and `ignition.platform.id=metal` kernel arguments if they are not already present.

Your customizations are applied and affect every subsequent boot of the PXE environment.

12.4.11.3.8.2. Modifying a live install PXE environment to use a custom certificate authority

You can provide certificate authority (CA) certificates to Ignition with the `--ignition-ca` flag of the customize subcommand. You can use the CA certificates during both the installation boot and when provisioning the installed system.

**NOTE**

Custom CA certificates affect how Ignition fetches remote resources but they do not affect the certificates installed onto the system.
Procedure

1. Download the **coreos-installer** binary from the **coreos-installer** image mirror page.

2. Retrieve the RHCOS **kernel**, **initramfs** and **rootfs** files from the **RHCOS image mirror** page and run the following command to create a new customized **initramfs** file for use with a custom CA:

   ```
   $ coreos-installer pxe customize rhcos-<version>-live-initramfs.x86_64.img \
   --ignition-ca cert.pem \
   -o rhcos-<version>-custom-initramfs.x86_64.img
   ```

3. Use the customized **initramfs** file in your PXE configuration. Add the **ignition.firstboot** and **ignition.platform.id=metal** kernel arguments if they are not already present.

   **IMPORTANT**
   The **coreos.inst.ignition_url** kernel parameter does not work with the **--ignition-ca** flag. You must use the **--dest-ignition** flag to create a customized image for each cluster.

Applying your custom CA certificate affects every subsequent boot of RHCOS.

12.4.11.3.8.3. Modifying a live install PXE environment with customized network settings

You can embed a NetworkManager keyfile into the live PXE environment and pass it through to the installed system with the **--network-keyfile** flag of the **customize** subcommand.

   **WARNING**
   When creating a connection profile, you must use a **.nmconnection** filename extension in the filename of the connection profile. If you do not use a **.nmconnection** filename extension, the cluster will apply the connection profile to the live environment, but it will not apply the configuration when the cluster first boots up the nodes, resulting in a setup that does not work.

Procedure

1. Download the **coreos-installer** binary from the **coreos-installer** image mirror page.

2. Create a connection profile for a bonded interface. For example, create the **bond0.nmconnection** file in your local directory with the following content:

   ```
   [connection]
   id=bond0
   type=bond
   interface-name=bond0
   multi-connect=1
   permissions=
   
   [ethernet]
   mac-address-blacklist=
   ```
Create a connection profile for a secondary interface to add to the bond. For example, create the `bond0-proxy-em1.nmconnection` file in your local directory with the following content:

```
[bond]
miiomon=100
mode=active-backup

[ipv4]
method=auto

[ipv6]
method=auto

[proxy]
```

3. Create a connection profile for a secondary interface to add to the bond. For example, create the `bond0-proxy-em2.nmconnection` file in your local directory with the following content:

```
[connection]
id=em1
type=ethernet
interface-name=em1
master=bond0
multi-connect=1
permissions=
slave-type=bond

[ethernet]
mac-address-blacklist=
```

4. Create a connection profile for a secondary interface to add to the bond. For example, create the `bond0-proxy-em2.nmconnection` file in your local directory with the following content:

```
[connection]
id=em2
type=ethernet
interface-name=em2
master=bond0
multi-connect=1
permissions=
slave-type=bond

[ethernet]
mac-address-blacklist=
```

5. Retrieve the RHCOS `kernel`, `initramfs` and `rootfs` files from the RHCOS image mirror page and run the following command to create a new customized `initramfs` file that contains your configured networking:

```
$ coreos-installer pxe customize rhcos-<version>-live-initramfs.x86_64.img \
   --network-keyfile bond0.nmconnection \
   --network-keyfile bond0-proxy-em1.nmconnection \
   --network-keyfile bond0-proxy-em2.nmconnection \
   -o rhcos-<version>-custom-initramfs.x86_64.img
```

6. Use the customized `initramfs` file in your PXE configuration. Add the `ignition.firstboot` and `ignition.platform.id=metal` kernel arguments if they are not already present.
Network settings are applied to the live system and are carried over to the destination system.

12.4.11.3.9. Advanced RHCOS installation reference

This section illustrates the networking configuration and other advanced options that allow you to modify the Red Hat Enterprise Linux CoreOS (RHCOS) manual installation process. The following tables describe the kernel arguments and command-line options you can use with the RHCOS live installer and the `coreos-installer` command.

12.4.11.3.9.1. Networking and bonding options for ISO installations

If you install RHCOS from an ISO image, you can add kernel arguments manually when you boot the image to configure networking for a node. If no networking arguments are specified, DHCP is activated in the initramfs when RHCOS detects that networking is required to fetch the Ignition config file.

**IMPORTANT**

When adding networking arguments manually, you must also add the `rd.neednet=1` kernel argument to bring the network up in the initramfs.

The following information provides examples for configuring networking and bonding on your RHCOS nodes for ISO installations. The examples describe how to use the `ip=`, `nameserver=`, and `bond=` kernel arguments.

**NOTE**

Ordering is important when adding the kernel arguments: `ip=`, `nameserver=`, and then `bond=`.

The networking options are passed to the `dracut` tool during system boot. For more information about the networking options supported by `dracut`, see the `dracut.cmdline` manual page.

The following examples are the networking options for ISO installation.

**Configuring DHCP or static IP addresses**

To configure an IP address, either use DHCP (`ip=dhcp`) or set an individual static IP address (`ip=<host_ip>`). If setting a static IP, you must then identify the DNS server IP address (`nameserver=<dns_ip>`) on each node. The following example sets:

- The node’s IP address to **10.10.10.2**
- The gateway address to **10.10.10.254**
- The netmask to **255.255.255.0**
- The hostname to **core0.example.com**
- The DNS server address to **4.4.4.41**
- The auto-configuration value to **none**. No auto-configuration is required when IP networking is configured statically.

```
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none
nameserver=4.4.4.41
```
NOTE
When you use DHCP to configure IP addressing for the RHCOS machines, the machines also obtain the DNS server information through DHCP. For DHCP-based deployments, you can define the DNS server address that is used by the RHCOS nodes through your DHCP server configuration.

Configuring an IP address without a static hostname
You can configure an IP address without assigning a static hostname. If a static hostname is not set by the user, it will be picked up and automatically set by a reverse DNS lookup. To configure an IP address without a static hostname refer to the following example:

- The node’s IP address to 10.10.10.2
- The gateway address to 10.10.10.254
- The netmask to 255.255.255.0
- The DNS server address to 4.4.4.41
- The auto-configuration value to none. No auto-configuration is required when IP networking is configured statically.

Specifying multiple network interfaces
You can specify multiple network interfaces by setting multiple ip= entries.

Configuring default gateway and route
Optional: You can configure routes to additional networks by setting an rd.route= value.

NOTE
When you configure one or multiple networks, one default gateway is required. If the additional network gateway is different from the primary network gateway, the default gateway must be the primary network gateway.

- Run the following command to configure the default gateway:
  ```
  ip=:10.10.10.254::
  ```
- Enter the following command to configure the route for the additional network:
  ```
  rd.route=20.20.20.0/24:20.20.20.254:enp2s0
  ```

Disabling DHCP on a single interface
You can disable DHCP on a single interface, such as when there are two or more network interfaces and only one interface is being used. In the example, the enp1s0 interface has a static networking configuration and DHCP is disabled for enp2s0, which is not used:
Combining DHCP and static IP configurations
You can combine DHCP and static IP configurations on systems with multiple network interfaces, for example:

```
[53x748]Combining DHCP and static IP configurations
You can combine DHCP and static IP configurations on systems with multiple network interfaces, for example:

[53x648]Configuring VLANs on individual interfaces
Optional: You can configure VLANs on individual interfaces by using the `vlan=` parameter.

To configure a VLAN on a network interface and use a static IP address, run the following command:
```

```
Configuring VLANs on individual interfaces
Optional: You can configure VLANs on individual interfaces by using the `vlan=` parameter.

To configure a VLAN on a network interface and use a static IP address, run the following command:

```
To configure a VLAN on a network interface and to use DHCP, run the following command:

```
To configure a VLAN on a network interface and to use DHCP, run the following command:

```
Providing multiple DNS servers
You can provide multiple DNS servers by adding a `nameserver=` entry for each server, for example:

```
Providing multiple DNS servers
You can provide multiple DNS servers by adding a `nameserver=` entry for each server, for example:

```
Bonding multiple network interfaces to a single interface
Optional: You can bond multiple network interfaces to a single interface by using the `bond=` option. Refer to the following examples:

```
Bonding multiple network interfaces to a single interface
Optional: You can bond multiple network interfaces to a single interface by using the `bond=` option. Refer to the following examples:

```
The syntax for configuring a bonded interface is: `bond=<name>[:<network_interfaces>] [:options]`

- `<name>` is the bonding device name (bond0), `<network_interfaces>` represents a comma-separated list of physical (ethernet) interfaces (em1, em2), and `options` is a comma-separated list of bonding options. Enter `modinfo bonding` to see available options.

- When you create a bonded interface using `bond=`, you must specify how the IP address is assigned and other information for the bonded interface.

  - To configure the bonded interface to use DHCP, set the bond’s IP address to `dhcp`. For example:

    ```
    bond=bond0:em1,em2:mode=active-backup
    ip=bond0:dhcp
    ```

  - To configure the bonded interface to use a static IP address, enter the specific IP address you want and related information. For example:

    ```
    bond=bond0:em1,em2:mode=active-backup
    ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:bond0: none
    ```
Bonding multiple SR-IOV network interfaces to a dual port NIC interface

**IMPORTANT**

Support for Day 1 operations associated with enabling NIC partitioning for SR-IOV devices is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see [Technology Preview Features Support Scope](#).

Optional: You can bond multiple SR-IOV network interfaces to a dual port NIC interface by using the `bond=` option.

On each node, you must perform the following tasks:

1. Create the SR-IOV virtual functions (VFs) following the guidance in [Managing SR-IOV devices](#). Follow the procedure in the “Attaching SR-IOV networking devices to virtual machines” section.

2. Create the bond, attach the desired VFs to the bond and set the bond link state up following the guidance in [Configuring network bonding](#). Follow any of the described procedures to create the bond.

The following examples illustrate the syntax you must use:

- The syntax for configuring a bonded interface is `bond=<name>[::<network_interfaces>][::options]`. `<name>` is the bonding device name (bond0), `<network_interfaces>` represents the virtual functions (VFs) by their known name in the kernel and shown in the output of the `ip link` command (eno1f0, eno2f0), and `options` is a comma-separated list of bonding options. Enter `modinfo bonding` to see available options.

- When you create a bonded interface using `bond=`, you must specify how the IP address is assigned and other information for the bonded interface.
  - To configure the bonded interface to use DHCP, set the bond’s IP address to `dhcp`. For example:
    ```
    bond=bond0:eno1f0,eno2f0:mode=active-backup
    ip=bond0:dhcp
    ```
  - To configure the bonded interface to use a static IP address, enter the specific IP address you want and related information. For example:
    ```
    bond=bond0:eno1f0,eno2f0:mode=active-backup
    ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:bond0:none
    ```

Using network teaming

Optional: You can use a network teaming as an alternative to bonding by using the `team=` parameter:

- The syntax for configuring a team interface is: `team=name::network_interfaces`
name is the team device name (team0) and network_interfaces represents a comma-separated list of physical (ethernet) interfaces (em1, em2).

NOTE
Teaming is planned to be deprecated when RHCOS switches to an upcoming version of RHEL. For more information, see this Red Hat Knowledgebase Article.

Use the following example to configure a network team:

```
team=team0:em1,em2
ip=team0:dhcp
```

### 12.4.11.3.9.2. coreos-installer options for ISO and PXE installations

You can install RHCOS by running `coreos-installer install <options> <device>` at the command prompt, after booting into the RHCOS live environment from an ISO image.

The following table shows the subcommands, options, and arguments you can pass to the `coreos-installer` command.

| Table 12.36. coreos-installer subcommands, command-line options, and arguments |
|----------------------------------|----------------------------------|
| **coreos-installer install subcommand** | **Description** |
| $ coreos-installer install <options> <device> | Embed an Ignition config in an ISO image. |

<p>| <strong>coreos-installer install subcommand options</strong> | <strong>Description</strong> |
| <strong>Option</strong> | <strong>Description</strong> |
| -u, --image-url &lt;url&gt; | Specify the image URL manually. |
| -f, --image-file &lt;path&gt; | Specify a local image file manually. Used for debugging. |
| -i, --ignition-file &lt;path&gt; | Embed an Ignition config from a file. |
| -I, --ignition-url &lt;URL&gt; | Embed an Ignition config from a URL. |
| --ignition-hash &lt;digest&gt; | Digest type-value of the Ignition config. |
| -p, --platform &lt;name&gt; | Override the Ignition platform ID for the installed system. |</p>
<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--console &lt;spec&gt;</td>
<td>Set the kernel and bootloader console for the installed system. For more information about the format of <code>&lt;spec&gt;</code>, see the Linux kernel serial console documentation.</td>
</tr>
<tr>
<td>--append-karg &lt;arg&gt;...</td>
<td>Append a default kernel argument to the installed system.</td>
</tr>
<tr>
<td>--delete-karg &lt;arg&gt;...</td>
<td>Delete a default kernel argument from the installed system.</td>
</tr>
<tr>
<td>-n, --copy-network</td>
<td>Copy the network configuration from the install environment.</td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
</tr>
<tr>
<td></td>
<td>The <code>--copy-network</code> option only copies networking configuration found under <code>/etc/NetworkManager/system-connections</code>. In particular, it does not copy the system hostname.</td>
</tr>
<tr>
<td>--network-dir &lt;path&gt;</td>
<td>For use with <code>-n</code>. Default is <code>/etc/NetworkManager/system-connections/</code>.</td>
</tr>
<tr>
<td>--save-partlabel &lt;lx&gt;..</td>
<td>Save partitions with this label glob.</td>
</tr>
<tr>
<td>--save-partindex &lt;id&gt;...</td>
<td>Save partitions with this number or range.</td>
</tr>
<tr>
<td>--insecure</td>
<td>Skip RHCOS image signature verification.</td>
</tr>
<tr>
<td>--insecure-ignition</td>
<td>Allow Ignition URL without HTTPS or hash.</td>
</tr>
<tr>
<td>--architecture &lt;name&gt;</td>
<td>Target CPU architecture. Valid values are <code>x86_64</code> and <code>aarch64</code>.</td>
</tr>
<tr>
<td>--preserve-on-error</td>
<td>Do not clear partition table on error.</td>
</tr>
<tr>
<td>-h, --help</td>
<td>Print help information.</td>
</tr>
</tbody>
</table>

coreos-installer install subcommand argument

<thead>
<tr>
<th>Subcommand</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>coreos-installer pxe customize &lt;options&gt; &lt;path&gt;</code></td>
<td>Customize a RHCOS live PXE boot config.</td>
</tr>
<tr>
<td><code>coreos-installer pxe ignition wrap &lt;options&gt;</code></td>
<td>Wrap an Ignition config in an image.</td>
</tr>
<tr>
<td><code>coreos-installer pxe ignition unwrap &lt;options&gt; &lt;image_name&gt;</code></td>
<td>Show the wrapped Ignition config in an image.</td>
</tr>
</tbody>
</table>

**coreos-installer PXE customize subcommand options**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--dest-ignition &lt;path&gt;</code></td>
<td>Merge the specified Ignition config file into a new configuration fragment for the destination system.</td>
</tr>
<tr>
<td><code>--dest-console &lt;spec&gt;</code></td>
<td>Specify the kernel and bootloader console for the destination system.</td>
</tr>
<tr>
<td><code>--dest-device &lt;path&gt;</code></td>
<td>Install and overwrite the specified destination device.</td>
</tr>
<tr>
<td><code>--network-keyfile &lt;path&gt;</code></td>
<td>Configure networking by using the specified NetworkManager keyfile for live and destination systems.</td>
</tr>
</tbody>
</table>
- `--ignition-ca <path>` Specify an additional TLS certificate authority to be trusted by Ignition.

- `--pre-install <path>` Run the specified script before installation.

- `post-install <path>` Run the specified script after installation.

- `--installer-config <path>` Apply the specified installer configuration file.

- `--live-ignition <path>` Merge the specified Ignition config file into a new configuration fragment for the live environment.

- `--output <path>` Write the initramfs to a new output file.

- `-o, --output <path>`

  **NOTE**

  This option is required for PXE environments.

- `-h, --help` Print help information.

### 12.4.11.3.9.3. coreos.inst boot options for ISO or PXE installations

You can automatically invoke `coreos-installer` options at boot time by passing `coreos.inst` boot arguments to the RHCOS live installer. These are provided in addition to the standard boot arguments.

- For ISO installations, the `coreos.inst` options can be added by interrupting the automatic boot at the bootloader menu. You can interrupt the automatic boot by pressing **TAB** while the **RHEL CoreOS (Live)** menu option is highlighted.

- For PXE or iPXE installations, the `coreos.inst` options must be added to the **APPEND** line before the RHCOS live installer is booted.

The following table shows the RHCOS live installer `coreos.inst` boot options for ISO and PXE installations.

**Table 12.37. coreos.inst boot options**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>coreos.inst.install_dev</td>
<td>Required. The block device on the system to install to. It is recommended to use the full path, such as <code>/dev/sda</code>, although <code>sda</code> is allowed.</td>
</tr>
<tr>
<td>coreos.inst.ignition_url</td>
<td>Optional: The URL of the Ignition config to embed into the installed system. If no URL is specified, no Ignition config is embedded. Only HTTP and HTTPS protocols are supported.</td>
</tr>
<tr>
<td>Argument</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>coreos.inst.save_partlabel</td>
<td>Optional: Comma-separated labels of partitions to preserve during the install. Glob-style wildcards are permitted. The specified partitions do not need to exist.</td>
</tr>
<tr>
<td>coreos.inst.save_partindex</td>
<td>Optional: Comma-separated indexes of partitions to preserve during the install. Ranges m-n are permitted, and either m or n can be omitted. The specified partitions do not need to exist.</td>
</tr>
<tr>
<td>coreos.inst.insecure</td>
<td>Optional: Permits the OS image that is specified by coreos.inst.image_url to be unsigned.</td>
</tr>
<tr>
<td>coreos.inst.image_url</td>
<td>Optional: Download and install the specified RHCOS image. This argument should not be used in production environments and is intended for debugging purposes only.</td>
</tr>
<tr>
<td></td>
<td>* This argument should not be used in production environments and is intended for debugging purposes only.</td>
</tr>
<tr>
<td></td>
<td>* While this argument can be used to install a version of RHCOS that does not match the live media, it is recommended that you instead use the media that matches the version you want to install.</td>
</tr>
<tr>
<td></td>
<td>* If you are using coreos.inst.image_url, you must also use coreos.inst.insecure. This is because the bare-metal media are not GPG-signed for OpenShift Container Platform.</td>
</tr>
<tr>
<td></td>
<td>* Only HTTP and HTTPS protocols are supported.</td>
</tr>
<tr>
<td>coreos.inst.skip_reboot</td>
<td>Optional: The system will not reboot after installing. After the install finishes, you will receive a prompt that allows you to inspect what is happening during installation. This argument should not be used in production environments and is intended for debugging purposes only.</td>
</tr>
<tr>
<td>coreos.inst.platform_id</td>
<td>Optional: The Ignition platform ID of the platform the RHCOS image is being installed on. Default is metal. This option determines whether or not to request an Ignition config from the cloud provider, such as VMware. For example: coreos.inst.platform_id=vmware.</td>
</tr>
</tbody>
</table>
### 12.4.11.4. Enabling multipathing with kernel arguments on RHCOS

RHCOS supports multipathing on the primary disk, allowing stronger resilience to hardware failure to achieve higher host availability.

You can enable multipathing at installation time for nodes that were provisioned in OpenShift Container Platform 4.8 or later. While postinstallation support is available by activating multipathing via the machine config, enabling multipathing during installation is recommended.

In setups where any I/O to non-optimized paths results in I/O system errors, you must enable multipathing at installation time.

**IMPORTANT**

On IBM Z® and IBM® LinuxONE, you can enable multipathing only if you configured your cluster for it during installation. For more information, see “Installing RHCOS and starting the OpenShift Container Platform bootstrap process” in *Installing a cluster with z/VM on IBM Z® and IBM® LinuxONE*.

The following procedure enables multipath at installation time and appends kernel arguments to the `coreos-installer install` command so that the installed system itself will use multipath beginning from the first boot.

**NOTE**

OpenShift Container Platform does not support enabling multipathing as a day-2 activity on nodes that have been upgraded from 4.6 or earlier.

**Procedure**

1. To enable multipath and start the `multipathd` daemon, run the following command:

   ```
   $ mpathconf --enable && systemctl start multipathd.service
   ```

   - Optional: If booting the PXE or ISO, you can instead enable multipath by adding `rd.multipath=default` from the kernel command line.

2. Append the kernel arguments by invoking the `coreos-installer` program:

   ```
   $ coreos-installer install /dev/mapper/mpatha \
   --append-karg rd.multipath=default \n   ```

#### Argument Table

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ignition.config.url</code></td>
<td>Optional: The URL of the Ignition config for the live boot. For example, this can be used to customize how <code>coreos-installer</code> is invoked, or to run code before or after the installation. This is different from <code>coreos.inst.ignition_url</code>, which is the Ignition config for the installed system.</td>
</tr>
</tbody>
</table>
Indicates the path of the single multipathed device.

- If there are multiple multipath devices connected to the machine, or to be more explicit, instead of using `/dev/mapper/mpatha`, it is recommended to use the World Wide Name (WWN) symlink available in `/dev/disk/by-id`. For example:

```
$ coreos-installer install /dev/disk/by-id/wwn-<wwn_ID> \
   --append-karg rd.multipath=default \ 
   --append-karg root=/dev/disk/by-label/dm-mpath-root \ 
   --append-karg rw
```

1. Indicates the WWN ID of the target multipathed device. For example, 00x194e957fcedb4841.

This symlink can also be used as the `coreos.inst.install_dev` kernel argument when using special `coreos.inst.*` arguments to direct the live installer. For more information, see "Installing RHCOS and starting the OpenShift Container Platform bootstrap process".

3. Check that the kernel arguments worked by going to one of the worker nodes and listing the kernel command line arguments (in `/proc/cmdline` on the host):

```
$ oc debug node/ip-10-0-141-105.ec2.internal
```

**Example output**

```
Starting pod/ip-10-0-141-105ec2internal-debug ...
To use host binaries, run `chroot /host`

sh-4.2# cat /host/proc/cmdline
...
   rd.multipath=default root=/dev/disk/by-label/dm-mpath-root
...
sh-4.2# exit
```

You should see the added kernel arguments.

### 12.4.11.5. Updating the bootloader using bootupd

To update the bootloader by using `bootupd`, you must either install `bootupd` on RHCOS machines manually or provide a machine config with the enabled `systemd` unit. Unlike `grubby` or other bootloader tools, `bootupd` does not manage kernel space configuration such as passing kernel arguments.

After you have installed `bootupd`, you can manage it remotely from the OpenShift Container Platform cluster.
NOTE

It is recommended that you use **bootupd** only on bare metal or virtualized hypervisor installations, such as for protection against the BootHole vulnerability.

**Manual install method**

You can manually install **bootupd** by using the **bootctl** command-line tool.

1. Inspect the system status:

```
# bootupctl status
```

**Example output for x86_64**

| Component EFI | Installed: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64 | Update: At latest version |

**Example output for aarch64**

| Component EFI | Installed: grub2-efi-aa64-1:2.02-99.el8_4.1.aarch64,shim-aa64-15.4-2.el8_1.aarch64 | Update: At latest version |

2. RHOCOS images created without **bootupd** installed on them require an explicit adoption phase. If the system status is **Adoptable**, perform the adoption:

```
# bootupctl adopt-and-update
```

**Example output**

- Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64

3. If an update is available, apply the update so that the changes take effect on the next reboot:

```
# bootupctl update
```

**Example output**

- Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64

**Machine config method**

Another way to enable **bootupd** is by providing a machine config.

- Provide a machine config file with the enabled **systemd** unit, as shown in the following example:

**Example output**

```
  variant: rhcos
  version: 1.1.0
```
12.4.12. Waiting for the bootstrap process to complete

The OpenShift Container Platform bootstrap process begins after the cluster nodes first boot into the persistent RHCOS environment that has been installed to disk. The configuration information provided through the Ignition config files is used to initialize the bootstrap process and install OpenShift Container Platform on the machines. You must wait for the bootstrap process to complete.

Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have obtained the installation program and generated the Ignition config files for your cluster.
- You installed RHCOS on your cluster machines and provided the Ignition config files that the OpenShift Container Platform installation program generated.

Procedure

1. Monitor the bootstrap process:

   $ ./openshift-install --dir <installation_directory> wait-for bootstrap-complete \  
   --log-level=info

1  For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2  To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

Example output

INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
INFO API v1.27.3 up
INFO Waiting up to 30m0s for bootstrapping to complete...
INFO It is now safe to remove the bootstrap resources
The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After the bootstrap process is complete, remove the bootstrap machine from the load balancer.

**IMPORTANT**

You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the bootstrap machine itself.

Additional resources

- See Monitoring installation progress for more information about monitoring the installation logs and retrieving diagnostic data if installation issues arise.

### 12.4.13. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

**Procedure**

1. Export the **kubeadmin** credentials:

   ```
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

   ```
   $ oc whoami
   ```

   **Example output**

   ```
   system:admin
   ```

### 12.4.14. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

**Prerequisites**
• You added machines to your cluster.

Procedure

1. Confirm that the cluster recognizes the machines:

   ```
   $ oc get nodes
   ```

   **Example output**

   ```
   NAME     STATUS    ROLES   AGE    VERSION
   master-0 Ready master 63m    v1.27.3
   master-1 Ready master 63m    v1.27.3
   master-2 Ready master 64m    v1.27.3
   ```

   The output lists all of the machines that you created.

   **NOTE**

   The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

   ```
   $ oc get csr
   ```

   **Example output**

   ```
   NAME        AGE     REQUESTOR                                    CONDITION
   csr-8b2br   15m     system:serviceaccount:openshift-machine-config-operator:node-bootstrapper    Pending
   csr-8vnps   15m     system:serviceaccount:openshift-machine-config-operator:node-bootstrapper    Pending
   ...          
   ```

   In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

   **NOTE**

   Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.
NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the `oc exec`, `oc rsh`, and `oc logs` commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the node-bootstrapper service account in the `system:node` or `system:admin` groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

  ```bash
  $ oc adm certificate approve <csr_name> 1
  
  1 <csr_name> is the name of a CSR from the list of current CSRs.
  
  - To approve all pending CSRs, run the following command:

  ```bash
  $ oc adm certificate approve <csr_name>
  ```

NOTE

Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

  ```bash
  $ oc get csr
  ```

Example output

| NAME      | AGE     | REQUESTOR                                                      | CONDITION          |
|-----------|---------|                                                               |                    |
| csr-bfd72 | 5m26s   | system:node:ip-10-0-50-126.us-east-2.compute.internal         | Pending            |
| csr-c57lv | 5m26s   | system:node:ip-10-0-95-157.us-east-2.compute.internal         | Pending            |

5. If the remaining CSRs are not approved, and are in the `Pending` status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

  ```bash
  $ oc adm certificate approve <csr_name> 1
  
  1 <csr_name> is the name of a CSR from the list of current CSRs.
  ```
To approve all pending CSRs, run the following command:

```bash
$ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs oc adm certificate approve
```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```bash
$ oc get nodes
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>74m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>worker-0</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>worker-1</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.27.3</td>
</tr>
</tbody>
</table>

**NOTE**

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

**Additional information**

- For more information on CSRs, see [Certificate Signing Requests](#).

**12.4.15. Initial Operator configuration**

After the control plane initializes, you must immediately configure some Operators so that they all become available.

**Prerequisites**

- Your control plane has initialized.

**Procedure**

1. Watch the cluster components come online:

```bash
$ watch -n5 oc get clusteroperators
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
<th>SINCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>authentication</td>
<td>4.14.0</td>

<td>38m</td>
</tr>
</tbody>
</table>
### 12.4.15.1. Disabling the default OperatorHub catalog sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

**Procedure**

- Disable the sources for the default catalogs by adding `disableAllDefaultSources: true` to the `OperatorHub` object:

  ```
  $ oc patch OperatorHub cluster --type json -p 
  '[{"op": "add", "path": "/spec/disableAllDefaultSources", "value": true}]'
  ```

---

### 2. Configure the Operators that are not available.

**Additional resources**

- See [Gathering logs from a failed installation](#) for details about gathering data in the event of a failed OpenShift Container Platform installation.

- See [Troubleshooting Operator issues](#) for steps to check Operator pod health across the cluster and gather Operator logs for diagnosis.
TIP

Alternatively, you can use the web console to manage catalog sources. From the Administration → Cluster Settings → Configuration → OperatorHub page, click the Sources tab, where you can create, update, delete, disable, and enable individual sources.

12.4.15.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the Recreate rollout strategy during upgrades.

12.4.15.2.1. Changing the image registry’s management state

To start the image registry, you must change the Image Registry Operator configuration’s managementState from Removed to Managed.

Procedure

- Change managementState Image Registry Operator configuration from Removed to Managed. For example:

  $ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec": {"managementState":"Managed"}}'

12.4.15.2.2. Configuring registry storage for bare metal and other manual installations

As a cluster administrator, following installation you must configure your registry to use storage.

Prerequisites

- You have access to the cluster as a user with the cluster-admin role.

- You have a cluster that uses manually-provisioned Red Hat Enterprise Linux CoreOS (RHCOS) nodes, such as bare metal.

- You have provisioned persistent storage for your cluster, such as Red Hat OpenShift Data Foundation.

IMPORTANT

OpenShift Container Platform supports ReadWriteOnce access for image registry storage when you have only one replica. ReadWriteOnce access also requires that the registry uses the Recreate rollout strategy. To deploy an image registry that supports high availability with two or more replicas, ReadWriteMany access is required.
Must have 100Gi capacity.

Procedure

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

   **NOTE**
   When you use shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

   ```bash
   $ oc get pod -n openshift-image-registry -l docker-registry=default
   No resources found in openshift-image-registry namespace
   
   **NOTE**
   If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

   ```bash
   $ oc edit configs.imageregistry.operator.openshift.io
   
   **Example output**
   
   storage:
   pvc:
   claim:

   Leave the `claim` field blank to allow the automatic creation of an `image-registry-storage` PVC.

4. Check the `clusteroperator` status:

   ```bash
   $ oc get clusteroperator image-registry
   
   **Example output**
   
<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
<th>SINCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>image-registry</td>
<td>4.14</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>6h50m</td>
</tr>
</tbody>
</table>

5. Ensure that your registry is set to managed to enable building and pushing of images.

   - Run:
$ oc edit configs.imageregistry/cluster

Then, change the line

managementState: Removed

to

managementState: Managed

12.4.15.2.3. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

Procedure

- To set the image registry storage to an empty directory:

  $ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec": {"storage": {"emptyDir":{}}}'}

  **WARNING**
  Configure this option for only non-production clusters.

If you run this command before the Image Registry Operator initializes its components, the `oc patch` command fails with the following error:

  Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found

  Wait a few minutes and run the command again.

12.4.15.2.4. Configuring block registry storage

To allow the image registry to use block storage types during upgrades as a cluster administrator, you can use the *Recreate* rollout strategy.

**IMPORTANT**

Block storage volumes, or block persistent volumes, are supported but not recommended for use with the image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

If you choose to use a block storage volume with the image registry, you must use a filesystem persistent volume claim (PVC).
Procedure

1. To set the image registry storage as a block storage type, patch the registry so that it uses the `Recreate` rollout strategy and runs with only one (1) replica:

   $ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec":
   {"rolloutStrategy":"Recreate","replicas":1}}'

2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.

3. Edit the registry configuration so that it references the correct PVC.

12.4.16. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

Prerequisites

- Your control plane has initialized.
- You have completed the initial Operator configuration.

Procedure

1. Confirm that all the cluster components are online with the following command:

   $ watch -n5 oc get clusteroperators

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
<th>SINCE</th>

</tr>
</tbody>
</table>
Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```bash
$ ./openshift-install --dir <installation_directory> wait-for install-complete
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

### Example output

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

### IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

2. Confirm that the Kubernetes API server is communicating with the pods.
   a. To view a list of all pods, use the following command:

   ```bash
   $ oc get pods --all-namespaces
   ```

### Example output

```
NAMESPACE                     NAME                                            READY   STATUS
OpenShift Container Platform 4.14 Installing 2212
```

```bash
$ ./openshift-install --dir <installation_directory> wait-for install-complete
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.
b. View the logs for a pod that is listed in the output of the previous command by using the following command:

```
$ oc logs <pod_name> -n <namespace>
```

Specify the pod name and namespace, as shown in the output of the previous command.

If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation.

See "Enabling multipathing with kernel arguments on RHCOS" in the Post-installation machine configuration tasks documentation for more information.

4. Register your cluster on the Cluster registration page.

### 12.4.17. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager Hybrid Cloud Console.

After you confirm that your OpenShift Cluster Manager Hybrid Cloud Console inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- See About remote health monitoring for more information about the Telemetry service

### 12.4.18. Next steps

- Validating an installation.
- Customize your cluster.
- Configure image streams for the Cluster Samples Operator and the must-gather tool.
Learn how to use Operator Lifecycle Manager (OLM) on restricted networks.

If the mirror registry that you used to install your cluster has a trusted CA, add it to the cluster by configuring additional trust stores.

If necessary, you can opt out of remote health reporting.

If necessary, see Registering your disconnected cluster.

12.5. SCALING A USER-PROVISIONED CLUSTER WITH THE BARE METAL OPERATOR

After deploying a user-provisioned infrastructure cluster, you can use the Bare Metal Operator (BMO) and other metal3 components to scale bare-metal hosts in the cluster. This approach helps you to scale a user-provisioned cluster in a more automated way.

12.5.1. About scaling a user-provisioned cluster with the Bare Metal Operator

You can scale user-provisioned infrastructure clusters by using the Bare Metal Operator (BMO) and other metal3 components. User-provisioned infrastructure installations do not feature the Machine API Operator. The Machine API Operator typically manages the lifecycle of bare-metal hosts in a cluster. However, it is possible to use the BMO and other metal3 components to scale nodes in user-provisioned clusters without requiring the Machine API Operator.

12.5.1.1. Prerequisites for scaling a user-provisioned cluster

- You installed a user-provisioned infrastructure cluster on bare metal.
- You have baseboard management controller (BMC) access to the hosts.

12.5.1.2. Limitations for scaling a user-provisioned cluster

- You cannot use a provisioning network to scale user-provisioned infrastructure clusters by using the Bare Metal Operator (BMO).
  - Consequentially, you can only use bare-metal host drivers that support virtual media networking booting, for example redfish-virtualmedia and idrac-virtualmedia.
- You cannot scale MachineSet objects in user-provisioned infrastructure clusters by using the BMO.

12.5.2. Configuring a provisioning resource to scale user-provisioned clusters

Create a Provisioning custom resource (CR) to enable Metal platform components on a user-provisioned infrastructure cluster.

**Prerequisites**

- You installed a user-provisioned infrastructure cluster on bare metal.

**Procedure**

1. Create a Provisioning CR.
a. Save the following YAML in the **provisioning.yaml** file:

```yaml
apiVersion: metal3.io/v1alpha1
kind: Provisioning
metadata:
  name: provisioning-configuration
spec:
  provisioningNetwork: "Disabled"
  watchAllNamespaces: false
```

2. Create the **Provisioning** CR by running the following command:

```
$ oc create -f provisioning.yaml
```

**Example output**

```
provisioning.metal3.io/provisioning-configuration created
```

**Verification**

- Verify that the provisioning service is running by running the following command:

```
$ oc get pods -n openshift-machine-api
```

**Example output**

```
NAME                                                  READY   STATUS    RESTARTS        AGE
cluster-autoscaler-operator-678c476f4c-jjdn5          2/2     Running   0               5d21h

### 12.5.3. Provisioning new hosts in a user-provisioned cluster by using the BMO

You can use the Bare Metal Operator (BMO) to provision bare-metal hosts in a user-provisioned cluster by creating a **BareMetalHost** custom resource (CR).
NOTE
To provision bare-metal hosts to the cluster by using the BMO, you must set the `spec.externallyProvisioned` specification in the `BareMetalHost` custom resource to `false`.

Prerequisites

- You created a user-provisioned bare-metal cluster.
- You have baseboard management controller (BMC) access to the hosts.
- You deployed a provisioning service in the cluster by creating a `Provisioning` CR.

Procedure

1. Create the `Secret` CR and the `BareMetalHost` CR.
   a. Save the following YAML in the `bmh.yaml` file:

   ```yaml
   ---
   apiVersion: v1
   kind: Secret
   metadata:
     name: worker1-bmc
     namespace: openshift-machine-api
   type: Opaque
   data:
     username: <base64_of_uid>
     password: <base64_of_pwd>
   ---
   apiVersion: metal3.io/v1alpha1
   kind: BareMetalHost
   metadata:
     name: worker1
     namespace: openshift-machine-api
   spec:
     bmc:
       address: <protocol>://<bmc_url>
       credentialsName: "worker1-bmc"
       bootMACAddress: <nic1_mac_address>
     externallyProvisioned: false
     customDeploy:
       method: install_coreos
       online: true
       userData:
         name: worker-user-data-managed
         namespace: openshift-machine-api
   ```

   1. You can only use bare-metal host drivers that support virtual media networking booting, for example `redfish-virtualmedia` and `idrac-virtualmedia`.
   2. You must set the `spec.externallyProvisioned` specification in the `BareMetalHost` custom resource to `false`. The default value is `false`. 

2216
2. Create the bare-metal host object by running the following command:

```
$ oc create -f bmh.yaml
```

**Example output**

```
secret/worker1-bmc created
baremetalhost.metal3.io/worker1 created
```

3. Approve all certificate signing requests (CSRs).

   a. Verify that the provisioning state of the host is **provisioned** by running the following command:

```
$ oc get bmh -A
```

**Example output**

```
NAMESPACE               NAME          STATE                    CONSUMER   ONLINE       ERROR   AGE
openshift-machine-api   controller1   externally provisioned              true             5m25s
openshift-machine-api   worker1       provisioned                         true             4m45s
```

   b. Get the list of pending CSRs by running the following command:

```
$ oc get csr
```

**Example output**

```
NAME        AGE   SIGNERNAME                                    REQUESTOR
REQUESTEDDURATION CONDITION
csr-gfm9f   33s   kubernetes.io/kube-apiserver-client-kubelet
    system:serviceaccount:openshift-machine-config-operator:node-bootstrapper <none> Pending
```

   c. Approve the CSR by running the following command:

```
$ oc adm certificate approve <csr_name>
```

**Example output**

```
certificatesigningrequest.certificates.k8s.io/<csr_name> approved
```

**Verification**

- Verify that the node is ready by running the following command:

```
$ oc get nodes
```

**Example output**
12.5.4. Optional: Managing existing hosts in a user-provisioned cluster by using the BMO

Optionally, you can use the Bare Metal Operator (BMO) to manage existing bare-metal controller hosts in a user-provisioned cluster by creating a **BareMetalHost** object for the existing host. It is not a requirement to manage existing user-provisioned hosts; however, you can enroll them as externally-provisioned hosts for inventory purposes.

**IMPORTANT**

To manage existing hosts by using the BMO, you must set the `spec.externallyProvisioned` specification in the **BareMetalHost** custom resource to `true` to prevent the BMO from re-provisioning the host.

**Prerequisites**

- You created a user-provisioned bare-metal cluster.
- You have baseboard management controller (BMC) access to the hosts.
- You deployed a provisioning service in the cluster by creating a **Provisioning** CR.

**Procedure**

1. Create the **Secret** CR and the **BareMetalHost** CR.
   a. Save the following YAML in the `controller.yaml` file:

```
---
apiVersion: v1
kind: Secret
data:
  username: <base64_of_uid>
  password: <base64_of_pwd>
---
apiVersion: metal3.io/v1alpha1
kind: BareMetalHost
type: Opaque
data:
  username: <base64_of_uid>
  password: <base64_of_pwd>
---
apiVersion: metal3.io/v1alpha1
kind: Provisioning
```
You can only use bare-metal host drivers that support virtual media networking booting, for example redfish-virtualmedia and idrac-virtualmedia.

You must set the value to true to prevent the BMO from re-provisioning the bare-metal controller host.

2. Create the bare-metal host object by running the following command:

   
   $ oc create -f controller.yaml

   
   Example output

   
   secret/controller1-bmc created
   baremetalhost.metal3.io/controller1 created

   
   Verification

   
   - Verify that the BMO created the bare-metal host object by running the following command:

     
     $ oc get bmh -A

     
     Example output

     
     NAMESPACE       NAME          STATE                    CONSUMER   ONLINE   ERROR AGE
     openshift-machine-api controller1  externally provisioned              true             13s

12.5.5. Removing hosts from a user-provisioned cluster by using the BMO

You can use the Bare Metal Operator (BMO) to remove bare-metal hosts from a user-provisioned cluster.

Prerequisites

- You created a user-provisioned bare-metal cluster.

- You have baseboard management controller (BMC) access to the hosts.

- You deployed a provisioning service in the cluster by creating a Provisioning CR.

Procedure

1. Cordon and drain the host by running the following command:

   
   $ oc adm drain app1 --force --ignore-daemonsets=true
2. Delete the `customDeploy` specification from the `BareMetalHost` CR.

   a. Edit the `BareMetalHost` CR for the host by running the following command:

      ```
      $ oc edit bmh -n openshift-machine-api <host_name>
      ...
      customDeploy:
      method: install_coreos
      ```

   b. Delete the lines `spec.customDeploy` and `spec.customDeploy.method`:

      ```
      ...
      customDeploy:
      method: install_coreos
      ```

   c. Verify that the provisioning state of the host changes to `deprovisioning` by running the following command:

      ```
      $ oc get bmh -A
      ```

**Example output**

<table>
<thead>
<tr>
<th>NAMESPACE</th>
<th>NAME</th>
<th>STATE</th>
<th>CONSUMER</th>
<th>ONLINE</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>openshift-machine-api</td>
<td>controller1</td>
<td>externally provisioned</td>
<td>true</td>
<td>58m</td>
<td></td>
</tr>
<tr>
<td>openshift-machine-api</td>
<td>worker1</td>
<td>deprovisioning</td>
<td>true</td>
<td>57m</td>
<td></td>
</tr>
</tbody>
</table>

3. Delete the node by running the following command:

   ```
   $ oc delete node <node_name>
   ```

**Verification**

- Verify the node is deleted by running the following command:
$ oc get nodes

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>controller1</td>
<td>Ready</td>
<td>master,worker</td>
<td>2d23h</td>
<td>v1.24.0+dc5a2fd</td>
</tr>
</tbody>
</table>

12.6. INSTALLATION CONFIGURATION PARAMETERS FOR BARE METAL

Before you deploy an OpenShift Container Platform cluster, you provide a customized `install-config.yaml` installation configuration file that describes the details for your environment.

12.6.1. Available installation configuration parameters for bare metal

The following tables specify the required, optional, and bare metal-specific installation configuration parameters that you can set as part of the installation process.

**NOTE**

After installation, you cannot modify these parameters in the `install-config.yaml` file.

12.6.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

**Table 12.38. Required parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion:</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is <code>v1</code>. The installation program may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>baseDomain:</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the <code>baseDomain</code> and <code>metadata.name</code> parameter values that uses the <code>&lt;metadata.name&gt;.&lt;baseDomain&gt;</code> format.</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
</tr>
</tbody>
</table>
### Parameter Details

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>metadata:</td>
<td>Kubernetes resource <code>ObjectMeta</code>, from which only the <code>name</code> parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata:</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of <code>{{.metadata.name}}. {{.baseDomain}}</code>.</td>
<td>String of lowercase letters and hyphens (-), such as <code>dev</code>.</td>
</tr>
<tr>
<td>platform:</td>
<td>The configuration for the specific platform upon which to perform the installation: <code>alibabacloud</code>, <code>aws</code>, <code>baremetal</code>, <code>azure</code>, <code>gcp</code>, <code>ibmcloud</code>, <code>nutanix</code>, <code>openstack</code>, <code>powersvs</code>, <code>vsphere</code>, or <code>{}</code>. For additional information about platform parameters, consult the table for your specific platform that follows.</td>
<td>Object</td>
</tr>
<tr>
<td>pullSecret:</td>
<td>Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.</td>
<td><code>{ &quot;auths&quot;: { &quot;cloud.openshift.com&quot;: { &quot;auth&quot;: &quot;b3Blb=&quot;, &quot;email&quot;: &quot;you@example.com&quot; }, &quot;quay.io&quot;: { &quot;auth&quot;: &quot;b3Blb=&quot;, &quot;email&quot;: &quot;you@example.com&quot; } } }</code></td>
</tr>
</tbody>
</table>

### 12.6.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

- If you use the Red Hat OpenShift Networking OVN-Kubernetes network plugin, both IPv4 and IPv6 address families are supported.
- If you use the Red Hat OpenShift Networking OpenShift SDN network plugin, only the IPv4 address family is supported.
If you configure your cluster to use both IP address families, review the following requirements:

- Both IP families must use the same network interface for the default gateway.
- Both IP families must have the default gateway.
- You must specify IPv4 and IPv6 addresses in the same order for all network configuration parameters. For example, in the following configuration IPv4 addresses are listed before IPv6 addresses.

```yaml
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
      hostPrefix: 23
    - cidr: fd00:10:128::/56
      hostPrefix: 64
  serviceNetwork:
    - 172.30.0.0/16
    - fd00:172:16::/112
```

**NOTE**

Globalnet is not supported with Red Hat OpenShift Data Foundation disaster recovery solutions. For regional disaster recovery scenarios, ensure that you use a nonoverlapping range of private IP addresses for the cluster and service networks in each cluster.

### Table 12.39. Network parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking:</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td>networking:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>networkType:</td>
<td>The Red Hat OpenShift Networking network plugin to install.</td>
<td>Either <strong>OpenShiftSDN</strong> or <strong>OVNKubernetes</strong>. <strong>OpenShiftSDN</strong> is a CNI plugin for all-Linux networks. <strong>OVNKubernetes</strong> is a CNI plugin for Linux networks and hybrid networks that contain both Linux and Windows servers. The default value is <strong>OVNKubernetes</strong>.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-----------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>networking: clusterNetwork:</td>
<td>The IP address blocks for pods.</td>
<td>The default value is <strong>10.128.0.0/14</strong> with a host prefix of <strong>/23</strong>.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>If you specify multiple IP address blocks, the blocks must not overlap.</td>
</tr>
<tr>
<td>networking: clusterNetwork: cidr:</td>
<td>Required if you use <code>networking.clusterNetwork</code>. An IP address block.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32. The prefix length for an IPv6 block is between 0 and 128. For example, <strong>10.128.0.0/14</strong> or <strong>fd01::/48</strong>.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>If you use the OpenShift SDN network plugin, specify an IPv4 network. If you use the OVN-Kubernetes network plugin, you can specify IPv4 and IPv6 networks.</td>
</tr>
<tr>
<td>networking: clusterNetwork: hostPrefix:</td>
<td>The subnet prefix length to assign to each individual node. For example, if <code>hostPrefix</code> is set to <strong>23</strong> then each node is assigned a <strong>/23</strong> subnet out of the given <code>cidr</code>. A <code>hostPrefix</code> value of <strong>23</strong> provides <strong>510</strong> (2^(32 - 23) - 2) pod IP addresses.</td>
<td>A subnet prefix.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>For an IPv4 network the default value is <strong>23</strong>. For an IPv6 network the default value is <strong>64</strong>. The default value is also the minimum value for IPv6.</td>
</tr>
<tr>
<td>networking: serviceNetwork:</td>
<td>The IP address block for services. The default value is <strong>172.30.0.0/16</strong>.</td>
<td>An array with an IP address block in CIDR format. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The OpenShift SDN and OVN-Kubernetes network plugins support only a single IP address block for the service network.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>If you use the OVN-Kubernetes network plugin, you can specify an IP address block for both of the IPv4 and IPv6 address families.</td>
</tr>
<tr>
<td>networking: machineNetwork:</td>
<td>The IP address blocks for machines.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>If you specify multiple IP address blocks, the blocks must not overlap.</td>
</tr>
</tbody>
</table>
**networking:**

*machineNetwork: cidr:*

Required if you use `networking.machineNetwork`. An IP address block. The default value is `10.0.0.0/16` for all platforms other than libvirt and IBM Power® Virtual Server. For libvirt, the default value is `192.168.126.0/24`. For IBM Power® Virtual Server, the default value is `192.168.0.0/24`.

NOTE

Set the `networking.machineNetwork` to match the CIDR that the preferred NIC resides in.

### 12.6.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

**Table 12.40. Optional parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle:</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes' trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>capabilities:</td>
<td>Controls the installation of optional core cluster components. You can reduce the footprint of your OpenShift Container Platform cluster by disabling optional components. For more information, see the &quot;Cluster capabilities&quot; page in <em>Installing</em>.</td>
<td>String array</td>
</tr>
<tr>
<td>baselineCapabilitySet:</td>
<td>Selects an initial set of optional capabilities to enable. Valid values are <code>None</code>, <code>v4.11</code>, <code>v4.12</code> and <code>vCurrent</code>. The default value is <code>vCurrent</code>.</td>
<td>String</td>
</tr>
<tr>
<td>capabilities:</td>
<td>Extends the set of optional capabilities beyond what you specify in <code>baselineCapabilitySet</code>. You may specify multiple capabilities in this parameter.</td>
<td>String array</td>
</tr>
</tbody>
</table>

---

**CHAPTER 12. INSTALLING ON BARE METAL**
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>cpuPartitioningMode:</td>
<td>Enables workload partitioning, which isolates OpenShift Container Platform services, cluster management workloads, and infrastructure pods to run on a reserved set of CPUs. Workload partitioning can only be enabled during installation and cannot be disabled after installation. While this field enables workload partitioning, it does not configure workloads to use specific CPUs. For more information, see the Workload partitioning page in the Scalability and Performance section.</td>
<td>None or AllNodes. None is the default value.</td>
</tr>
<tr>
<td>compute:</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of MachinePool objects.</td>
</tr>
<tr>
<td>compute: architecture:</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, clusters with varied architectures are not supported. All pools must specify the same architecture. Valid values are amd64 and arm64.</td>
<td>String</td>
</tr>
<tr>
<td>compute: hyperthreading:</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>compute: name:</td>
<td>Required if you use compute. The name of the machine pool.</td>
<td>worker</td>
</tr>
</tbody>
</table>

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>compute: platform:</td>
<td>Required if you use compute. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the controlPlane.platform parameter value.</td>
<td>alibabacloud, aws, azure, gcp, ibmcloud, nutanix, openstack, powervs, vsphere, or {}</td>
</tr>
<tr>
<td>compute: replicas:</td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td>featureSet:</td>
<td>Enables the cluster for a feature set. A feature set is a collection of OpenShift Container Platform features that are not enabled by default. For more information about enabling a feature set during installation, see &quot;Enabling features using feature gates&quot;.</td>
<td>String. The name of the feature set to enable, such as TechPreviewNoUpgrade.</td>
</tr>
<tr>
<td>controlPlane:</td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of MachinePool objects.</td>
</tr>
<tr>
<td>controlPlane:</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, clusters with varied architectures are not supported. All pools must specify the same architecture. Valid values are amd64 and arm64.</td>
<td>String</td>
</tr>
<tr>
<td>controlPlane:</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
</tbody>
</table>

**important**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.
<table>
<thead>
<tr>
<th>Parameter</th>

<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlPlane: name:</td>
<td>Required if you use controlPlane. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td>controlPlane: platform:</td>
<td>Required if you use controlPlane. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the compute.platform parameter value.</td>
<td>alibabacloud, aws, azure, gcp, ibmcloud, nutanix, openstack, powervs, vsphere, or {}</td>
</tr>
<tr>
<td>controlPlane: replicas:</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
<tr>
<td>credentialsMode:</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual or an empty string (&quot;&quot;&quot;).[1]</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td>fips:</td>
<td>Enable or disable FIPS mode. The default is <strong>false</strong> (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</td>
<td><strong>false</strong> or <strong>true</strong></td>
</tr>
</tbody>
</table>

**IMPORTANT**

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see [Installing the system in FIPS mode](#).

When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures.

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>imageContentSources:</td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects. Includes a source and, optionally, mirrors, as described in the following rows of this table.</td>
</tr>
<tr>
<td>imageContentSources: source:</td>
<td>Required if you use imageContentSources. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td>imageContentSources: mirrors:</td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
<tr>
<td>publish:</td>
<td>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</td>
<td>Internal or External. The default value is External. Setting this field to Internal is not supported on non-cloud platforms.</td>
</tr>
<tr>
<td>sshKey:</td>
<td>The SSH key to authenticate access to your cluster machines.</td>
<td>For example, sshKey: ssh-ed25519 AAAA...</td>
</tr>
</tbody>
</table>

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

1. Not all CCO modes are supported for all cloud providers. For more information about CCO modes, see the "Managing cloud provider credentials" entry in the Authentication and authorization content.
CHAPTER 13. INSTALLING ON-PREMISE WITH ASSISTED INSTALLER

13.1. INSTALLING AN ON-PREMISE CLUSTER USING THE ASSISTED INSTALLER

You can install OpenShift Container Platform on on-premise hardware or on-premise VMs by using the Assisted Installer. Installing OpenShift Container Platform by using the Assisted Installer supports x86_64, AArch64, ppc64le, and s390x CPU architectures.

13.1.1. Using the Assisted Installer

The OpenShift Container Platform Assisted Installer is a user-friendly installation solution offered on the Red Hat Hybrid Cloud Console. The Assisted Installer supports the various deployment platforms with a focus on bare metal, Nutanix, and vSphere infrastructures.

The Assisted Installer provides installation functionality as a service. This software-as-a-service (SaaS) approach has the following advantages:

- **Web user interface**: The web user interface performs cluster installation without the user having to create the installation configuration files manually.

- **No bootstrap node**: A bootstrap node is not required when installing with the Assisted Installer. The bootstrapping process executes on a node within the cluster.

- **Hosting**: The Assisted Installer hosts:
  - Ignition files
  - The installation configuration
  - A discovery ISO
  - The installer

- **Streamlined installation workflow**: Deployment does not require in-depth knowledge of OpenShift Container Platform. The Assisted Installer provides reasonable defaults and provides the installer as a service, which:
  - Eliminates the need to install and run the OpenShift Container Platform installer locally.
  - Ensures the latest version of the installer up to the latest tested z-stream releases. Older versions remain available, if needed.
  - Enables building automation by using the API without the need to run the OpenShift Container Platform installer locally.

- **Advanced networking**: The Assisted Installer supports IPv4 networking with SDN and OVN, IPv6 and dual stack networking with OVN only, NMState-based static IP addressing, and an HTTP/S proxy. OVN is the default Container Network Interface (CNI) for OpenShift Container Platform 4.12 and later releases, but you can use SDN.

- **Preinstallation validation**: The Assisted Installer validates the configuration before installation to ensure a high probability of success. Validation includes:
- Ensuring network connectivity
- Ensuring sufficient network bandwidth
- Ensuring connectivity to the registry
- Ensuring time synchronization between cluster nodes
- Verifying that the cluster nodes meet the minimum hardware requirements
- Validating the installation configuration parameters

**REST API:** The Assisted Installer has a REST API, enabling automation.

The Assisted Installer supports installing OpenShift Container Platform on premises in a connected environment, including with an optional HTTP/S proxy. It can install the following:

- Highly available OpenShift Container Platform or Single Node OpenShift (SNO)
- OpenShift Container Platform on bare metal, Nutanix, or vSphere with full platform integration, or other virtualization platforms without integration
- Optionally OpenShift Virtualization and OpenShift Data Foundation (formerly OpenShift Container Storage)

The user interface provides an intuitive interactive workflow where automation does not exist or is not required. Users may also automate installations using the REST API.

See [Install OpenShift with the Assisted Installer](#) to create an OpenShift Container Platform cluster with the Assisted Installer. See the [Assisted Installer for OpenShift Container Platform](#) documentation for details on using the Assisted Installer.

### 13.1.2. API support for the Assisted Installer

Supported APIs for the Assisted Installer are stable for a minimum of three months from the announcement of deprecation.
CHAPTER 14. INSTALLING AN ON-PREMISE CLUSTER WITH THE AGENT-BASED INSTALLER

14.1. PREPARING TO INSTALL WITH THE AGENT-BASED INSTALLER

14.1.1. About the Agent-based Installer

The Agent-based installation method provides the flexibility to boot your on-premises servers in any way that you choose. It combines the ease of use of the Assisted Installation service with the ability to run offline, including in air-gapped environments. Agent-based installation is a subcommand of the OpenShift Container Platform installer. It generates a bootable ISO image containing all of the information required to deploy an OpenShift Container Platform cluster, with an available release image.

The configuration is in the same format as for the installer-provisioned infrastructure and user-provisioned infrastructure installation methods. The Agent-based Installer can also optionally generate or accept Zero Touch Provisioning (ZTP) custom resources. ZTP allows you to provision new edge sites with declarative configurations of bare-metal equipment.

14.1.2. Understanding Agent-based Installer

As an OpenShift Container Platform user, you can leverage the advantages of the Assisted Installer hosted service in disconnected environments.

The Agent-based installation comprises a bootable ISO that contains the Assisted discovery agent and the Assisted Service. Both are required to perform the cluster installation, but the latter runs on only one of the hosts.

The `openshift-install agent create image` subcommand generates an ephemeral ISO based on the inputs that you provide. You can choose to provide inputs through the following manifests:

Preferred:

- `install-config.yaml`
- `agent-config.yaml`

or

Optional: ZTP manifests

- `cluster-manifests/cluster-deployment.yaml`
- `cluster-manifests/agent-cluster-install.yaml`
- `cluster-manifests/pull-secret.yaml`
- `cluster-manifests/infraenv.yaml`
- `cluster-manifests/cluster-image-set.yaml`
- `cluster-manifests/nmstateconfig.yaml`
- `mirror/registries.conf`
- `mirror/ca-bundle.crt`
14.1.2.1. Agent-based Installer workflow

One of the control plane hosts runs the Assisted Service at the start of the boot process and eventually becomes the bootstrap host. This node is called the rendezvous host (node 0). The Assisted Service ensures that all the hosts meet the requirements and triggers an OpenShift Container Platform cluster deployment. All the nodes have the Red Hat Enterprise Linux CoreOS (RHCOS) image written to the disk. The non-bootstrap nodes reboot and initiate a cluster deployment. Once the nodes are rebooted, the rendezvous host reboots and joins the cluster. The bootstrapping is complete and the cluster is deployed.

**Figure 14.1. Node installation workflow**

You can install a disconnected OpenShift Container Platform cluster through the `openshift-install agent create image` subcommand for the following topologies:

- A single-node OpenShift Container Platform cluster (SNO) A node that is both a master and worker.
• A three-node OpenShift Container Platform cluster: A compact cluster that has three master nodes that are also worker nodes.

• Highly available OpenShift Container Platform cluster (HA) Three master nodes with any number of worker nodes.

### 14.1.2.2. Recommended resources for topologies

Recommended cluster resources for the following topologies:

<table>
<thead>
<tr>
<th>Topology</th>
<th>Number of master nodes</th>
<th>Number of worker nodes</th>
<th>vCPU</th>
<th>Memory</th>
<th>Storage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single-node cluster</td>
<td>1</td>
<td>0</td>
<td>8 vCPU cores</td>
<td>16GB of RAM</td>
<td>120GB</td>
</tr>
<tr>
<td>Compact cluster</td>
<td>3</td>
<td>0 or 1</td>
<td>8 vCPU cores</td>
<td>16GB of RAM</td>
<td>120GB</td>
</tr>
<tr>
<td>HA cluster</td>
<td>3</td>
<td>2 and above</td>
<td>8 vCPU cores</td>
<td>16GB of RAM</td>
<td>120GB</td>
</tr>
</tbody>
</table>

The following platforms are supported:

- baremetal
- vsphere
- none

**IMPORTANT**

The **none** option requires the provision of DNS name resolution and load balancing infrastructure in your cluster. See the *Requirements for a cluster using the platform "none" option* section for more information.

**Additional resources**

- *Requirements for a cluster using the platform "none" option*
- *Increase the network MTU*
- *Adding worker nodes to single-node OpenShift clusters*

### 14.1.3. About FIPS compliance

For many OpenShift Container Platform customers, regulatory readiness, or compliance, on some level is required before any systems can be put into production. That regulatory readiness can be imposed by national standards, industry standards or the organization’s corporate governance framework. Federal Information Processing Standards (FIPS) compliance is one of the most critical components required in highly secure environments to ensure that only supported cryptographic technologies are allowed on nodes.
IMPORTANT

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see Installing the system in FIPS mode. When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures.

14.1.4. Configuring FIPS through the Agent-based Installer

During a cluster deployment, the Federal Information Processing Standards (FIPS) change is applied when the Red Hat Enterprise Linux CoreOS (RHCOS) machines are deployed in your cluster. For Red Hat Enterprise Linux (RHEL) machines, you must enable FIPS mode when you install the operating system on the machines that you plan to use as worker machines.

You can enable FIPS mode through the preferred method of install-config.yaml and agent-config.yaml:

1. You must set value of the fips field to True in the install-config.yaml file:

   Sample install-config.yaml file

   ```yaml
   apiVersion: v1
   baseDomain: test.example.com
   metadata:
     name: sno-cluster
   fips: True
   ```

2. Optional: If you are using the GitOps ZTP manifests, you must set the value of fips as True in the Agent-install.openshift.io/install-config-overrides field in the agent-cluster-install.yaml file:

   Sample agent-cluster-install.yaml file

   ```yaml
   apiVersion: extensions.hive.openshift.io/v1beta1
   kind: AgentClusterInstall
   metadata:
     annotations:
      agent-install.openshift.io/install-config-overrides: '{"fips": True}'
     name: sno-cluster
   namespace: sno-cluster-test
   ```

Additional resources

- OpenShift Security Guide Book
- Support for FIPS cryptography

14.1.5. About networking

The rendezvous IP must be known at the time of generating the agent ISO, so that during the initial boot all the hosts can check in to the assisted service. If the IP addresses are assigned using a Dynamic
Host Configuration Protocol (DHCP) server, then the `rendezvousIP` field must be set to an IP address of one of the hosts that will become part of the deployed control plane. In an environment without a DHCP server, you can define IP addresses statically.

In addition to static IP addresses, you can apply any network configuration that is in NMState format. This includes VLANs and NIC bonds.

### 14.1.5.1. DHCP

**Preferred method: `install-config.yaml` and `agent-config.yaml`**

You must specify the value for the `rendezvousIP` field. The `networkConfig` fields can be left blank:

**Sample agent-config.yaml file**

```yaml
apiVersion: v1alpha1
kind: AgentConfig
metadata:
  name: sno-cluster
rendezvousIP: 192.168.111.80
```

1. The IP address for the rendezvous host.

### 14.1.5.2. Static networking

a. **Preferred method: `install-config.yaml` and `agent-config.yaml`**

**Sample agent-config.yaml file**

```yaml
cat > agent-config.yaml << EOF
apiVersion: v1alpha1
kind: AgentConfig
metadata:
  name: sno-cluster
rendezvousIP: 192.168.111.80
hosts:
  - hostname: master-0
  interfaces:
    - name: eno1
      macAddress: 00:ef:44:21:e6:a5
      networkConfig:
        interfaces:
          - name: eno1
            type: ethernet
            state: up
            mac-address: 00:ef:44:21:e6:a5
            ipv4:
              enabled: true
              address:
                - ip: 192.168.111.80
                prefix-length: 23
              dhcp: false
            dns-resolver:
EOF
```

2. The IP address for the rendezvous host.
If a value is not specified for the `rendezvousIP` field, one address will be chosen from the static IP addresses specified in the `networkConfig` fields.

The MAC address of an interface on the host, used to determine which host to apply the configuration to.

The static IP address of the target bare metal host.

The static IP address’s subnet prefix for the target bare metal host.

The DNS server for the target bare metal host.

Next hop address for the node traffic. This must be in the same subnet as the IP address set for the specified interface.

b. Optional method: GitOps ZTP manifests

The optional method of the GitOps ZTP custom resources comprises 6 custom resources; you can configure static IPs in the `nmstateconfig.yaml` file.

```yaml
apiVersion: agent-install.openshift.io/v1beta1
type: NMStateConfig
metadata:
  name: master-0
  namespace: openshift-machine-api
  labels:
    cluster0-nmstate-label-name: cluster0-nmstate-label-value
spec:
  config:
    interfaces:
      - name: eth0
type: ethernet
state: up
mac-address: 52:54:01:aa:aa:a1
ipv4:
  enabled: true
address:
  - ip: 192.168.122.2
    prefix-length: 23
dhcp: false
dns-resolver:
  config:
    server:
      - 192.168.122.1
EOF
```
1. The static IP address of the target bare metal host.
2. The static IP address’s subnet prefix for the target bare metal host.
3. The DNS server for the target bare metal host.
4. Next hop address for the node traffic. This must be in the same subnet as the IP address set for the specified interface.
5. The MAC address of an interface on the host, used to determine which host to apply the configuration to.

The rendezvous IP is chosen from the static IP addresses specified in the `config` fields.

### 14.1.6. Requirements for a cluster using the platform "none" option

This section describes the requirements for an Agent-based OpenShift Container Platform installation that is configured to use the platform `none` option.

#### 14.1.6.1. Platform "none" DNS requirements

In OpenShift Container Platform deployments, DNS name resolution is required for the following components:

- The Kubernetes API
- The OpenShift Container Platform application wildcard
- The control plane and compute machines

Reverse DNS resolution is also required for the Kubernetes API, the control plane machines, and the compute machines.

DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the hostnames for all the nodes, unless the hostnames are provided by DHCP. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

**NOTE**

It is recommended to use a DHCP server to provide the hostnames to each cluster node.

The following DNS records are required for an OpenShift Container Platform cluster using the platform...
none option and they must be in place before installation. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>`.

Table 14.2. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes API</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the API load balancer. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td></td>
<td>api-int.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to internally identify the API load balancer. These records must be resolvable from all the nodes within the cluster.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>IMPORTANT</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>The API server must be able to resolve the worker nodes by the hostnames that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.</td>
</tr>
<tr>
<td>Routes</td>
<td>*&lt;component&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A wildcard DNS A/AAAA or CNAME record that refers to the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster. For example, console-openshift-console.apps.&lt;cluster_name&gt;.&lt;base_domain&gt; is used as a wildcard route to the OpenShift Container Platform console.</td>
</tr>
<tr>
<td>Control plane</td>
<td>&lt;master&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>machines</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Compute machines</td>
<td>&lt;worker&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>NOTE</strong></td>
<td></td>
<td>In OpenShift Container Platform 4.4 and later, you do not need to specify etcd host and SRV records in your DNS configuration.</td>
</tr>
</tbody>
</table>
TIP

You can use the `dig` command to verify name and reverse name resolution.

14.1.6.1.1. Example DNS configuration for platform "none" clusters

This section provides A and PTR record configuration samples that meet the DNS requirements for deploying OpenShift Container Platform using the platform none option. The samples are not meant to provide advice for choosing one DNS solution over another.

In the examples, the cluster name is ocp4 and the base domain is example.com.

Example DNS A record configuration for a platform "none" cluster

The following example is a BIND zone file that shows sample A records for name resolution in a cluster using the platform none option.

Example 14.1. Sample DNS zone database

```plaintext
$TTL 1W
@ IN SOA ns1.example.com. root (  
  2019070700 ; serial  
  3H ; refresh (3 hours)  
  30M ; retry (30 minutes)  
  2W ; expiry (2 weeks)  
  1W ) ; minimum (1 week)  
IN NS ns1.example.com.  
IN MX 10 smtp.example.com.  
ns1.example.com.  IN A 192.168.1.5  
smtp.example.com.  IN A 192.168.1.5  
helper.example.com.  IN A 192.168.1.5  
helper.ocp4.example.com. IN A 192.168.1.5  
api.ocp4.example.com. IN A 192.168.1.5  
api-int.ocp4.example.com. IN A 192.168.1.5  
*.apps.ocp4.example.com. IN A 192.168.1.5  
master0.ocp4.example.com. IN A 192.168.1.97  
master1.ocp4.example.com. IN A 192.168.1.98  
master2.ocp4.example.com. IN A 192.168.1.99  
worker0.ocp4.example.com. IN A 192.168.1.11  
worker1.ocp4.example.com. IN A 192.168.1.7  
:EOF
```

1 Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer.

2 Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer and is used for internal cluster communications.
Provides name resolution for the wildcard routes. The record refers to the IP address of the application ingress load balancer. The application ingress load balancer targets the machines.

**NOTE**

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

Provides name resolution for the control plane machines.

Provides name resolution for the compute machines.

**Example DNS PTR record configuration for a platform "none" cluster**

The following example BIND zone file shows sample PTR records for reverse name resolution in a cluster using the platform none option.

**Example 14.2. Sample DNS zone database for reverse records**

```plaintext
$TTL 1W
@ IN SOA ns1.example.com. root (2019070700 ; serial
3H ; refresh (3 hours)
30M ; retry (30 minutes)
2W ; expiry (2 weeks)
1W ) ; minimum (1 week)
IN NS ns1.example.com.
;
5.1.168.192.in-addr.arpa. IN PTR api.ocp4.example.com. 1
5.1.168.192.in-addr.arpa. IN PTR api-int.ocp4.example.com. 2
;
97.1.168.192.in-addr.arpa. IN PTR master0.ocp4.example.com. 3
98.1.168.192.in-addr.arpa. IN PTR master1.ocp4.example.com. 4
99.1.168.192.in-addr.arpa. IN PTR master2.ocp4.example.com. 5
;
11.1.168.192.in-addr.arpa. IN PTR worker0.ocp4.example.com. 6
7.1.168.192.in-addr.arpa. IN PTR worker1.ocp4.example.com. 7
;
;EOF
```

1. Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer.

2. Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer and is used for internal cluster communications.

3. Provides reverse DNS resolution for the control plane machines.

6. Provides reverse DNS resolution for the compute machines.
NOTE
A PTR record is not required for the OpenShift Container Platform application wildcard.

14.1.6.2. Platform "none" Load balancing requirements

Before you install OpenShift Container Platform, you must provision the API and application Ingress load balancing infrastructure. In production scenarios, you can deploy the API and application Ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

NOTE
These requirements do not apply to single-node OpenShift clusters using the platform none option.

NOTE
If you want to deploy the API and application Ingress load balancers with a Red Hat Enterprise Linux (RHEL) instance, you must purchase the RHEL subscription separately.

The load balancing infrastructure must meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.
   - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

   **IMPORTANT**
   Do not configure session persistence for an API load balancer.

Configure the following ports on both the front and back of the load balancers:

<table>
<thead>
<tr>
<th>Table 14.3. API load balancer</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Port</strong></td>
</tr>
<tr>
<td>---------</td>
</tr>
<tr>
<td>6443</td>
</tr>
<tr>
<td>22623</td>
</tr>
</tbody>
</table>
NOTE

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the /readyz endpoint to the removal of the API server instance from the pool. Within the time frame after /readyz returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application Ingress load balancer**: Provides an ingress point for application traffic flowing in from outside the cluster. A working configuration for the Ingress router is required for an OpenShift Container Platform cluster.

Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

TIP

If the true IP address of the client can be seen by the application Ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

Configure the following ports on both the front and back of the load balancers:

<table>
<thead>
<tr>
<th>Table 14.4. Application Ingress load balancer</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
</tr>
<tr>
<td>-------</td>
</tr>
<tr>
<td>443</td>
</tr>
<tr>
<td>80</td>
</tr>
</tbody>
</table>

NOTE

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application Ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

14.1.6.2.1. Example load balancer configuration for platform "none" clusters

This section provides an example API and application Ingress load balancer configuration that meets the load balancing requirements for clusters using the platform none option. The sample is an /etc/haproxy/haproxy.cfg configuration for an HAProxy load balancer. The example is not meant to
provide advice for choosing one load balancing solution over another.

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

**NOTE**

If you are using HAProxy as a load balancer and SELinux is set to enforcing, you must ensure that the HAProxy service can bind to the configured TCP port by running `setsebool -P haproxy_connect_any=1`.

**Example 14.3. Sample API and application Ingress load balancer configuration**

```
global
log 127.0.0.1 local2
pidfile /var/run/haproxy.pid
maxconn 4000

daemon
defaults
mode http
log global
option dontlognull
option http-server-close
option redispatch
retries 3
timeout http-request 10s
timeout queue 1m
timeout connect 10s
timeout client 1m
timeout server 1m
timeout http-keep-alive 10s
timeout check 10s
maxconn 3000

listen api-server-6443
  bind *:6443
d  mode tcp
  server master0 master0.ocp4.example.com:6443 check inter 1s
  server master1 master1.ocp4.example.com:6443 check inter 1s
  server master2 master2.ocp4.example.com:6443 check inter 1s

listen machine-config-server-22623
  bind *:22623
d
  mode tcp
  server master0 master0.ocp4.example.com:22623 check inter 1s
  server master1 master1.ocp4.example.com:22623 check inter 1s
  server master2 master2.ocp4.example.com:22623 check inter 1s

listen ingress-router-443
  bind *:443
  mode tcp
  balance source
  server worker0 worker0.ocp4.example.com:443 check inter 1s
  server worker1 worker1.ocp4.example.com:443 check inter 1s

listen ingress-router-80
  bind *:80
```
Port **6443** handles the Kubernetes API traffic and points to the control plane machines.

Port **22623** handles the machine config server traffic and points to the control plane machines.

Port **443** handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

Port **80** handles the HTTP traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

**NOTE**
If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application Ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

**TIP**
If you are using HAProxy as a load balancer, you can check that the haproxy process is listening on ports **6443, 22623, 443**, and **80** by running `netstat -nltnupe` on the HAProxy node.

### 14.1.7. Example: Bonds and VLAN interface node network configuration

The following **agent-config.yaml** file is an example of a manifest for bond and VLAN interfaces.

```yaml
apiVersion: v1alpha1
kind: AgentConfig
rendezvousIP: 10.10.10.14
hosts:
  - hostname: master0
    role: master
    interfaces:
      - name: enp0s4
        macAddress: 00:21:50:90:c0:10
      - name: enp0s5
        macAddress: 00:21:50:90:c0:20

networkConfig:
  interfaces:
    - name: bond0.300
      type: vlan
      state: up
      vlan:
        base-iface: bond0
        id: 300
        ipv4: enabled: true
```
address:
  - ip: 10.10.10.14
    prefix-length: 24
dhcp: false
- name: bond0
  type: bond
  state: up
mac-address: 00:21:50:90:c0:10
ipv4:
  enabled: false
ipv6:
  enabled: false
link-aggregation:
  mode: active-backup
  options:
    miimon: "150"
  port:
    - enp0s4
    - enp0s5
dns-resolver:
  config:
    server:
      - 10.10.10.11
      - 10.10.10.12
routes:
  config:
    - destination: 0.0.0.0/0
      next-hop-address: 10.10.10.10
      next-hop-interface: bond0.300
      table-id: 254

1. Name of the interface.
2. The type of interface. This example creates a VLAN.
3. The type of interface. This example creates a bond.
4. The mac address of the interface.
5. The **mode** attribute specifies the bonding mode.
6. Specifies the MII link monitoring frequency in milliseconds. This example inspects the bond link every 150 milliseconds.
7. Optional: Specifies the search and server settings for the DNS server.
8. Next hop address for the node traffic. This must be in the same subnet as the IP address set for the specified interface.
9. Next hop interface for the node traffic.

### 14.1.8. Example: Bonds and SR-IOV dual-nic node network configuration
IMPORTANT

Support for Day 1 operations associated with enabling NIC partitioning for SR-IOV devices is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see Technology Preview Features Support Scope.

The following `agent-config.yaml` file is an example of a manifest for dual port NIC with a bond and SR-IOV interfaces:

```yaml
apiVersion: v1alpha1
kind: AgentConfig
rendezvousIP: 10.10.10.14
hosts:
  - hostname: worker-1
    interfaces:
      - name: eno1
        macAddress: 0:c:42:a1:55:f3:06
      - name: eno2
        macAddress: 0:c:42:a1:55:f3:07
networkConfig:
  interfaces:
    - name: eno1
      type: ethernet
      state: up
      mac-address: 0:c:42:a1:55:f3:06
      ipv4:
        enabled: true
dhcp: false
      ethernet:
        sr-iov:
          total-vfs: 2
      ipv6:
        enabled: false

- name: sriov:eno1:0
  type: ethernet
  state: up
  ipv4:
    enabled: false
dhcp: false

- name: sriov:eno1:1
  type: ethernet
  state: down
  - name: eno2
    type: ethernet
    state: up
```
The `networkConfig` field contains information about the network configuration of the host, with subfields including `interfaces`, `dns-resolver`, and `routes`.

The `interfaces` field is an array of network interfaces defined for the host.

The name of the interface.
4 The type of interface. This example creates an ethernet interface.
5 Set this to false to disable DHCP for the physical function (PF) if it is not strictly required.
6 Set this to the number of SR-IOV virtual functions (VFs) to instantiate.
7 Set this to up.
8 Set this to false to disable IPv4 addressing for the VF attached to the bond.
9 Sets a minimum transmission rate, in Mbps, for the VF. This sample value sets a rate of 100 Mbps.
   - This value must be less than or equal to the maximum transmission rate.
   - Intel NICs do not support the min-tx-rate parameter. For more information, see BZ#1772847.
10 Sets a maximum transmission rate, in Mbps, for the VF. This sample value sets a rate of 200 Mbps.
11 Sets the desired bond mode.
12 Sets the preferred port of the bonding interface. The primary device is the first of the bonding interfaces to be used and is not abandoned unless it fails. This setting is particularly useful when one NIC in the bonding interface is faster and, therefore, able to handle a bigger load. This setting is only valid when the bonding interface is in active-backup mode (mode 1) and balance-tlb (mode 5).
13 Sets a static IP address for the bond interface. This is the node IP address.
14 Sets bond0 as the gateway for the default route.

Additional resources
- Configuring network bonding

14.1.9. Sample install-config.yaml file for bare metal

You can customize the install-config.yaml file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com 1
compute: 2
- name: worker
  replicas: 0 3
controlPlane: 4
  name: master
  replicas: 1 5
metadata:
  name: sno-cluster 6
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14 7
  hostPrefix: 23 8
```
The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, -, and the first line of the controlPlane section must not. Only one control plane pool is used.

This parameter controls the number of compute machines that the Agent-based installation waits to discover before triggering the installation process. It is the number of compute machines that must be booted with the generated ISO.

NOTE
If you are installing a three-node cluster, do not deploy any compute machines when you install the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

The cluster name that you specified in your DNS records.

A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to access the pods from an external network, you must configure load balancers and routers to manage the traffic.

NOTE
Class E CIDR range is reserved for a future use. To use the Class E CIDR range, you must ensure your networking environment accepts the IP addresses within the Class E CIDR range.

The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23, then each node is assigned a /23 subnet out of the given cidr, which allows for 510 ($2^{32} - 2^{32} - 2$) pod IP addresses. If you are required to provide access to nodes from an external network, configure load balancers and routers to manage the traffic.

The cluster network plugin to install. The supported values are OVNKubernetes (default value) and OpenShiftSDN.

The IP address pool to use for service IP addresses. You can enter only one IP address pool. This block must not overlap with existing physical networks. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.
You must set the platform to **none** for a single-node cluster. You can set the platform to **vsphere**, **baremetal**, or **none** for multi-node clusters.

**NOTE**

If you set the platform to **vsphere** or **baremetal**, you can configure IP address endpoints for cluster nodes in three ways:

- IPv4
- IPv6
- IPv4 and IPv6 in parallel (dual-stack)

**Example of dual-stack networking**

```yaml
networking:
  clusterNetwork:
  - cidr: 172.21.0.0/16
    hostPrefix: 23
  - cidr: fd02::/48
    hostPrefix: 64
  machineNetwork:
  - cidr: 192.168.11.0/16
  - cidr: 2001:DB8::/32
  serviceNetwork:
  - 172.22.0.0/16
  - fd03::/112
  networkType: OVNKubernetes
  platform:
  baremetal:
  apiVIPs:
  - 192.168.11.3
  - 2001:DB8::4
  ingressVIPs:
  - 192.168.11.4
  - 2001:DB8::5
```

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures.

This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.
The SSH public key for the core user in Red Hat Enterprise Linux CoreOS (RHCOS).

NOTE
For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

14.1.10. Validation checks before agent ISO creation
The Agent-based Installer performs validation checks on user defined YAML files before the ISO is created. Once the validations are successful, the agent ISO is created.

install-config.yaml
- baremetal, vsphere and none platforms are supported.
- If none is used as a platform, the number of control plane replicas must be 1 and the total number of worker replicas must be 0.
- The networkType parameter must be OVNKubernetes in the case of none platform.
- apiVIPs and ingressVIPs parameters must be set for bare metal and vSphere platforms.
- Some host-specific fields in the bare metal platform configuration that have equivalents in agent-config.yaml file are ignored. A warning message is logged if these fields are set.

agent-config.yaml
- Each interface must have a defined MAC address. Additionally, all interfaces must have a different MAC address.
- At least one interface must be defined for each host.
- World Wide Name (WWN) vendor extensions are not supported in root device hints.
- The role parameter in the host object must have a value of either master or worker.

14.1.10.1. ZTP manifests
agent-cluster-install.yaml
- For IPv6, the only supported value for the networkType parameter is OVNKubernetes. The OpenshiftSDN value can be used only for IPv4.

cluster-image-set.yaml
- The ReleaseImage parameter must match the release defined in the installer.

14.1.11. About root device hints
The rootDeviceHints parameter enables the installer to provision the Red Hat Enterprise Linux CoreOS (RHCOS) image to a particular device. The installer examines the devices in the order it discovers them,
and compares the discovered values with the hint values. The installer uses the first discovered device that matches the hint value. The configuration can combine multiple hints, but a device must match all hints for the installer to select it.

Table 14.5. Subfields

<table>
<thead>
<tr>
<th>Subfield</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>deviceName</strong></td>
<td>A string containing a Linux device name such as <code>/dev/vda</code> or <code>/dev/disk/by-path/</code>. It is recommended to use the <code>/dev/disk/by-path/&lt;device_path&gt;</code> link to the storage location. The hint must match the actual value exactly.</td>
</tr>
<tr>
<td><strong>hctl</strong></td>
<td>A string containing a SCSI bus address like <code>0:0:0:0</code>. The hint must match the actual value exactly.</td>
</tr>
<tr>
<td><strong>model</strong></td>
<td>A string containing a vendor-specific device identifier. The hint can be a substring of the actual value.</td>
</tr>
<tr>
<td><strong>vendor</strong></td>
<td>A string containing the name of the vendor or manufacturer of the device. The hint can be a substring of the actual value.</td>
</tr>
<tr>
<td><strong>serialNumber</strong></td>
<td>A string containing the device serial number. The hint must match the actual value exactly.</td>
</tr>
<tr>
<td><strong>minSizeGigabytes</strong></td>
<td>An integer representing the minimum size of the device in gigabytes.</td>
</tr>
<tr>
<td><strong>wwn</strong></td>
<td>A string containing the unique storage identifier. The hint must match the actual value exactly.</td>
</tr>
<tr>
<td><strong>rotational</strong></td>
<td>A boolean indicating whether the device should be a rotating disk (true) or not (false).</td>
</tr>
</tbody>
</table>

Example usage

```
- name: master-0
  role: master
  rootDeviceHints:
    deviceName: "/dev/sda"
```

14.1.12. Next steps

- Installing a cluster with the Agent-based Installer

14.2. UNDERSTANDING DISCONNECTED INSTALLATION MIRRORING
You can use a mirror registry for disconnected installations and to ensure that your clusters only use container images that satisfy your organization’s controls on external content. Before you install a cluster on infrastructure that you provision in a disconnected environment, you must mirror the required container images into that environment. To mirror container images, you must have a registry for mirroring.

14.2.1. Mirroring images for a disconnected installation through the Agent-based Installer

You can use one of the following procedures to mirror your OpenShift Container Platform image repository to your mirror registry:

- Mirroring images for a disconnected installation
- Mirroring images for a disconnected installation using the oc-mirror plugin

14.2.2. About mirroring the OpenShift Container Platform image repository for a disconnected registry

To use mirror images for a disconnected installation with the Agent-based Installer, you must modify the `install-config.yaml` file.

You can mirror the release image by using the output of either the `oc adm release mirror` or `oc mirror` command. This is dependent on which command you used to set up the mirror registry.

The following example shows the output of the `oc adm release mirror` command.

```bash
$ oc adm release mirror
```

Example output

To use the new mirrored repository to install, add the following section to the `install-config.yaml`:

```yaml
ingressContentSources:

mirrors:
virthost.ostest.test.metalkube.org:5000/localimages/local-release-image
source: quay.io/openshift-release-dev/ocp-v4.0-art-dev
mirrors:
virthost.ostest.test.metalkube.org:5000/localimages/local-release-image
source: registry.ci.openshift.org/ocp/release

spec:
repositoryDigestMirrors:
- mirrors:
  - virthost.ostest.test.metalkube.org:5000/openshift/release
source: quay.io/openshift-release-dev/ocp-v4.0-art-dev
```

The following example shows part of the `imageContentSourcePolicy.yaml` file generated by the oc-mirror plugin. The file can be found in the results directory, for example `oc-mirror-workspace/results-1682697932/`.

Example `imageContentSourcePolicy.yaml` file

```yaml
spec:
repositoryDigestMirrors:
- mirrors:
  - virthost.ostest.test.metalkube.org:5000/openshift/release
source: quay.io/openshift-release-dev/ocp-v4.0-art-dev
```
14.2.2.1. Configuring the Agent-based Installer to use mirrored images

You must use the output of either the `oc adm release mirror` command or the oc-mirror plugin to configure the Agent-based Installer to use mirrored images.

**Procedure**

1. If you used the oc-mirror plugin to mirror your release images:
   a. Open the `imageContentSourcePolicy.yaml` located in the results directory, for example `oc-mirror-workspace/results-1682697932/`.
   b. Copy the text in the `repositoryDigestMirrors` section of the yaml file.

2. If you used the `oc adm release mirror` command to mirror your release images:
   - Copy the text in the `imageContentSources` section of the command output.

3. Paste the copied text into the `imageContentSources` field of the `install-config.yaml` file.

4. Add the certificate file used for the mirror registry to the `additionalTrustBundle` field of the `yaml` file.

   **IMPORTANT**
   
   The value must be the contents of the certificate file that you used for your mirror registry. The certificate file can be an existing, trusted certificate authority, or the self-signed certificate that you generated for the mirror registry.

   **Example install-config.yaml file**

   ```yaml
   additionalTrustBundle: |
   -----BEGIN CERTIFICATE-----
   ZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZ
   -----END CERTIFICATE-----
   ```

5. If you are using GitOps ZTP manifests: add the `registries.conf` and `ca-bundle.crt` files to the `mirror` path to add the mirror configuration in the agent ISO image.

   **NOTE**

   You can create the `registries.conf` file from the output of either the `oc adm release mirror` command or the `oc mirror` plugin. The format of the `/etc/containers/registries.conf` file has changed. It is now version 2 and in TOML format.

   **Example registries.conf file**

   ```toml
   [[[registry]]
   ```
14.3. INSTALLING AN OPENSHIFT CONTAINER PLATFORM CLUSTER WITH THE AGENT-BASED INSTALLER

Use the following procedures to install an OpenShift Container Platform cluster using the Agent-based Installer.

14.3.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- If you use a firewall or proxy, you configured it to allow the sites that your cluster requires access to.

14.3.2. Installing OpenShift Container Platform with the Agent-based Installer

The following procedures deploy a single-node OpenShift Container Platform in a disconnected environment. You can use these procedures as a basis and modify according to your requirements.

14.3.2.1. Downloading the Agent-based Installer

Use this procedure to download the Agent-based Installer and the CLI needed for your installation.

**Procedure**

1. Log in to the OpenShift Container Platform web console using your login credentials.
2. Navigate to Datacenter.
3. Click Run Agent-based Installer locally.
4. Select the operating system and architecture for the OpenShift Installer and Command line interface.
5. Click Download Installer to download and extract the install program.
6. You can either download or copy the pull secret by clicking on Download pull secret or Copy pull secret.
7. Click **Download command-line tools** and place the **openshift-install** binary in a directory that is on your **PATH**.

### 14.3.2.2. Creating the preferred configuration inputs

Use this procedure to create the preferred configuration inputs used to create the agent image.

**Procedure**

1. Install **nmstate** dependency by running the following command:

   ```
   $ sudo dnf install /usr/bin/nmstatectl -y
   ```

2. Place the **openshift-install** binary in a directory that is on your **PATH**.

3. Create a directory to store the install configuration by running the following command:

   ```
   $ mkdir ~/<directory_name>
   ```

   **NOTE**

   This is the preferred method for the Agent-based installation. Using GitOps ZTP manifests is optional.

4. Create the **install-config.yaml** file:

   ```
   $ cat << EOF > ./my-cluster/install-config.yaml
   apiVersion: v1
   baseDomain: test.example.com
   compute:
   - architecture: amd64
     hyperthreading: Enabled
     name: worker
     replicas: 0
   controlPlane:
   - architecture: amd64
     hyperthreading: Enabled
     name: master
     replicas: 1
   metadata:
   - name: sno-cluster
   networking:
   clusterNetwork:
   - cidr: 10.128.0.0/14
   - hostPrefix: 23
   machineNetwork:
   - cidr: 192.168.0.0/16
   - networkType: OVNKubernetes
   serviceNetwork:
   - 172.30.0.0/16
   platform:
   none: {}
   ```
CHAPTER 14. INSTALLING AN ON-PREMISE CLUSTER WITH THE AGENT-BASED INSTALLER

1. Specify the system architecture, valid values are `amd64` and `arm64`.
2. Required. Specify your cluster name.
3. Specify the cluster network plugin to install. The supported values are `OVNKubernetes` and `OpenShiftSDN`. The default value is `OVNKubernetes`.
4. Specify your pull secret.
5. Specify your SSH public key.

**NOTE**

If you set the platform to `vSphere` or `baremetal`, you can configure IP address endpoints for cluster nodes in three ways:

- IPv4
- IPv6
- IPv4 and IPv6 in parallel (dual-stack)

IPv6 is supported only on bare metal platforms.

Example of dual-stack networking

```
networking:
  clusterNetwork:
    - cidr: 172.21.0.0/16
      hostPrefix: 23
    - cidr: fd02::/48
      hostPrefix: 64
  machineNetwork:
    - cidr: 192.168.11.0/16
    - cidr: 2001:DB8::/32
  serviceNetwork:
    - 172.22.0.0/16
    - fd03::/112
  networkType: OVKubernetes
  platform:
    baremetal:
      apiVIPs:
        - 192.168.11.3
        - 2001:DB8::4
      ingressVIPs:
        - 192.168.11.4
        - 2001:DB8::5
```

5. Create the `agent-config.yaml` file:
This IP address is used to determine which node performs the bootstrapping process as well as running the **assisted-service** component. You must provide the rendezvous IP address when you do not specify at least one host’s IP address in the `networkConfig` parameter. If this address is not provided, one IP address is selected from the provided hosts’ `networkConfig`.

**Optional:** Host configuration. The number of hosts defined must not exceed the total number of hosts defined in the `install-config.yaml` file, which is the sum of the values of the `compute.replicas` and `controlPlane.replicas` parameters.

**Optional:** Overrides the hostname obtained from either the Dynamic Host Configuration Protocol (DHCP) or a reverse DNS lookup. Each host must have a unique hostname supplied by one of these methods.

**Enables provisioning of the Red Hat Enterprise Linux CoreOS (RHCOS) image to a particular device. It examines the devices in the order it discovers them, and compares the discovered values with the hint values. It uses the first discovered device that matches the hint value.**

```yaml
$ cat > agent-config.yaml << EOF
apiVersion: v1beta1
kind: AgentConfig
metadata:
  name: sno-cluster
rendezvousIP: 192.168.111.80
hosts:
  - hostname: master-0
    interfaces:
      - name: eno1
        macAddress: 00:ef:44:21:e6:a5
    rootDeviceHints:
      deviceName: /dev/sdb
    networkConfig:
      interfaces:
        - name: eno1
          type: ethernet
          state: up
          mac-address: 00:ef:44:21:e6:a5
          ipv4:
            enabled: true
            address:
              - ip: 192.168.111.80
                prefix-length: 23
            dhcp: false
          dns-resolver:
            config:
              server:
                - 192.168.111.1
          routes:
            config:
              - destination: 0.0.0.0/0
                next-hop-address: 192.168.111.2
                next-hop-interface: eno1
                table-id: 254
EOF
```

1. This IP address is used to determine which node performs the bootstrapping process as well as running the **assisted-service** component. You must provide the rendezvous IP address when you do not specify at least one host’s IP address in the `networkConfig` parameter. If this address is not provided, one IP address is selected from the provided hosts’ `networkConfig`.

2. Optional: Host configuration. The number of hosts defined must not exceed the total number of hosts defined in the `install-config.yaml` file, which is the sum of the values of the `compute.replicas` and `controlPlane.replicas` parameters.

3. Optional: Overrides the hostname obtained from either the Dynamic Host Configuration Protocol (DHCP) or a reverse DNS lookup. Each host must have a unique hostname supplied by one of these methods.

4. Enables provisioning of the Red Hat Enterprise Linux CoreOS (RHCOS) image to a particular device. It examines the devices in the order it discovers them, and compares the discovered values with the hint values. It uses the first discovered device that matches the hint value.
Optional: Configures the network interface of a host in NMState format.

14.3.2.3. Optional: Creating additional manifest files

You can create additional manifests to further configure your cluster beyond the configurations available in the `install-config.yaml` and `agent-config.yaml` files.

14.3.2.3.1. Disk partitioning

In general, you should use the default disk partitioning that is created during the RHCOS installation. However, there are cases where you might want to create a separate partition for a directory that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the `/var` directory or a subdirectory of `/var`. For example:

- `/var/lib/containers`: Holds container-related content that can grow as more images and containers are added to a system.
- `/var/lib/etcd`: Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.
- `/var`: Holds data that you might want to keep separate for purposes such as auditing.

**IMPORTANT**

For disk sizes larger than 100GB, and especially larger than 1TB, create a separate `/var` partition.

Storing the contents of a `/var` directory separately makes it easier to grow storage for those areas as needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

The use of a separate partition for the `/var` directory or a subdirectory of `/var` also prevents data growth in the partitioned directory from filling up the root file system.

The following procedure sets up a separate `/var` partition by adding a machine config manifest that is wrapped into the Ignition config file for a node type during the preparation phase of an installation.

**Procedure**

1. On your installation host, create the `openshift` subdirectory within the installation directory:

   ```
   $ mkdir <installation_directory>/openshift
   ```

2. Create a Butane config that configures the additional partition. For example, name the file `$HOME/clusterconfig/98-var-partition.bu`, change the disk device name to the name of the storage device on the worker systems, and set the storage size as appropriate. This example places the `/var` directory on a separate partition:

   ```yaml
   variant: openshift
   version: 4.14.0
   metadata:
   ```
The storage device name of the disk that you want to partition.

When adding a data partition to the boot disk, a minimum offset value of 25000 mebibytes is recommended. The root file system is automatically resized to fill all available space up to the specified offset. If no offset value is specified, or if the specified value is smaller than the recommended minimum, the resulting root file system will be too small, and future reinstalls of RHCOS might overwrite the beginning of the data partition.

The size of the data partition in mebibytes.

The `prjquota` mount option must be enabled for filesystems used for container storage.

NOTE

When creating a separate `/var` partition, you cannot use different instance types for compute nodes, if the different instance types do not have the same device name.

3. Create a manifest from the Butane config and save it to the `clusterconfig/openshift` directory. For example, run the following command:

```bash
$ butane $HOME/clusterconfig/98-var-partition.bu -o $HOME/clusterconfig/openshift/98-var-partition.yaml
```

14.3.2.4. Optional: Using ZTP manifests

You can use GitOps Zero Touch Provisioning (ZTP) manifests to configure your installation beyond the options available through the `install-config.yaml` and `agent-config.yaml` files.

NOTE

GitOps ZTP manifests can be generated with or without configuring the `install-config.yaml` and `agent-config.yaml` files beforehand. If you chose to configure the `install-config.yaml` and `agent-config.yaml` files, the configurations will be imported to the ZTP cluster manifests when they are generated.
Prerequisites

- You have placed the openshift-install binary in a directory that is on your PATH.
- Optional: You have created and configured the install-config.yaml and agent-config.yaml files.

Procedure

1. Use the following command to generate ZTP cluster manifests:

   ```
   $ openshift-install agent create cluster-manifests --dir <installation_directory>
   ``

   **IMPORTANT**
   
   If you have created the install-config.yaml and agent-config.yaml files, those files are deleted and replaced by the cluster manifests generated through this command.

   Any configurations made to the install-config.yaml and agent-config.yaml files are imported to the ZTP cluster manifests when you run the openshift-install agent create cluster-manifests command.

2. Navigate to the cluster-manifests directory:

   ```
   $ cd <installation_directory>/cluster-manifests
   ```

3. Configure the manifest files in the cluster-manifests directory. For sample files, see the "Sample GitOps ZTP custom resources" section.

4. Disconnected clusters: If you did not define mirror configuration in the install-config.yaml file before generating the ZTP manifests, perform the following steps:

   a. Navigate to the mirror directory:

   ```
   $ cd ../mirror
   ```

   b. Configure the manifest files in the mirror directory.

Additional resources

- [Sample GitOps ZTP custom resources](#)
- See [Challenges of the network far edge](#) to learn more about GitOps Zero Touch Provisioning (ZTP).

**14.3.2.5. Optional: Encrypting the disk**

Use this procedure to encrypt your disk or partition while installing OpenShift Container Platform with the Agent-based Installer.

Prerequisites
- You have created and configured the `install-config.yaml` and `agent-config.yaml` files, unless you are using ZTP manifests.
- You have placed the `openshift-install` binary in a directory that is on your PATH.

**Procedure**

1. Use the following command to generate ZTP cluster manifests:

   ```
   $ openshift-install agent create cluster-manifests --dir <installation_directory>
   ```

   **IMPORTANT**

   If you have created the `install-config.yaml` and `agent-config.yaml` files, those files are deleted and replaced by the cluster manifests generated through this command.

   Any configurations made to the `install-config.yaml` and `agent-config.yaml` files are imported to the ZTP cluster manifests when you run the `openshift-install agent create cluster-manifests` command.

   **NOTE**

   If you have already generated ZTP manifests, skip this step.

2. Navigate to the `cluster-manifests` directory:

   ```
   $ cd <installation_directory>/cluster-manifests
   ```

3. Add the following section to the `agent-cluster-install.yaml` file:

   ```yaml
   diskEncryption:
     enableOn: all
     mode: tang
     tangServers: "server1": "http://tang-server-1.example.com:7500"
   ```

   - **1** Specify which nodes to enable disk encryption on. Valid values are 'none', 'all', 'master', and 'worker'.
   - **2** Specify which disk encryption mode to use. Valid values are 'tpmv2' and 'tang'.
   - **3** Optional: If you are using Tang, specify the Tang servers.

**Additional resources**

- [About disk encryption](#)

**14.3.2.6. Creating and booting the agent image**

Use this procedure to boot the agent image on your machines.

**Procedure**
1. Create the agent image by running the following command:

```bash
$ openshift-install --dir <install_directory> agent create image
```

**NOTE**

Red Hat Enterprise Linux CoreOS (RHCOS) supports multipathing on the primary disk, allowing stronger resilience to hardware failure to achieve higher host availability. Multipathing is enabled by default in the agent ISO image, with a default `/etc/multipath.conf` configuration.

2. Boot the `agent.x86_64.iso` or `agent.aarch64.iso` image on the bare metal machines.

### 14.3.2.7. Verifying that the current installation host can pull release images

After you boot the agent image and network services are made available to the host, the agent console application performs a pull check to verify that the current host can retrieve release images.

If the primary pull check passes, you can quit the application to continue with the installation. If the pull check fails, the application performs additional checks, as seen in the **Additional checks** section of the TUI, to help you troubleshoot the problem. A failure for any of the additional checks is not necessarily critical as long as the primary pull check succeeds.

If there are host network configuration issues that might cause an installation to fail, you can use the console application to make adjustments to your network configurations.

**IMPORTANT**

If the agent console application detects host network configuration issues, the installation workflow will be halted until the user manually stops the console application and signals the intention to proceed.

**Procedure**

1. Wait for the agent console application to check whether or not the configured release image can be pulled from a registry.

2. If the agent console application states that the installer connectivity checks have passed, wait for the prompt to time out to continue with the installation.

**NOTE**

You can still choose to view or change network configuration settings even if the connectivity checks have passed.

However, if you choose to interact with the agent console application rather than letting it time out, you must manually quit the TUI to proceed with the installation.

3. If the agent console application checks have failed, which is indicated by a red icon beside the **Release image URL** pull check, use the following steps to reconfigure the host’s network settings:
a. Read the **Check Errors** section of the TUI. This section displays error messages specific to the failed checks.

![TUI Displaying Check Errors]

b. Select **Configure network** to launch the NetworkManager TUI.

c. Select **Edit a connection** and select the connection you want to reconfigure.

d. Edit the configuration and select **OK** to save your changes.

e. Select **Back** to return to the main screen of the NetworkManager TUI.

f. Select **Activate a Connection**.

g. Select the reconfigured network to deactivate it.

h. Select the reconfigured network again to reactivate it.

i. Select **Back** and then select **Quit** to return to the agent console application.

j. Wait at least five seconds for the continuous network checks to restart using the new network configuration.

k. If the **Release image URL** pull check succeeds and displays a green icon beside the URL, select **Quit** to exit the agent console application and continue with the installation.

---

**14.3.2.8. Tracking and verifying installation progress**

Use the following procedure to track installation progress and to verify a successful installation.

**Procedure**
1. Optional: To know when the bootstrap host (rendezvous host) reboots, run the following command:

   ```bash
   $ ./openshift-install --dir <install_directory> agent wait-for bootstrap-complete \  
   --log-level=info
   ``

   For `<install_directory>`, specify the path to the directory where the agent ISO was generated.

   To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

   **Example output**

   ```
   INFO Bootstrap configMap status is complete
   INFO cluster bootstrap is complete
   
   The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.
   ```

2. To track the progress and verify successful installation, run the following command:

   ```bash
   $ openshift-install --dir <install_directory> agent wait-for install-complete
   ``

   For `<install_directory>` directory, specify the path to the directory where the agent ISO was generated.

   **Example output**

   ```
   INFO Cluster is installed
   INFO Install complete!
   INFO To access the cluster as the system:admin user when using 'oc', run
   INFO export KUBECONFIG=/home/core/installer/auth/kubeconfig
   INFO Access the OpenShift web-console here: https://console-openshift-console.apps.sno-cluster.test.example.com
   ``

**NOTE**

If you are using the optional method of GitOps ZTP manifests, you can configure IP address endpoints for cluster nodes through the `AgentClusterInstall.yaml` file in three ways:

- IPv4
- IPv6
- IPv4 and IPv6 in parallel (dual-stack)

IPv6 is supported only on bare metal platforms.
Example of dual-stack networking

apiVIP: \textcolor{red}{192.168.11.3}

ingressVIP: \textcolor{red}{192.168.11.4}

clusterDeploymentRef:
  name: mycluster

imageSetRef:
  name: openshift-4.14

networking:
  clusterNetwork:
    - cidr: \textcolor{red}{172.21.0.0/16}
      hostPrefix: 23
    - cidr: \textcolor{red}{fd02::/48}
      hostPrefix: 64

machineNetwork:
  - cidr: \textcolor{red}{192.168.11.0/16}
    - cidr: \textcolor{red}{2001:DB8::/32}

serviceNetwork:
  - cidr: \textcolor{red}{172.22.0.0/16}
    - fd03::/112

networkType: OVNKubernetes

Additional resources

- See Deploying with dual-stack networking.

- See Configuring a three-node cluster to deploy three-node clusters in bare metal environments.
- See About root device hints.
- See NMState state examples.

14.3.3. Sample GitOps ZTP custom resources

Optional: You can use GitOps Zero Touch Provisioning (ZTP) custom resource (CR) objects to install an OpenShift Container Platform cluster with the Agent-based Installer.

You can customize the following GitOps ZTP custom resources to specify more details about your OpenShift Container Platform cluster. The following sample GitOps ZTP custom resources are for a single-node cluster.

agent-cluster-install.yaml

apiVersion: extensions.hive.openshift.io/v1beta1
kind: AgentClusterInstall
metadata:
  name: test-agent-cluster-install
  namespace: cluster0
spec:
  clusterDeploymentRef:
    name: ostest
  imageSetRef:
cluster-deployment.yaml

    macAddress: 52:54:01:aa:aa:a1

pull-secret.yaml

apiVersion: v1
class: Secret
type: kubernetes.io/dockerconfigjson
metadata:
  name: pull-secret
Additional resources

- See Challenges of the network far edge to learn more about GitOps Zero Touch Provisioning (ZTP).

14.3.4. Gathering log data from a failed Agent-based installation

Use the following procedure to gather log data about a failed Agent-based installation to provide for a support case.

Procedure

1. Run the following command and collect the output:

   ```
   $ ./openshift-install --dir <install_directory> agent wait-for bootstrap-complete --log-level=debug
   ```

   **Example error message**

   ```
   ...
   ERROR Bootstrap failed to complete: : bootstrap process timed out: context deadline exceeded
   ```

2. If the output from the previous command indicates a failure, or if the bootstrap is not progressing, run the following command on node 0 and collect the output:

   ```
   $ ssh core@<node-ip> sudo /usr/local/bin/agent-gather -O > <local_tmp_path>/agent-gather.tar.xz
   ```

   **NOTE**

   You only need to gather data from node 0, but gathering this data from every node can be helpful.

3. If the bootstrap completes and the cluster nodes reboot, run the following command and collect the output:

   ```
   $ ./openshift-install --dir <install_directory> agent wait-for install-complete --log-level=debug
   ```

4. If the output from the previous command indicates a failure, perform the following steps:

   a. Export the `kubeconfig` file to your environment by running the following command:

   ```
   $ export KUBECONFIG=<install_directory>/auth/kubeconfig
   ```

   b. To gather information for debugging, run the following command:

   ```
   $ oc adm must-gather
   ```
14.4. PREPARING PXE ASSETS FOR OPENSHIFT CONTAINER PLATFORM

Use the following procedures to create the assets needed to PXE boot an OpenShift Container Platform cluster using the Agent-based Installer.

The assets you create in these procedures will deploy a single-node OpenShift Container Platform installation. You can use these procedures as a basis and modify configurations according to your requirements.

14.4.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.

14.4.2. Downloading the Agent-based Installer

Use this procedure to download the Agent-based Installer and the CLI needed for your installation.

Procedure

1. Log in to the OpenShift Container Platform web console using your login credentials.
2. Navigate to Datacenter.
3. Click Run Agent-based Installer locally.
4. Select the operating system and architecture for the OpenShift Installer and Command line interface.
5. Click Download Installer to download and extract the install program.
6. You can either download or copy the pull secret by clicking on Download pull secret or Copy pull secret.
7. Click Download command-line tools and place the openshift-install binary in a directory that is on your PATH.

14.4.3. Creating the preferred configuration inputs

Use this procedure to create the preferred configuration inputs used to create the PXE files.

Procedure

c. Create a compressed file from the must-gather directory that was just created in your working directory by running the following command:

   $ tar cvaf must-gather.tar.gz <must_gather_directory>

5. Excluding the /auth subdirectory, attach the installation directory used during the deployment to your support case on the Red Hat Customer Portal.

6. Attach all other data gathered from this procedure to your support case.
1. Install `nmstate` dependency by running the following command:

   ```
   $ sudo dnf install /usr/bin/nmstatectl -y
   ```

2. Place the `openshift-install` binary in a directory that is on your PATH.

3. Create a directory to store the install configuration by running the following command:

   ```
   $ mkdir ~/<directory_name>
   ```

   **NOTE**
   This is the preferred method for the Agent-based installation. Using GitOps ZTP manifests is optional.

4. Create the `install-config.yaml` file:

   ```
   $ cat << EOF > ./my-cluster/install-config.yaml
   apiVersion: v1
   baseDomain: test.example.com
   compute:
   - architecture: amd64
     hyperthreading: Enabled
     name: worker
     replicas: 0
   controlPlane:
     architecture: amd64
     hyperthreading: Enabled
     name: master
     replicas: 1
   metadata:
     name: sno-cluster
   networking:
     clusterNetwork:
     - cidr: 10.128.0.0/14
       hostPrefix: 23
     machineNetwork:
     - cidr: 192.168.0.0/16
       networkType: OVNKubernetes
     serviceNetwork:
     - 172.30.0.0/16
   platform:
   - none: {}
   pullSecret: '<pull_secret>'
   sshKey: '<ssh_pub_key>'
   EOF
   ```

   **1** Specify the system architecture, valid values are `amd64` and `arm64`.

   **2** Required. Specify your cluster name.

   **3** Specify the cluster network plugin to install. The supported values are `OVNKubernetes` and `OpenShiftSDN`. The default value is `OVNKubernetes`. 
4 Specify your pull secret.
5 Specify your SSH public key.

NOTE
If you set the platform to **vSphere** or **baremetal**, you can configure IP address endpoints for cluster nodes in three ways:

- IPv4
- IPv6
- IPv4 and IPv6 in parallel (dual-stack)

IPv6 is supported only on bare metal platforms.

Example of dual-stack networking

```
networking:
  clusterNetwork:
    - cidr: 172.21.0.0/16
      hostPrefix: 23
    - cidr: fd02::/48
      hostPrefix: 64
  machineNetwork:
    - cidr: 192.168.11.0/16
    - cidr: 2001:DB8::/32
  serviceNetwork:
    - 172.22.0.0/16
    - fd03::/112
  networkType: OVN Kubernetes
platform:
  baremetal:
    apiVIPS:
      - 192.168.11.3
      - 2001:DB8::4
    ingressVIPS:
      - 192.168.11.4
      - 2001:DB8::5
```

5. Create the **agent-config.yaml** file:

```
$ cat > agent-config.yaml << EOF
apiVersion: v1beta1
kind: AgentConfig
metadata:
  name: sno-cluster
hosts:
  - hostname: master-0
    interfaces:
      - name: eno1
        macAddress: 00:ef:44:21:e6:a5
```

2274
This IP address is used to determine which node performs the bootstrapping process as well as running the **assisted-service** component. You must provide the rendezvous IP address when you do not specify at least one host's IP address in the `networkConfig` parameter. If this address is not provided, one IP address is selected from the provided hosts' `networkConfig`.

Optional: Host configuration. The number of hosts defined must not exceed the total number of hosts defined in the `install-config.yaml` file, which is the sum of the values of the `compute.replicas` and `controlPlane.replicas` parameters.

Optional: Overrides the hostname obtained from either the Dynamic Host Configuration Protocol (DHCP) or a reverse DNS lookup. Each host must have a unique hostname supplied by one of these methods.

Enables provisioning of the Red Hat Enterprise Linux CoreOS (RHCOS) image to a particular device. It examines the devices in the order it discovers them, and compares the discovered values with the hint values. It uses the first discovered device that matches the hint value.

Optional: Configures the network interface of a host in NMState format.

6. Optional: To create an iPXE script, add the `bootArtifactsBaseURL` to the `agent-config.yaml` file:
name: sno-cluster
rendezvousIP: 192.168.111.80
bootArtifactsBaseUrl: <asset_server_URL>

Where <asset_server_URL> is the URL of the server you will upload the PXE assets to.

Additional resources

- Deploying with dual-stack networking.
- Configuring the install-config yaml file.
- See Configuring a three-node cluster to deploy three-node clusters in bare metal environments.
- About root device hints.
- NMState state examples.

### 14.4.4. Creating the PXE assets

Use the following procedure to create the assets and optional script to implement in your PXE infrastructure.

#### Procedure

1. Create the PXE assets by running the following command:

   ```
   $ openshift-install agent create pxe-files
   ```

   The generated PXE assets and optional iPXE script can be found in the `boot-artifacts` directory.

   **Example filesystem with PXE assets and optional iPXE script**

   ```
   boot-artifacts
   ├── agent.x86_64-initrd.img
   ├── agent.x86_64.ipxe
   ├── agent.x86_64-rootfs.img
   └── agent.x86_64-vmlinuz
   ```

   **NOTE**

   Red Hat Enterprise Linux CoreOS (RHCOS) supports multipathing on the primary disk, allowing stronger resilience to hardware failure to achieve higher host availability. Multipathing is enabled by default in the agent ISO image, with a default `/etc/multipath.conf` configuration.

2. Upload the PXE assets and optional script to your infrastructure where they will be accessible during the boot process.
NOTE

If you generated an iPXE script, the location of the assets must match the `bootArtifactsBaseURL` you added to the `agent-config.yaml` file.

14.4.5. Additional resources

- See Installing an OpenShift Container Platform cluster with the Agent-based Installer to learn about more configurations available with the Agent-based Installer.

14.5. PREPARING AN AGENT-BASED INSTALLED CLUSTER FOR THE MULTICLUSTER ENGINE FOR KUBERNETES OPERATOR

You can install the multicluster engine for Kubernetes Operator and deploy a hub cluster with the Agent-based OpenShift Container Platform Installer. The following procedure is partially automated and requires manual steps after the initial cluster is deployed.

14.5.1. Prerequisites

- You have read the following documentation:
  - Cluster lifecycle with multicluster engine operator overview.
  - Persistent storage using local volumes.
  - Using ZTP to provision clusters at the network far edge.
  - Preparing to install with the Agent-based Installer.
- You have access to the internet to obtain the necessary container images.
- You have installed the OpenShift CLI (`oc`).
- If you are installing in a disconnected environment, you must have a configured local mirror registry for disconnected installation mirroring.

14.5.2. Preparing an Agent-based cluster deployment for the multicluster engine for Kubernetes Operator while disconnected

You can mirror the required OpenShift Container Platform container images, the multicluster engine for Kubernetes Operator, and the Local Storage Operator (LSO) into your local mirror registry in a disconnected environment. Ensure that you note the local DNS hostname and port of your mirror registry.

NOTE

To mirror your OpenShift Container Platform image repository to your mirror registry, you can use either the `oc adm release image` or `oc mirror` command. In this procedure, the `oc mirror` command is used as an example.

Procedure
1. Create an `<assets_directory>` folder to contain valid `install-config.yaml` and `agent-config.yaml` files. This directory is used to store all the assets.

2. To mirror an OpenShift Container Platform image repository, the multicluster engine, and the LSO, create a `ImageSetConfiguration.yaml` file with the following settings:

**Example ImageSetConfiguration.yaml**

```yaml
kind: ImageSetConfiguration
apiVersion: mirror.openshift.io/v1alpha2
archiveSize: 4
storageConfig:
  imageURL: <your-local-registry-dns-name>:<your-local-registry-port>/mirror/oc-mirror-metadata
  skipTLS: true
mirror:
  platform:
    architectures:
      - "amd64"
  channels:
    - name: stable-4.14
      type: ocp
  additionalImages:
    - name: registry.redhat.io/ubi9/ubi:latest
  operators:
      packages:
        - name: multicluster-engine
        - name: local-storage-operator
```

1. Specify the maximum size, in GiB, of each file within the image set.
2. Set the back-end location to receive the image set metadata. This location can be a registry or local directory. It is required to specify `storageConfig` values.
3. Set the registry URL for the storage backend.
4. Set the channel that contains the OpenShift Container Platform images for the version you are installing.
5. Set the Operator catalog that contains the OpenShift Container Platform images that you are installing.
6. Specify only certain Operator packages and channels to include in the image set. Remove this field to retrieve all packages in the catalog.
7. The multicluster engine packages and channels.
8. The LSO packages and channels.

**NOTE**

This file is required by the `oc mirror` command when mirroring content.
3. To mirror a specific OpenShift Container Platform image repository, the multicloud engine, and the LSO, run the following command:

```
$ oc mirror --dest-skip-tls --config ocp-mce-imageset.yaml docker://<your-local-registry-dns-name>:<your-local-registry-port>
```

4. Update the registry and certificate in the `install-config.yaml` file:

**Example imageContentSources.yaml**

```yaml
imageContentSources:
- source: "quay.io/openshift-release-dev/ocp-release"
  mirrors:
    - "<your-local-registry-dns-name>:<your-local-registry-port>/openshift/release-images"
    - "<your-local-registry-dns-name>:<your-local-registry-port>/openshift/release"
- source: "quay.io/openshift-release-dev/ocp-v4.0-art-dev"
  mirrors:
    - "<your-local-registry-dns-name>:<your-local-registry-port>/openshift/release"
    - "<your-local-registry-dns-name>:<your-local-registry-port>/ubi9"
- source: "registry.redhat.io/ubi9"
  mirrors:
    - "<your-local-registry-dns-name>:<your-local-registry-port>/ubi9"
- source: "registry.redhat.io/multicluster-engine"
  mirrors:
    - "<your-local-registry-dns-name>:<your-local-registry-port>/multicluster-engine"
    - "<your-local-registry-dns-name>:<your-local-registry-port>/rhel8"
    - "<your-local-registry-dns-name>:<your-local-registry-port>/rheil8"
- source: "registry.redhat.io/redhat"
  mirrors:
    - "<your-local-registry-dns-name>:<your-local-registry-port>/redhat"
    - "<your-local-registry-dns-name>:<your-local-registry-port>/rheil8"
```

Additionally, ensure your certificate is present in the `additionalTrustBundle` field of the `install-config.yaml`.

**Example install-config.yaml**

```yaml
additionalTrustBundle: |
    -----BEGIN CERTIFICATE-----
    zzzzzzzzzzzz
    -----END CERTIFICATE-----
```

**IMPORTANT**

The `oc mirror` command creates a folder called `oc-mirror-workspace` with several outputs. This includes the `imageContentSourcePolicy.yaml` file that identifies all the mirrors you need for OpenShift Container Platform and your selected Operators.

5. Generate the cluster manifests by running the following command:

```
$ openshift-install agent create cluster-manifests
```

This command updates the cluster manifests folder to include a `mirror` folder that contains your mirror configuration.
14.5.3. Preparing an Agent-based cluster deployment for the multicluster engine for Kubernetes Operator while connected

Create the required manifests for the multicluster engine for Kubernetes Operator, the Local Storage Operator (LSO), and to deploy an agent-based OpenShift Container Platform cluster as a hub cluster.

Procedure

1. Create a sub-folder named **openshift** in the `<assets_directory>` folder. This sub-folder is used to store the extra manifests that will be applied during the installation to further customize the deployed cluster. The `<assets_directory>` folder contains all the assets including the `install-config.yaml` and `agent-config.yaml` files.

   **NOTE**
   The installer does not validate extra manifests.

2. For the multicluster engine, create the following manifests and save them in the `<assets_directory>/openshift` folder:

   **Example mce_namespace.yaml**

   ```yaml
   apiVersion: v1
   kind: Namespace
   metadata:
     labels:
       openshift.io/cluster-monitoring: "true"
     name: multicluster-engine
   ```

   **Example mce_operatorgroup.yaml**

   ```yaml
   apiVersion: operators.coreos.com/v1
   kind: OperatorGroup
   metadata:
     name: multicluster-engine-operatorgroup
     namespace: multicluster-engine
   spec:
     targetNamespaces:
       - multicluster-engine
   ```

   **Example mce_subscription.yaml**

   ```yaml
   apiVersion: operators.coreos.com/v1alpha1
   kind: Subscription
   metadata:
     name: multicluster-engine
     namespace: multicluster-engine
   spec:
     channel: "stable-2.3"
     name: multicluster-engine
     source: redhat-operators
     sourceNamespace: openshift-marketplace
   ```
NOTE

You can install a distributed unit (DU) at scale with the Red Hat Advanced Cluster Management (RHACM) using the assisted installer (AI). These distributed units must be enabled in the hub cluster. The AI service requires persistent volumes (PVs), which are manually created.

3. For the AI service, create the following manifests and save them in the `<assets_directory>/openshift` folder:

Example `lso_namespace.yaml`

```yaml
apiVersion: v1
kind: Namespace
metadata:
  annotations:
    openshift.io/cluster-monitoring: "true"
name: openshift-local-storage
```

Example `lso_operatorgroup.yaml`

```yaml
apiVersion: operators.coreos.com/v1
kind: OperatorGroup
metadata:
  name: local-operator-group
  namespace: openshift-local-storage
spec:
targetNamespaces:
  - openshift-local-storage
```

Example `lso_subscription.yaml`

```yaml
apiVersion: operators.coreos.com/v1alpha1
kind: Subscription
metadata:
  name: local-storage-operator
  namespace: openshift-local-storage
spec:
  installPlanApproval: Automatic
  name: local-storage-operator
  source: redhat-operators
  sourceNamespace: openshift-marketplace
```
NOTE

After creating all the manifests, your filesystem must display as follows:

Example Filesystem

```plaintext
<assets_directory>
  └─ install-config.yaml
  └─ agent-config.yaml
  └─ /openshift
        └─ /mce_namespace.yaml
        └─ /mce_operatorgroup.yaml
        └─ /mce_subscription.yaml
        └─ /lso_namespace.yaml
        └─ /lso_operatorgroup.yaml
        └─ /lso_subscription.yaml
```

4. Create the agent ISO image by running the following command:

```plaintext
$ openshift-install agent create image --dir <assets_directory>
```

5. When the image is ready, boot the target machine and wait for the installation to complete.

6. To monitor the installation, run the following command:

```plaintext
$ openshift-install agent wait-for install-complete --dir <assets_directory>
```

NOTE

To configure a fully functional hub cluster, you must create the following manifests and manually apply them by running the command:

```plaintext
$ oc apply -f <manifest-name>
```

The order of the manifest creation is important and where required, the waiting condition is displayed.

7. For the PVs that are required by the AI service, create the following manifests:

```yaml
apiVersion: local.storage.openshift.io/v1
kind: LocalVolume
metadata:
  name: assisted-service
  namespace: openshift-local-storage
spec:
  logLevel: Normal
  managementState: Managed
  storageClassDevices:
  - devicePaths:
    - /dev/vda
    - /dev/vdb
  storageClassName: assisted-service
  volumeMode: Filesystem
```

8. Use the following command to wait for the availability of the PVs, before applying the subsequent manifests:
$ oc wait localvolume -n openshift-local-storage assisted-service --for condition=Available --timeout 10m

NOTE

The `devicePath` is an example and may vary depending on the actual hardware configuration used.

9. Create a manifest for a multicloud-engine instance.

Example MultiClusterEngine.yaml

```yaml
apiVersion: multicluster.openshift.io/v1
kind: MultiClusterEngine
metadata:
  name: multicloudengine
spec: {}
```

10. Create a manifest to enable the AI service.

Example agentserviceconfig.yaml

```yaml
apiVersion: agent-install.openshift.io/v1beta1
kind: AgentServiceConfig
metadata:
  name: agent
  namespace: assisted-installer
spec:
databaseStorage:
  storageClassName: assisted-service
  accessModes:
  - ReadWriteOnce
resources:
  requests:
    storage: 10Gi
filesystemStorage:
  storageClassName: assisted-service
  accessModes:
  - ReadWriteOnce
resources:
  requests:
    storage: 10Gi
```

11. Create a manifest to deploy subsequently spoke clusters.

Example clusterimageset.yaml

```yaml
apiVersion: hive.openshift.io/v1
kind: ClusterImageSet
metadata:
```
12. Create a manifest to import the agent installed cluster (that hosts the multicluster engine and the Assisted Service) as the hub cluster.

Example autoimport.yaml

```yaml
apiVersion: cluster.open-cluster-management.io/v1
kind: ManagedCluster
metadata:
  labels:
    local-cluster: "true"
  cloud: auto-detect
  vendor: auto-detect
name: local-cluster
spec:
  hubAcceptsClient: true
```

13. Wait for the managed cluster to be created.

```
$ oc wait -n multicluster-engine managedclusters local-cluster --for condition=ManagedClusterJoined=True --timeout 10m
```

Verification

- To confirm that the managed cluster installation is successful, run the following command:

```
$ oc get managedcluster
NAME     HUB ACCEPTED MANAGED CLUSTER URLS              JOINED AVAILABLE AGE
local-cluster true         https://<your cluster url>:6443 True   True   77m
```

Additional resources

- The Local Storage Operator
CHAPTER 15. INSTALLING ON A SINGLE NODE

15.1. PREPARING TO INSTALL ON A SINGLE NODE

15.1.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You have read the documentation on selecting a cluster installation method and preparing it for users.

15.1.2. About OpenShift on a single node

You can create a single-node cluster with standard installation methods. OpenShift Container Platform on a single node is a specialized installation that requires the creation of a special Ignition configuration file. The primary use case is for edge computing workloads, including intermittent connectivity, portable clouds, and 5G radio access networks (RAN) close to a base station. The major tradeoff with an installation on a single node is the lack of high availability.

**IMPORTANT**

The use of OpenShiftSDN with single-node OpenShift is not supported. OVN-Kubernetes is the default network plugin for single-node OpenShift deployments.

15.1.3. Requirements for installing OpenShift on a single node

Installing OpenShift Container Platform on a single node alleviates some of the requirements for high availability and large scale clusters. However, you must address the following requirements:

- **Administration host:** You must have a computer to prepare the ISO, to create the USB boot drive, and to monitor the installation.

For the **ppc64le** platform, the host should prepare the ISO, but does not need to create the USB boot drive. The ISO can be mounted to PowerVM directly.

**NOTE**

ISO is not required for IBM Z® installations.

- **CPU Architecture:** Installing OpenShift Container Platform on a single node supports **x86_64**, **arm64**, **ppc64le**, and **s390x** CPU architectures.
- **Supported platforms:** Installing OpenShift Container Platform on a single node is supported on bare metal, vSphere, AWS, Red Hat OpenStack, OpenShift Virtualization, IBM Power®, and IBM Z® platforms.
- **Production-grade server:** Installing OpenShift Container Platform on a single node requires a server with sufficient resources to run OpenShift Container Platform services and a production workload.

Table 15.1. Minimum resource requirements
### Profile

<table>
<thead>
<tr>
<th>Profile</th>
<th>vCPU</th>
<th>Memory</th>
<th>Storage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Minimum</td>
<td>8 vCPU cores</td>
<td>16 GB of RAM</td>
<td>120 GB</td>
</tr>
</tbody>
</table>

**NOTE**

- One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or hyperthreading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio:
  
  \[(\text{threads per core} \times \text{cores}) \times \text{sockets} = \text{vCPUs}\]

- Adding Operators during the installation process might increase the minimum resource requirements.

The server must have a Baseboard Management Controller (BMC) when booting with virtual media.

**NOTE**

BMC is not supported on IBM Z® and IBM Power®.

- **Networking:** The server must have access to the internet or access to a local registry if it is not connected to a routable network. The server must have a DHCP reservation or a static IP address for the Kubernetes API, ingress route, and cluster node domain names. You must configure the DNS to resolve the IP address to each of the following fully qualified domain names (FQDN):

**Table 15.2. Required DNS records**

<table>
<thead>
<tr>
<th>Usage</th>
<th>FQDN</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes API</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>Add a DNS A/AAAA or CNAME record. This record must be resolvable by clients external to the cluster.</td>
</tr>
<tr>
<td>Internal API</td>
<td>api-int.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>Add a DNS A/AAAA or CNAME record when creating the ISO manually. This record must be resolvable by nodes within the cluster.</td>
</tr>
<tr>
<td>Ingress route</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>Add a wildcard DNS A/AAAA or CNAME record that targets the node. This record must be resolvable by clients external to the cluster.</td>
</tr>
</tbody>
</table>

Without persistent IP addresses, communications between the **apiserver** and **etcd** might fail.
15.2. INSTALLING OPENSShift ON A SINGLE NODE

You can install single-node OpenShift using the web-based Assisted Installer and a discovery ISO that you generate using the Assisted Installer. You can also install single-node OpenShift by using coreos-installer to generate the installation ISO.

15.2.1. Installing single-node OpenShift using the Assisted Installer

To install OpenShift Container Platform on a single node, use the web-based Assisted Installer wizard to guide you through the process and manage the installation.

15.2.1.1. Generating the discovery ISO with the Assisted Installer

Installing OpenShift Container Platform on a single node requires a discovery ISO, which the Assisted Installer can generate.

Procedure

1. On the administration host, open a browser and navigate to Red Hat OpenShift Cluster Manager.
2. Click Create Cluster to create a new cluster.
3. In the Cluster name field, enter a name for the cluster.
4. In the Base domain field, enter a base domain. For example:

   example.com

   All DNS records must be subdomains of this base domain and include the cluster name, for example:

   <cluster-name>.example.com

   **NOTE**
   You cannot change the base domain or cluster name after cluster installation.

5. Select Install single node OpenShift (SNO) and complete the rest of the wizard steps. Download the discovery ISO.

6. Make a note of the discovery ISO URL for installing with virtual media.

   **NOTE**
   If you enable OpenShift Virtualization during this process, you must have a second local storage device of at least 50GiB for your virtual machines.

Additional resources

- Persistent storage using logical volume manager storage
- What you can do with OpenShift Virtualization
15.2.1.2. Installing single-node OpenShift with the Assisted Installer

Use the Assisted Installer to install the single-node cluster.

Procedure

1. Attach the RHCOS discovery ISO to the target host.
2. Configure the boot drive order in the server BIOS settings to boot from the attached discovery ISO and then reboot the server.
3. On the administration host, return to the browser. Wait for the host to appear in the list of discovered hosts. If necessary, reload the Assisted Clusters page and select the cluster name.
4. Complete the install wizard steps. Add networking details, including a subnet from the available subnets. Add the SSH public key if necessary.
5. Monitor the installation’s progress. Watch the cluster events. After the installation process finishes writing the operating system image to the server’s hard disk, the server restarts.
6. Remove the discovery ISO, and reset the server to boot from the installation drive. The server restarts several times automatically, deploying the control plane.

Additional resources

- Creating a bootable ISO image on a USB drive
- Booting from an HTTP-hosted ISO image using the Redfish API
- Adding worker nodes to single-node OpenShift clusters

15.2.2. Installing single-node OpenShift manually

To install OpenShift Container Platform on a single node, first generate the installation ISO, and then boot the server from the ISO. You can monitor the installation using the openshift-install installation program.

15.2.2.1. Generating the installation ISO with coreos-installer

Installing OpenShift Container Platform on a single node requires an installation ISO, which you can generate with the following procedure.

Prerequisites

- Install podman.

Procedure

1. Set the OpenShift Container Platform version:

   $ OCP_VERSION=<ocp_version>  

   Replace <ocp_version> with the current version, for example, latest-4.14
2. Set the host architecture:

   $ ARCH=<architecture>  

   1 Replace `<architecture>` with the target host architecture, for example, `aarch64` or `x86_64`.

3. Download the OpenShift Container Platform client (`oc`) and make it available for use by entering the following commands:

   ```
   $ tar zxf oc.tar.gz
   $ chmod +x oc
   ```

4. Download the OpenShift Container Platform installer and make it available for use by entering the following commands:

   ```
   $ tar zxf openshift-install-linux.tar.gz
   $ chmod +x openshift-install
   ```

5. Retrieve the RHCOS ISO URL by running the following command:

   ```
   $ ISO_URL=$(./openshift-install coreos print-stream-json | grep location | grep $ARCH | grep iso | cut -d" -f4)
   ```

6. Download the RHCOS ISO:

   ```
   $ curl -L $ISO_URL -o rhcos-live.iso
   ```

7. Prepare the `install-config.yaml` file:

   ```yaml
   apiVersion: v1
   baseDomain: <domain>  
   compute:  
     - name: worker
       replicas: 0  
   controlPlane:  
     name: master
     replicas: 1
   metadata:  
     name: <name>
   networking:  
     clusterNetwork:  
   ```
Add the cluster domain name.

Set the **compute** replicas to 0. This makes the control plane node schedulable.

Set the **controlPlane** replicas to 1. In conjunction with the previous **compute** setting, this setting ensures the cluster runs on a single node.

Set the **metadata** name to the cluster name.

Set the **networking** details. OVN-Kubernetes is the only allowed network plugin type for single-node clusters.

Set the **cidr** value to match the subnet of the single-node OpenShift cluster.

Set the path to the installation disk drive, for example, `/dev/disk/by-id/wwn-0x64cd98f04fde100024684cf3034da5c2`.

Copy the **pull secret** from the Red Hat OpenShift Cluster Manager and add the contents to this configuration setting.

Add the public SSH key from the administration host so that you can log in to the cluster after installation.

---

8. Generate OpenShift Container Platform assets by running the following commands:

```
$ mkdir ocp
$ cp install-config.yaml ocp
$ ./openshift-install --dir=ocp create single-node-ignition-config
```

9. Embed the ignition data into the RHCOS ISO by running the following commands:

```
$ alias coreos-installer='podman run --privileged --pull always --rm ' \
   -v /dev:/dev -v /run/udev:/run/udev -v $PWD:/data \
   -w /data quay.io/coreos/coreos-installer:release' \
$ coreos-installer iso ignition embed -fi ocp/bootstrap-in-place-for-live-iso.ign rhcos-live.iso
```
15.2.2.2. Monitoring the cluster installation using openshift-install

Use `openshift-install` to monitor the progress of the single-node cluster installation.

**Procedure**

1. Attach the modified RHCOS installation ISO to the target host.
2. Configure the boot drive order in the server BIOS settings to boot from the attached discovery ISO and then reboot the server.
3. On the administration host, monitor the installation by running the following command:

   ```
   $ ./openshift-install --dir=ocp wait-for install-complete
   ```

   The server restarts several times while deploying the control plane.

**Verification**

- After the installation is complete, check the environment by running the following command:

  ```
  $ export KUBECONFIG=ocp/auth/kubeconfig
  
  $ oc get nodes
  ```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>control-plane.example.com</td>
<td>Ready</td>
<td>master, worker</td>
<td>10m</td>
<td>v1.27.3</td>
</tr>
</tbody>
</table>

**Additional resources**

- Creating a bootable ISO image on a USB drive
- Booting from an HTTP-hosted ISO image using the Redfish API
- Adding worker nodes to single-node OpenShift clusters

15.2.3. Installing single-node OpenShift on cloud providers

15.2.3.1. Additional requirements for installing single-node OpenShift on a cloud provider

The documentation for installer-provisioned installation on cloud providers is based on a high availability cluster consisting of three control plane nodes. When referring to the documentation, consider the differences between the requirements for a single-node OpenShift cluster and a high availability cluster.
- A high availability cluster requires a temporary bootstrap machine, three control plane machines, and at least two compute machines. For a single-node OpenShift cluster, you need only a temporary bootstrap machine and one cloud instance for the control plane node and no worker nodes.

- The minimum resource requirements for high availability cluster installation include a control plane node with 4 vCPUs and 100GB of storage. For a single-node OpenShift cluster, you must have a minimum of 8 vCPU cores and 120GB of storage.

- The `controlPlane.replicas` setting in the `install-config.yaml` file should be set to 1.

- The `compute.replicas` setting in the `install-config.yaml` file should be set to 0. This makes the control plane node schedulable.

### 15.2.3.2. Supported cloud providers for single-node OpenShift

The following table contains a list of supported cloud providers and CPU architectures.

<table>
<thead>
<tr>
<th>Cloud provider</th>
<th>CPU architecture</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amazon Web Service (AWS)</td>
<td>x86_64 and AArch64</td>
</tr>
<tr>
<td>Microsoft Azure</td>
<td>x86_64</td>
</tr>
<tr>
<td>Google Cloud Platform (GCP)</td>
<td>x86_64 and AArch64</td>
</tr>
</tbody>
</table>

### 15.2.3.3. Installing single-node OpenShift on AWS

Installing a single-node cluster on AWS requires installer-provisioned installation using the "Installing a cluster on AWS with customizations" procedure.

**Additional resources**

- Installing a cluster on AWS with customizations

### 15.2.3.4. Installing single-node OpenShift on Azure

Installing a single node cluster on Azure requires installer-provisioned installation using the “Installing a cluster on Azure with customizations” procedure.

**Additional resources**

- Installing a cluster on Azure with customizations

### 15.2.3.5. Installing single-node OpenShift on GCP

Installing a single node cluster on GCP requires installer-provisioned installation using the "Installing a cluster on GCP with customizations" procedure.

**Additional resources**
15.2.4. Creating a bootable ISO image on a USB drive

You can install software using a bootable USB drive that contains an ISO image. Booting the server with the USB drive prepares the server for the software installation.

**Procedure**

1. On the administration host, insert a USB drive into a USB port.

2. Create a bootable USB drive, for example:

   ```
   # dd if=<path_to_iso> of=<path_to_usb> status=progress
   ```

   where:

   - `<path_to_iso>` is the relative path to the downloaded ISO file, for example, `rhcos-live.iso`.
   - `<path_to_usb>` is the location of the connected USB drive, for example, `/dev/sdb`.

   After the ISO is copied to the USB drive, you can use the USB drive to install software on the server.

15.2.5. Booting from an HTTP-hosted ISO image using the Redfish API

You can provision hosts in your network using ISOs that you install using the Redfish Baseboard Management Controller (BMC) API.

**Prerequisites**

1. Download the installation Red Hat Enterprise Linux CoreOS (RHCOS) ISO.

**Procedure**

1. Copy the ISO file to an HTTP server accessible in your network.

2. Boot the host from the hosted ISO file, for example:

   a. Call the redfish API to set the hosted ISO as the VirtualMedia boot media by running the following command:

   ```
   $ curl -k -u <bmc_username>:<bmc_password> -d '{"Image":"<hosted_iso_file>", "Inserted": true}' -H "Content-Type: application/json" -X POST <host_bmc_address>/redfish/v1/Managers/iDRAC.Embedded.1/VirtualMedia/CD/Actions/VirtualMedia.InsertMedia
   ```

   Where:

   - `<bmc_username>:<bmc_password>` is the username and password for the target host BMC.
   - `<hosted_iso_file>`
Is the URL for the hosted installation ISO, for example:
http://webserver.example.com/rhcos-live-minimal.iso. The ISO must be accessible from the target host machine.

<host_bmc_address>
Is the BMC IP address of the target host machine.

b. Set the host to boot from the VirtualMedia device by running the following command:

$ curl -k -u <bmc_username>:<bmc_password> -X PATCH -H 'Content-Type: application/json' -d '{"Boot": {"BootSourceOverrideTarget": "Cd", "BootSourceOverrideMode": "UEFI", "BootSourceOverrideEnabled": "Once"}}'
<host_bmc_address>/redfish/v1/Systems/System.Embedded.1

c. Reboot the host:

$ curl -k -u <bmc_username>:<bmc_password> -d '{"ResetType": "ForceRestart"}' -H 'Content-type: application/json' -X POST
<host_bmc_address>/redfish/v1/Systems/System.Embedded.1/Actions/ComputerSystem.Reset

d. Optional: If the host is powered off, you can boot it using the {"ResetType": "On"} switch. Run the following command:

$ curl -k -u <bmc_username>:<bmc_password> -d '{"ResetType": "On"}' -H 'Content-type: application/json' -X POST
<host_bmc_address>/redfish/v1/Systems/System.Embedded.1/Actions/ComputerSystem.Reset

15.2.6. Creating a custom live RHCOS ISO for remote server access

In some cases, you cannot attach an external disk drive to a server, however, you need to access the server remotely to provision a node. It is recommended to enable SSH access to the server. You can create a live RHCOS ISO with SSHd enabled and with predefined credentials so that you can access the server after it boots.

Prerequisites

- You installed the butane utility.

Procedure

1. Download the coreos-installer binary from the coreos-installer image mirror page.

3. Create the embedded.yaml file that the butane utility uses to create the Ignition file:

```yaml
variant: openshift
version: 4.14.0
metadata:
  name: sshd
labels:
  machineconfiguration.openshift.io/role: worker
```
passwd:
users:
  - name: core
    ssh_authorized_keys:
      - 'ssh_key'

1. The **core** user has sudo privileges.

4. Run the **butane** utility to create the Ignition file using the following command:

   $ butane -pr embedded.yaml -o embedded.ign

5. After the Ignition file is created, you can include the configuration in a new live RHCOS ISO, which is named **rhcos-sshd-4.14.0-x86_64-live.x86_64.iso**, with the **coreos-installer** utility:

   $ coreos-installer iso ignition embed -i embedded.ign rhcos-4.14.0-x86_64-live.x86_64.iso -o rhcos-sshd-4.14.0-x86_64-live.x86_64.iso

**Verification**

- Check that the custom live ISO can be used to boot the server by running the following command:

  # coreos-installer iso ignition show rhcos-sshd-4.14.0-x86_64-live.x86_64.iso

**Example output**

```json
{
  "ignition": {
    "version": "3.2.0"
  },
  "passwd": {
    "users": [
      {
        "name": "core",
        "sshAuthorizedKeys": [
          "ssh-rsa AAAAB3NzaC1yc2EAAAADAQABAAABAQZnG8AIzlIDAhyENpK2qKtt8EboRw9z7NxijRzopbPu215mocaJgjiwJjh1cyYhgPhAp6M/ttTk74O17g4588Apx4bwJep6oWTU35LkY8ZxkGVPAJL8kVITdKQviD3XX1i4QfnDom4tm4gVbR0gNT1wznhLP+LKYm2Ohr9D7p9NBnAdro6k+++XWgkDeijLRUTwdeEyWumlW1f8G0Mg8Y1Xzr13BUo3+8aeY7HlKJMDtofbkz/C8ESYA/7HJc5FxFOXbapWWoVSSDjrr9OmlL9T1F6+cQk3s+eoKiz2bgNPRgEEwiVBsCN4grA+RzLCAOpec+2dTJrQvFqsDaloSdag@sonnelicht.local"
        ]
      }
    ]
  }
}
```

### 15.2.7. Installing single-node OpenShift with IBM Z and IBM LinuxONE
Installing a single-node cluster on IBM Z® and IBM® LinuxONE requires user-provisioned installation using either the "Installing a cluster with RHEL KVM on IBM Z® and IBM® LinuxONE" or the "Installing a cluster with z/VM on IBM Z® and IBM® LinuxONE" procedure.

NOTE

Installing a single-node cluster on IBM Z® simplifies installation for development and test environments and requires less resource requirements at entry level.

Hardware requirements

- The equivalent of two Integrated Facilities for Linux (IFL), which are SMT2 enabled, for each cluster.
- At least one network connection to both connect to the LoadBalancer service and to serve data for traffic outside the cluster.

NOTE

You can use dedicated or shared IFLs to assign sufficient compute resources. Resource sharing is one of the key strengths of IBM Z®. However, you must adjust capacity correctly on each hypervisor layer and ensure sufficient resources for every OpenShift Container Platform cluster.

Additional resources

- Installing a cluster with z/VM on IBM Z® and IBM® LinuxONE
- Installing a cluster with RHEL KVM on IBM Z® and IBM® LinuxONE

15.2.7.1. Installing single-node OpenShift with z/VM on IBM Z and IBM LinuxONE

Prerequisites

- You have installed podman.

Procedure

1. Set the OpenShift Container Platform version by running the following command:

   $ OCP_VERSION=<ocp_version>  

   Replace <ocp_version> with the current version, for example, latest-4.14

2. Set the host architecture by running the following command:

   $ ARCH=<architecture>  

   Replace <architecture> with the target host architecture s390x.

3. Download the OpenShift Container Platform client (oc) and make it available for use by entering the following commands:
4. Download the OpenShift Container Platform installer and make it available for use by entering the following commands:

```
$ tar zxf oc.tar.gz
$ chmod +x oc
```

```
$ tar zxvf openshift-install-linux.tar.gz
$ chmod +x openshift-install
```

5. Prepare the `install-config.yaml` file:

```yaml
apiVersion: v1
baseDomain: <domain>  
compute:
  - name: worker
    replicas: 0
controlPlane:
  name: master
  replicas: 1
metadata:
  name: <name>
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
      hostPrefix: 23
  machineNetwork:
    - cidr: 10.0.0.0/16
  networkType: OVNKubernetes
  serviceNetwork:
    - 172.30.0.0/16
platform:
  none: {} 
bootstrapInPlace:
  installationDisk: /dev/disk/by-id/<disk_id>
pullSecret: '<pull_secret>'
sshKey: |<ssh_key>
```

1. Add the cluster domain name.
2. Set the `compute` replicas to 0. This makes the control plane node schedulable.
3. Set the `controlPlane` replicas to 1. In conjunction with the previous `compute` setting, this setting ensures the cluster runs on a single node.
4. Set the **metadata** name to the cluster name.

5. Set the **networking** details. OVN-Kubernetes is the only allowed network plugin type for single-node clusters.

6. Set the **cidr** value to match the subnet of the single-node OpenShift cluster.

7. Set the path to the installation disk drive, for example, `/dev/disk/by-id/wwn-0x64cd98f04fde100024684cf3034da5c2`.

8. Copy the pull secret from the Red Hat OpenShift Cluster Manager and add the contents to this configuration setting.

9. Add the public SSH key from the administration host so that you can log in to the cluster after installation.

---

6. Generate OpenShift Container Platform assets by running the following commands:

   ```
   $ mkdir ocp
   $ cp install-config.yaml ocp
   $ ./openshift-install --dir=ocp create single-node-ignition-config
   ```

7. Obtain the RHEL **kernel**, **initramfs**, and **rootfs** artifacts from the Product Downloads page on the Red Hat Customer Portal or from the RHCOS image mirror page.

   **IMPORTANT**

   The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate **kernel**, **initramfs**, and **rootfs** artifacts described in the following procedure.

   The file names contain the OpenShift Container Platform version number. They resemble the following examples:

   **kernel**
   ```
   rhcos-<version>-live-kernel-<architecture>
   ```

   **initramfs**
   ```
   rhcos-<version>-live-initramfs.<architecture>.img
   ```

   **rootfs**
   ```
   rhcos-<version>-live-rootfs.<architecture>.img
   ```

   **NOTE**

   The **rootfs** image is the same for FCP and DASD.

8. Move the following artifacts and files to an HTTP or HTTPS server:
9. Create parameter files for a particular virtual machine:

Example parameter file

```
rd.neednet=1 \  
    coreos.live.roots_url={rhcos_liveos}:8080/rootfs.img \  
    ignition.config.url={rhcos_ign}:8080/ignition/bootstrap-in-place-for-live-iso.ign \  
    ip=encbddd0:dhcp::02:00:00:02:34:02 \  
    rd.znet=qeth,0.0.bdd0,0.0.bdd1,0.0.bdd2,layer2=1 \  
    rd.dasd=0.0.4411 \  
    rd.zfcp=0.0.8001,0x50050763040051e3,0x40004063000000000 \  
    zfcp.allow_lun_scan=0 \  
    rd.luks.options=discard \  
    ignition.firstboot ignition.platform.id=metal \  
    console=tty1 console=ttyS1,115200n8
```

1. For the `coreos.live.roots_url` artifact, specify the matching `rootfs` artifact for the kernel and initramfs you are booting. Only HTTP and HTTPS protocols are supported.

2. For the `ignition.config.url` parameter, specify the Ignition file for the machine role. Only HTTP and HTTPS protocols are supported.

3. For the `ip` parameter, assign the IP address automatically using DHCP or manually as described in "Installing a cluster with z/VM on IBM Z® and IBM® LinuxONE".

4. For installations on DASD-type disks, use `rd.dasd=` to specify the DASD where RHCOS is to be installed. Omit this entry for FCP-type disks.

5. For installations on FCP-type disks, use `rd.zfcp=adapter,wwpn,lun` to specify the FCP disk where RHCOS is to be installed. Omit this entry for DASD-type disks.

Leave all other parameters unchanged.

10. Transfer the following artifacts, files, and images to z/VM. For example by using FTP:

- kernel and initramfs artifacts
- Parameter files
- RHCOS images
  For details about how to transfer the files with FTP and boot from the virtual reader, see Installing under Z/VM.

11. Punch the files to the virtual reader of the z/VM guest virtual machine that is to become your bootstrap node.

12. Log in to CMS on the bootstrap machine.

13. IPL the bootstrap machine from the reader by running the following command:
$ cp ipl c

14. After the first reboot of the virtual machine, run the following commands directly after one another:

   a. To boot a DASD device after first reboot, run the following commands:

   ```
   $ cp i <devno> clear loadparm prompt
   ```
   
   where:

   `<devno>`
   Specifies the device number of the boot device as seen by the guest.

   ```
   $ cp vi vmsg 0 <kernel_parameters>
   ```
   
   where:

   `<kernel_parameters>`
   Specifies a set of kernel parameters to be stored as system control program data (SCPDATA). When booting Linux, these kernel parameters are concatenated to the end of the existing kernel parameters that are used by your boot configuration. The combined parameter string must not exceed 896 characters.

   b. To boot an FCP device after first reboot, run the following commands:

   ```
   $ cp set loaddev portname <wwpn> lun <lun>
   ```
   
   where:

   `<wwpn>`
   Specifies the target port and `<lun>` the logical unit in hexadecimal format.

   ```
   $ cp set loaddev bootprog <n>
   ```
   
   where:

   `<n>`
   Specifies the kernel to be booted.

   ```
   $ cp set loaddev scpdata {APPEND|NEW} '<kernel_parameters>'
   ```
   
   where:

   `<kernel_parameters>`
   Specifies a set of kernel parameters to be stored as system control program data (SCPDATA). When booting Linux, these kernel parameters are concatenated to the end of the existing kernel parameters that are used by your boot configuration. The combined parameter string must not exceed 896 characters.

   `<APPEND|NEW>`
   Optional: Specify `APPEND` to append kernel parameters to existing SCPDATA. This is the default. Specify `NEW` to replace existing SCPDATA.
Example

```bash
$ cp set loaddev scpdata
    ’rd.zfcp=0.8001,0x500507630a0350a4,0x4000409D00000000
    ip=encbddd0:dhcp::02:00:00:02:34:02 rd.neednet=1’
```

To start the IPL and boot process, run the following command:

```bash
$ cp i <devno>
```

where:

- `<devno>`

  Specifies the device number of the boot device as seen by the guest.

### 15.2.7.2. Installing single-node OpenShift with RHEL KVM on IBM Z and IBM LinuxONE

**Prerequisites**

- You have installed podman.

**Procedure**

1. Set the OpenShift Container Platform version by running the following command:

   ```bash
   $ OCP_VERSION=<ocp_version>  
   ```

   Replace `<ocp_version>` with the current version, for example, `latest-4.14`

2. Set the host architecture by running the following command:

   ```bash
   $ ARCH=<architecture>  
   ```

   Replace `<architecture>` with the target host architecture `s390x`.

3. Download the OpenShift Container Platform client (oc) and make it available for use by entering the following commands:

   ```bash
   $ tar zxf oc.tar.gz
   $ chmod +x oc
   ```

4. Download the OpenShift Container Platform installer and make it available for use by entering the following commands:

   ```bash
   ```
5. Prepare the **install-config.yaml** file:

```yaml
apiVersion: v1
baseDomain: <domain>  
compute:
- name: worker
  replicas: 0
controlPlane:
  name: master
  replicas: 1
metadata:
  name: <name>
networking:
  clusterNetwork:
  - cidr: 10.128.0.0/14
    hostPrefix: 23
  machineNetwork:
  - cidr: 10.0.0.0/16
  networkType: OVNKubernetes
  serviceNetwork:
  - 172.30.0.0/16
platform:
  none: {}
bootstrapInPlace:
  installationDisk: /dev/disk/by-id/<disk_id>
pullSecret: '<pull_secret>'
sshKey: |<ssh_key>
```

1. Add the cluster domain name.
2. Set the `compute` replicas to 0. This makes the control plane node schedulable.
3. Set the `controlPlane` replicas to 1. In conjunction with the previous `compute` setting, this setting ensures the cluster runs on a single node.
4. Set the `metadata` name to the cluster name.
5. Set the `networking` details. OVN-Kubernetes is the only allowed network plugin type for single-node clusters.
6. Set the `cidr` value to match the subnet of the single-node OpenShift cluster.
7. Set the path to the installation disk drive, for example, `/dev/disk/by-id/wwn-0x64cd98f04fde100024684cf3034da5c2`.
8. Copy the pull secret from the Red Hat OpenShift Cluster Manager and add the contents to this configuration setting.
Add the public SSH key from the administration host so that you can log in to the cluster after installation.

6. Generate OpenShift Container Platform assets by running the following commands:

```bash
$ mkdir ocp
$ cp install-config.yaml ocp
$ ./openshift-install --dir=ocp create single-node-ignition-config
```

7. Obtain the RHEL kernel, initramfs, and rootfs artifacts from the Product Downloads page on the Red Hat Customer Portal or from the RHCOS image mirror page.

**IMPORTANT**

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate kernel, initramfs, and rootfs artifacts described in the following procedure.

The file names contain the OpenShift Container Platform version number. They resemble the following examples:

- **kernel**
  
  `rhcos-<version>-live-kernel-<architecture>`

- **initramfs**
  
  `rhcos-<version>-live-initramfs.<architecture>.img`

- **rootfs**
  
  `rhcos-<version>-live-rootfs.<architecture>.img`

8. Before you launch virt-install, move the following files and artifacts to an HTTP or HTTPS server:

- Downloaded RHEL live kernel, initramfs, and rootfs artifacts
- Ignition files

9. Create the KVM guest nodes by using the following components:

- RHEL kernel and initramfs artifacts
- Ignition files
- The new disk image
- Adjusted parm line arguments

```bash
$ virt-install \ 
  --name {vn_name} \ 
  --autostart \ 
```

```bash
```
---memory={memory_mb}\ 
--cpu host\ 
--vcpus {vcpus}\ 
--location {media_location},kernel={rhcos_kernel},initrd={rhcos_initrd}\ 
--disk size=100\ 
--network network={virt_network_parm}\ 
--graphics none\ 
--noautoconsole\ 
--extra-args "ip=${IP}::${GATEWAY}:${MASK}:${VM_NAME}:none"\ 
--extra-args "nameserver=${NAME_SERVER}"\ 
--extra-args "ip= dhcp rd.neednet=1 ignition.platform.id=metal ignition.firstboot"\ 
--extra-args "coreos.live.rootfs_url={rhcos_liveos}"\ 
--extra-args "ignition.config.url={rhcos_ign}"\ 
--extra-args "random.trust_cpu=on rd.luks.options=discard"\ 
--extra-args "console=tty1 console=ttyS1,115200n8"\ 
--wait

1. For the --location parameter, specify the location of the kernel/initrd on the HTTP or HTTPS server.

2. For the coreos.live.rootfs_url= artifact, specify the matching rootfs artifact for the kernel and initramfs you are booting. Only HTTP and HTTPS protocols are supported.

3. For the ignition.config.url= parameter, specify the Ignition file for the machine role. Only HTTP and HTTPS protocols are supported.

15.2.8. Installing single-node OpenShift with IBM Power

Installing a single-node cluster on IBM Power® requires user-provisioned installation using the "Installing a cluster with IBM Power®" procedure.

**NOTE**

Installing a single-node cluster on IBM Power® simplifies installation for development and test environments and requires less resource requirements at entry level.

**Hardware requirements**

- The equivalent of two Integrated Facilities for Linux (IFL), which are SMT2 enabled, for each cluster.
- At least one network connection to connect to the LoadBalancer service and to serve data for traffic outside of the cluster.

**NOTE**

You can use dedicated or shared IFLs to assign sufficient compute resources. Resource sharing is one of the key strengths of IBM Power®. However, you must adjust capacity correctly on each hypervisor layer and ensure sufficient resources for every OpenShift Container Platform cluster.

**Additional resources**
15.2.8.1. Setting up basion for single-node OpenShift with IBM Power®

Prior to installing single-node OpenShift on IBM Power®, you must set up bastion. Setting up a bastion server for single-node OpenShift on IBM Power® requires the configuration of the following services:

- PXE is used for the single-node OpenShift cluster installation. PXE requires the following services to be configured and run:
  - DNS to define api, api-int, and *.apps
  - DHCP service to enable PXE and assign an IP address to single-node OpenShift node
  - HTTP to provide ignition and RHCOS rootfs image
  - TFTP to enable PXE
- You must install **dnsmasq** to support DNS, DHCP and PXE, httpd for HTTP.

Use the following procedure to configure a bastion server that meets these requirements.

**Procedure**

1. Use the following command to install **grub2**, which is required to enable PXE for PowerVM:

   ```
   grub2-mknetdir --net-directory=/var/lib/tftpboot
   ```

   **Example /var/lib/tftpboot/boot/grub2/grub.cfg file**

   ```
   default=0
   fallback=1
   timeout=1
   if [ ${net_default_mac} == fa:b0:45:27:43:20 ]; then
     menuentry "CoreOS (BIOS)" {
       echo "Loading kernel"
       linux "/rhcos/kernel" ip=dhcp rd.neednet=1 ignition.platform.id=metal ignition.firstboot
       coreos.live.rootsfs_url=http://192.168.10.5:8000/install/rootfs.img
       ignition.config.url=http://192.168.10.5:8000/ignition/sno.ign
       echo "Loading initrd"
       initrd "/rhcos/initramfs.img"
     }
   fi
   ```

2. Use the following commands to download RHCOS image files from the mirror repo for PXE.

   a. Enter the following command to assign the **RHCOS_URL** variable the follow 4.12 URL:

   ```
   ```

   b. Enter the following command to navigate to the `/var/lib/tftpboot/rhcos` directory:

   ```
   $ cd /var/lib/tftpboot/rhcos
   ```
c. Enter the following command to download the specified RHCOS kernel file from the URL stored in the `RHCOS_URL` variable:

```
$ wget ${RHCOS_URL}/rhcos-live-kernel-ppc64le -o kernel
```

d. Enter the following command to download the RHCOS initramfs file from the URL stored in the `RHCOS_URL` variable:

```
$ wget ${RHCOS_URL}/rhcos-live-initramfs.ppc64le.img -o initramfs.img
```

e. Enter the following command to navigate to the `/var//var/www/html/install/` directory:

```
$ cd /var//var/www/html/install/
```

f. Enter the following command to download, and save, the RHCOS root filesystem image file from the URL stored in the `RHCOS_URL` variable:

```
$ wget ${RHCOS_URL}/rhcos-live-rootsfs.ppc64le.img -o rootfs.img
```

3. To create the ignition file for a single-node OpenShift cluster, you must create the `install-config.yaml` file.

a. Enter the following command to create the work directory that holds the file:

```
$ mkdir -p ~/sno-work
```

b. Enter the following command to navigate to the `~/sno-work` directory:

```
$ cd ~/sno-work
```

c. Use the following sample file can to create the required `install-config.yaml` in the `~/sno-work` directory:

```
apiVersion: v1
baseDomain: <domain>
compute:
  - name: worker
    replicas: 0
controlPlane:
  name: master
  replicas: 1
metadata:
  name: <name>
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
      hostPrefix: 23
  machineNetwork:
    - cidr: 10.0.0.0/16
  networkType: OVNKubernetes
  serviceNetwork:
    - 172.30.0.0/16
platform:
```
Add the cluster domain name.

Set the `compute` replicas to 0. This makes the control plane node schedulable.

Set the `controlPlane` replicas to 1. In conjunction with the previous `compute` setting, this setting ensures that the cluster runs on a single node.

Set the `metadata` name to the cluster name.

Set the `networking` details. OVN-Kubernetes is the only allowed network plugin type for single-node clusters.

Set the `cidr` value to match the subnet of the single-node OpenShift cluster.

Copy the pull secret from the Red Hat OpenShift Cluster Manager and add the contents to this configuration setting.

Add the public SSH key from the administration host so that you can log in to the cluster after installation.

4. Download the `openshift-install` image to create the ignition file and copy it to the `http` directory.
   a. Enter the following command to download the `openshift-install-linux-4.12.0` .tar file:

   ```bash
   ```

   b. Enter the following command to unpack the `openshift-install-linux-4.12.0.tar.gz` archive:

   ```bash
   $ tar xzvf openshift-install-linux-4.12.0.tar.gz
   ```

   c. Enter the following command to

   ```bash
   $ ./openshift-install --dir=~/.sno-work create create single-node-ignition-config
   ```

   d. Enter the following command to create the ignition file:

   ```bash
   $ cp ~/sno-work/single-node-ignition-config.ign /var/www/html/ignition/sno.ign
   ```

   e. Enter the following command to restore SELinux file for the `/var/www/html` directory:

   ```bash
   $ restorecon -vR /var/www/html || true
   ```
Bastion now has all the required files and is properly configured in order to install single-node OpenShift.

15.2.8.2. Installing single-node OpenShift with IBM Power

Prerequisites

- You have set up bastion.

Procedure

There are two steps for the single-node OpenShift cluster installation. First the single-node OpenShift logical partition (LPAR) needs to boot up with PXE, then you need to monitor the installation progress.

1. Use the following command to boot powerVM with netboot:

   ```
   $ lpar_netboot -i -D -f -t ent -m <sno_mac> -s auto -d auto -S <server_ip> -C <sno_ip> -G <gateway> <lpar_name> default_profile <cec_name>
   ```

   where:

   - **sno_mac**: Specifies the MAC address of the single-node OpenShift cluster.
   - **sno_ip**: Specifies the IP address of the single-node OpenShift cluster.
   - **server_ip**: Specifies the IP address of bastion (PXE server).
   - **gateway**: Specifies the Network's gateway IP.
   - **lpar_name**: Specifies the single-node OpenShift lpar name in HMC.
   - **cec_name**: Specifies the System name where the sno_lpar resides

2. After the single-node OpenShift LPAR boots up with PXE, use the `openshift-install` command to monitor the progress of installation:

   a. Run the following command after the bootstrap is complete:

   ```
   ./openshift-install wait-for bootstrap-complete
   ```

   b. Run the following command after it returns successfully:

   ```
   ./openshift-install wait-for install-complete
   ```
CHAPTER 16. DEPLOYING INSTALLER-PROVISIONED CLUSTERS ON BARE METAL

16.1. OVERVIEW

Installer-provisioned installation on bare metal nodes deploys and configures the infrastructure that an OpenShift Container Platform cluster runs on. This guide provides a methodology to achieving a successful installer-provisioned bare-metal installation. The following diagram illustrates the installation environment in phase 1 of deployment:

For the installation, the key elements in the previous diagram are:

- **Provisioner**: A physical machine that runs the installation program and hosts the bootstrap VM that deploys the control plane of a new OpenShift Container Platform cluster.

- **Bootstrap VM**: A virtual machine used in the process of deploying an OpenShift Container Platform cluster.

- **Network bridges**: The bootstrap VM connects to the bare metal network and to the provisioning network, if present, via network bridges, `eno1` and `eno2`.

- **API VIP**: An API virtual IP address (VIP) is used to provide failover of the API server across the control plane nodes. The API VIP first resides on the bootstrap VM. A script generates the `keepalived.conf` configuration file before launching the service. The VIP moves to one of the control plane nodes after the bootstrap process has completed and the bootstrap VM stops.

In phase 2 of the deployment, the provisioner destroys the bootstrap VM automatically and moves the virtual IP addresses (VIPs) to the appropriate nodes.

The `keepalived.conf` file sets the control plane machines with a lower Virtual Router Redundancy Protocol (VRRP) priority than the bootstrap VM, which ensures that the API on the control plane machines is fully functional before the API VIP moves from the bootstrap VM to the control plane. Once
the API VIP moves to one of the control plane nodes, traffic sent from external clients to the API VIP routes to an haproxy load balancer running on that control plane node. This instance of haproxy load balances the API VIP traffic across the control plane nodes.

The Ingress VIP moves to the worker nodes. The keepalived instance also manages the Ingress VIP.

The following diagram illustrates phase 2 of deployment:

After this point, the node used by the provisioner can be removed or repurposed. From here, all additional provisioning tasks are carried out by the control plane.

**IMPORTANT**

The provisioning network is optional, but it is required for PXE booting. If you deploy without a provisioning network, you must use a virtual media baseboard management controller (BMC) addressing option such as redfish-virtualmedia or idrac-virtualmedia.

**16.2. PREREQUISITES**

Installer-provisioned installation of OpenShift Container Platform requires:

1. One provisioner node with Red Hat Enterprise Linux (RHEL) 8.x installed. The provisioner can be removed after installation.

2. Three control plane nodes

3. Baseboard management controller (BMC) access to each node

4. At least one network:
   a. One required routable network
   b. One optional provisioning network
Before starting an installer-provisioned installation of OpenShift Container Platform, ensure the hardware environment meets the following requirements.

### 16.2.1. Node requirements

Installer-provisioned installation involves a number of hardware node requirements:

- **CPU architecture**: All nodes must use x86_64 or aarch64 CPU architecture.

- **Similar nodes**: Red Hat recommends nodes have an identical configuration per role. That is, Red Hat recommends nodes be the same brand and model with the same CPU, memory, and storage configuration.

- **Baseboard Management Controller**: The provisioner node must be able to access the baseboard management controller (BMC) of each OpenShift Container Platform cluster node. You may use IPMI, Redfish, or a proprietary protocol.

- **Latest generation**: Nodes must be of the most recent generation. Installer-provisioned installation relies on BMC protocols, which must be compatible across nodes. Additionally, RHEL 8 ships with the most recent drivers for RAID controllers. Ensure that the nodes are recent enough to support RHEL 8 for the provisioner node and RHCOS 8 for the control plane and worker nodes.

- **Registry node**: (Optional) If setting up a disconnected mirrored registry, it is recommended the registry reside in its own node.

- **Provisioner node**: Installer-provisioned installation requires one provisioner node.

- **Control plane**: Installer-provisioned installation requires three control plane nodes for high availability. You can deploy an OpenShift Container Platform cluster with only three control plane nodes, making the control plane nodes schedulable as worker nodes. Smaller clusters are more resource efficient for administrators and developers during development, production, and testing.

- **Worker nodes**: While not required, a typical production cluster has two or more worker nodes.

**IMPORTANT**

Do not deploy a cluster with only one worker node, because the cluster will deploy with routers and ingress traffic in a degraded state.

- **Network interfaces**: Each node must have at least one network interface for the routable baremetal network. Each node must have one network interface for a provisioning network when using the provisioning network for deployment. Using the provisioning network is the default configuration.
NOTE

Only one network card (NIC) on the same subnet can route traffic through the gateway. By default, Address Resolution Protocol (ARP) uses the lowest numbered NIC. Use a single NIC for each node in the same subnet to ensure that network load balancing works as expected. When using multiple NICs for a node in the same subnet, use a single bond or team interface. Then add the other IP addresses to that interface in the form of an alias IP address. If you require fault tolerance or load balancing at the network interface level, use an alias IP address on the bond or team interface. Alternatively, you can disable a secondary NIC on the same subnet or ensure that it has no IP address.

- **Unified Extensible Firmware Interface (UEFI):** Installer-provisioned installation requires UEFI boot on all OpenShift Container Platform nodes when using IPv6 addressing on the provisioning network. In addition, UEFI Device PXE Settings must be set to use the IPv6 protocol on the provisioning network NIC, but omitting the provisioning network removes this requirement.

**IMPORTANT**

When starting the installation from virtual media such as an ISO image, delete all old UEFI boot table entries. If the boot table includes entries that are not generic entries provided by the firmware, the installation might fail.

- **Secure Boot:** Many production scenarios require nodes with Secure Boot enabled to verify the node only boots with trusted software, such as UEFI firmware drivers, EFI applications, and the operating system. You may deploy with Secure Boot manually or managed.

  1. **Manually:** To deploy an OpenShift Container Platform cluster with Secure Boot manually, you must enable UEFI boot mode and Secure Boot on each control plane node and each worker node. Red Hat supports Secure Boot with manually enabled UEFI and Secure Boot only when installer-provisioned installations use Redfish virtual media. See "Configuring nodes for Secure Boot manually" in the "Configuring nodes" section for additional details.

  2. **Managed:** To deploy an OpenShift Container Platform cluster with managed Secure Boot, you must set the `bootMode` value to `UEFISecurityBoot` in the `install-config.yaml` file. Red Hat supports installer-provisioned installation with managed Secure Boot on 10th generation HPE hardware and 13th generation Dell hardware running firmware version 2.75.75.75 or greater. Deploying with managed Secure Boot does not require Redfish virtual media. See "Configuring managed Secure Boot" in the "Setting up the environment for an OpenShift installation" section for details.

**NOTE**

Red Hat does not support Secure Boot with self-generated keys.

### 16.2.2. Planning a bare metal cluster for OpenShift Virtualization

If you will use OpenShift Virtualization, it is important to be aware of several requirements before you install your bare metal cluster.

- If you want to use live migration features, you must have multiple worker nodes at the time of cluster installation. This is because live migration requires the cluster-level high availability (HA) flag to be set to true. The HA flag is set when a cluster is installed and cannot be changed.
afterwards. If there are fewer than two worker nodes defined when you install your cluster, the HA flag is set to false for the life of the cluster.

**NOTE**

You can install OpenShift Virtualization on a single-node cluster, but single-node OpenShift does not support high availability.

- Live migration requires shared storage. Storage for OpenShift Virtualization must support and use the ReadWriteMany (RWX) access mode.
- If you plan to use Single Root I/O Virtualization (SR-IOV), ensure that your network interface controllers (NICs) are supported by OpenShift Container Platform.

**Additional resources**

- Preparing your cluster for OpenShift Virtualization
- About Single Root I/O Virtualization (SR-IOV) hardware networks
- Connecting a virtual machine to an SR-IOV network

### 16.2.3. Firmware requirements for installing with virtual media

The installation program for installer-provisioned OpenShift Container Platform clusters validates the hardware and firmware compatibility with Redfish virtual media. The installation program does not begin installation on a node if the node firmware is not compatible. The following tables list the minimum firmware versions tested and verified to work for installer-provisioned OpenShift Container Platform clusters deployed by using Redfish virtual media.

**NOTE**

Red Hat does not test every combination of firmware, hardware, or other third-party components. For further information about third-party support, see Red Hat third-party support policy. For information about updating the firmware, see the hardware documentation for the nodes or contact the hardware vendor.

#### Table 16.1. Firmware compatibility for HP hardware with Redfish virtual media

<table>
<thead>
<tr>
<th>Model</th>
<th>Management</th>
<th>Firmware versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>10th Generation</td>
<td>iLO5</td>
<td>2.63 or later</td>
</tr>
</tbody>
</table>

#### Table 16.2. Firmware compatibility for Dell hardware with Redfish virtual media

<table>
<thead>
<tr>
<th>Model</th>
<th>Management</th>
<th>Firmware versions</th>
</tr>
</thead>
<tbody>
<tr>
<td>15th Generation</td>
<td>iDRAC 9</td>
<td>v6.10.30.00</td>
</tr>
<tr>
<td>14th Generation</td>
<td>iDRAC 9</td>
<td>v6.10.30.00</td>
</tr>
</tbody>
</table>
**NOTE**

For Dell servers, ensure the OpenShift Container Platform cluster nodes have AutoAttach enabled through the iDRAC console. The menu path is Configuration → Virtual Media → Attach Mode → AutoAttach. With iDRAC 9 firmware version 04.40.00.00 and all releases up to including the 5.xx series, the virtual console plugin defaults to eHTML5, an enhanced version of HTML5, which causes problems with the InsertVirtualMedia workflow. Set the plugin to use HTML5 to avoid this issue. The menu path is Configuration → Virtual console → Plug-in Type → HTML5.

Unable to discover new bare metal hosts using the BMC

### 16.2.4. Network requirements

Installer-provisioned installation of OpenShift Container Platform involves several network requirements. First, installer-provisioned installation involves an optional non-routable provisioning network for provisioning the operating system on each bare metal node. Second, installer-provisioned installation involves a routable baremetal network.

#### 16.2.4.1. Ensuring required ports are open

Certain ports must be open between cluster nodes for installer-provisioned installations to complete successfully. In certain situations, such as using separate subnets for far edge worker nodes, you must ensure that the nodes in these subnets can communicate with nodes in the other subnets on the

---

**Model** | **Management** | **Firmware versions**
---|---|---
13th Generation | iDRAC 8 | v2.75.75.75 or later
following required ports.

Table 16.3. Required ports

<table>
<thead>
<tr>
<th>Port</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>67,68</td>
<td>When using a provisioning network, cluster nodes access the <code>dnsmasq</code> DHCP server over their provisioning network interfaces using ports 67 and 68.</td>
</tr>
<tr>
<td>69</td>
<td>When using a provisioning network, cluster nodes communicate with the TFTP server on port 69 using their provisioning network interfaces. The TFTP server runs on the bootstrap VM. The bootstrap VM runs on the provisioner node.</td>
</tr>
<tr>
<td>80</td>
<td>When not using the image caching option or when using virtual media, the provisioner node must have port 80 open on the <code>baremetal</code> machine network interface to stream the Red Hat Enterprise Linux CoreOS (RHCOS) image from the provisioner node to the cluster nodes.</td>
</tr>
<tr>
<td>123</td>
<td>The cluster nodes must access the NTP server on port 123 using the <code>baremetal</code> machine network.</td>
</tr>
<tr>
<td>5050</td>
<td>The Ironic Inspector API runs on the control plane nodes and listens on port 5050. The Inspector API is responsible for hardware introspection, which collects information about the hardware characteristics of the bare metal nodes.</td>
</tr>
<tr>
<td>6180</td>
<td>When deploying with virtual media and not using TLS, the provisioner node and the control plane nodes must have port 6180 open on the <code>baremetal</code> machine network interface so that the baseboard management controller (BMC) of the worker nodes can access the RHCOS image. Starting with OpenShift Container Platform 4.13, the default HTTP port is 6180.</td>
</tr>
<tr>
<td>6183</td>
<td>When deploying with virtual media and using TLS, the provisioner node and the control plane nodes must have port 6183 open on the <code>baremetal</code> machine network interface so that the BMC of the worker nodes can access the RHCOS image.</td>
</tr>
</tbody>
</table>
### 16.2.4.2. Increase the network MTU

Before deploying OpenShift Container Platform, increase the network maximum transmission unit (MTU) to 1500 or more. If the MTU is lower than 1500, the Ironic image that is used to boot the node might fail to communicate with the Ironic inspector pod, and inspection will fail. If this occurs, installation stops because the nodes are not available for installation.

### 16.2.4.3. Configuring NICs

OpenShift Container Platform deploys with two networks:

- **provisioning**: The provisioning network is an optional non-routable network used for provisioning the underlying operating system on each node that is a part of the OpenShift Container Platform cluster. The network interface for the provisioning network on each cluster node must have the BIOS or UEFI configured to PXE boot.

  The `provisioningNetworkInterface` configuration setting specifies the provisioning network NIC name on the control plane nodes, which must be identical on the control plane nodes. The `bootMACAddress` configuration setting provides a means to specify a particular NIC on each node for the provisioning network.

  The provisioning network is optional, but it is required for PXE booting. If you deploy without a provisioning network, you must use a virtual media BMC addressing option such as `redfish-virtualmedia` or `idrac-virtualmedia`.

- **baremetal**: The baremetal network is a routable network. You can use any NIC to interface with the baremetal network provided the NIC is not configured to use the provisioning network.

<table>
<thead>
<tr>
<th>Port</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6385</td>
<td>The Ironic API server runs initially on the bootstrap VM and later on the control plane nodes and listens on port 6385. The Ironic API allows clients to interact with Ironic for bare metal node provisioning and management, including operations like enrolling new nodes, managing their power state, deploying images, and cleaning the hardware.</td>
</tr>
<tr>
<td>8080</td>
<td>When using image caching without TLS, port 8080 must be open on the provisioner node and accessible by the BMC interfaces of the cluster nodes.</td>
</tr>
<tr>
<td>8083</td>
<td>When using the image caching option with TLS, port 8083 must be open on the provisioner node and accessible by the BMC interfaces of the cluster nodes.</td>
</tr>
<tr>
<td>9999</td>
<td>By default, the Ironic Python Agent (IPA) listens on TCP port 9999 for API calls from the Ironic conductor service. This port is used for communication between the bare metal node where IPA is running and the Ironic conductor service.</td>
</tr>
</tbody>
</table>
When using a VLAN, each NIC must be on a separate VLAN corresponding to the appropriate network.

16.2.4.4. DNS requirements

Clients access the OpenShift Container Platform cluster nodes over the baremetal network. A network administrator must configure a subdomain or subzone where the canonical name extension is the cluster name.

<cluster_name>.<base_domain>

For example:

test-cluster.example.com

OpenShift Container Platform includes functionality that uses cluster membership information to generate A/AAAA records. This resolves the node names to their IP addresses. After the nodes are registered with the API, the cluster can disperse node information without using CoreDNS-mDNS. This eliminates the network traffic associated with multicast DNS.

In OpenShift Container Platform deployments, DNS name resolution is required for the following components:

- The Kubernetes API
- The OpenShift Container Platform application wildcard ingress API

A/AAAA records are used for name resolution and PTR records are used for reverse name resolution. Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records or DHCP to set the hostnames for all the nodes.

Installer-provisioned installation includes functionality that uses cluster membership information to generate A/AAAA records. This resolves the node names to their IP addresses. In each record, <cluster_name> is the cluster name and <base_domain> is the base domain that you specify in the install-config.yaml file. A complete DNS record takes the form: <component>.<cluster_name>.<base_domain>.

Table 16.4. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes API</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>An A/AAAA record and a PTR record identify the API load balancer. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>
### Componenent | Record | Description
--- | --- | ---
Routes | *.apps.<cluster_name>.<base_domain>. | The wildcard A/AAAA record refers to the application ingress load balancer. The application ingress load balancer targets the nodes that run the Ingress Controller pods. The Ingress Controller pods run on the worker nodes by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.

For example, `console-openshift-console.apps.<cluster_name>.<base_domain>` is used as a wildcard route to the OpenShift Container Platform console.

**TIP**

You can use the `dig` command to verify DNS resolution.

### 16.2.4.5. Dynamic Host Configuration Protocol (DHCP) requirements

By default, installer-provisioned installation deploys `ironic-dnsmasq` with DHCP enabled for the `provisioning` network. No other DHCP servers should be running on the `provisioning` network when the `provisioningNetwork` configuration setting is set to `managed`, which is the default value. If you have a DHCP server running on the `provisioning` network, you must set the `provisioningNetwork` configuration setting to `unmanaged` in the `install-config.yaml` file.

Network administrators must reserve IP addresses for each node in the OpenShift Container Platform cluster for the `baremetal` network on an external DHCP server.

### 16.2.4.6. Reserving IP addresses for nodes with the DHCP server

For the `baremetal` network, a network administrator must reserve a number of IP addresses, including:

1. Two unique virtual IP addresses.
   - One virtual IP address for the API endpoint.
   - One virtual IP address for the wildcard ingress endpoint.
2. One IP address for the provisioner node.
3. One IP address for each control plane node.
4. One IP address for each worker node, if applicable.

**RESERVING IP ADDRESSES SO THEY BECOME STATIC IP ADDRESSES**

Some administrators prefer to use static IP addresses so that each node’s IP address remains constant in the absence of a DHCP server. To configure static IP addresses with NMState, see "(Optional) Configuring node network interfaces" in the "Setting up the environment for an OpenShift installation" section.
NETWORKING BETWEEN EXTERNAL LOAD BALANCERS AND CONTROL PLANE NODES

External load balancing services and the control plane nodes must run on the same L2 network, and on the same VLAN when using VLANs to route traffic between the load balancing services and the control plane nodes.

IMPORTANT

The storage interface requires a DHCP reservation or a static IP.

The following table provides an exemplary embodiment of fully qualified domain names. The API and Nameserver addresses begin with canonical name extensions. The hostnames of the control plane and worker nodes are exemplary, so you can use any host naming convention you prefer.

<table>
<thead>
<tr>
<th>Usage</th>
<th>Host Name</th>
<th>IP</th>
</tr>
</thead>
<tbody>
<tr>
<td>API</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>&lt;ip&gt;</td>
</tr>
<tr>
<td>Ingress LB (apps)</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>&lt;ip&gt;</td>
</tr>
<tr>
<td>Provisioner node</td>
<td>provisioner.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>&lt;ip&gt;</td>
</tr>
<tr>
<td>Control-plane-0</td>
<td>openshift-control-plane-0.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>&lt;ip&gt;</td>
</tr>
<tr>
<td>Control-plane-1</td>
<td>openshift-control-plane-1.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>&lt;ip&gt;</td>
</tr>
<tr>
<td>Control-plane-2</td>
<td>openshift-control-plane-2.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>&lt;ip&gt;</td>
</tr>
<tr>
<td>Worker-0</td>
<td>openshift-worker-0.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>&lt;ip&gt;</td>
</tr>
<tr>
<td>Worker-1</td>
<td>openshift-worker-1.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>&lt;ip&gt;</td>
</tr>
<tr>
<td>Worker-n</td>
<td>openshift-worker-n.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>&lt;ip&gt;</td>
</tr>
</tbody>
</table>

NOTE

If you do not create DHCP reservations, the installer requires reverse DNS resolution to set the hostnames for the Kubernetes API node, the provisioner node, the control plane nodes, and the worker nodes.

16.2.4.7. Provisioner node requirements

You must specify the MAC address for the provisioner node in your installation configuration. The
bootMacAddress specification is typically associated with PXE network booting. However, the Ironic provisioning service also requires the bootMacAddress specification to identify nodes during the inspection of the cluster, or during node redeployment in the cluster.

The provisioner node requires layer 2 connectivity for network booting, DHCP and DNS resolution, and local network communication. The provisioner node requires layer 3 connectivity for virtual media booting.

16.2.4.8. Network Time Protocol (NTP)

Each OpenShift Container Platform node in the cluster must have access to an NTP server. OpenShift Container Platform nodes use NTP to synchronize their clocks. For example, cluster nodes use SSL certificates that require validation, which might fail if the date and time between the nodes are not in sync.

IMPORTANT

Define a consistent clock date and time format in each cluster node’s BIOS settings, or installation might fail.

You can reconfigure the control plane nodes to act as NTP servers on disconnected clusters, and reconfigure worker nodes to retrieve time from the control plane nodes.

16.2.4.9. Port access for the out-of-band management IP address

The out-of-band management IP address is on a separate network from the node. To ensure that the out-of-band management can communicate with the provisioner node during installation, the out-of-band management IP address must be granted access to port 6180 on the provisioner node and on the OpenShift Container Platform control plane nodes. TLS port 6183 is required for virtual media installation, for example, by using Redfish.

16.2.5. Configuring nodes

Configuring nodes when using the provisioning network
Each node in the cluster requires the following configuration for proper installation.

WARNING

A mismatch between nodes will cause an installation failure.

While the cluster nodes can contain more than two NICs, the installation process only focuses on the first two NICs. In the following table, NIC1 is a non-routable network (provisioning) that is only used for the installation of the OpenShift Container Platform cluster.

<table>
<thead>
<tr>
<th>NIC</th>
<th>Network</th>
<th>VLAN</th>
</tr>
</thead>
<tbody>
<tr>
<td>NIC1</td>
<td>provisioning</td>
<td>&lt;provisioning_vlan&gt;</td>
</tr>
</tbody>
</table>
The Red Hat Enterprise Linux (RHEL) 8.x installation process on the provisioner node might vary. To install Red Hat Enterprise Linux (RHEL) 8.x using a local Satellite server or a PXE server, PXE-enable NIC2.

<table>
<thead>
<tr>
<th>NIC</th>
<th>Network</th>
<th>VLAN</th>
</tr>
</thead>
<tbody>
<tr>
<td>NIC2</td>
<td>baremetal</td>
<td>&lt;baremetal_vlan&gt;</td>
</tr>
</tbody>
</table>

PXE Boot order

<table>
<thead>
<tr>
<th>PXE Boot order</th>
<th>NIC</th>
<th>Network</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>NIC1</td>
<td>PXE-enabled provisioning network</td>
</tr>
<tr>
<td>2</td>
<td>NIC2</td>
<td>baremetal network. PXE-enabled is optional.</td>
</tr>
</tbody>
</table>

**NOTE**

Ensure PXE is disabled on all other NICs.

Configure the control plane and worker nodes as follows:

<table>
<thead>
<tr>
<th>PXE Boot order</th>
<th>NIC</th>
<th>Network</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>NIC1</td>
<td>PXE-enabled (provisioning network)</td>
</tr>
</tbody>
</table>

**Configuring nodes without the provisioning network**
The installation process requires one NIC:

<table>
<thead>
<tr>
<th>NIC</th>
<th>Network</th>
<th>VLAN</th>
</tr>
</thead>
<tbody>
<tr>
<td>NiCx</td>
<td>baremetal</td>
<td>&lt;baremetal_vlan&gt;</td>
</tr>
</tbody>
</table>

NiCx is a routable network (baremetal) that is used for the installation of the OpenShift Container Platform cluster, and routable to the internet.

**IMPORTANT**

The provisioning network is optional, but it is required for PXE booting. If you deploy without a provisioning network, you must use a virtual media BMC addressing option such as redfish-virtualmedia or idrac-virtualmedia.

**Configuring nodes for Secure Boot manually**

Secure Boot prevents a node from booting unless it verifies the node is using only trusted software, such as UEFI firmware drivers, EFI applications, and the operating system.
NOTE

Red Hat only supports manually configured Secure Boot when deploying with Redfish virtual media.

To enable Secure Boot manually, refer to the hardware guide for the node and execute the following:

Procedure

1. Boot the node and enter the BIOS menu.
2. Set the node’s boot mode to **UEFI Enabled**.
3. Enable Secure Boot.

IMPORTANT

Red Hat does not support Secure Boot with self-generated keys.

16.2.6. Out-of-band management

Nodes typically have an additional NIC used by the baseboard management controllers (BMCs). These BMCs must be accessible from the provisioner node.

Each node must be accessible via out-of-band management. When using an out-of-band management network, the provisioner node requires access to the out-of-band management network for a successful OpenShift Container Platform installation.

The out-of-band management setup is out of scope for this document. Using a separate management network for out-of-band management can enhance performance and improve security. However, using the provisioning network or the bare metal network are valid options.

NOTE

The bootstrap VM features a maximum of two network interfaces. If you configure a separate management network for out-of-band management, and you are using a provisioning network, the bootstrap VM requires routing access to the management network through one of the network interfaces. In this scenario, the bootstrap VM can then access three networks:

- the bare metal network
- the provisioning network
- the management network routed through one of the network interfaces

16.2.7. Required data for installation

Prior to the installation of the OpenShift Container Platform cluster, gather the following information from all cluster nodes:

- Out-of-band management IP
  - Examples
When using the **provisioning network**

- NIC (**provisioning**) MAC address
- NIC (**baremetal**) MAC address

When omitting the **provisioning network**

- NIC (**baremetal**) MAC address

### 16.2.8. Validation checklist for nodes

#### When using the **provisioning network**

- NIC1 VLAN is configured for the **provisioning** network.
- NIC1 for the **provisioning** network is PXE-enabled on the provisioner, control plane, and worker nodes.
- NIC2 VLAN is configured for the **baremetal** network.
- PXE has been disabled on all other NICs.
- DNS is configured with API and Ingress endpoints.
- Control plane and worker nodes are configured.
- All nodes accessible via out-of-band management.
- (Optional) A separate management network has been created.
- Required data for installation.

#### When omitting the **provisioning network**

- NIC1 VLAN is configured for the **baremetal** network.
- DNS is configured with API and Ingress endpoints.
- Control plane and worker nodes are configured.
- All nodes accessible via out-of-band management.
- (Optional) A separate management network has been created.
- Required data for installation.

### 16.3. SETTING UP THE ENVIRONMENT FOR AN OPENSHEET INSTALLATION
16.3.1. Installing RHEL on the provisioner node

With the configuration of the prerequisites complete, the next step is to install RHEL 8.x on the provisioner node. The installer uses the provisioner node as the orchestrator while installing the OpenShift Container Platform cluster. For the purposes of this document, installing RHEL on the provisioner node is out of scope. However, options include but are not limited to using a RHEL Satellite server, PXE, or installation media.

16.3.2. Preparing the provisioner node for OpenShift Container Platform installation

Perform the following steps to prepare the environment.

Procedure

1. Log in to the provisioner node via `ssh`.

2. Create a non-root user (`kni`) and provide that user with `sudo` privileges:

   ```
   # useradd kni
   # passwd kni
   # echo "kni ALL=(root) NOPASSWD:ALL" | tee -a /etc/sudoers.d/kni
   # chmod 0440 /etc/sudoers.d/kni
   # su - kni -c "ssh-keygen -t ed25519 -f /home/kni/.ssh/id_rsa -N ""
   # su - kni
   ```

3. Create an `ssh` key for the new user:

4. Log in as the new user on the provisioner node:

   ```
   # su - kni
   ```

5. Use Red Hat Subscription Manager to register the provisioner node:

   ```
   $ sudo subscription-manager register --username=<user> --password=<pass> --auto-attach
   $ sudo subscription-manager repos --enable=rhel-8-for-<architecture>-appstream-rpms --enable=rhel-8-for-<architecture>-baseos-rpms
   ```

   **NOTE**

   For more information about Red Hat Subscription Manager, see Using and Configuring Red Hat Subscription Manager.

6. Install the following packages:

   ```
   $ sudo dnf install -y libvirt qemu-kvm mkisofs python3-devel jq ipmitool
   ```

7. Modify the user to add the `libvirt` group to the newly created user:
$ sudo usermod --append --groups libvirt <user>

8. Restart **firewalld** and enable the **http** service:

```bash
$ sudo systemctl start firewalld
$ sudo firewall-cmd --zone=public --add-service=http --permanent
$ sudo firewall-cmd --reload
```

9. Start and enable the **libvirtd** service:

```bash
$ sudo systemctl enable libvirtd --now
```

10. Create the **default** storage pool and start it:

```bash
$ sudo virsh pool-define-as --name default --type dir --target /var/lib/libvirt/images
$ sudo virsh pool-start default
$ sudo virsh pool-autostart default
```

11. Create a **pull-secret.txt** file:

```bash
$ vim pull-secret.txt
```

In a web browser, navigate to Install OpenShift on Bare Metal with installer-provisioned infrastructure. Click **Copy pull secret**. Paste the contents into the **pull-secret.txt** file and save the contents in the **kni** user’s home directory.

### 16.3.3. Checking NTP server synchronization

The OpenShift Container Platform installation program installs the **chrony** Network Time Protocol (NTP) service on the cluster nodes. To complete installation, each node must have access to an NTP time server. You can verify NTP server synchronization by using the **chrony** service.

For disconnected clusters, you must configure the NTP servers on the control plane nodes. For more information see the **Additional resources** section.

**Prerequisites**

- You installed the **chrony** package on the target node.

**Procedure**

1. Log in to the node by using the **ssh** command.

2. View the NTP servers available to the node by running the following command:

```bash
$ chronyc sources
```
3. Use the `ping` command to ensure that the node can access an NTP server, for example:

```
$ ping time.cloudflare.com
```

**Example output**

```
PING time.cloudflare.com (162.159.200.123) 56(84) bytes of data.
  64 bytes from time.cloudflare.com (162.159.200.123): icmp_seq=1 ttl=54 time=32.3 ms
  64 bytes from time.cloudflare.com (162.159.200.123): icmp_seq=2 ttl=54 time=30.9 ms
  64 bytes from time.cloudflare.com (162.159.200.123): icmp_seq=3 ttl=54 time=36.7 ms
...```

**Additional resources**

- Optional: Configuring NTP for disconnected clusters
- Network Time Protocol (NTP)

**16.3.4. Configuring networking**

Before installation, you must configure the networking on the provisioner node. Installer-provisioned clusters deploy with a bare-metal bridge and network, and an optional provisioning bridge and network.
NOTE
You can also configure networking from the web console.

Procedure

1. Export the bare-metal network NIC name:
   
   $ export PUB_CONN=<baremetal_nic_name>

2. Configure the bare-metal network:

   NOTE
   The SSH connection might disconnect after executing these steps.

   $ sudo nohup bash -c "
   nmcli con down \"$PUB_CONN\n   nmcli con delete \"$PUB_CONN\n   # RHEL 8.1 appends the word \"System\" in front of the connection, delete in case it exists
   nmcli con down \"System $PUB_CONN\n   nmcli con delete \"System $PUB_CONN\n   nmcli connection add ifname baremetal type bridge con-name baremetal bridge.stp no
   nmcli con add type bridge-slave ifname \"$PUB_CONN\n   master baremetal
   pkill dhclient;dhclient baremetal
   "

3. Optional: If you are deploying with a provisioning network, export the provisioning network NIC name:

   $ export PROV_CONN=<prov_nic_name>
4. Optional: If you are deploying with a provisioning network, configure the provisioning network:

```bash
$ sudo nohup bash -c "
    nmcli con down "$PROV_CONN"
    nmcli con delete "$PROV_CONN"
    nmcli connection add ifname provisioning type bridge con-name provisioning
    nmcli con add type bridge-slave ifname "$PROV_CONN" master provisioning
    nmcli connection modify provisioning ipv6.addresses fd00:1101::1/64 ipv6.method manual
    nmcli con down provisioning
    nmcli con up provisioning"
```

**NOTE**

The ssh connection might disconnect after executing these steps.

The IPv6 address can be any address as long as it is not routable via the bare-metal network.

Ensure that UEFI is enabled and UEFI PXE settings are set to the IPv6 protocol when using IPv6 addressing.

5. Optional: If you are deploying with a provisioning network, configure the IPv4 address on the provisioning network connection:

```bash
$ nmcli connection modify provisioning ipv4.addresses 172.22.0.254/24 ipv4.method manual
```

6. `ssh` back into the **provisioner** node (if required):

```bash
# ssh kni@provisioner.<cluster-name>.<domain>
```

7. Verify the connection bridges have been properly created:

```bash
$ sudo nmcli con show
```

<table>

16.3.5. Establishing communication between subnets

In a typical OpenShift Container Platform cluster setup, all nodes, including the control plane and worker nodes, reside in the same network. However, for edge computing scenarios, it can be beneficial to locate worker nodes closer to the edge. This often involves using different network segments or subnets for the remote worker nodes than the subnet used by the control plane and local worker nodes. Such a setup can reduce latency for the edge and allow for enhanced scalability. However, the network must be configured properly before installing OpenShift Container Platform to ensure that the edge subnets containing the remote worker nodes can reach the subnet containing the control plane nodes and receive traffic from the control plane too.
IMPORTANT

All control plane nodes must run in the same subnet. When using more than one subnet, you can also configure the Ingress VIP to run on the control plane nodes by using a manifest. See "Configuring network components to run on the control plane" for details.

Deploying a cluster with multiple subnets requires using virtual media.

This procedure details the network configuration required to allow the remote worker nodes in the second subnet to communicate effectively with the control plane nodes in the first subnet and to allow the control plane nodes in the first subnet to communicate effectively with the remote worker nodes in the second subnet.

In this procedure, the cluster spans two subnets:

- The first subnet (10.0.0.0) contains the control plane and local worker nodes.
- The second subnet (192.168.0.0) contains the edge worker nodes.

Procedure

1. Configure the first subnet to communicate with the second subnet:
   a. Log in as root to a control plane node by running the following command:
      
      ```
      $ sudo su -
      ```
   b. Get the name of the network interface:
      
      ```
      # nmcli dev status
      ```
   c. Add a route to the second subnet (192.168.0.0) via the gateway:
      
      ```
      # nmcli connection modify <interface_name> +ipv4.routes "192.168.0.0/24 via <gateway>"
      ```
   + Replace `<interface_name>` with the interface name. Replace `<gateway>` with the IP address of the actual gateway.

   + Example
   +
      
      ```
      # nmcli connection modify eth0 +ipv4.routes "192.168.0.0/24 via 192.168.0.1"
      ```
   
   a. Apply the changes:
      
      ```
      # nmcli connection up <interface_name>
      ```
   Replace `<interface_name>` with the interface name.
   b. Verify the routing table to ensure the route has been added successfully:
      
      ```
      # ip route
      ```
c. Repeat the previous steps for each control plane node in the first subnet.

   **NOTE**
   Adjust the commands to match your actual interface names and gateway.

   1. Configure the second subnet to communicate with the first subnet:

d. Log in as root to a remote worker node:

   `$ sudo su -`

e. Get the name of the network interface:

   ```
   # nmcli dev status
   ```

f. Add a route to the first subnet (10.0.0.0) via the gateway:

   ```
   # nmcli connection modify <interface_name> +ipv4.routes "10.0.0.0/24 via <gateway>"
   ```

   Replace `<interface_name>` with the interface name. Replace `<gateway>` with the IP address of the actual gateway.

   **Example**

   ```
   # nmcli connection modify eth0 +ipv4.routes "10.0.0.0/24 via 10.0.0.1"
   ```

g. Apply the changes:

   ```
   # nmcli connection up <interface_name>
   ```

   Replace `<interface_name>` with the interface name.

h. Verify the routing table to ensure the route has been added successfully:

   ```
   # ip route
   ```

i. Repeat the previous steps for each worker node in the second subnet.

   **NOTE**
   Adjust the commands to match your actual interface names and gateway.

   1. Once you have configured the networks, test the connectivity to ensure the remote worker nodes can reach the control plane nodes and the control plane nodes can reach the remote worker nodes.

j. From the control plane nodes in the first subnet, ping a remote worker node in the second subnet:

   ```
   $ ping <remote_worker_node_ip_address>
   ```
If the ping is successful, it means the control plane nodes in the first subnet can reach the remote worker nodes in the second subnet. If you don’t receive a response, review the network configurations and repeat the procedure for the node.

k. From the remote worker nodes in the second subnet, ping a control plane node in the first subnet:

```bash
$ ping <control_plane_node_ip_address>
```

If the ping is successful, it means the remote worker nodes in the second subnet can reach the control plane in the first subnet. If you don’t receive a response, review the network configurations and repeat the procedure for the node.

### 16.3.6. Retrieving the OpenShift Container Platform installer

Use the `stable-4.x` version of the installation program and your selected architecture to deploy the generally available stable version of OpenShift Container Platform:

```bash
$ export VERSION=stable-4.14
$ export RELEASE_ARCH=<architecture>
$ export RELEASE_IMAGE=$(curl -s https://mirror.openshift.com/pub/openshift-v4/$RELEASE_ARCH/clients/ocp/$VERSION/release.txt | grep 'Pull From: quay.io' | awk -F ' ' '{print $3}')
```

### 16.3.7. Extracting the OpenShift Container Platform installer

After retrieving the installer, the next step is to extract it.

**Procedure**

1. Set the environment variables:

   ```bash
   $ export cmd=openshift-baremetal-install
   $ export pullsecret_file=~/pull-secret.txt
   $ export extract_dir=$(pwd)
   $ curl -s https://mirror.openshift.com/pub/openshift-v4/clients/ocp/$VERSION/openshift-client-linux.tar.gz | tar zxvf -
   $ sudo cp oc /usr/local/bin
   $ oc adm release extract --registry-config "$pullsecret_file" --command="$cmd" --to "$extract_dir" "$RELEASE_IMAGE"
   ```
16.3.8. Optional: Creating an RHCOS images cache

To employ image caching, you must download the Red Hat Enterprise Linux CoreOS (RHCOS) image used by the bootstrap VM to provision the cluster nodes. Image caching is optional, but it is especially useful when running the installation program on a network with limited bandwidth.

**NOTE**

The installation program no longer needs the `clusterOSImage` RHCOS image because the correct image is in the release payload.

If you are running the installation program on a network with limited bandwidth and the RHCOS images download takes more than 15 to 20 minutes, the installation program will timeout. Caching images on a web server will help in such scenarios.

**WARNING**

If you enable TLS for the HTTPD server, you must confirm the root certificate is signed by an authority trusted by the client and verify the trusted certificate chain between your OpenShift Container Platform hub and spoke clusters and the HTTPD server. Using a server configured with an untrusted certificate prevents the images from being downloaded to the image creation service. Using untrusted HTTPS servers is not supported.

Install a container that contains the images.

**Procedure**

1. Install **podman**:
   ```bash
   $ sudo dnf install -y podman
   ```

2. Open firewall port **8080** to be used for RHCOS image caching:
   ```bash
   $ sudo firewall-cmd --add-port=8080/tcp --zone=public --permanent
   $ sudo firewall-cmd --reload
   ```

3. Create a directory to store the **bootstraposimage**:
   ```bash
   $ mkdir /home/kni/rhcos_image_cache
   ```

4. Set the appropriate SELinux context for the newly created directory:
   ```bash
   $ sudo semanage fcontext -a -t httpd_sys_content_t "/home/kni/rhcos_image_cache(/.*)?"
   ```
5. Get the URI for the RHCOS image that the installation program will deploy on the bootstrap VM:

   $ export RHOCOS_QEMU_URI=$(/usr/local/bin/openshift-baremetal-install coreos print-stream-json | jq -r --arg ARCH ";architecture[$ARCH].artifacts.qemu.formats["qcow2.gz"].disk.location\n
6. Get the name of the image that the installation program will deploy on the bootstrap VM:

   $ export RHOCOS_QEMU_NAME=${RHOCOS_QEMU_URI##*/}

7. Get the SHA hash for the RHCOS image that will be deployed on the bootstrap VM:

   $ export RHOCOS_QEMU_UNCOMPRESSED_SHA256=$(/usr/local/bin/openshift-baremetal-install coreos print-stream-json | jq -r --arg ARCH ";architecture[$ARCH].artifacts.qemu.formats["qcow2.gz"].disk["uncompressed-sha256"]\n
8. Download the image and place it in the /home/kni/rhcos_image_cache directory:

   $ curl -L ${RHOCOS_QEMU_URI} -o /home/kni/rhcos_image_cache/${RHOCOS_QEMU_NAME}

9. Confirm SELinux type is of httpd_sys_content_t for the new file:

   $ ls -Z /home/kni/rhcos_image_cache

10. Create the pod:

    $ podman run -d --name rhcos_image_cache \
        -v /home/kni/rhcos_image_cache:/var/www/html \n        -p 8080:8080/tcp \n        quay.io/centos7/httpd-24-centos7:latest

    Creates a caching webserver with the name rhcos_image_cache. This pod serves the bootstrapOSImage image in the install-config.yaml file for deployment.

11. Generate the bootstrapOSImage configuration:

    $ export BAREMETAL_IP=$(ip addr show dev baremetal | awk '/inet /{print $2}' | cut -d"/" -f1)

    $ export BOOTSTRAP_OS_IMAGE="http://${BAREMETAL_IP}:8080/${RHOCOS_QEMU_NAME}?sha256=${RHOCOS_QEMU_UNCOMPRESSED_SHA256}"

    $ echo "    bootstrapOSImage=${BOOTSTRAP_OS_IMAGE}"

12. Add the required configuration to the install-config.yaml file under platform.baremetal:
Replace `<bootstrap_os_image>` with the value of `$BOOTSTRAP_OS_IMAGE`.

See the "Configuring the install-config.yaml file" section for additional details.

16.3.9. Configuring the install-config.yaml file

16.3.9.1. Configuring the install-config.yaml file

The `install-config.yaml` file requires some additional details. Most of the information teaches the installation program and the resulting cluster enough about the available hardware that it is able to fully manage it.

NOTE

The installation program no longer needs the `clusterOSImage` RHCOS image because the correct image is in the release payload.

1. Configure `install-config.yaml`. Change the appropriate variables to match the environment, including `pullSecret` and `sshKey`:

```
apiVersion: v1
baseDomain: <domain>
metadata:
  name: <cluster_name>
networking:
  machineNetwork:
    - cidr: <public_cidr>
  networkType: OVNKubernetes
compute:
  - name: worker
    replicas: 2
controlPlane:
  name: master
  replicas: 3
platform:
  baremetal: {}
platform:
  baremetal:
    apiVIPS:
      - <api_ip>
  ingressVIPS:
    - <wildcard_ip>
  provisioningNetworkCIDR: <CIDR>
bootstrapExternalStaticIP: <bootstrap_static_ip_address>
bootstrapExternalStaticGateway: <bootstrap_static_gateway>
hosts:
  - name: openshift-master-0
    role: master
    bmc:
```
Scale the worker machines based on the number of worker nodes that are part of the OpenShift Container Platform cluster. Valid options for the `replicas` value are 0 and integers greater than or equal to 2. Set the number of replicas to 0 to deploy a three-node cluster, which contains only three control plane machines. A three-node cluster is a smaller, more resource-efficient cluster that can be used for testing, development, and production. You cannot install the cluster with only one worker.

When deploying a cluster with static IP addresses, you must set the `bootstrapExternalStaticIP` configuration setting to specify the static IP address of the bootstrap VM when there is no DHCP server on the bare-metal network.

When deploying a cluster with static IP addresses, you must set the `bootstrapExternalStaticGateway` configuration setting to specify the gateway IP address for the bootstrap VM when there is no DHCP server on the bare-metal network.
for the bootstrap VM when there is no DHCP server on the bare-metal network.

See the BMC addressing sections for more options.

To set the path to the installation disk drive, enter the kernel name of the disk. For example, `/dev/sda`.

**IMPORTANT**

Because the disk discovery order is not guaranteed, the kernel name of the disk can change across booting options for machines with multiple disks. For instance, `/dev/sda` becomes `/dev/sdb` and vice versa. To avoid this issue, you must use persistent disk attributes, such as the disk World Wide Name (WWN). To use the disk WWN, replace the `deviceName` parameter with the `wwnWithExtension` parameter. Depending on the parameter that you use, enter the disk name, for example, `/dev/sda` or the disk WWN, for example, "0x64cd98f04fde100024684cf3034da5c2". Ensure that you enter the disk WWN value within quotes so that it is used as a string value and not a hexadecimal value.

Failure to meet these requirements for the `rootDeviceHints` parameter might result in the following error:

```plaintext
ironic-inspector inspection failed: No disks satisfied root device hints
```

**NOTE**

Before OpenShift Container Platform 4.12, the cluster installation program only accepted an IPv4 address or and IPv6 address for the `apiVIP` and `ingressVIP` configuration settings. In OpenShift Container Platform 4.12 and later, these configuration settings are deprecated. Instead, use a list format in the `apiVIPs` and `ingressVIPs` configuration settings to specify IPv4 addresses, IPv6 addresses or both IP address formats.

2. Create a directory to store the cluster configuration:

```
$ mkdir ~/clusterconfigs
```

3. Copy the `install-config.yaml` file to the new directory:

```
$ cp install-config.yaml ~/clusterconfigs
```

4. Ensure all bare metal nodes are powered off prior to installing the OpenShift Container Platform cluster:

```
$ ipmitool -I lanplus -U <user> -P <password> -H <management-server-ip> power off
```

5. Remove old bootstrap resources if any are left over from a previous deployment attempt:

```
for i in $(sudo virsh list | tail -n +3 | grep bootstrap | awk '{print $2}'); do
do
    sudo virsh destroy $i;
```
sudo virsh undefine $i;
sudo virsh vol-delete $i --pool $i;
sudo virsh vol-delete $i.ign --pool $i;
sudo virsh pool-destroy $i;
sudo virsh pool-undefine $i;
done

16.3.9.2. Additional install-config parameters

See the following tables for the required parameters, the \texttt{hosts} parameter, and the \texttt{bmc} parameter for the \texttt{install-config.yaml} file.

Table 16.5. Required parameters

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>baseDomain</td>
<td></td>
<td>The domain name for the cluster. For example, \texttt{example.com}.</td>
</tr>
<tr>
<td>bootMode</td>
<td>UEFI</td>
<td>The boot mode for a node. Options are \texttt{legacy}, \texttt{UEFI}, and \texttt{UEFISecureBoot}. If \texttt{bootMode} is not set, Ironic sets it while inspecting the node.</td>
</tr>
<tr>
<td>bootstrapExternalStaticDNS</td>
<td></td>
<td>The static network DNS of the bootstrap node. This can be useful in environments without a DHCP server.</td>
</tr>
<tr>
<td>bootstrapExternalStaticIP</td>
<td></td>
<td>The static IP address for the bootstrap VM. You must set this value when deploying a cluster with static IP addresses when there is no DHCP server on the bare-metal network.</td>
</tr>
<tr>
<td>bootstrapExternalStaticGateway</td>
<td></td>
<td>The static IP address of the gateway for the bootstrap VM. You must set this value when deploying a cluster with static IP addresses when there is no DHCP server on the bare-metal network.</td>
</tr>
</tbody>
</table>
| sshKey                   |         | The \texttt{sshKey} configuration setting contains the key in the 
\texttt{~/.ssh/id_rsa.pub} file required to access the control plane nodes and worker nodes. Typically, this key is from the \texttt{provisioner} node. |
<p>| pullSecret               |         | The \texttt{pullSecret} configuration setting contains a copy of the pull secret downloaded from the \texttt{Install OpenShift on Bare Metal} page when preparing the provisioner node. |
| metadata: name:          |         | The name to be given to the OpenShift Container Platform cluster. For example, \texttt{openshift}. |</p>

</tr>
</tbody>
</table>

**NOTE**

Before OpenShift Container Platform 4.12, the cluster installation program only accepted an IPv4 address or an IPv6 address for the `apiVIP` configuration setting. From OpenShift Container Platform 4.12 or later, the `apiVIP` configuration setting is deprecated. Instead, use a list format for the `apiVIPs` configuration setting to specify an IPv4 address, an IPv6 address or both IP address formats.

Before OpenShift Container Platform 4.12, the cluster installation program only accepted an IPv4 address or an IPv6 address for the `ingressVIP` configuration setting. In OpenShift Container Platform 4.12 and later, the `ingressVIP` configuration setting is deprecated. Instead, use a list format for the `ingressVIPs` configuration setting to specify an IPv4 addresses, an IPv6 addresses or both IP address formats.
## Table 16.6. Optional Parameters

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>provisioningDHCPRange</td>
<td>172.22.0.10, 172.22.0.100</td>
<td>Defines the IP range for nodes on the provisioning network.</td>
</tr>
<tr>
<td>provisioningNetworkCIDR</td>
<td>172.22.0.0/24</td>
<td>The CIDR for the network to use for provisioning. This option is required when not using the default address range on the provisioning network.</td>
</tr>
<tr>
<td>clusterProvisioningIP</td>
<td>The third IP address of the provisioningNetworkCIDR.</td>
<td>The IP address within the cluster where the provisioning services run. Defaults to the third IP address of the provisioning subnet. For example, 172.22.0.3.</td>
</tr>
<tr>
<td>bootstrapProvisioningIP</td>
<td>The second IP address of the provisioningNetworkCIDR.</td>
<td>The IP address on the bootstrap VM where the provisioning services run while the installer is deploying the control plane (master) nodes. Defaults to the second IP address of the provisioning subnet. For example, 172.22.0.2 or 2620:52:0:1307::2.</td>
</tr>
<tr>
<td>externalBridge</td>
<td>baremetal</td>
<td>The name of the bare-metal bridge of the hypervisor attached to the bare-metal network.</td>
</tr>
<tr>
<td>provisioningBridge</td>
<td>provisioning</td>
<td>The name of the provisioning bridge on the provisioner host attached to the provisioning network.</td>
</tr>
<tr>
<td>architecture</td>
<td></td>
<td>Defines the host architecture for your cluster. Valid values are amd64 or arm64.</td>
</tr>
<tr>
<td>defaultMachinePlatform</td>
<td></td>
<td>The default configuration used for machine pools without a platform configuration.</td>
</tr>
<tr>
<td>bootstrapOSImage</td>
<td></td>
<td>A URL to override the default operating system image for the bootstrap node. The URL must contain a SHA-256 hash of the image. For example: <a href="https://mirror.openshift.com/rhcos-">https://mirror.openshift.com/rhcos-</a>&lt;version&gt;-qemu.qcow2.gz?sha256=&lt;uncompressed_sha256&gt;.</td>
</tr>
</tbody>
</table>
The `provisioningNetwork` configuration setting determines whether the cluster uses the provisioning network. If it does, the configuration setting also determines if the cluster manages the network.

**Disabled**: Set this parameter to `Disabled` to disable the requirement for a provisioning network. When set to `Disabled`, you must only use virtual media based provisioning, or bring up the cluster using the assisted installer. If `Disabled` and using power management, BMCs must be accessible from the bare-metal network. If `Disabled`, you must provide two IP addresses on the bare-metal network that are used for the provisioning services.

**Managed**: Set this parameter to `Managed`, which is the default, to fully manage the provisioning network, including DHCP, TFTP, and so on.

**Unmanaged**: Set this parameter to `Unmanaged` to enable the provisioning network but take care of manual configuration of DHCP. Virtual media provisioning is recommended but PXE is still available if required.

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>provisioningNetwork</code></td>
<td></td>
<td>The <code>provisioningNetwork</code> configuration setting determines whether the cluster uses the provisioning network. If it does, the configuration setting also determines if the cluster manages the network.</td>
</tr>
<tr>
<td><code>httpProxy</code></td>
<td></td>
<td>Set this parameter to the appropriate HTTP proxy used within your environment.</td>
</tr>
<tr>
<td><code>httpsProxy</code></td>
<td></td>
<td>Set this parameter to the appropriate HTTPS proxy used within your environment.</td>
</tr>
<tr>
<td><code>noProxy</code></td>
<td></td>
<td>Set this parameter to the appropriate list of exclusions for proxy usage within your environment.</td>
</tr>
</tbody>
</table>

**Hosts**
The `hosts` parameter is a list of separate bare metal assets used to build the cluster.

**Table 16.7. Hosts**

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td></td>
<td>The name of the <code>BareMetalHost</code> resource to associate with the details. For example, <code>openshift-master-0</code>.</td>
</tr>
<tr>
<td>role</td>
<td></td>
<td>The role of the bare metal node. Either <code>master</code> or <code>worker</code>.</td>
</tr>
<tr>
<td>bmc</td>
<td></td>
<td>Connection details for the baseboard management controller. See the BMC addressing section for additional details.</td>
</tr>
</tbody>
</table>
The MAC address of the NIC that the host uses for the provisioning network. Ironic retrieves the IP address using the `bootMACAddress` configuration setting. Then, it binds to the host.

**NOTE**
You must provide a valid MAC address from the host if you disabled the provisioning network.

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bootMACAddress</td>
<td></td>
<td>The MAC address of the NIC that the host uses for the provisioning network. Ironic retrieves the IP address using the <code>bootMACAddress</code> configuration setting. Then, it binds to the host.</td>
</tr>
<tr>
<td>networkConfig</td>
<td></td>
<td>Set this optional parameter to configure the network interface of a host. See &quot;(Optional) Configuring host network interfaces&quot; for additional details.</td>
</tr>
</tbody>
</table>

### 16.3.9.3. BMC addressing

Most vendors support Baseboard Management Controller (BMC) addressing with the Intelligent Platform Management Interface (IPMI). IPMI does not encrypt communications. It is suitable for use within a data center over a secured or dedicated management network. Check with your vendor to see if they support Redfish network boot. Redfish delivers simple and secure management for converged, hybrid IT and the Software Defined Data Center (SDDC). Redfish is human readable and machine capable, and leverages common internet and web services standards to expose information directly to the modern tool chain. If your hardware does not support Redfish network boot, use IPMI.

**IPMI**

Hosts using IPMI use the `ipmi://<out-of-band-ip>::<port>` address format, which defaults to port 623 if not specified. The following example demonstrates an IPMI configuration within the `install-config.yaml` file.

```yaml
platform:
  baremetal:
    hosts:
      - name: openshift-master-0
        role: master
        bmc:
          address: ipmi://<out-of-band-ip>
          username: <user>
          password: <password>
```

**IMPORTANT**

The **provisioning** network is required when PXE booting using IPMI for BMC addressing. It is not possible to PXE boot hosts without a **provisioning** network. If you deploy without a **provisioning** network, you must use a virtual media BMC addressing option such as `redfish-virtualmedia` or `idrac-virtualmedia`. See “Redfish virtual media for HPE iLO” in the "BMC addressing for HPE iLO" section or “Redfish virtual media for Dell iDRAC” in the "BMC addressing for Dell iDRAC" section for additional details.
**Redfish network boot**

To enable Redfish, use `redfish://` or `redfish+http://` to disable TLS. The installer requires both the hostname or the IP address and the path to the system ID. The following example demonstrates a Redfish configuration within the `install-config.yaml` file.

```yaml
platform:
baremetal:
hosts:
  - name: openshift-master-0
    role: master
    bmc:
      address: redfish://<out-of-band-ip>/redfish/v1/Systems/1
      username: <user>
      password: <password>
```

While it is recommended to have a certificate of authority for the out-of-band management addresses, you must include `disableCertificateVerification: True` in the `bmc` configuration if using self-signed certificates. The following example demonstrates a Redfish configuration using the `disableCertificateVerification: True` configuration parameter within the `install-config.yaml` file.

```yaml
platform:
baremetal:
hosts:
  - name: openshift-master-0
    role: master
    bmc:
      address: redfish://<out-of-band-ip>/redfish/v1/Systems/1
      username: <user>
      password: <password>
disableCertificateVerification: True
```

**Redfish APIs**

Several redfish API endpoints are called onto your BCM when using the bare-metal installer-provisioned infrastructure.

**IMPORTANT**

You need to ensure that your BMC supports all of the redfish APIs before installation.

**List of redfish APIs**

- Power on
  
  ```bash
  ```

- Power off
  
  ```bash
  ```

- Temporary boot using `pxe`
Set BIOS boot mode using **Legacy** or **UEFI**

```bash
curl -u $USER:$PASS -X PATCH -H "Content-Type: application/json"
https://$Server/redfish/v1/Systems/$SystemID/ -d '{"Boot": {"BootSourceOverrideTarget": "pxe", "BootSourceOverrideEnabled": "Once"}}'
```

List of redfish-virtualmedia APIs

- Set temporary boot device using **cd** or **dvd**

```bash
curl -u $USER:$PASS -X PATCH -H "Content-Type: application/json"
https://$Server/redfish/v1/Systems/$SystemID/ -d '{"Boot": {"BootSourceOverrideTarget": "cd", "BootSourceOverrideEnabled": "Once"}}'
```

- Mount virtual media

```bash
curl -u $USER:$PASS -X PATCH -H "Content-Type: application/json" -H "If-Match: "
https://$Server/redfish/v1/Managers/$ManagerID/VirtualMedia/$VmediaId -d '{"Image": "https://example.com/test.iso", "TransferProtocolType": "HTTPS", "UserName": "", "Password": ""}'}
```

**NOTE**

The **PowerOn** and **PowerOff** commands for redfish APIs are the same for the redfish-virtualmedia APIs.

**IMPORTANT**

HTTPS and HTTP are the only supported parameter types for **TransferProtocolTypes**.

### 16.3.9.4. BMC addressing for Dell iDRAC

The **address** field for each **bmc** entry is a URL for connecting to the OpenShift Container Platform cluster nodes, including the type of controller in the URL scheme and its location on the network.

```yaml
platform:
    baremetal:
        hosts:
            - name: <hostname>
              role: <master | worker>
        bmc:
            address: <address>  
              username: <user>
              password: <password>
```

1. The **address** configuration setting specifies the protocol.
For Dell hardware, Red Hat supports integrated Dell Remote Access Controller (iDRAC) virtual media, Redfish network boot, and IPMI.

### BMC address formats for Dell iDRAC

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Address Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>iDRAC virtual media</td>
<td><code>idrac-virtualmedia://&lt;out-of-band-ip&gt;/redfish/v1/Systems/System.Embedded.1</code></td>
</tr>
<tr>
<td>Redfish network boot</td>
<td><code>redfish://&lt;out-of-band-ip&gt;/redfish/v1/Systems/System.Embedded.1</code></td>
</tr>
<tr>
<td>IPMI</td>
<td><code>ipmi://&lt;out-of-band-ip&gt;</code></td>
</tr>
</tbody>
</table>

**IMPORTANT**

Use `idrac-virtualmedia` as the protocol for Redfish virtual media. `redfish-virtualmedia` will not work on Dell hardware. Dell’s `idrac-virtualmedia` uses the Redfish standard with Dell’s OEM extensions.

See the following sections for additional details.

**Redfish virtual media for Dell iDRAC**

For Redfish virtual media on Dell servers, use `idrac-virtualmedia://` in the `address` setting. Using `redfish-virtualmedia://` will not work.

**NOTE**

Use `idrac-virtualmedia://` as the protocol for Redfish virtual media. Using `redfish-virtualmedia://` will not work on Dell hardware, because the `idrac-virtualmedia://` protocol corresponds to the `idrac` hardware type and the Redfish protocol in Ironic. Dell’s `idrac-virtualmedia://` protocol uses the Redfish standard with Dell’s OEM extensions. Ironic also supports the `idrac` type with the WSMAN protocol. Therefore, you must specify `idrac-virtualmedia://` to avoid unexpected behavior when electing to use Redfish with virtual media on Dell hardware.

The following example demonstrates using iDRAC virtual media within the `install-config.yaml` file.

```yaml
platform:
  baremetal:
    hosts:
      - name: openshift-master-0
        role: master
        bmc:
          address: idrac-virtualmedia://<out-of-band-ip>/redfish/v1/Systems/System.Embedded.1
          username: <user>
          password: <password>
```

While it is recommended to have a certificate of authority for the out-of-band management addresses, you must include `disableCertificateVerification: True` in the `bmc` configuration if using self-signed certificates.
NOTE

Ensure the OpenShift Container Platform cluster nodes have AutoAttach enabled through the iDRAC console. The menu path is: Configuration → Virtual Media → Attach Mode → AutoAttach.

The following example demonstrates a Redfish configuration using the disableCertificateVerification: True configuration parameter within the install-config.yaml file.

```yaml
platform:
  baremetal:
    hosts:
      - name: openshift-master-0
        role: master
        bmc:
          address: idrac-virtualmedia://<out-of-band-ip>/redfish/v1/Systems/System.Embedded.1
          username: <user>
          password: <password>
          disableCertificateVerification: True

Redfish network boot for iDRAC

To enable Redfish, use redfish:// or redfish+http:// to disable transport layer security (TLS). The installer requires both the hostname or the IP address and the path to the system ID. The following example demonstrates a Redfish configuration within the install-config.yaml file.

```yaml
platform:
  baremetal:
    hosts:
      - name: openshift-master-0
        role: master
        bmc:
          address: redfish://<out-of-band-ip>/redfish/v1/Systems/System.Embedded.1
          username: <user>
          password: <password>

While it is recommended to have a certificate of authority for the out-of-band management addresses, you must include disableCertificateVerification: True in the bmc configuration if using self-signed certificates. The following example demonstrates a Redfish configuration using the disableCertificateVerification: True configuration parameter within the install-config.yaml file.

```yaml
platform:
  baremetal:
    hosts:
      - name: openshift-master-0
        role: master
        bmc:
          address: redfish://<out-of-band-ip>/redfish/v1/Systems/System.Embedded.1
          username: <user>
          password: <password>
          disableCertificateVerification: True
```
NOTE

There is a known issue on Dell iDRAC 9 with firmware version 04.40.00.00 and all releases up to including the 5.xx series for installer-provisioned installations on bare metal deployments. The virtual console plugin defaults to eHTML5, an enhanced version of HTML5, which causes problems with the InsertVirtualMedia workflow. Set the plugin to use HTML5 to avoid this issue. The menu path is Configuration → Virtual console → Plug-in Type → HTML5.

Ensure the OpenShift Container Platform cluster nodes have AutoAttach enabled through the iDRAC console. The menu path is: Configuration → Virtual Media → Attach Mode → AutoAttach.

16.3.9.5. BMC addressing for HPE iLO

The address field for each bmc entry is a URL for connecting to the OpenShift Container Platform cluster nodes, including the type of controller in the URL scheme and its location on the network.

Table 16.8. BMC address formats for HPE iLO

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Address Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Redfish virtual media</td>
<td>redfish-virtualmedia://&lt;out-of-band-ip&gt;/redfish/v1/Systems/1</td>
</tr>
<tr>
<td>Redfish network boot</td>
<td>redfish://&lt;out-of-band-ip&gt;/redfish/v1/Systems/1</td>
</tr>
<tr>
<td>IPMI</td>
<td>ipmi://&lt;out-of-band-ip&gt;</td>
</tr>
</tbody>
</table>

See the following sections for additional details.

Redfish virtual media for HPE iLO

To enable Redfish virtual media for HPE servers, use redfish-virtualmedia:// in the address setting. The following example demonstrates using Redfish virtual media within the install-config.yaml file.
While it is recommended to have a certificate of authority for the out-of-band management addresses, you must include `disableCertificateVerification: True` in the `bmc` configuration if using self-signed certificates. The following example demonstrates a Redfish configuration using the `disableCertificateVerification: True` configuration parameter within the `install-config.yaml` file.

```
platform:
baremetal:
hosts:
  - name: openshift-master-0
    role: master
    bmc:
      address: redfish-virtualmedia://<out-of-band-ip>/redfish/v1/Systems/1
      username: <user>
      password: <password>

NOTE
Redfish virtual media is not supported on 9th generation systems running iLO4, because Ironic does not support iLO4 with virtual media.

Redfish network boot for HPE iLO
To enable Redfish, use `redfish://` or `redfish+http://` to disable TLS. The installer requires both the hostname or the IP address and the path to the system ID. The following example demonstrates a Redfish configuration within the `install-config.yaml` file.

```
platform:
baremetal:
hosts:
  - name: openshift-master-0
    role: master
    bmc:
      address: redfish://<out-of-band-ip>/redfish/v1/Systems/1
      username: <user>
      password: <password>
```
16.3.9.6. BMC addressing for Fujitsu iRMC

The `address` field for each `bmc` entry is a URL for connecting to the OpenShift Container Platform cluster nodes, including the type of controller in the URL scheme and its location on the network.

For Fujitsu hardware, Red Hat supports integrated Remote Management Controller (iRMC) and IPMI.

### Table 16.9. BMC address formats for Fujitsu iRMC

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Address Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>iRMC</td>
<td><code>irmc://&lt;out-of-band-ip&gt;</code></td>
</tr>
<tr>
<td>IPMI</td>
<td><code>ipmi://&lt;out-of-band-ip&gt;</code></td>
</tr>
</tbody>
</table>

**iRMC**

Fujitsu nodes can use `irmc://<out-of-band-ip>` and defaults to port 443. The following example demonstrates an iRMC configuration within the `install-config.yaml` file.

```yaml
platform:
  baremetal:
    hosts:
      - name: <hostname>
        role: <master | worker>
        bmc:
          address: <address>
          username: <user>
          password: <password>
```

**NOTE**

Currently Fujitsu supports iRMC S5 firmware version 3.05P and above for installer-provisioned installation on bare metal.
16.3.9.7. Root device hints

The `rootDeviceHints` parameter enables the installer to provision the Red Hat Enterprise Linux CoreOS (RHCOS) image to a particular device. The installer examines the devices in the order it discovers them, and compares the discovered values with the hint values. The installer uses the first discovered device that matches the hint value. The configuration can combine multiple hints, but a device must match all hints for the installer to select it.

Table 16.10. Subfields

<table>
<thead>
<tr>
<th>Subfield</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>deviceName</code></td>
<td>A string containing a Linux device name such as <code>/dev/vda</code> or <code>/dev/disk/by-path/</code>. It is recommended to use the <code>/dev/disk/by-path/&lt;device_path&gt;</code> link to the storage location. The hint must match the actual value exactly.</td>
</tr>
<tr>
<td><code>hctl</code></td>
<td>A string containing a SCSI bus address like <code>0:0:0:0</code>. The hint must match the actual value exactly.</td>
</tr>
<tr>
<td><code>model</code></td>
<td>A string containing a vendor-specific device identifier. The hint can be a substring of the actual value.</td>
</tr>
<tr>
<td><code>vendor</code></td>
<td>A string containing the name of the vendor or manufacturer of the device. The hint can be a substring of the actual value.</td>
</tr>
<tr>
<td><code>serialNumber</code></td>
<td>A string containing the device serial number. The hint must match the actual value exactly.</td>
</tr>
<tr>
<td><code>minSizeGigabytes</code></td>
<td>An integer representing the minimum size of the device in gigabytes.</td>
</tr>
<tr>
<td><code>wwn</code></td>
<td>A string containing the unique storage identifier. The hint must match the actual value exactly.</td>
</tr>
<tr>
<td><code>wwnWithExtension</code></td>
<td>A string containing the unique storage identifier with the vendor extension appended. The hint must match the actual value exactly.</td>
</tr>
<tr>
<td><code>wwnVendorExtension</code></td>
<td>A string containing the unique vendor storage identifier. The hint must match the actual value exactly.</td>
</tr>
<tr>
<td><code>rotational</code></td>
<td>A boolean indicating whether the device should be a rotating disk (true) or not (false).</td>
</tr>
</tbody>
</table>

Example usage
16.3.9.8. Optional: Setting proxy settings

To deploy an OpenShift Container Platform cluster using a proxy, make the following changes to the `install-config.yaml` file.

```yaml
- name: master-0
  role: master
  bmc:
    address: ipmi://10.10.0.3:6203
    username: admin
    password: redhat
    bootMACAddress: de:ad:be:ef:00:40
  rootDeviceHints:
    deviceName: "/dev/sda"
```

The following is an example of `noProxy` with values.

```yaml
noProxy: .example.com,172.22.0.0/24,10.10.0.0/24
```

With a proxy enabled, set the appropriate values of the proxy in the corresponding key/value pair.

Key considerations:

- If the proxy does not have an HTTPS proxy, change the value of `httpsProxy` from `https://` to `http://`.
- If using a provisioning network, include it in the `noProxy` setting, otherwise the installer will fail.
- Set all of the proxy settings as environment variables within the provisioner node. For example, `HTTP_PROXY`, `HTTPS_PROXY`, and `NO_PROXY`.

**NOTE**

When provisioning with IPv6, you cannot define a CIDR address block in the `noProxy` settings. You must define each address separately.

16.3.9.9. Optional: Deploying with no provisioning network

To deploy an OpenShift Container Platform cluster without a provisioning network, make the following changes to the `install-config.yaml` file.

```yaml
platform:
  baremetal:
    apiVIPs:
      - <api_VIP>
```
Add the `provisioningNetwork` configuration setting, if needed, and set it to `Disabled`.

**IMPORTANT**

The `provisioning` network is required for PXE booting. If you deploy without a `provisioning` network, you must use a virtual media BMC addressing option such as `redfish-virtualmedia` or `idrac-virtualmedia`. See "Redfish virtual media for HPE iLO" in the "BMC addressing for HPE iLO" section or "Redfish virtual media for Dell iDRAC" in the "BMC addressing for Dell iDRAC" section for additional details.

### 16.3.9.10. Optional: Deploying with dual-stack networking

For dual-stack networking in OpenShift Container Platform clusters, you can configure IPv4 and IPv6 address endpoints for cluster nodes. To configure IPv4 and IPv6 address endpoints for cluster nodes, edit the `machineNetwork`, `clusterNetwork`, and `serviceNetwork` configuration settings in the `install-config.yaml` file. Each setting must have two CIDR entries each. For a cluster with the IPv4 family as the primary address family, specify the IPv4 setting first. For a cluster with the IPv6 family as the primary address family, specify the IPv6 setting first.

```yaml
machineNetwork:
  - cidr: {{ extcidrnet }}
  - cidr: {{ extcidrnet6 }}
clusterNetwork:
  - cidr: 10.128.0.0/14
    hostPrefix: 23
  - cidr: fd02::/48
    hostPrefix: 64
serviceNetwork:
  - 172.30.0.0/16
  - fd03::/112
```

To provide an interface to the cluster for applications that use IPv4 and IPv6 addresses, configure IPv4 and IPv6 virtual IP (VIP) address endpoints for the Ingress VIP and API VIP services. To configure IPv4 and IPv6 address endpoints, edit the `apiVIPs` and `ingressVIPs` configuration settings in the `install-config.yaml` file. The `apiVIPs` and `ingressVIPs` configuration settings use a list format. The order of the list indicates the primary and secondary VIP address for each service.

```yaml
platform:
  baremetal:
    apiVIPs:
      - <api_ipv4>
      - <api_ipv6>
    ingressVIPs:
      - <wildcard_ipv4>
      - <wildcard_ipv6>
```
NOTE

For a cluster with dual-stack networking configuration, you must assign both IPv4 and IPv6 addresses to the same interface.

16.3.9.11. Optional: Configuring host network interfaces

Before installation, you can set the `networkConfig` configuration setting in the `install-config.yaml` file to configure host network interfaces using NMState.

The most common use case for this functionality is to specify a static IP address on the bare-metal network, but you can also configure other networks such as a storage network. This functionality supports other NMState features such as VLAN, VXLAN, bridges, bonds, routes, MTU, and DNS resolver settings.

Prerequisites

- Configure a PTR DNS record with a valid hostname for each node with a static IP address.
- Install the NMState CLI (`nmstate`).

Procedure

1. Optional: Consider testing the NMState syntax with `nmstatectl gc` before including it in the `install-config.yaml` file, because the installer will not check the NMState YAML syntax.

    NOTE

    Errors in the YAML syntax might result in a failure to apply the network configuration. Additionally, maintaining the validated YAML syntax is useful when applying changes using Kubernetes NMState after deployment or when expanding the cluster.

    a. Create an NMState YAML file:

    ```yaml
    interfaces:
    - name: <nic1_name>  
      type: ethernet  
      state: up  
      ipv4:
        address:
          - ip: <ip_address>  
            prefix-length: 24  
            enabled: true  
      dns-resolver:
        config:
          server:
            - <dns_ip_address>  
      routes:
        config:
          - destination: 0.0.0.0/0
            next-hop-address: <next_hop_ip_address>  
            next-hop-interface: <next_hop_nic1_name>
    ```
Replace `<nic1_name>`, `<ip_address>`, `<dns_ip_address>`, `<next_hop_ip_address>` and `<next_hop_nic1_name>` with appropriate values.

b. Test the configuration file by running the following command:

```
$ nmstatectl gc <nmstate_yaml_file>
```

Replace `<nmstate_yaml_file>` with the configuration file name.

2. Use the `networkConfig` configuration setting by adding the NMState configuration to hosts within the `install-config.yaml` file:

```yaml
hosts:
  - name: openshift-master-0
    role: master
    bmc:
      address: redfish+http://<out_of_band_ip>/redfish/v1/Systems/
      username: <user>
      password: <password>
      disableCertificateVerification: null
    bootMACAddress: <NIC1_mac_address>
    bootMode: UEFI
    rootDeviceHints:
      deviceName: "/dev/sda"
    networkConfig:
      interfaces:
        - name: <nic1_name>
          type: ethernet
          state: up
          ipv4:
            address:
              - ip: `<ip_address>`
                prefix-length: 24
            enabled: true
          dns-resolver:
            config:
              server:
                - `<dns_ip_address>`
          routes:
            config:
              - destination: 0.0.0.0/0
                next-hop-address: `<next_hop_ip_address>`
                next-hop-interface: `<next_hop_nic1_name>`
```

1. Add the NMState YAML syntax to configure the host interfaces.

2. Replace `<nic1_name>`, `<ip_address>`, `<dns_ip_address>`, `<next_hop_ip_address>` and `<next_hop_nic1_name>` with appropriate values.
After deploying the cluster, you cannot modify the `networkConfig` configuration setting of `install-config.yaml` file to make changes to the host network interface. Use the Kubernetes NMState Operator to make changes to the host network interface after deployment.

### 16.3.9.12. Configuring host network interfaces for subnets

For edge computing scenarios, it can be beneficial to locate worker nodes closer to the edge. To locate remote worker nodes in subnets, you might use different network segments or subnets for the remote worker nodes than you used for the control plane subnet and local worker nodes. You can reduce latency for the edge and allow for enhanced scalability by setting up subnets for edge computing scenarios.

If you have established different network segments or subnets for remote worker nodes as described in the section on “Establishing communication between subnets”, you must specify the subnets in the `machineNetwork` configuration setting if the workers are using static IP addresses, bonds or other advanced networking. When setting the node IP address in the `networkConfig` parameter for each remote worker node, you must also specify the gateway and the DNS server for the subnet containing the control plane nodes when using static IP addresses. This ensures the remote worker nodes can reach the subnet containing the control plane nodes and that they can receive network traffic from the control plane.

**IMPORTANT**

All control plane nodes must run in the same subnet. When using more than one subnet, you can also configure the Ingress VIP to run on the control plane nodes by using a manifest. See “Configuring network components to run on the control plane” for details.

Deploying a cluster with multiple subnets requires using virtual media, such as `redfish-virtualmedia` and `idrac-virtualmedia`.

**Procedure**

1. Add the subnets to the `machineNetwork` in the `install-config.yaml` file when using static IP addresses:

   ```yaml
   networking:
     machineNetwork:
     - cidr: 10.0.0.0/24
     - cidr: 192.168.0.0/24
     networkType: OVNKubernetes
   
   2. Add the gateway and DNS configuration to the `networkConfig` parameter of each edge worker node using NMState syntax when using a static IP address or advanced networking such as bonds:

   ```yaml
   networkConfig:
     nmstate:
       interfaces:
       - name: <interface_name>  # 1
         type: ethernet
         state: up
         ipv4:
           enabled: true
   ```
16.3.9.13. Optional: Configuring address generation modes for SLAAC in dual-stack networks

For dual-stack clusters that use Stateless Address AutoConfiguration (SLAAC), you must specify a global value for the `ipv6.addr-gen-mode` network setting. You can set this value using NMState to configure the ramdisk and the cluster configuration files. If you don’t configure a consistent `ipv6.addr-gen-mode` in these locations, IPv6 address mismatches can occur between CSR resources and BareMetalHost resources in the cluster.

Prerequisites

- Install the NMState CLI (`nmstate`).

Procedure

1. Optional: Consider testing the NMState YAML syntax with the `nmstatectl gc` command before including it in the `install-config.yaml` file because the installation program will not check the NMState YAML syntax.
   a. Create an NMState YAML file:

   ```yaml
   interfaces:
   - name: eth0
     ipv6:
       addr-gen-mode: <address_mode>  
   ```

   Replace `<address_mode>` with the type of address generation mode required for IPv6 addresses in the cluster. Valid values are `eui64`, `stable-privacy`, or `random`.

   b. Test the configuration file by running the following command:

   ```bash
   $ nmstatectl gc <nmstate_yaml_file>  
   ```

   Replace `<nmstate_yaml_file>` with the name of the test configuration file.
2. Add the NMState configuration to the `hosts.networkConfig` section within the `install-config.yaml` file:

```yaml
hosts:
  - name: openshift-master-0
    role: master
    bmc:
      address: redfish+http://<out_of_band_ip>/redfish/v1/Systems/
      username: <user>
      password: <password>
      disableCertificateVerification: null
    bootMACAddress: <NIC1_mac_address>
    bootMode: UEFI
    rootDeviceHints:
      deviceName: "/dev/sda"
    networkConfig:
      interfaces:
        - name: eth0
          ipv6:
            addr-gen-mode: <address_mode> ①
```

Replace `<address_mode>` with the type of address generation mode required for IPv6 addresses in the cluster. Valid values are `eui64`, `stable-privacy`, or `random`.

### 16.3.9.14. Optional: Configuring host network interfaces for dual port NIC

**IMPORTANT**

Support for Day 1 operations associated with enabling NIC partitioning for SR-IOV devices is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see [Technology Preview Features Support Scope](#).

Before installation, you can set the `networkConfig` configuration setting in the `install-config.yaml` file to configure host network interfaces using NMState to support dual port NIC.

**Prequisites**

- Configure a PTR DNS record with a valid hostname for each node with a static IP address.
- Install the NMState CLI (`nmstate`).

**NOTE**

Errors in the YAML syntax might result in a failure to apply the network configuration. Additionally, maintaining the validated YAML syntax is useful when applying changes using Kubernetes NMState after deployment or when expanding the cluster.
Procedure

1. Add the NMState configuration to the `networkConfig` field to hosts within the `install-config.yaml` file:

```yaml
hosts:
  - hostname: worker-1
    interfaces:
      - name: eno1
        macAddress: 0c:42:a1:55:f3:06
      - name: eno2
        macAddress: 0c:42:a1:55:f3:07

networkConfig:
  interfaces:
    - name: eno1
      type: ethernet
      state: up
      mac-address: 0c:42:a1:55:f3:06
      ipv4:
        enabled: true
dhcp: false
      ethernet:
        sr-iov:
          total-vfs: 2
      ipv6:
        enabled: false
dhcp: false
    - name: sriov:eno1:0
      type: ethernet
      state: up
      ipv4:
        enabled: false
      ipv6:
        enabled: false
    - name: sriov:eno1:1
      type: ethernet
      state: down
    - name: eno2
      type: ethernet
      state: up
      mac-address: 0c:42:a1:55:f3:07
      ipv4:
        enabled: true
ethernet:
        sr-iov:
          total-vfs: 2
      ipv6:
        enabled: false
    - name: sriov:eno2:0
      type: ethernet
      state: up
      ipv4:
        enabled: false
      ipv6:
        enabled: false
```
The `networkConfig` field contains information about the network configuration of the host, with subfields including `interfaces`, `dns-resolver`, and `routes`.

The `interfaces` field is an array of network interfaces defined for the host.

The name of the interface.

The type of interface. This example creates a ethernet interface.

Set this to `false` to disable DHCP for the physical function (PF) if it is not strictly required.

Set to the number of SR-IOV virtual functions (VFs) to instantiate.

Set this to `up`.

Set this to `false` to disable IPv4 addressing for the VF attached to the bond.

Sets a minimum transmission rate, in Mbps, for the VF. This sample value sets a rate of 100 Mbps.

- This value must be less than or equal to the maximum transmission rate.
Intel NICs do not support the `min-tx-rate` parameter. For more information, see BZ#1772847.

10 Sets a maximum transmission rate, in Mbps, for the VF. This sample value sets a rate of 200 Mbps.

11 Sets the desired bond mode.

12 Sets the preferred port of the bonding interface. The primary device is the first of the bonding interfaces to be used and is not abandoned unless it fails. This setting is particularly useful when one NIC in the bonding interface is faster and, therefore, able to handle a bigger load. This setting is only valid when the bonding interface is in active-backup mode (mode 1) and balance-tlb (mode 5).

13 Sets a static IP address for the bond interface. This is the node IP address.

14 Sets `bond0` as the gateway for the default route.

**IMPORTANT**

After deploying the cluster, you cannot modify the `networkConfig` configuration setting of `install-config.yaml` file to make changes to the host network interface. Use the Kubernetes NMState Operator to make changes to the host network interface after deployment.

Additional resources

- Configuring network bonding

### 16.3.9.15. Configuring multiple cluster nodes

You can simultaneously configure OpenShift Container Platform cluster nodes with identical settings. Configuring multiple cluster nodes avoids adding redundant information for each node to the `install-config.yaml` file. This file contains specific parameters to apply an identical configuration to multiple nodes in the cluster.

Compute nodes are configured separately from the controller node. However, configurations for both node types use the highlighted parameters in the `install-config.yaml` file to enable multi-node configuration. Set the `networkConfig` parameters to `BOND`, as shown in the following example:

```yaml
hosts:
- name: otest-master-0
  [...]
  networkConfig: &BOND
  interfaces:
  - name: bond0
    type: bond
    state: up
    ipv4:
      dhcp: true
      enabled: true
    link-aggregation:
      mode: active-backup
      port:
```

2360
16.3.9.16. Optional: Configuring managed Secure Boot

You can enable managed Secure Boot when deploying an installer-provisioned cluster using Redfish BMC addressing, such as `redfish`, `redfish-virtualmedia`, or `idrac-virtualmedia`. To enable managed Secure Boot, add the `bootMode` configuration setting to each node:

**Example**

```yaml
hosts:
  - name: openshift-master-0
    role: master
    bmc:
      address: redfish://<out_of_band_ip> ①
      username: <username>
      password: <password>
      bootMACAddress: <NIC1_mac_address>
      rootDeviceHints:
        deviceName: "/dev/sda"
    bootMode: UEFISecureBoot ②
```

① Ensure the `bmc.address` setting uses `redfish`, `redfish-virtualmedia`, or `idrac-virtualmedia` as the protocol. See "BMC addressing for HPE iLO" or "BMC addressing for Dell iDRAC" for additional details.

② The `bootMode` setting is UEFI by default. Change it to `UEFISecureBoot` to enable managed Secure Boot.

**NOTE**

See "Configuring nodes" in the "Prerequisites" to ensure the nodes can support managed Secure Boot. If the nodes do not support managed Secure Boot, see "Configuring nodes for Secure Boot manually" in the "Configuring nodes" section. Configuring Secure Boot manually requires Redfish virtual media.

**NOTE**

Red Hat does not support Secure Boot with IPMI, because IPMI does not provide Secure Boot management facilities.
16.3.10. Manifest configuration files

16.3.10.1. Creating the OpenShift Container Platform manifests

1. Create the OpenShift Container Platform manifests.

   $ ./openshift-baremetal-install --dir ~/clusterconfigs create manifests

   INFO Consuming Install Config from target directory
   WARNING Making control-plane schedulable by setting MastersSchedulable to true for
   Scheduler cluster settings
   WARNING Discarding the OpenShift Manifest that was provided in the target directory
   because its dependencies are dirty and it needs to be regenerated

16.3.10.2. Optional: Configuring NTP for disconnected clusters

OpenShift Container Platform installs the **chrony** Network Time Protocol (NTP) service on the cluster nodes.

OpenShift Container Platform nodes must agree on a date and time to run properly. When worker nodes retrieve the date and time from the NTP servers on the control plane nodes, it enables the installation and operation of clusters that are not connected to a routable network and thereby do not have access to a higher stratum NTP server.

**Procedure**

   **NOTE**
   See “Creating machine configs with Butane” for information about Butane.

   **Butane config example**

   ```
   variant: openshift
   version: 4.14.0
   ```
You must replace `<cluster-name>` with the name of the cluster and replace `<domain>` with the fully qualified domain name.

2. Use Butane to generate a MachineConfig object file, `99-master-chrony-conf-override.yaml`, containing the configuration to be delivered to the control plane nodes:

```
$ butane 99-master-chrony-conf-override.bu -o 99-master-chrony-conf-override.yaml
```

3. Create a Butane config, `99-worker-chrony-conf-override.bu`, including the contents of the `chrony.conf` file for the worker nodes that references the NTP servers on the control plane nodes.

Butane config example

```
stratumweight 0
driftfile /var/lib/chrony/drift
rtcsync
makestep 10 3
bindommaddress 127.0.0.1
bindommaddress ::1
keyfile /etc/chrony.keys
commandkey 1
generatecommandkey
noclientlog
logchange 0.5
logdir /var/log/chrony

# Configure the control plane nodes to serve as local NTP servers
# for all worker nodes, even if they are not in sync with an
# upstream NTP server.

# Allow NTP client access from the local network.
allow all
# Serve time even if not synchronized to a time source.
local stratum 3 orphan
```

1 You must replace `<cluster-name>` with the name of the cluster and replace `<domain>` with the fully qualified domain name.
1. You must replace `<cluster-name>` with the name of the cluster and replace `<domain>` with the fully qualified domain name.

4. Use Butane to generate a `MachineConfig` object file, `99-worker-chrony-conf-override.yaml`, containing the configuration to be delivered to the worker nodes:

   ```shell
   ```

16.3.10.3. Configuring network components to run on the control plane

You can configure networking components to run exclusively on the control plane nodes. By default, OpenShift Container Platform allows any node in the machine config pool to host the `ingressVIP` virtual IP address. However, some environments deploy worker nodes in separate subnets from the control plane nodes, which requires configuring the `ingressVIP` virtual IP address to run on the control plane nodes.

**IMPORTANT**

When deploying remote workers in separate subnets, you must place the `ingressVIP` virtual IP address exclusively with the control plane nodes.
Procedure

1. Change to the directory storing the `install-config.yaml` file:
   
   ```
   $ cd ~/clusterconfigs
   ```

2. Switch to the `manifests` subdirectory:
   
   ```
   $ cd manifests
   ```

3. Create a file named `cluster-network-avoid-workers-99-config.yaml`:
   
   ```
   $ touch cluster-network-avoid-workers-99-config.yaml
   ```

4. Open the `cluster-network-avoid-workers-99-config.yaml` file in an editor and enter a custom resource (CR) that describes the Operator configuration:

   ```yaml
   apiVersion: machineconfiguration.openshift.io/v1
   kind: MachineConfig
   metadata:
     name: 50-worker-fix-ipi-rwn
     labels:
       machineconfiguration.openshift.io/role: worker
   spec:
     config:
       ignition:
         version: 3.2.0
       storage:
       files:
         - path: /etc/kubernetes/manifests/keepalived.yaml
   ```
This manifest places the ingressVIP virtual IP address on the control plane nodes. Additionally, this manifest deploys the following processes on the control plane nodes only:

- openshift-ingress-operator
- keepalived

6. Create a manifests/cluster-ingress-default-ingresscontroller.yaml file:

   ```yaml
   apiVersion: operator.openshift.io/v1
   kind: IngressController
   metadata:
     name: default
     namespace: openshift-ingress-operator
   spec:
     nodePlacement:
       nodeSelector:
         matchLabels:
           node-role.kubernetes.io/master: ""
   
   $ sed -i "s;mastersSchedulable: false;mastersSchedulable: true;g"
   manifests/cluster-ingress-default-ingresscontroller.yaml
   
   NOTE
   If control plane nodes are not schedulable after completing this procedure, deploying the cluster will fail.

16.3.10.4. Optional: Deploying routers on worker nodes

During installation, the installer deploys router pods on worker nodes. By default, the installer installs two router pods. If a deployed cluster requires additional routers to handle external traffic loads destined for services within the OpenShift Container Platform cluster, you can create a yaml file to set an appropriate number of router replicas.

IMPORTANT
Deploying a cluster with only one worker node is not supported. While modifying the router replicas will address issues with the degraded state when deploying with one worker, the cluster loses high availability for the ingress API, which is not suitable for production environments.
NOTE
By default, the installer deploys two routers. If the cluster has no worker nodes, the installer deploys the two routers on the control plane nodes by default.

Procedure
1. Create a `router-replicas.yaml` file:

   ```yaml
   apiVersion: operator.openshift.io/v1
   kind: IngressController
   metadata:
     name: default
     namespace: openshift-ingress-operator
   spec:
     replicas: <num-of-router-pods>
     endpointPublishingStrategy:
       type: HostNetwork
     nodePlacement:
       nodeSelector:
         matchLabels:
           node-role.kubernetes.io/worker: ""
   
   NOTE
   Replace `<num-of-router-pods>` with an appropriate value. If working with just one worker node, set `replicas:` to 1. If working with more than 3 worker nodes, you can increase `replicas:` from the default value 2 as appropriate.

2. Save and copy the `router-replicas.yaml` file to the `clusterconfigs/openshift` directory:

   ```bash
   $ cp ~/router-replicas.yaml clusterconfigs/openshift/99_router-replicas.yaml
   
   $ cp ~/router-replicas.yaml clusterconfigs/openshift/99_openshift-cluster-api_hosts-*.yaml
   
   $ vim clusterconfigs/openshift/99_openshift-cluster-api_hosts-*.yaml
   
   spec:
     firmware:
       simultaneousMultithreadingEnabled: true
       sriovEnabled: true
       virtualizationEnabled: true
   
   16.3.10.5. Optional: Configuring the BIOS
The following procedure configures the BIOS during the installation process.

Procedure
1. Create the manifests.

2. Modify the `BareMetalHost` resource file corresponding to the node:

   ```bash
   $ vim clusterconfigs/openshift/99_openshift-cluster-api_hosts-*.yaml
   
   spec:
     firmware:
       simultaneousMultithreadingEnabled: true
       sriovEnabled: true
       virtualizationEnabled: true
   ```
Red Hat supports three BIOS configurations. Only servers with BMC type `irmc` are supported. Other types of servers are currently not supported.

4. Create the cluster.

Additional resources

- Bare metal configuration

16.3.10.6. Optional: Configuring the RAID

The following procedure configures a redundant array of independent disks (RAID) during the installation process.

NOTE

1. OpenShift Container Platform supports hardware RAID for baseboard management controllers (BMCs) using the iRMC protocol only. OpenShift Container Platform 4.14 does not support software RAID.

2. If you want to configure a hardware RAID for the node, verify that the node has a RAID controller.

Procedure

1. Create the manifests.

2. Modify the `BareMetalHost` resource corresponding to the node:

   ```bash
   $ vim clusterconfigs/openshift/99_openshift-cluster-api_hosts-*.yaml
   ```

   **NOTE**

   The following example uses a hardware RAID configuration because OpenShift Container Platform 4.14 does not support software RAID.

   a. If you added a specific RAID configuration to the `spec` section, this causes the node to delete the original RAID configuration in the `preparing` phase and perform a specified configuration on the RAID. For example:

   ```yaml
   spec:
     raid:
       hardwareRAIDVolumes:
         - level: "0"  # required
           name: "sda"
           numberOfPhysicalDisks: 1
           rotational: true
           sizeGibibytes: 0
   ```

   **level** is a required field, and the others are optional fields.
b. If you added an empty RAID configuration to the `spec` section, the empty configuration causes the node to delete the original RAID configuration during the `preparing` phase, but does not perform a new configuration. For example:

```yaml
spec:
  raid:
    hardwareRAIDVolumes: []
```

c. If you do not add a `raid` field in the `spec` section, the original RAID configuration is not deleted, and no new configuration will be performed.

3. Create the cluster.

16.3.10.7. Optional: Configuring storage on nodes

You can make changes to operating systems on OpenShift Container Platform nodes by creating `MachineConfig` objects that are managed by the Machine Config Operator (MCO).

The `MachineConfig` specification includes an ignition config for configuring the machines at first boot. This config object can be used to modify files, systemd services, and other operating system features running on OpenShift Container Platform machines.

Procedure

Use the ignition config to configure storage on nodes. The following `MachineSet` manifest example demonstrates how to add a partition to a device on a primary node. In this example, apply the manifest before installation to have a partition named `recovery` with a size of 16 GiB on the primary node.

1. Create a `custom-partitions.yaml` file and include a `MachineConfig` object that contains your partition layout:

```yaml
apiVersion: machineconfiguration.openshift.io/v1
kind: MachineConfig
metadata:
  labels:
    machineconfiguration.openshift.io/role: primary
  name: 10_primary_storage_config
spec:
  config:
    ignition:
      version: 3.2.0
    storage:
      disks:
        - device: /dev/xxyN
          partitions:
            - label: recovery
              startMiB: 32768
              sizeMiB: 16384
          filesystems:
            - device: /dev/disk/by-partlabel/recovery
              label: recovery
              format: xfs
```

2. Save and copy the `custom-partitions.yaml` file to the `clusterconfigs/openshift` directory:
16.3.11. Creating a disconnected registry

In some cases, you might want to install an OpenShift Container Platform cluster using a local copy of the installation registry. This could be for enhancing network efficiency because the cluster nodes are on a network that does not have access to the internet.

A local, or mirrored, copy of the registry requires the following:

- A certificate for the registry node. This can be a self-signed certificate.
- A web server that a container on a system will serve.
- An updated pull secret that contains the certificate and local repository information.

NOTE

Creating a disconnected registry on a registry node is optional. If you need to create a disconnected registry on a registry node, you must complete all of the following subsections.

Prerequisites

- If you have already prepared a mirror registry for Mirroring images for a disconnected installation, you can skip directly to Modify the install-config.yaml file to use the disconnected registry.

16.3.11.1. Preparing the registry node to host the mirrored registry

The following steps must be completed prior to hosting a mirrored registry on bare metal.

Procedure

1. Open the firewall port on the registry node:

   ```
   $ sudo firewall-cmd --add-port=5000/tcp --zone=libvirt --permanent
   $ sudo firewall-cmd --add-port=5000/tcp --zone=public --permanent
   $ sudo firewall-cmd --reload
   ```

2. Install the required packages for the registry node:

   ```
   $ sudo yum -y install python3 podman httpd httpd-tools jq
   ```

Additional resources

- Bare metal configuration
- Partition naming scheme
3. Create the directory structure where the repository information will be held:

```bash
$ sudo mkdir -p /opt/registry/[auth, certs, data]
```

16.3.11.2. Mirroring the OpenShift Container Platform image repository for a disconnected registry

Complete the following steps to mirror the OpenShift Container Platform image repository for a disconnected registry.

**Prerequisites**

- Your mirror host has access to the internet.
- You configured a mirror registry to use in your restricted network and can access the certificate and credentials that you configured.
- You downloaded the pull secret from the Red Hat OpenShift Cluster Manager and modified it to include authentication to your mirror repository.

**Procedure**

1. Review the OpenShift Container Platform downloads page to determine the version of OpenShift Container Platform that you want to install and determine the corresponding tag on the Repository Tags page.

2. Set the required environment variables:

   a. Export the release version:

   ```bash
   $ OCP_RELEASE=<release_version>
   ```

   For `<release_version>`, specify the tag that corresponds to the version of OpenShift Container Platform to install, such as 4.5.4.

   b. Export the local registry name and host port:

   ```bash
   $ LOCAL_REGISTRY=<local_registry_host_name>:<local_registry_host_port>
   ```

   For `<local_registry_host_name>`, specify the registry domain name for your mirror repository, and for `<local_registry_host_port>`, specify the port that it serves content on.

   c. Export the local repository name:

   ```bash
   $ LOCAL_REPOSITORY='<local_repository_name>'
   ```

   For `<local_repository_name>`, specify the name of the repository to create in your registry, such as `ocp4/openshift4`.

   d. Export the name of the repository to mirror:

   ```bash
   $ PRODUCT_REPO='openshift-release-dev'
   ```

   For a production release, you must specify `openshift-release-dev`.
e. Export the path to your registry pull secret:

```bash
$ LOCAL_SECRET_JSON='<path_to_pull_secret>'
```

For `<path_to_pull_secret>`, specify the absolute path to and file name of the pull secret for your mirror registry that you created.

f. Export the release mirror:

```bash
$ RELEASE_NAME="ocp-release"
```

For a production release, you must specify `ocp-release`.

g. Export the type of architecture for your cluster:

```bash
$ ARCHITECTURE=<cluster_architecture>
```

1 Specify the architecture of the cluster, such as `x86_64`, `aarch64`, `s390x`, or `ppc64le`.

h. Export the path to the directory to host the mirrored images:

```bash
$ REMOVABLE_MEDIA_PATH=<path>
```

1 Specify the full path, including the initial forward slash (`/`) character.

3. Mirror the version images to the mirror registry:

- If your mirror host does not have internet access, take the following actions:

  i. Connect the removable media to a system that is connected to the internet.

  ii. Review the images and configuration manifests to mirror:

  ```bash
  $ oc adm release mirror -a ${LOCAL_SECRET_JSON} \
      --from=quay.io/${PRODUCT_REPO}/${RELEASE_NAME}:${OCP_RELEASE}-${ARCHITECTURE} \
      --to=${LOCAL_REGISTRY}/${LOCAL_REPOSITORY} \
      --to-release-image=${LOCAL_REGISTRY}/${LOCAL_REPOSITORY}:${OCP_RELEASE}-${ARCHITECTURE} --dry-run
  ```

  iii. Record the entire `imageContentSources` section from the output of the previous command. The information about your mirrors is unique to your mirrored repository, and you must add the `imageContentSources` section to the `install-config.yaml` file during installation.

  iv. Mirror the images to a directory on the removable media:

  ```bash
  $ oc adm release mirror -a ${LOCAL_SECRET_JSON} --to-dir=${REMOVABLE_MEDIA_PATH}/mirror \
      quay.io/${PRODUCT_REPO}/${RELEASE_NAME}:${OCP_RELEASE}-${ARCHITECTURE} \
      --to-release-image=${LOCAL_REGISTRY}/${LOCAL_REPOSITORY}:${OCP_RELEASE}-${ARCHITECTURE} --dry-run
  ```
v. Take the media to the restricted network environment and upload the images to the local container registry.

\[
$ oc image mirror -a ${LOCAL_SECRET_JSON} --from-dir=${REMOVABLE_MEDIA_PATH}/mirror "file://openshift/release:${OCP_RELEASE}" ${LOCAL_REGISTRY}/${LOCAL_REPOSITORY}
\]

For **REMOVABLE_MEDIA_PATH**, you must use the same path that you specified when you mirrored the images.

- If the local container registry is connected to the mirror host, take the following actions:
  
  i. Directly push the release images to the local registry by using following command:

\[
$ oc adm release mirror -a ${LOCAL_SECRET_JSON} --from=quay.io/${PRODUCT_REPO}/${RELEASE_NAME}:${OCP_RELEASE}-${ARCHITECTURE} --to=${LOCAL_REGISTRY}/${LOCAL_REPOSITORY} --to-release-image=${LOCAL_REGISTRY}/${LOCAL_REPOSITORY}:${OCP_RELEASE}-${ARCHITECTURE}
\]

This command pulls the release information as a digest, and its output includes the **imageContentSources** data that you require when you install your cluster.

  ii. Record the entire **imageContentSources** section from the output of the previous command. The information about your mirrors is unique to your mirrored repository, and you must add the **imageContentSources** section to the **install-config.yaml** file during installation.

**NOTE**

The image name gets patched to Quay.io during the mirroring process, and the podman images will show Quay.io in the registry on the bootstrap virtual machine.

4. To create the installation program that is based on the content that you mirrored, extract it and pin it to the release:

- If your mirror host does not have internet access, run the following command:

\[
$ oc adm release extract -a ${LOCAL_SECRET_JSON} --command=openshift-baremetal-install "$FILE${LOCAL_REGISTRY}/${LOCAL_REPOSITORY}:${OCP_RELEASE}"
\]

- If the local container registry is connected to the mirror host, run the following command:

\[
$ oc adm release extract -a ${LOCAL_SECRET_JSON} --command=openshift-baremetal-install "$FILE${LOCAL_REGISTRY}/${LOCAL_REPOSITORY}:${OCP_RELEASE}-${ARCHITECTURE}"
\]
IMPORTANT

To ensure that you use the correct images for the version of OpenShift Container Platform that you selected, you must extract the installation program from the mirrored content.

You must perform this step on a machine with an active internet connection.

If you are in a disconnected environment, use the --image flag as part of must-gather and point to the payload image.

5. For clusters using installer-provisioned infrastructure, run the following command:

```bash
$ openshift-baremetal-install
```

16.3.11.3. Modify the install-config.yaml file to use the disconnected registry

On the provisioner node, the `install-config.yaml` file should use the newly created pull-secret from the `pull-secret-update.txt` file. The `install-config.yaml` file must also contain the disconnected registry node’s certificate and registry information.

Procedure

1. Add the disconnected registry node’s certificate to the `install-config.yaml` file:

```bash
$ echo "additionalTrustBundle: |" >> install-config.yaml
$ sed -e 's/^/  /' /opt/registry/certs/domain.crt >> install-config.yaml
```

The certificate should follow the "additionalTrustBundle: |" line and be properly indented, usually by two spaces.

2. Add the mirror information for the registry to the `install-config.yaml` file:

```bash
$ echo "imageContentSources:" >> install-config.yaml
$ echo "  - registry.example.com:5000/ocp4/openshift4" >> install-config.yaml
$ echo "  source: quay.io/openshift-release-dev/ocp-release" >> install-config.yaml
$ echo "  - registry.example.com:5000/ocp4/openshift4" >> install-config.yaml
$ echo "  source: quay.io/openshift-release-dev/ocp-v4.0-art-dev" >> install-config.yaml
```

Replace `registry.example.com` with the registry’s fully qualified domain name.

```bash
$ echo "  - registry.example.com:5000/ocp4/openshift4" >> install-config.yaml
$ echo "  source: quay.io/openshift-release-dev/ocp-v4.0-art-dev" >> install-config.yaml
```

Replace `registry.example.com` with the registry’s fully qualified domain name.

```bash
$ echo "  - registry.example.com:5000/ocp4/openshift4" >> install-config.yaml
```

Replace `registry.example.com` with the registry’s fully qualified domain name.
16.3.12. Validation checklist for installation

☐ OpenShift Container Platform installer has been retrieved.

☐ OpenShift Container Platform installer has been extracted.

☐ Required parameters for the install-config.yaml have been configured.

☐ The hosts parameter for the install-config.yaml has been configured.

☐ The bmc parameter for the install-config.yaml has been configured.

☐ Conventions for the values configured in the bmc address field have been applied.

☐ Created the OpenShift Container Platform manifests.

☐ (Optional) Deployed routers on worker nodes.

☐ (Optional) Created a disconnected registry.

☐ (Optional) Validate disconnected registry settings if in use.

16.3.13. Deploying the cluster via the OpenShift Container Platform installer

Run the OpenShift Container Platform installer:

```bash
$ ./openshift-baremetal-install --dir ~/clusterconfigs --log-level debug create cluster
```

16.3.14. Following the installation

During the deployment process, you can check the installation’s overall status by issuing the tail command to the .openshift_install.log log file in the install directory folder:

```bash
$ tail -f /path/to/install-dir/.openshift_install.log
```

16.3.15. Verifying static IP address configuration

If the DHCP reservation for a cluster node specifies an infinite lease, after the installer successfully provisions the node, the dispatcher script checks the node’s network configuration. If the script determines that the network configuration contains an infinite DHCP lease, it creates a new connection using the IP address of the DHCP lease as a static IP address.

**NOTE**

The dispatcher script might run on successfully provisioned nodes while the provisioning of other nodes in the cluster is ongoing.

Verify the network configuration is working properly.

**Procedure**

1. Check the network interface configuration on the node.
2. Turn off the DHCP server and reboot the OpenShift Container Platform node and ensure that the network configuration works properly.

16.3.16. Preparing to reinstall a cluster on bare metal

Before you reinstall a cluster on bare metal, you must perform cleanup operations.

Procedure

1. Remove or reformat the disks for the bootstrap, control plane node, and worker nodes. If you are working in a hypervisor environment, you must add any disks you removed.

2. Delete the artifacts that the previous installation generated:

   ```bash
   $ cd /bin/rm -rf auth/bootstrap.ign master.ign worker.ign metadata.json .openshift_install.log .openshift_install_state.json
   ``

3. Generate new manifests and Ignition config files. See “Creating the Kubernetes manifest and Ignition config files” for more information.

4. Upload the new bootstrap, control plane, and compute node Ignition config files that the installation program created to your HTTP server. This will overwrite the previous Ignition files.

16.3.17. Additional resources

- OpenShift Container Platform Creating the Kubernetes manifest and Ignition config files
- Understanding update channels and releases

16.4. INSTALLER-PROVISIONED POSTINSTALLATION CONFIGURATION

After successfully deploying an installer-provisioned cluster, consider the following postinstallation procedures.

16.4.1. Optional: Configuring NTP for disconnected clusters

OpenShift Container Platform installs the `chrony` Network Time Protocol (NTP) service on the cluster nodes. Use the following procedure to configure NTP servers on the control plane nodes and configure worker nodes as NTP clients of the control plane nodes after a successful deployment.
OpenShift Container Platform nodes must agree on a date and time to run properly. When worker nodes retrieve the date and time from the NTP servers on the control plane nodes, it enables the installation and operation of clusters that are not connected to a routable network and thereby do not have access to a higher stratum NTP server.

**Procedure**

1. Create a Butane config, `99-master-chrony-conf-override.bu`, including the contents of the `chrony.conf` file for the control plane nodes.

   **NOTE**

   See “Creating machine configs with Butane” for information about Butane.

   **Butane config example**

   ```yaml
   variant: openshift
   version: 4.14.0
   metadata:
     name: 99-master-chrony-conf-override
     labels:          # Machine Config Operator manages this file
     machineconfiguration.openshift.io/role: master
   storage:
     files:
     - path: /etc/chrony.conf
       mode: 0644
       overwrite: true
       contents:
         inline:
           # Use public servers from the pool.ntp.org project.
           # Please consider joining the pool (https://www.pool.ntp.org/join.html).

           # The Machine Config Operator manages this file
           server openshift-master-0.<cluster-name>.<domain> iburst
           server openshift-master-1.<cluster-name>.<domain> iburst
           server openshift-master-2.<cluster-name>.<domain> iburst
           stratumweight 0
   ```
You must replace `<cluster-name>` with the name of the cluster and replace `<domain>` with the fully qualified domain name.

2. Use Butane to generate a MachineConfig object file, `99-master-chrony-conf-override.yaml`, containing the configuration to be delivered to the control plane nodes:

   ```bash
   $ butane 99-master-chrony-conf-override.bu -o 99-master-chrony-conf-override.yaml
   ```

3. Create a Butane config, `99-worker-chrony-conf-override.bu`, including the contents of the `chrony.conf` file for the worker nodes that references the NTP servers on the control plane nodes.

**Butane config example**

```yaml
variant: openshift
version: 4.14.0
metadata:
  name: 99-worker-chrony-conf-override
  labels:
    machineconfiguration.openshift.io/role: worker
storage:
  files:
  - path: /etc/chrony.conf
    mode: 0644
    overwrite: true
    contents:
      inline:
        # The Machine Config Operator manages this file.
        server openshift-master-0.<cluster-name>.<domain> iburst 1
        server openshift-master-1.<cluster-name>.<domain> iburst
        server openshift-master-2.<cluster-name>.<domain> iburst
        stratumweight 0
```
You must replace `<cluster-name>` with the name of the cluster and replace `<domain>` with the fully qualified domain name.

4. Use Butane to generate a `MachineConfig` object file, `99-worker-chrony-conf-override.yaml`, containing the configuration to be delivered to the worker nodes:

   ```bash
   ```

5. Apply the `99-master-chrony-conf-override.yaml` policy to the control plane nodes.

   ```bash
   $ oc apply -f 99-master-chrony-conf-override.yaml
   ```

   **Example output**

   ```bash
   machineconfig.machineconfiguration.openshift.io/99-master-chrony-conf-override created
   ```

6. Apply the `99-worker-chrony-conf-override.yaml` policy to the worker nodes.

   ```bash
   $ oc apply -f 99-worker-chrony-conf-override.yaml
   ```

   **Example output**

   ```bash
   machineconfig.machineconfiguration.openshift.io/99-worker-chrony-conf-override created
   ```

7. Check the status of the applied NTP settings.

   ```bash
   $ oc describe machineconfigpool
   ```

### 16.4.2. Enabling a provisioning network after installation

The assisted installer and installer-provisioned installation for bare metal clusters provide the ability to deploy a cluster without a provisioning network. This capability is for scenarios such as proof-of-concept clusters or deploying exclusively with Redfish virtual media when each node’s baseboard management controller is routable via the baremetal network.

You can enable a provisioning network after installation using the Cluster Baremetal Operator (CBO).

**Prerequisites**
A dedicated physical network must exist, connected to all worker and control plane nodes.

You must isolate the native, untagged physical network.

The network cannot have a DHCP server when the `provisioningNetwork` configuration setting is set to Managed.

You can omit the `provisioningInterface` setting in OpenShift Container Platform 4.10 to use the `bootMACAddress` configuration setting.

### Procedure

1. When setting the `provisioningInterface` setting, first identify the provisioning interface name for the cluster nodes. For example, eth0 or eno1.

2. Enable the Preboot eXecution Environment (PXE) on the `provisioning` network interface of the cluster nodes.

3. Retrieve the current state of the `provisioning` network and save it to a provisioning custom resource (CR) file:

   ```bash
   $ oc get provisioning -o yaml > enable-provisioning-nw.yaml
   $ vim ~/enable-provisioning-nw.yaml
   ```

4. Modify the provisioning CR file:

   ```bash
   $ vim ~/enable-provisioning-nw.yaml
   ```

   Scroll down to the `provisioningNetwork` configuration setting and change it from Disabled to Managed. Then, add the `provisioningIP`, `provisioningNetworkCIDR`, `provisioningDHCPRange`, `provisioningInterface`, and `watchAllNameSpaces` configuration settings after the `provisioningNetwork` setting. Provide appropriate values for each setting.

   ```yaml
   apiVersion: v1
   items:
     - apiVersion: metal3.io/v1alpha1
       kind: Provisioning
       metadata:
         name: provisioning-configuration
       spec:
         provisioningNetwork: 1
         provisioningIP: 2
         provisioningNetworkCIDR: 3
         provisioningDHCPRange: 4
         provisioningInterface: 5
         watchAllNameSpaces: 6
   ```

   1. The `provisioningNetwork` is one of Managed, Unmanaged, or Disabled. When set to Managed, Metal3 manages the provisioning network and the CBO deploys the Metal3 pod with a configured DHCP server. When set to Unmanaged, the system administrator configures the DHCP server manually.

   2. The `provisioningIP` is the static IP address that the DHCP server and ironic use to provision the network. This static IP address must be within the `provisioning` subnet, and outside of the DHCP range. If you configure this setting, it must have a valid IP address.
even if the `provisioning` network is `Disabled`. The static IP address is bound to the metal3 pod. If the metal3 pod fails and moves to another server, the static IP address also moves to the new server.

3. The Classless Inter-Domain Routing (CIDR) address. If you configure this setting, it must have a valid CIDR address even if the `provisioning` network is `Disabled`. For example: 192.168.0.1/24.

4. The DHCP range. This setting is only applicable to a Managed provisioning network. Omit this configuration setting if the `provisioning` network is `Disabled`. For example: 192.168.0.64, 192.168.0.253.

5. The NIC name for the `provisioning` interface on cluster nodes. The `provisioningInterface` setting is only applicable to Managed and Unmanaged provisioning networks. Omit the `provisioningInterface` configuration setting if the `provisioning` network is `Disabled`. Omit the `provisioningInterface` configuration setting to use the `bootMACAddress` configuration setting instead.

6. Set this setting to `true` if you want metal3 to watch namespaces other than the default `openshift-machine-api` namespace. The default value is `false`.

5. Save the changes to the provisioning CR file.

6. Apply the provisioning CR file to the cluster:
   
   ```bash
   $ oc apply -f enable-provisioning-nw.yaml
   ```

### 16.4.3. Configuring an external load balancer

You can configure an OpenShift Container Platform cluster to use an external load balancer in place of the default load balancer.

**IMPORTANT**

Configuring an external load balancer depends on your vendor’s load balancer.

The information and examples in this section are for guideline purposes only. Consult the vendor documentation for more specific information about the vendor’s load balancer.

Red Hat supports the following services for an external load balancer:

- OpenShift API
- Ingress Controller

You can choose to configure one or both of these services for an external load balancer. Configuring only the Ingress Controller service is a common configuration option.

The following configuration options are supported for external load balancers:

- Use a node selector to map the Ingress Controller to a specific set of nodes. You must assign a static IP address to each node in this set, or configure each node to receive the same IP address from the Dynamic Host Configuration Protocol (DHCP). Infrastructure nodes commonly receive this type of configuration.
• Target all IP addresses on a subnet. This configuration can reduce maintenance overhead, because you can create and destroy nodes within those networks without reconfiguring the load balancer targets. If you deploy your ingress pods by using a machine set on a smaller network, such as a /27 or /28, you can simplify your load balancer targets.

**TIP**

You can list all IP addresses that exist in a network by checking the machine config pool’s resources.

**Considerations**

• For a front-end IP address, you can use the same IP address for the front-end IP address, the Ingress Controller’s load balancer, and API load balancer. Check the vendor’s documentation for this capability.

• For a back-end IP address, ensure that an IP address for an OpenShift Container Platform control plane node does not change during the lifetime of the external load balancer. You can achieve this by completing one of the following actions:
  - Assign a static IP address to each control plane node.
  - Configure each node to receive the same IP address from the DHCP every time the node requests a DHCP lease. Depending on the vendor, the DHCP lease might be in the form of an IP reservation or a static DHCP assignment.

• Manually define each node that runs the Ingress Controller in the external load balancer for the Ingress Controller back-end service. For example, if the Ingress Controller moves to an undefined node, a connection outage can occur.

**OpenShift API prerequisites**

• You defined a front-end IP address.

• TCP ports 6443 and 22623 are exposed on the front-end IP address of your load balancer. Check the following items:
  - Port 6443 provides access to the OpenShift API service.
  - Port 22623 can provide ignition startup configurations to nodes.

• The front-end IP address and port 6443 are reachable by all users of your system with a location external to your OpenShift Container Platform cluster.

• The front-end IP address and port 22623 are reachable only by OpenShift Container Platform nodes.

• The load balancer backend can communicate with OpenShift Container Platform control plane nodes on port 6443 and 22623.

**Ingress Controller prerequisites**

• You defined a front-end IP address.

• TCP ports 443 and 80 are exposed on the front-end IP address of your load balancer.
The front-end IP address, port 80 and port 443 are be reachable by all users of your system with a location external to your OpenShift Container Platform cluster.

The front-end IP address, port 80 and port 443 are reachable to all nodes that operate in your OpenShift Container Platform cluster.

The load balancer backend can communicate with OpenShift Container Platform nodes that run the Ingress Controller on ports 80, 443, and 1936.

Prerequisite for health check URL specifications

You can configure most load balancers by setting health check URLs that determine if a service is available or unavailable. OpenShift Container Platform provides these health checks for the OpenShift API, Machine Configuration API, and Ingress Controller backend services.

The following examples demonstrate health check specifications for the previously listed backend services:

Example of a Kubernetes API health check specification

Path: HTTPS:6443/readyz
Healthy threshold: 2
Unhealthy threshold: 2
Timeout: 10
Interval: 10

Example of a Machine Config API health check specification

Path: HTTPS:22623/healthz
Healthy threshold: 2
Unhealthy threshold: 2
Timeout: 10
Interval: 10

Example of an Ingress Controller health check specification

Path: HTTP:1936/healthz/ready
Healthy threshold: 2
Unhealthy threshold: 2
Timeout: 5
Interval: 10

Procedure

1. Configure the HAProxy Ingress Controller, so that you can enable access to the cluster from your load balancer on ports 6443, 443, and 80:

   Example HAProxy configuration

   ```
   #...
   listen my-cluster-api-6443
     bind 192.168.1.100:6443
     mode tcp
     balance roundrobin
   ```
2. Use the `curl` CLI command to verify that the external load balancer and its resources are operational:

   a. Verify that the cluster machine configuration API is accessible to the Kubernetes API server resource, by running the following command and observing the response:

   ```
   $ curl https://<loadbalancer_ip_address>:6443/version --insecure
   ```

   If the configuration is correct, you receive a JSON object in response:

   ```
   ```
b. Verify that the cluster machine configuration API is accessible to the Machine config server resource, by running the following command and observing the output:

```
$ curl -v https://<loadbalancer_ip_address>:22623/healthz --insecure
```

If the configuration is correct, the output from the command shows the following response:

```
HTTP/1.1 200 OK
Content-Length: 0
```

c. Verify that the controller is accessible to the Ingress Controller resource on port 80, by running the following command and observing the output:

```
$ curl -I -L -H "Host: console-openshift-console.apps.<cluster_name>.<base_domain>" http://<load_balancer_front_end_IP_address>
```

If the configuration is correct, the output from the command shows the following response:

```
HTTP/1.1 302 Found
content-length: 0
location: https://console-openshift-console.apps.ocp4.private.opequon.net/
cache-control: no-cache
```

d. Verify that the controller is accessible to the Ingress Controller resource on port 443, by running the following command and observing the output:

```
$ curl -I -L --insecure --resolve console-openshift-console.apps.<cluster_name>.<base_domain> http://<load_balancer_front_end_IP_address>:443
```

If the configuration is correct, the output from the command shows the following response:

```
HTTP/1.1 200 OK
referrer-policy: strict-origin-when-cross-origin
set-cookie: csrf-token=UlYWOyQ62LWjw2h003xtYSKlh1a0Py2hhctw0WmV2YEdhJjFyQwWcGBsja261dG LgaY0O nxzVErhiXt6QepA7g==; Path=/; Secure; SameSite=Lax
x-content-type-options: nosniff
x-dns-prefetch-control: off
x-frame-options: DENY
x-xss-protection: 1; mode=block
date: Wed, 04 Oct 2023 16:29:38 GMT
content-type: text/html; charset=utf-8
```
3. Configure the DNS records for your cluster to target the front-end IP addresses of the external load balancer. You must update records to your DNS server for the cluster API and applications over the load balancer.

Examples of modified DNS records

- `<load_balancer_ip_address>` A `api.<cluster_name>.<base_domain>`
  A record pointing to Load Balancer Front End

- `<load_balancer_ip_address>` A `apps.<cluster_name>.<base_domain>`
  A record pointing to Load Balancer Front End

**IMPORTANT**

DNS propagation might take some time for each DNS record to become available. Ensure that each DNS record propagates before validating each record.

4. Use the `curl` CLI command to verify that the external load balancer and DNS record configuration are operational:

a. Verify that you can access the cluster API, by running the following command and observing the output:

```bash
$ curl https://api.<cluster_name>.<base_domain>:6443/version --insecure
```

If the configuration is correct, you receive a JSON object in response:

```
{
  "major": "1",
  "minor": "11+",
  "gitVersion": "v1.11.0+ad103ed",
  "gitCommit": "ad103ed",
  "gitTreeState": "clean",
  "buildDate": "2019-01-09T06:44:10Z",
  "goVersion": "go1.10.3",
  "compiler": "gc",
  "platform": "linux/amd64"
}
```

b. Verify that you can access the cluster machine configuration, by running the following command and observing the output:

```bash
$ curl -v https://api.<cluster_name>.<base_domain>:22623/healthz --insecure
```

If the configuration is correct, the output from the command shows the following response:
c. Verify that you can access each cluster application on port, by running the following command and observing the output:

```bash
$ curl http://console-openshift-console.apps.<cluster_name>.<base_domain> -I -L --insecure
```

If the configuration is correct, the output from the command shows the following response:

```
HTTP/1.1 200 OK
Content-Length: 0
```

```
HTTP/1.1 302 Found
content-length: 0
location: https://console-openshift-console.apps.<cluster_name>.<base_domain>/
cache-control: no-cache
referrer-policy: strict-origin-when-cross-origin
set-cookie: csrf-token=9HoZgztdNzjJkg/JuLJMeoKNSlfiVv2YgZc09c3TBOPU4Nf6kDXaJH1LdicNhN1UsQWzon4Dor9GWfopaTEQ==; Path=/; Secure
x-content-type-options: nosniff
x-dns-prefetch-control: off
x-frame-options: DENY
x-xss-protection: 1; mode=block
date: Tue, 17 Nov 2020 08:42:10 GMT
content-type: text/html; charset=utf-8
```

```
set-cookie: 1e2670d92730b515ce3a1bb65da45062=9b714eb87e93cf34853e87a92d6894be; path=/; HttpOnly; Secure; SameSite=None
```

```
cache-control: private
```

d. Verify that you can access each cluster application on port 443, by running the following command and observing the output:

```bash
$ curl https://console-openshift-console.apps.<cluster_name>.<base_domain> -I -L --insecure
```

If the configuration is correct, the output from the command shows the following response:

```
HTTP/1.1 200 OK
referrer-policy: strict-origin-when-cross-origin
set-cookie: csrf-token=UlYWOyQ62LWjw2h003xtYSKIh1a0Py2hhctw0WmV2YEdhJjFyQwWcGBsja261dG
LgaY0OxzxVErhlXi6QepA7g==; Path=/; Secure; SameSite=Lax
x-content-type-options: nosniff
x-dns-prefetch-control: off
x-frame-options: DENY
x-xss-protection: 1; mode=block
date: Wed, 04 Oct 2023 16:29:38 GMT
content-type: text/html; charset=utf-8
```

```
set-cookie: 1e2670d92730b515ce3a1bb65da45062=1bf5e9573c9a2760c964ed1659cc1673; path=/; HttpOnly; Secure; SameSite=None
```

```
cache-control: private
```

CHAPTER 16. DEPLOYING INSTALLER-PROVISIONED CLUSTERS ON BARE METAL

2387
16.5. EXPANDING THE CLUSTER

After deploying an installer-provisioned OpenShift Container Platform cluster, you can use the following procedures to expand the number of worker nodes. Ensure that each prospective worker node meets the prerequisites.

NOTE

Expanding the cluster using RedFish Virtual Media involves meeting minimum firmware requirements. See Firmware requirements for installing with virtual media in the Prerequisites section for additional details when expanding the cluster using RedFish Virtual Media.

16.5.1. Preparing the bare metal node

To expand your cluster, you must provide the node with the relevant IP address. This can be done with a static configuration, or with a DHCP (Dynamic Host Configuration protocol) server. When expanding the cluster using a DHCP server, each node must have a DHCP reservation.

RESERVING IP ADDRESSES SO THEY BECOME STATIC IP ADDRESSES

Some administrators prefer to use static IP addresses so that each node’s IP address remains constant in the absence of a DHCP server. To configure static IP addresses with NMState, see "Optional: Configuring host network interfaces in the install-config.yaml file" in the "Setting up the environment for an OpenShift installation" section for additional details.

Preparing the bare metal node requires executing the following procedure from the provisioner node.

Procedure

1. Get the oc binary:

   $ sudo cp oc /usr/local/bin

2. Power off the bare metal node by using the baseboard management controller (BMC), and ensure it is off.

3. Retrieve the user name and password of the bare metal node’s baseboard management controller. Then, create base64 strings from the user name and password:

   $ echo -ne "root" | base64

   $ echo -ne "password" | base64

4. Create a configuration file for the bare metal node. Depending on whether you are using a static configuration or a DHCP server, use one of the following example bmh.yaml files, replacing values in the YAML to match your environment:
$ vim bmh.yaml

- Static configuration `bmh.yaml`:

```yaml
---
apiVersion: v1
kind: Secret
metadata:
  name: openshift-worker-<num>-network-config-secret
  namespace: openshift-machine-api
  type: Opaque
stringData:
  nmstate:
  interfaces:
    - name: <nic1_name>
      type: ethernet
      state: up
      ipv4:
        address:
          - ip: <ip_address>
            prefix-length: 24
            enabled: true
dns-resolver:
  config:
    server:
      - <dns_ip_address>
routes:
  config:
    - destination: 0.0.0.0/0
      next-hop-address: <next_hop_ip_address>
      next-hop-interface: <next_hop_nic1_name>
---
apiVersion: v1
kind: Secret
metadata:
  name: openshift-worker-<num>-bmc-secret
  namespace: openshift-machine-api
  type: Opaque
data:
  username: <base64_of_uid>
  password: <base64_of_pwd>
---
apiVersion: metal3.io/v1alpha1
kind: BareMetalHost
metadata:
  name: openshift-worker-<num>
  namespace: openshift-machine-api
spec:
  online: True
bootMACAddress: <nic1_mac_address>
bmc:
  address: <protocol>://<bmc_url>
  credentialsName: openshift-worker-<num>-bmc-secret
```
To configure the network interface for a newly created node, specify the name of the secret that contains the network configuration. Follow the `nmstate` syntax to define the network configuration for your node. See "Optional: Configuring host network interfaces in the install-config.yaml file" for details on configuring NMState syntax.

Replace `<num>` for the worker number of the bare metal node in the `name` fields, the `credentialsName` field, and the `preprovisioningNetworkDataName` field.

Add the NMState YAML syntax to configure the host interfaces.

Optional: If you have configured the network interface with `nmstate`, and you want to disable an interface, set `state: up` with the IP addresses set to `enabled: false` as shown:

```
---
interfaces:
  - name: <nic_name>
    type: ethernet
    state: up
    ipv4:
      enabled: false
    ipv6:
      enabled: false
```

Replace `<nic1_name>`, `<ip_address>`, `<dns_ip_address>`, `<next_hop_ip_address>` and `<next_hop_nic1_name>` with appropriate values.

Replace `<base64_of_uid>` and `<base64_of_pwd>` with the base64 string of the user name and password.

Replace `<nic1_mac_address>` with the MAC address of the bare metal node’s first NIC. See the "BMC addressing" section for additional BMC configuration options.

Replace `<protocol>` with the BMC protocol, such as IPMI, RedFish, or others. Replace `<bmc_url>` with the URL of the bare metal node’s baseboard management controller.

To skip certificate validation, set `disableCertificateVerification` to true.

Replace `<bmc_username>` and `<bmc_password>` with the string of the BMC user name and password.

Optional: Replace `<root_device_hint>` with a device path if you specify a root device hint.

Optional: If you have configured the network interface for the newly created node, provide the network configuration secret name in the `preprovisioningNetworkDataName` of the BareMetalHost CR.
CHAPTER 16. DEPLOYING INSTALLER-PROVISIONED CLUSTERS ON BARE METAL

- DHCP configuration `bmh.yaml`:

```yaml
---
apiVersion: v1
kind: Secret
metadata:
  name: openshift-worker-<num>-bmc-secret
  namespace: openshift-machine-api
  type: Opaque
data:
  username: <base64_of_uid>
  password: <base64_of_pwd>
---
apiVersion: metal3.io/v1alpha1
kind: BareMetalHost
metadata:
  name: openshift-worker-<num>
  namespace: openshift-machine-api
spec:
  online: True
  bootMACAddress: <nic1_mac_address>
  bmc:
    address: <protocol>://<bmc_url>
    credentialsName: openshift-worker-<num>-bmc-secret
    disableCertificateVerification: True
    username: <bmc_username>
    password: <bmc_password>
  rootDeviceHints:
    deviceName: <root_device_hint>
  preprovisioningNetworkDataName: openshift-worker-<num>-network-config-secret
```

1. Replace `<num>` for the worker number of the bare metal node in the `name` fields, the `credentialsName` field, and the `preprovisioningNetworkDataName` field.

2. Replace `<base64_of_uid>` and `<base64_of_pwd>` with the base64 string of the user name and password.

3. Replace `<nic1_mac_address>` with the MAC address of the bare metal node’s first NIC. See the “BMC addressing” section for additional BMC configuration options.

4. Replace `<protocol>` with the BMC protocol, such as IPMI, RedFish, or others. Replace `<bmc_url>` with the URL of the bare metal node’s baseboard management controller.

5. To skip certificate validation, set `disableCertificateVerification` to true.

6. Replace `<bmc_username>` and `<bmc_password>` with the string of the BMC user name and password.

7. Optional: Replace `<root_device_hint>` with a device path if you specify a root device hint.

8. Optional: If you have configured the network interface for the newly created node, provide the network configuration secret name in the `preprovisioningNetworkDataName` of the BareMetalHost CR.
NOTE
If the MAC address of an existing bare metal node matches the MAC address of a bare metal host that you are attempting to provision, then the Ironic installation will fail. If the host enrollment, inspection, cleaning, or other Ironic steps fail, the Bare Metal Operator retries the installation continuously. See "Diagnosing a host duplicate MAC address" for more information.

5. Create the bare metal node:

$ oc -n openshift-machine-api create -f bmh.yaml

Example output
secret/openshift-worker-<num>-network-config-secret created
secret/openshift-worker-<num>-bmc-secret created
baremetalhost.metal3.io/openshift-worker-<num> created

Where <num> will be the worker number.

6. Power up and inspect the bare metal node:

$ oc -n openshift-machine-api get bmh openshift-worker-<num>

Where <num> is the worker node number.

Example output

NAME STATE CONSUMER ONLINE ERROR
openshift-worker-<num> available true

NOTE
To allow the worker node to join the cluster, scale the machineset object to the number of the BareMetalHost objects. You can scale nodes either manually or automatically. To scale nodes automatically, use the metal3.io/autoscale-to-hosts annotation for machineset.

Additional resources

- See Optional: Configuring host network interfaces in the install-config.yaml file for details on configuring the NMState syntax.
- See Automatically scaling machines to the number of available bare metal hosts for details on automatically scaling machines.

16.5.2. Replacing a bare-metal control plane node

Use the following procedure to replace an installer-provisioned OpenShift Container Platform control plane node.
IMPORTANT

If you reuse the BareMetalHost object definition from an existing control plane host, do not leave the externallyProvisioned field set to true.

Existing control plane BareMetalHost objects may have the externallyProvisioned flag set to true if they were provisioned by the OpenShift Container Platform installation program.

Prerequisites

- You have access to the cluster as a user with the cluster-admin role.
- You have taken an etcd backup.

IMPORTANT

Take an etcd backup before performing this procedure so that you can restore your cluster if you encounter any issues. For more information about taking an etcd backup, see the Additional resources section.

Procedure

1. Ensure that the Bare Metal Operator is available:

   $ oc get clusteroperator baremetal

   Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
<th>SINCE</th>
<th>MESSAGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>baremetal</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>3d15h</td>
<td></td>
</tr>
</tbody>
</table>

2. Remove the old BareMetalHost and Machine objects:

   $ oc delete bmh -n openshift-machine-api <host_name>
   $ oc delete machine -n openshift-machine-api <machine_name>

   Replace <host_name> with the name of the host and <machine_name> with the name of the machine. The machine name appears under the CONSUMER field.

   After you remove the BareMetalHost and Machine objects, then the machine controller automatically deletes the Node object.

3. Create the new BareMetalHost object and the secret to store the BMC credentials:

   $ cat <<EOF | oc apply -f -
   apiVersion: v1
   kind: Secret
   metadata:
     name: control-plane-<num>-bmc-secret
   namespace: openshift-machine-api
   data:
     username: <base64_of_uid>
     password: <base64_of_pwd>
   EOF
Replace `<num>` for the control plane number of the bare metal node in the `name` fields and the `credentialsName` field.

Replace `<base64_of_uid>` with the `base64` string of the user name.

Replace `<base64_of_pwd>` with the `base64` string of the password.

Replace `<protocol>` with the BMC protocol, such as `redfish`, `redfish-virtualmedia`, `idrac-virtualmedia`, or others. Replace `<bmc_ip>` with the IP address of the bare metal node’s baseboard management controller. For additional BMC configuration options, see “BMC addressing” in the Additional resources section.

Replace `<NIC1_mac_address>` with the MAC address of the bare metal node’s first NIC.

After the inspection is complete, the `BareMetalHost` object is created and available to be provisioned.

4. View available `BareMetalHost` objects:

```
$ oc get bmh -n openshift-machine-api
```

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATE</th>
<th>CONSUMER</th>
<th>ONLINE</th>
<th>ERROR</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>control-plane-1.example.com</td>
<td>available</td>
<td>control-plane-1</td>
<td>true</td>
<td></td>
<td>1h10m</td>
</tr>
<tr>
<td>control-plane-2.example.com</td>
<td>externally provisioned</td>
<td>control-plane-2</td>
<td>true</td>
<td></td>
<td>4h53m</td>
</tr>
<tr>
<td>control-plane-3.example.com</td>
<td>externally provisioned</td>
<td>control-plane-3</td>
<td>true</td>
<td></td>
<td>4h53m</td>
</tr>
<tr>
<td>compute-1.example.com</td>
<td>provisioned</td>
<td>compute-1-ktmmx</td>
<td>true</td>
<td></td>
<td>4h53m</td>
</tr>
<tr>
<td>compute-1.example.com</td>
<td>provisioned</td>
<td>compute-2-l2zmb</td>
<td>true</td>
<td></td>
<td>4h53m</td>
</tr>
</tbody>
</table>

There are no MachineSet objects for control plane nodes, so you must create a Machine object instead. You can copy the providerSpec from another control plane Machine object.

5. Create a Machine object:

```
$ cat <<EOF | oc apply -f -
apiVersion: machine.openshift.io/v1beta1
kind: Machine
metadata:
  annotations:
    metal3.io/BareMetalHost: openshift-machine-api/control-plane-<num> ①
  labels:
    machine.openshift.io/cluster-api-cluster: control-plane-<num> ②
    machine.openshift.io/cluster-api-machine-role: master
    machine.openshift.io/cluster-api-machine-type: master
  name: control-plane-<num> ③
namespace: openshift-machine-api
spec:
  metadata: {}
  providerSpec:
    value:
      apiVersion: baremetal.cluster.k8s.io/v1alpha1
      customDeploy:
        method: install_coreos
        hostSelector: {}
      image:
        checksum: ""
        url: ""
      kind: BareMetalMachineProviderSpec
      metadata:
        creationTimestamp: null
      userData:
        name: master-user-data-managed
EOF
```

① ② ③ Replace <num> for the control plane number of the bare metal node in the name, labels and annotations fields.

6. To view the BareMetalHost objects, run the following command:

```
$ oc get bmh -A
```

Example output

```
NAME                          STATE                    CONSUMER                   ONLINE   ERROR   AGE
control-plane-1.example.com   provisioned              control-plane-1            true             2h53m
control-plane-2.example.com   externally provisioned   control-plane-2            true
                           5h53m
control-plane-3.example.com   externally provisioned   control-plane-3            true
                           5h53m
compute-1.example.com         provisioned              compute-1-ktmmx            true
                           5h53m
compute-2.example.com         provisioned              compute-2-l2zmb            true
                           5h53m
```

2395
7. After the RHCOS installation, verify that the **BareMetalHost** is added to the cluster:

```
$ oc get nodes
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>control-plane-1.example.com</td>
<td>available</td>
<td>master</td>
<td>4m2s</td>
<td>v1.27.6</td>
</tr>
<tr>
<td>control-plane-2.example.com</td>
<td>available</td>
<td>master</td>
<td>141m</td>
<td>v1.27.6</td>
</tr>
<tr>
<td>control-plane-3.example.com</td>
<td>available</td>
<td>master</td>
<td>141m</td>
<td>v1.27.6</td>
</tr>
<tr>
<td>compute-1.example.com</td>
<td>available</td>
<td>worker</td>
<td>87m</td>
<td>v1.27.6</td>
</tr>
<tr>
<td>compute-2.example.com</td>
<td>available</td>
<td>worker</td>
<td>87m</td>
<td>v1.27.6</td>
</tr>
</tbody>
</table>

**NOTE**

After replacement of the new control plane node, the etcd pod running in the new node is in **crashloopback** status. See "Replacing an unhealthy etcd member" in the Additional resources section for more information.

**Additional resources**

- Replacing an unhealthy etcd member
- Backing up etcd
- Bare metal configuration
- BMC addressing

### 16.5.3. Preparing to deploy with Virtual Media on the baremetal network

If the **provisioning** network is enabled and you want to expand the cluster using Virtual Media on the **baremetal** network, use the following procedure.

**Prerequisites**

- There is an existing cluster with a **baremetal** network and a **provisioning** network.

**Procedure**

1. Edit the **provisioning** custom resource (CR) to enable deploying with Virtual Media on the **baremetal** network:

   ```
oc edit provisioning
```

   ```yaml
   apiVersion: metal3.io/v1alpha1
   kind: Provisioning
   metadata:
     creationTimestamp: "2021-08-05T18:51:50Z"
   finalizers:
     - provisioning.metal3.io
   generation: 8
   name: provisioning-configuration
   ```
Add `virtualMediaViaExternalNetwork: true` to the `provisioning` CR.

2. If the image URL exists, edit the `machineset` to use the API VIP address. This step only applies to clusters installed in versions 4.9 or earlier.

```
oc edit machineset
```

```
apiVersion: machine.openshift.io/v1beta1
group: apps
kind: MachineSet
metadata:
  creationTimestamp: "2021-08-05T18:51:52Z"
generation: 11
labels:
  machine.openshift.io/cluster-api-cluster: ostest-hwmdt
  machine.openshift.io/cluster-api-machine-role: worker
  machine.openshift.io/cluster-api-machine-type: worker
name: ostest-hwmdt-worker-0
namespace: openshift-machine-api

        fullyLabeledReplicas: 2
        observedGeneration: 11
        readyReplicas: 2
        replicas: 2

1. Edit the checksum URL to use the API VIP address.
2. Edit the url URL to use the API VIP address.

16.5.4. Diagnosing a duplicate MAC address when provisioning a new host in the cluster

If the MAC address of an existing bare-metal node in the cluster matches the MAC address of a bare-metal host you are attempting to add to the cluster, the Bare Metal Operator associates the host with the existing node. If the host enrollment, inspection, cleaning, or other Ironic steps fail, the Bare Metal Operator retries the installation continuously. A registration error is displayed for the failed bare-metal host.

You can diagnose a duplicate MAC address by examining the bare-metal hosts that are running in the openshift-machine-api namespace.

Prerequisites

- Install an OpenShift Container Platform cluster on bare metal.
- Install the OpenShift Container Platform CLI `oc`.
- Log in as a user with `cluster-admin` privileges.

Procedure

To determine whether a bare-metal host that fails provisioning has the same MAC address as an existing node, do the following:
1. Get the bare-metal hosts running in the **openshift-machine-api** namespace:

   ```
   $ oc get bmh -n openshift-machine-api
   ```

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>PROVISIONING STATUS</th>
<th>CONSUMER</th>
</tr>
</thead>
<tbody>
<tr>
<td>openshift-master-0</td>
<td>OK</td>
<td>externally provisioned</td>
<td>openshift-zpwpq-master-0</td>
</tr>
<tr>
<td>openshift-master-1</td>
<td>OK</td>
<td>externally provisioned</td>
<td>openshift-zpwpq-master-1</td>
</tr>
<tr>
<td>openshift-master-2</td>
<td>OK</td>
<td>externally provisioned</td>
<td>openshift-zpwpq-master-2</td>
</tr>
<tr>
<td>openshift-worker-0</td>
<td>OK</td>
<td>provisioned</td>
<td>openshift-zpwpq-worker-0-lv84n</td>
</tr>
<tr>
<td>openshift-worker-1</td>
<td>OK</td>
<td>provisioned</td>
<td>openshift-zpwpq-worker-0-zd8lm</td>
</tr>
<tr>
<td>openshift-worker-2</td>
<td>error</td>
<td>registering</td>
<td></td>
</tr>
</tbody>
</table>

2. To see more detailed information about the status of the failing host, run the following command replacing `<bare_metal_host_name>` with the name of the host:

   ```
   $ oc get -n openshift-machine-api bmh <bare_metal_host_name> -o yaml
   ```

   **Example output**

   ```
   ...
   status:
   errorCount: 12
   errorMessage: MAC address b4:96:91:1d:7c:20 conflicts with existing node openshift-worker-1
   errorType: registration error
   ...
   ```

### 16.5.5. Provisioning the bare metal node

Provisioning the bare metal node requires executing the following procedure from the provisioner node.

**Procedure**

1. Ensure the **STATE** is **available** before provisioning the bare metal node.

   ```
   $ oc -n openshift-machine-api get bmh openshift-worker-<num>
   ```

   Where `<num>` is the worker node number.

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATE</th>
<th>ONLINE</th>
<th>ERROR</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>openshift-worker</td>
<td>available</td>
<td>true</td>
<td></td>
<td>34h</td>
</tr>
</tbody>
</table>

2. Get a count of the number of worker nodes.

   ```
   $ oc get nodes
   ```

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>openshift-master-1.openshift.example.com</td>
<td>Ready master</td>
<td>30h</td>
<td>v1.27.3</td>
<td></td>
</tr>
<tr>
<td>openshift-master-2.openshift.example.com</td>
<td>Ready master</td>
<td>30h</td>
<td>v1.27.3</td>
<td></td>
</tr>
</tbody>
</table>
3. Get the compute machine set.

   $ oc get machinesets -n openshift-machine-api

   NAME          DESIRED CURRENT READY AVAILABLE AGE
   ...           1         1      1        1  55m
   openshift-worker-0.example.com  1         1      1        1  55m
   openshift-worker-1.example.com  1         1      1        1  55m

4. Increase the number of worker nodes by one.

   $ oc scale --replicas=<num> machineset <machineset> -n openshift-machine-api

   Replace `<num>` with the new number of worker nodes. Replace `<machineset>` with the name of the compute machine set from the previous step.

5. Check the status of the bare metal node.

   $ oc -n openshift-machine-api get bmh openshift-worker-<num>

   Where `<num>` is the worker node number. The STATE changes from `ready` to `provisioning`.

   NAME                    STATE             CONSUMER                          ONLINE   ERROR
   openshift-worker-<num>  provisioning      openshift-worker-<num>-65tjz      true

   The `provisioning` status remains until the OpenShift Container Platform cluster provisions the node. This can take 30 minutes or more. After the node is provisioned, the state will change to `provisioned`.

   NAME                    STATE             CONSUMER                          ONLINE   ERROR
   openshift-worker-<num>  provisioned       openshift-worker-<num>-65tjz      true

6. After provisioning completes, ensure the bare metal node is ready.

   $ oc get nodes

   NAME          STATUS ROLES AGE VERSION
   openshift-master-1.openshift.example.com Ready master 30h 1.27.3
   openshift-master-2.openshift.example.com Ready master 30h 1.27.3
   openshift-master-3.openshift.example.com Ready master 30h 1.27.3
   openshift-worker-0.openshift.example.com Ready worker 30h 1.27.3
   openshift-worker-1.openshift.example.com Ready worker 30h 1.27.3
   openshift-worker-<num>.openshift.example.com Ready worker 3m27s 1.27.3

   You can also check the kubelet.

   $ ssh openshift-worker-<num>
16.6. TROUBLESHOOTING

16.6.1. Troubleshooting the installer workflow

Prior to troubleshooting the installation environment, it is critical to understand the overall flow of the installer-provisioned installation on bare metal. The diagrams below provide a troubleshooting flow with a step-by-step breakdown for the environment.

Workflow 1 of 4 illustrates a troubleshooting workflow when the `install-config.yaml` file has errors or the Red Hat Enterprise Linux CoreOS (RHCOS) images are inaccessible. Troubleshooting suggestions can be found at Troubleshooting `install-config.yaml`.
Workflow 2 of 4 illustrates a troubleshooting workflow for bootstrap VM issues, bootstrap VMs that cannot boot up the cluster nodes, and inspecting logs. When installing an OpenShift Container Platform cluster without the provisioning network, this workflow does not apply.
Workflow 3 of 4 illustrates a troubleshooting workflow for cluster nodes that will not PXE boot. If installing using RedFish Virtual Media, each node must meet minimum firmware requirements for the installer to deploy the node. See Firmware requirements for installing with virtual media in the Prerequisites section for additional details.

Workflow 4 of 4 illustrates a troubleshooting workflow from a non-accessible API to a validated installation.

16.6.2. Troubleshooting install-config.yaml

The install-config.yaml configuration file represents all of the nodes that are part of the OpenShift Container Platform cluster. The file contains the necessary options consisting of but not limited to apiVersion, baseDomain, imageContentSources and virtual IP addresses. If errors occur early in the deployment of the OpenShift Container Platform cluster, the errors are likely in the install-config.yaml configuration file.

Procedure

1. Use the guidelines in YAML-tips.
2. Verify the YAML syntax is correct using syntax-check.
3. Verify the Red Hat Enterprise Linux CoreOS (RHCOS) QEMU images are properly defined and accessible via the URL provided in the install-config.yaml. For example:
If the output is **200**, there is a valid response from the webserver storing the bootstrap VM image.

### 16.6.3. Bootstrap VM issues

The OpenShift Container Platform installation program spawns a bootstrap node virtual machine, which handles provisioning the OpenShift Container Platform cluster nodes.

**Procedure**

1. About 10 to 15 minutes after triggering the installation program, check to ensure the bootstrap VM is operational using the `virsh` command:

   ```bash
   $ sudo virsh list
   
   Id   Name                           State
   --------------------------------------------
   12    openshift-xf6fq-bootstrap      running
   
   📌 NOTE
   
   The name of the bootstrap VM is always the cluster name followed by a random set of characters and ending in the word "bootstrap."

   If the bootstrap VM is not running after 10-15 minutes, troubleshoot why it is not running. Possible issues include:

2. Verify `libvirtd` is running on the system:

   ```bash
   $ systemctl status libvirtd
   
   ● libvirtd.service - Virtualization daemon
     Loaded: loaded (/usr/lib/systemd/system/libvirtd.service; enabled; vendor preset: enabled)
     Active: active (running) since Tue 2020-03-03 21:21:07 UTC; 3 weeks 5 days ago
     Docs: man:libvirtd(8)
     https://libvirt.org
     Main PID: 9850 (libvirtd)
     Tasks: 20 (limit: 32768)
     Memory: 74.8M
     CGroup: /system.slice/libvirtd.service
             └─ 9850 /usr/sbin/libvirtd
   
   If the bootstrap VM is operational, log in to it.

3. Use the `virsh console` command to find the IP address of the bootstrap VM:

   ```bash
   $ sudo virsh console example.com
   
   OpenShift Container Platform 4.14 Installing
   2404
IMPORTANT
When deploying an OpenShift Container Platform cluster without the provisioning network, you must use a public IP address and not a private IP address like 172.22.0.2.

4. After you obtain the IP address, log in to the bootstrap VM using the ssh command:

```
$ ssh core@172.22.0.2
```

If you are not successful logging in to the bootstrap VM, you have likely encountered one of the following scenarios:

- You cannot reach the 172.22.0.0/24 network. Verify the network connectivity between the provisioner and the provisioning network bridge. This issue might occur if you are using a provisioning network.

- You cannot reach the bootstrap VM through the public network. When attempting to SSH via baremetal network, verify connectivity on the provisioner host specifically around the baremetal network bridge.

- You encountered Permission denied (publickey,password,keyboard-interactive). When attempting to access the bootstrap VM, a Permission denied error might occur. Verify that the SSH key for the user attempting to log in to the VM is set within the install-config.yaml file.

16.6.3.1. Bootstrap VM cannot boot up the cluster nodes
During the deployment, it is possible for the bootstrap VM to fail to boot the cluster nodes, which prevents the VM from provisioning the nodes with the RHCOS image. This scenario can arise due to:

- A problem with the install-config.yaml file.

- Issues with out-of-band network access when using the baremetal network.

To verify the issue, there are three containers related to ironic:

- ironic

- ironic-inspector
Procedure

1. Log in to the bootstrap VM:

   $ ssh core@172.22.0.2

2. To check the container logs, execute the following:

   [core@localhost ~]$ sudo podman logs -f <container_name>

Replace `<container_name>` with one of `ironic` or `ironic-inspector`. If you encounter an issue where the control plane nodes are not booting up from PXE, check the `ironic` pod. The `ironic` pod contains information about the attempt to boot the cluster nodes, because it attempts to log in to the node over IPMI.

Potential reason

The cluster nodes might be in the **ON** state when deployment started.

Solution

Power off the OpenShift Container Platform cluster nodes before you begin the installation over IPMI:

   $ ipmitool -I lanplus -U root -P <password> -H <out_of_band_ip> power off

16.6.3.2. Inspecting logs

When experiencing issues downloading or accessing the RHCOS images, first verify that the URL is correct in the `install-config.yaml` configuration file.

Example of internal webserver hosting RHCOS images

- bootstrapOSImage: http://<ip:port>/rhcos-43.81.202001142154.0-qemu.<architecture>.qcow2.gz?sha256=9d999f55ff1d44f7ed7c106508e5d9edcd04dc3c060950d34d36bf1cd127837e0c
- clusterOSImage: http://<ip:port>/rhcos-43.81.202001142154.0-openstack.<architecture>.qcow2.gz?sha256=a1bda656fa0892f7b936f86b6a6086b90e5d9edcd04dc3c060950d34d36bf1cd127837e0c

The `coreos-downloader` container downloads resources from a webserver or from the external quay.io registry, whichever the `install-config.yaml` configuration file specifies. Verify that the `coreos-downloader` container is up and running and inspect its logs as needed.

Procedure

1. Log in to the bootstrap VM:

   $ ssh core@172.22.0.2

2. Check the status of the `coreos-downloader` container within the bootstrap VM by running the following command:

   [core@localhost ~]$ sudo podman logs -f coreos-downloader

If the bootstrap VM cannot access the URL to the images, use the `curl` command to verify that the VM can access the images.
3. To inspect the **bootkube** logs that indicate if all the containers launched during the deployment phase, execute the following:

```
[core@localhost ~]$ journalctl -xe
[core@localhost ~]$ journalctl -b -f -u bootkube.service
```

4. Verify all the pods, including **dnsmasq**, **mariadb**, **httpd**, and **ironic**, are running:

```
[core@localhost ~]$ sudo podman ps
```

5. If there are issues with the pods, check the logs of the containers with issues. To check the logs of the **ironic** service, run the following command:

```
[core@localhost ~]$ sudo podman logs ironic
```

### 16.6.4. Cluster nodes will not PXE boot

When OpenShift Container Platform cluster nodes will not PXE boot, execute the following checks on the cluster nodes that will not PXE boot. This procedure does not apply when installing an OpenShift Container Platform cluster without the **provisioning** network.

**Procedure**

1. Check the network connectivity to the **provisioning** network.

2. Ensure PXE is enabled on the NIC for the **provisioning** network and PXE is disabled for all other NICs.

3. Verify that the **install-config.yaml** configuration file has the proper hardware profile and boot MAC address for the NIC connected to the **provisioning** network. For example:

   **control plane node settings**
   ```yaml
   bootMACAddress: 24:6E:96:1B:96:90  # MAC of bootable provisioning NIC
   hardwareProfile: default          #control plane node settings
   ```

   **Worker node settings**
   ```yaml
   bootMACAddress: 24:6E:96:1B:96:90  # MAC of bootable provisioning NIC
   hardwareProfile: unknown          #worker node settings
   ```

### 16.6.5. Unable to discover new bare metal hosts using the BMC

In some cases, the installation program will not be able to discover the new bare metal hosts and issue an error, because it cannot mount the remote virtual media share.

For example:

```
```
In this situation, if you are using virtual media with an unknown certificate authority, you can configure your baseboard management controller (BMC) remote file share settings to trust an unknown certificate authority to avoid this error.

**NOTE**

This resolution was tested on OpenShift Container Platform 4.11 with Dell iDRAC 9 and firmware version 5.10.50.

16.6.6. The API is not accessible

When the cluster is running and clients cannot access the API, domain name resolution issues might impede access to the API.

**Procedure**

1. **Hostname Resolution**: Check the cluster nodes to ensure they have a fully qualified domain name, and not just `localhost.localdomain`. For example:

   ```
   $ hostname
   
   If a hostname is not set, set the correct hostname. For example:
   
   $ hostnamectl set-hostname <hostname>
   
   2. **Incorrect Name Resolution**: Ensure that each node has the correct name resolution in the DNS server using `dig` and `nslookup`. For example:

   ```
   $ dig api.<cluster_name>.example.com
   
   ; <<>> Dig 9.11.4-P2-RedHat-9.11.4-26.P2.el8 <<>> api.<cluster_name>.example.com
   ;; global options: +cmd
   ;; Got answer:
   ;; ->>HEADER<<- opcode: QUERY, status: NOERROR, id: 37551
   ```
The output in the foregoing example indicates that the appropriate IP address for the `api.<cluster_name>.example.com` VIP is `10.19.13.86`. This IP address should reside on the baremetal network.

16.6.7. Troubleshooting worker nodes that cannot join the cluster

Installer-provisioned clusters deploy with a DNS server that includes a DNS entry for the `api-int.<cluster_name>.<base_domain>` URL. If the nodes within the cluster use an external or upstream DNS server to resolve the `api-int.<cluster_name>.<base_domain>` URL and there is no such entry, worker nodes might fail to join the cluster. Ensure that all nodes in the cluster can resolve the domain name.

Procedure

1. Add a DNS A/AAAA or CNAME record to internally identify the API load balancer. For example, when using dnsmasq, modify the `dnsmasq.conf` configuration file:

   ```
   $ sudo nano /etc/dnsmasq.conf

   address=/api-int.<cluster_name>.<base_domain>/$IP_address
   address=/api-int.mycluster.example.com/192.168.1.10
   address=/api-int.mycluster.example.com/2001:0db8:85a3:0000:0000:8a2e:0370:7334
   ```

2. Add a DNS PTR record to internally identify the API load balancer. For example, when using dnsmasq, modify the `dnsmasq.conf` configuration file:

   ```
   $ sudo nano /etc/dnsmasq.conf

   ptr-record=$IP_address.in-addr.arpa,api-int.<cluster_name>.<base_domain>
   ptr-record=10.1.168.192.in-addr.arpa,api-int.mycluster.example.com
   ```

3. Restart the DNS server. For example, when using dnsmasq, execute the following command:

   ```
   ```
These records must be resolvable from all the nodes within the cluster.

### 16.6.8. Cleaning up previous installations

In the event of a previous failed deployment, remove the artifacts from the failed attempt before attempting to deploy OpenShift Container Platform again.

**Procedure**

1. Power off all bare metal nodes prior to installing the OpenShift Container Platform cluster:
   ```bash
   $ sudo systemctl restart dnsmasq
   ``

   These records must be resolvable from all the nodes within the cluster.

2. Remove all old bootstrap resources if any are left over from a previous deployment attempt:
   ```bash
   for i in $(sudo virsh list | tail -n +3 | grep bootstrap | awk '{print $2}');
   do
     sudo virsh destroy $i;
     sudo virsh undefine $i;
     sudo virsh vol-delete $i --pool $i;
     sudo virsh vol-delete $i.ign --pool $i;
     sudo virsh pool-destroy $i;
     sudo virsh pool-undefine $i;
   done
   ``

3. Remove the following from the `clusterconfigs` directory to prevent Terraform from failing:
   ```bash
   $ rm -rf ~/clusterconfigs/auth ~/clusterconfigs/terraform* ~/clusterconfigs/tls ~/clusterconfigs/metadata.json
   ``

### 16.6.9. Issues with creating the registry

When creating a disconnected registry, you might encounter a "User Not Authorized" error when attempting to mirror the registry. This error might occur if you fail to append the new authentication to the existing `pull-secret.txt` file.

**Procedure**

1. Check to ensure authentication is successful:
   ```bash
   $ /usr/local/bin/oc adm release mirror \
   --from=$UPSTREAM_REPO \
   --to-release-image=$LOCAL_REG/$LOCAL_REPO:$VERSION \n   --to=$LOCAL_REG/$LOCAL_REPO
   ```
NOTE

Example output of the variables used to mirror the install images:

```
UPSTREAM_REPO=${RELEASE_IMAGE}
LOCAL_REG=<registry_FQDN>:<registry_port>
LOCAL_REPO='ocp4/openshift4'
```

The values of `RELEASE_IMAGE` and `VERSION` were set during the `Retrieving OpenShift Installer` step of the `Setting up the environment for an OpenShift installation` section.

2. After mirroring the registry, confirm that you can access it in your disconnected environment:

```
$ curl -k -u <user>:<password> https://registry.example.com:<registry_port>/v2/_catalog
{"repositories":["<Repo_Name>"]}
```

16.6.10. Miscellaneous issues

16.6.10.1. Addressing the runtime network not ready error

After the deployment of a cluster you might receive the following error:

```
```

The Cluster Network Operator is responsible for deploying the networking components in response to a special object created by the installer. It runs very early in the installation process, after the control plane (master) nodes have come up, but before the bootstrap control plane has been torn down. It can be indicative of more subtle installer issues, such as long delays in bringing up control plane (master) nodes or issues with `apiserver` communication.

Procedure

1. Inspect the pods in the `openshift-network-operator` namespace:

```
$ oc get all -n openshift-network-operator
```

```
NAME                                    READY STATUS            RESTARTS   AGE
pod/network-operator-69dfd7b577-bg89v   0/1   ContainerCreating 0          149m
```

2. On the `provisioner` node, determine that the network configuration exists:

```
$ kubectl get network.config.openshift.io cluster -oyaml
```

```
apiVersion: config.openshift.io/v1
kind: Network
metadata:
  name: cluster
spec:
  serviceNetwork:
    - 172.30.0.0/16
```
If it does not exist, the installer did not create it. To determine why the installer did not create it, execute the following:

3. Check that the **network-operator** is running:

   ```
   $ kubectl -n openshift-network-operator get pods
   ```

4. Retrieve the logs:

   ```
   $ kubectl -n openshift-network-operator logs -l "name=network-operator"
   ```

On high availability clusters with three or more control plane (master) nodes, the Operator will perform leader election and all other Operators will sleep. For additional details, see **Troubleshooting**.

### 16.6.10.2. Addressing the "No disk found with matching rootDeviceHints" error message

After you deploy a cluster, you might receive the following error message:

```
No disk found with matching rootDeviceHints
```

To address the `No disk found with matching rootDeviceHints` error message, a temporary workaround is to change the `rootDeviceHints` to `minSizeGigabytes: 300`.

After you change the `rootDeviceHints` settings, boot the CoreOS and then verify the disk information by using the following command:

```
$ udevadm info /dev/sda
```

If you are using DL360 Gen 10 servers, be aware that they have an SD-card slot that might be assigned the `/dev/sda` device name. If no SD card is present in the server, it can cause conflicts. Ensure that the SD card slot is disabled in the server’s BIOS settings.

If the `minSizeGigabytes` workaround is not fulfilling the requirements, you might need to revert `rootDeviceHints` back to `/dev/sda`. This change allows ironic images to boot successfully.

An alternative approach to fixing this problem is by using the serial ID of the disk. However, be aware that finding the serial ID can be challenging and might make the configuration file less readable. If you choose this path, ensure that you gather the serial ID using the previously documented command and incorporate it into your configuration.

### 16.6.10.3. Cluster nodes not getting the correct IPv6 address over DHCP

If the cluster nodes are not getting the correct IPv6 address over DHCP, check the following:

1. Ensure the reserved IPv6 addresses reside outside the DHCP range.
2. In the IP address reservation on the DHCP server, ensure the reservation specifies the correct DHCP Unique Identifier (DUID). For example:

```
# This is a dnsmasq dhcp reservation, 'id:00:03:00:01' is the client id and '18:db:f2:8c:d5:9f' is
# the MAC Address for the NIC
id:00:03:00:01:18:db:f2:8c:d5:9f,openshift-master-1,[2620:52:0:1302::6]
```

3. Ensure that route announcements are working.

4. Ensure that the DHCP server is listening on the required interfaces serving the IP address ranges.

### 16.6.10.4. Cluster nodes not getting the correct hostname over DHCP

During IPv6 deployment, cluster nodes must get their hostname over DHCP. Sometimes the `NetworkManager` does not assign the hostname immediately. A control plane (master) node might report an error such as:

```
Failed Units: 2
NetworkManager-wait-online.service
nodeip-configuration.service
```

This error indicates that the cluster node likely booted without first receiving a hostname from the DHCP server, which causes `kubelet` to boot with a `localhost.localdomain` hostname. To address the error, force the node to renew the hostname.

**Procedure**

1. Retrieve the hostname:

   ```
   [core@master-X ~]$ hostname
   ```

   If the hostname is `localhost`, proceed with the following steps.

   ```
   NOTE
   Where X is the control plane node number.
   ```

2. Force the cluster node to renew the DHCP lease:

   ```
   [core@master-X ~]$ sudo nmcli con up "<bare_metal_nic>"
   ```

   Replace `<bare_metal_nic>` with the wired connection corresponding to the `baremetal` network.

3. Check hostname again:

   ```
   [core@master-X ~]$ hostname
   ```

4. If the hostname is still `localhost.localdomain`, restart `NetworkManager`:

   ```
   [core@master-X ~]$ sudo systemctl restart NetworkManager
   ```
5. If the hostname is still `localhost.localdomain`, wait a few minutes and check again. If the hostname remains `localhost.localdomain`, repeat the previous steps.

6. Restart the `nodeip-configuration` service:
   ```bash
   [core@master-X ~]$ sudo systemctl restart nodeip-configuration.service
   
   This service will reconfigure the `kubelet` service with the correct hostname references.
   ```

7. Reload the unit files definition since the kubelet changed in the previous step:
   ```bash
   [core@master-X ~]$ sudo systemctl daemon-reload
   ```

8. Restart the `kubelet` service:
   ```bash
   [core@master-X ~]$ sudo systemctl restart kubelet.service
   ```

9. Ensure `kubelet` booted with the correct hostname:
   ```bash
   [core@master-X ~]$ sudo journalctl -fu kubelet.service
   ```

If the cluster node is not getting the correct hostname over DHCP after the cluster is up and running, such as during a reboot, the cluster will have a pending **csr**. Do not approve a **csr**, or other issues might arise.

### Addressing a csr

1. Get CSRs on the cluster:
   ```bash
   $ oc get csr
   ```

2. Verify if a pending **csr** contains **Subject Name: localhost.localdomain**:
   ```bash
   $ oc get csr <pending_csr> -o jsonpath='{.spec.request}' | base64 --decode | openssl req -noout -text
   ```

3. Remove any **csr** that contains **Subject Name: localhost.localdomain**:
   ```bash
   $ oc delete csr <wrong_csr>
   ```

### 16.6.10.5. Routes do not reach endpoints

During the installation process, it is possible to encounter a Virtual Router Redundancy Protocol (VRRP) conflict. This conflict might occur if a previously used OpenShift Container Platform node that was once part of a cluster deployment using a specific cluster name is still running but not part of the current OpenShift Container Platform cluster deployment using that same cluster name. For example, a cluster was deployed using the cluster name `openshift`, deploying three control plane (master) nodes and three worker nodes. Later, a separate install uses the same cluster name `openshift`, but this redeployment only installed three control plane (master) nodes, leaving the three worker nodes from a previous deployment in an **ON** state. This might cause a Virtual Router Identifier (VRID) conflict and a VRRP conflict.

1. Get the route:
2. Check the service endpoint:

$ oc get route oauth-openshift

3. Attempt to reach the service from a control plane (master) node:

$ oc get svc oauth-openshift

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>CLUSTER-IP</th>
<th>EXTERNAL-IP</th>
<th>PORT(S)</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>oauth-openshift</td>
<td>ClusterIP</td>
<td>172.30.19.162</td>
<td>&lt;none&gt;</td>
<td>443/TCP</td>
<td>59m</td>
</tr>
</tbody>
</table>

3. Attempt to reach the service from a control plane (master) node:

[core@master0 ~] $ curl -k https://172.30.19.162

```json
{
    "kind": "Status",
    "apiVersion": "v1",
    "metadata": {
    },
    "status": "Failure",
    "message": "forbidden: User "system:anonymous" cannot get path """,
    "reason": "Forbidden",
    "details": {
    },
    "code": 403
}
```

4. Identify the authentication-operator errors from the provisioner node:

$ oc logs deployment/authentication-operator -n openshift-authentication-operator

```
```

Solution

1. Ensure that the cluster name for every deployment is unique, ensuring no conflict.

2. Turn off all the rogue nodes which are not part of the cluster deployment that are using the same cluster name. Otherwise, the authentication pod of the OpenShift Container Platform cluster might never start successfully.

16.6.10.6. Failed Ignition during Firstboot

During the Firstboot, the Ignition configuration may fail.

Procedure

1. Connect to the node where the Ignition configuration failed:
Failed Units: 1
machine-config-daemon-firstboot.service

2. Restart the `machine-config-daemon-firstboot` service:

```
[core@worker-X ~]$ sudo systemctl restart machine-config-daemon-firstboot.service
```

16.6.10.7. NTP out of sync

The deployment of OpenShift Container Platform clusters depends on NTP synchronized clocks among the cluster nodes. Without synchronized clocks, the deployment may fail due to clock drift if the time difference is greater than two seconds.

**Procedure**

1. Check for differences in the **AGE** of the cluster nodes. For example:

```
$ oc get nodes
```

```
NAME                                 STATUS   ROLES      AGE     VERSION  
master-0.cloud.example.com           Ready    master    145m     v1.27.3  
master-1.cloud.example.com           Ready    master    135m     v1.27.3  
master-2.cloud.example.com           Ready    master    145m     v1.27.3  
worker-2.cloud.example.com           Ready    worker    100m     v1.27.3  
```

2. Check for inconsistent timing delays due to clock drift. For example:

```
$ oc get bmh -n openshift-machine-api
```

```
master-1   error registering master-1  ipmi://<out_of_band_ip>
```

```
$ sudo timedatectl
```

```
Local time: Tue 2020-03-10 18:20:02 UTC
Universal time: Tue 2020-03-10 18:20:02 UTC
RTC time: Tue 2020-03-10 18:36:53
Time zone: UTC (UTC, +0000)
System clock synchronized: no
NTP service: active
RTC in local TZ: no
```

**Addressing clock drift in existing clusters**

1. Create a Butane config file including the contents of the `chrony.conf` file to be delivered to the nodes. In the following example, create `99-master-chrony.bu` to add the file to the control plane nodes. You can modify the file for worker nodes or repeat this procedure for the worker role.

```
NOTE
See "Creating machine configs with Butane" for information about Butane.
```

2416
1. Replace `<NTP_server>` with the IP address of the NTP server.

2. Use Butane to generate a `MachineConfig` object file, `99-master-chrony.yaml`, containing the configuration to be delivered to the nodes:

```
$ butane 99-master-chrony.bu -o 99-master-chrony.yaml
```

3. Apply the `MachineConfig` object file:

```
$ oc apply -f 99-master-chrony.yaml
```

4. Ensure the `System clock synchronized` value is `yes`:

```
$ sudo timedatectl
```

```
Local time: Tue 2020-03-10 19:10:02 UTC
Universal time: Tue 2020-03-10 19:10:02 UTC
  RTC time: Tue 2020-03-10 19:36:53
Time zone: UTC (UTC, +0000)
System clock synchronized: yes
  NTP service: active
  RTC in local TZ: no
```

To setup clock synchronization prior to deployment, generate the manifest files and add this file to the `openshift` directory. For example:
Then, continue to create the cluster.

### 16.6.11. Reviewing the installation

After installation, ensure the installer deployed the nodes and pods successfully.

**Procedure**

1. When the OpenShift Container Platform cluster nodes are installed appropriately, the following *Ready* state is seen within the *STATUS* column:

   ```bash
   $ oc get nodes
   NAME                   STATUS   ROLES           AGE  VERSION
   master-0.example.com   Ready    master,worker   4h   v1.27.3
   master-1.example.com   Ready    master,worker   4h   v1.27.3
   master-2.example.com   Ready    master,worker   4h   v1.27.3
   ```

2. Confirm the installer deployed all pods successfully. The following command removes any pods that are still running or have completed as part of the output.

   ```bash
   $ oc get pods --all-namespaces | grep -iv running | grep -iv complete
   ```
CHAPTER 17. INSTALLING IBM CLOUD BARE METAL (CLASSIC)

17.1. PREREQUISITES

You can use installer-provisioned installation to install OpenShift Container Platform on IBM Cloud® Bare Metal (Classic) nodes. This document describes the prerequisites and procedures when installing OpenShift Container Platform on IBM Cloud® nodes.

**IMPORTANT**

Red Hat supports IPMI and PXE on the provisioning network only. Red Hat has not tested Red Fish, virtual media, or other complementary technologies such as Secure Boot on IBM Cloud® deployments. A provisioning network is required.

Installer-provisioned installation of OpenShift Container Platform requires:

- One node with Red Hat Enterprise Linux CoreOS (RHCOS) 8.x installed, for running the provisioner
- Three control plane nodes
- One routable network
- One provisioning network

Before starting an installer-provisioned installation of OpenShift Container Platform on IBM Cloud® Bare Metal (Classic), address the following prerequisites and requirements.

17.1.1. Setting up IBM Cloud Bare Metal (Classic) infrastructure

To deploy an OpenShift Container Platform cluster on IBM Cloud® Bare Metal (Classic) infrastructure, you must first provision the IBM Cloud® nodes.

**IMPORTANT**

Red Hat supports IPMI and PXE on the **provisioning** network only. Red Hat has not tested Red Fish, virtual media, or other complementary technologies such as Secure Boot on IBM Cloud® deployments. The **provisioning** network is required.

You can customize IBM Cloud® nodes using the IBM Cloud® API. When creating IBM Cloud® nodes, you must consider the following requirements.

**Use one data center per cluster**

All nodes in the OpenShift Container Platform cluster must run in the same IBM Cloud® data center.

**Create public and private VLANs**

Create all nodes with a single public VLAN and a single private VLAN.

**Ensure subnets have sufficient IP addresses**

IBM Cloud® public VLAN subnets use a /28 prefix by default, which provides 16 IP addresses. That is sufficient for a cluster consisting of three control plane nodes, four worker nodes, and two IP addresses for the API VIP and Ingress VIP on the **baremetal** network. For larger clusters, you might need a smaller
IBM Cloud® private VLAN subnets use a /26 prefix by default, which provides 64 IP addresses. IBM Cloud® Bare Metal (Classic) uses private network IP addresses to access the Baseboard Management Controller (BMC) of each node. OpenShift Container Platform creates an additional subnet for the **provisioning** network. Network traffic for the **provisioning** network subnet routes through the private VLAN. For larger clusters, you might need a smaller prefix.

**Table 17.1. IP addresses per prefix**

<table>
<thead>
<tr>
<th>IP addresses</th>
<th>Prefix</th>
</tr>
</thead>
<tbody>
<tr>
<td>32</td>
<td>/27</td>
</tr>
<tr>
<td>64</td>
<td>/26</td>
</tr>
<tr>
<td>128</td>
<td>/25</td>
</tr>
<tr>
<td>256</td>
<td>/24</td>
</tr>
</tbody>
</table>

**Configuring NICs**

OpenShift Container Platform deploys with two networks:

- **provisioning**: The **provisioning** network is a non-routable network used for provisioning the underlying operating system on each node that is a part of the OpenShift Container Platform cluster.

- **baremetal**: The **baremetal** network is a routable network. You can use any NIC order to interface with the **baremetal** network, provided it is not the NIC specified in the **provisioningNetworkInterface** configuration setting or the NIC associated to a node’s **bootMACAddress** configuration setting for the **provisioning** network.

While the cluster nodes can contain more than two NICs, the installation process only focuses on the first two NICs. For example:

<table>
<thead>
<tr>
<th>NIC</th>
<th>Network</th>
<th>VLAN</th>
</tr>
</thead>
<tbody>
<tr>
<td>NIC1</td>
<td><strong>provisioning</strong></td>
<td>&lt;provisioning_vlan&gt;</td>
</tr>
<tr>
<td>NIC2</td>
<td><strong>baremetal</strong></td>
<td>&lt;baremetal_vlan&gt;</td>
</tr>
</tbody>
</table>

In the previous example, NIC1 on all control plane and worker nodes connects to the non-routable network (**provisioning**) that is only used for the installation of the OpenShift Container Platform cluster. NIC2 on all control plane and worker nodes connects to the routable **baremetal** network.

<table>
<thead>
<tr>
<th>PXE</th>
<th>Boot order</th>
</tr>
</thead>
<tbody>
<tr>
<td>NIC1 PXE-enabled <strong>provisioning</strong> network</td>
<td>1</td>
</tr>
<tr>
<td>NIC2 <strong>baremetal</strong> network.</td>
<td>2</td>
</tr>
</tbody>
</table>
NOTE
Ensure PXE is enabled on the NIC used for the provision network and is disabled on all other NICs.

Configuring canonical names
Clients access the OpenShift Container Platform cluster nodes over the baremetal network. Configure IBM Cloud® subdomains or subzones where the canonical name extension is the cluster name.

```
<cluster_name>.<domain>
```

For example:

```
test-cluster.example.com
```

Creating DNS entries
You must create DNS A record entries resolving to unused IP addresses on the public subnet for the following:

<table>
<thead>
<tr>
<th>Usage</th>
<th>Host Name</th>
<th>IP</th>
</tr>
</thead>
<tbody>
<tr>
<td>API</td>
<td>api.&lt;cluster_name&gt;.&lt;domain&gt;</td>
<td>&lt;ip&gt;</td>
</tr>
<tr>
<td>Ingress LB (apps)</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;domain&gt;</td>
<td>&lt;ip&gt;</td>
</tr>
</tbody>
</table>

Control plane and worker nodes already have DNS entries after provisioning.

The following table provides an example of fully qualified domain names. The API and Nameserver addresses begin with canonical name extensions. The host names of the control plane and worker nodes are examples, so you can use any host naming convention you prefer.

<table>
<thead>
<tr>
<th>Usage</th>
<th>Host Name</th>
<th>IP</th>
</tr>
</thead>
<tbody>
<tr>
<td>API</td>
<td>api.&lt;cluster_name&gt;.&lt;domain&gt;</td>
<td>&lt;ip&gt;</td>
</tr>
<tr>
<td>Ingress LB (apps)</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;domain&gt;</td>

</tbody>
</table>
OpenShift Container Platform includes functionality that uses cluster membership information to generate A records. This resolves the node names to their IP addresses. After the nodes are registered with the API, the cluster can disperse node information without using CoreDNS-mDNS. This eliminates the network traffic associated with multicast DNS.

**IMPORTANT**

After provisioning the IBM Cloud® nodes, you must create a DNS entry for the api.<cluster_name>.<domain> domain name on the external DNS because removing CoreDNS causes the local entry to disappear. Failure to create a DNS record for the api.<cluster_name>.<domain> domain name in the external DNS server prevents worker nodes from joining the cluster.

**Network Time Protocol (NTP)**

Each OpenShift Container Platform node in the cluster must have access to an NTP server. OpenShift Container Platform nodes use NTP to synchronize their clocks. For example, cluster nodes use SSL certificates that require validation, which might fail if the date and time between the nodes are not in sync.

**IMPORTANT**

Define a consistent clock date and time format in each cluster node’s BIOS settings, or installation might fail.

**Configure a DHCP server**

IBM Cloud® Bare Metal (Classic) does not run DHCP on the public or private VLANs. After provisioning IBM Cloud® nodes, you must set up a DHCP server for the public VLAN, which corresponds to OpenShift Container Platform’s baremetal network.

**NOTE**

The IP addresses allocated to each node do not need to match the IP addresses allocated by the IBM Cloud® Bare Metal (Classic) provisioning system.

See the “Configuring the public subnet” section for details.

**Ensure BMC access privileges**

The “Remote management” page for each node on the dashboard contains the node’s intelligent platform management interface (IPMI) credentials. The default IPMI privileges prevent the user from...
making certain boot target changes. You must change the privilege level to `OPERATOR` so that Ironic can make those changes.

In the `install-config.yaml` file, add the `privilegelevel` parameter to the URLs used to configure each BMC. See the "Configuring the install-config.yaml file" section for additional details. For example:

```
ipmi://<IP>:<port>?privilegelevel=OPERATOR
```

Alternatively, contact IBM Cloud® support and request that they increase the IPMI privileges to `ADMINISTRATOR` for each node.

Create bare metal servers
Create bare metal servers in the IBM Cloud® dashboard by navigating to `Create resource → Bare Metal Servers for Classic`.

Alternatively, you can create bare metal servers with the `ibmcloud` CLI utility. For example:

```
$ ibmcloud sl hardware create --hostname <SERVERNAME> \
   --domain <DOMAIN> \
   --size <SIZE> \
   --os <OS-TYPE> \
   --datacenter <DC-NAME> \
   --port-speed <SPEED> \
   --billing <BILLING>
```

See [Installing the stand-alone IBM Cloud® CLI](#) for details on installing the IBM Cloud® CLI.

**NOTE**

IBM Cloud® servers might take 3–5 hours to become available.

17.2. SETTING UP THE ENVIRONMENT FOR AN OPENSHPIFT CONTAINER PLATFORM INSTALLATION

17.2.1. Preparing the provisioner node on IBM Cloud(R) Bare Metal (Classic) infrastructure

Perform the following steps to prepare the provisioner node.

**Procedure**

1. Log in to the provisioner node via `ssh`.
2. Create a non-root user (`kni`) and provide that user with `sudo` privileges:

   ```
   # useradd kni
   # passwd kni
   # echo "kni ALL=(root) NOPASSWD:ALL" | tee -a /etc/sudoers.d/kni
   # chmod 0440 /etc/sudoers.d/kni
   ```
3. Create an **ssh** key for the new user:

```bash
# su - kni -c "ssh-keygen -f /home/kni/.ssh/id_rsa -N ""
```

4. Log in as the new user on the provisioner node:

```bash
# su - kni
```

5. Use Red Hat Subscription Manager to register the provisioner node:

```bash
$ sudo subscription-manager register --username=<user> --password=<pass> --auto-attach

$ sudo subscription-manager repos --enable=rhel-8-for-x86_64-appstream-rpms \
   --enable=rhel-8-for-x86_64-baseos-rpms
```

**NOTE**
For more information about Red Hat Subscription Manager, see Using and Configuring Red Hat Subscription Manager.

6. Install the following packages:

```bash
$ sudo dnf install -y libvirt qemu-kvm mkisofs python3-devel jq ipmitool
```

7. Modify the user to add the **libvirt** group to the newly created user:

```bash
$ sudo usermod --append --groups libvirt kni
```

8. Start **firewalld**:

```bash
$ sudo systemctl start firewalld
```

9. Enable **firewalld**:

```bash
$ sudo systemctl enable firewalld
```

10. Start the **http** service:

```bash
$ sudo firewall-cmd --zone=public --add-service=http --permanent

$ sudo firewall-cmd --reload
```

11. Start and enable the **libvirtd** service:

```bash
$ sudo systemctl enable libvirtd --now
```

12. Set the ID of the provisioner node:

```bash
$ PRVN_HOST_ID=<ID>
```
You can view the ID with the following `ibmcloud` command:

$ ibmcloud sl hardware list

13. Set the ID of the public subnet:

$ PUBLICSUBNETID=<ID>

You can view the ID with the following `ibmcloud` command:

$ ibmcloud sl subnet list

14. Set the ID of the private subnet:

$ PRIVSUBNETID=<ID>

You can view the ID with the following `ibmcloud` command:

$ ibmcloud sl subnet list

15. Set the provisioner node public IP address:

$ PRVN_PUB_IP=$(ibmcloud sl hardware detail $PRVN_HOST_ID --output JSON | jq .primaryIpAddress -r)

16. Set the CIDR for the public network:

$ PUBLICCIDR=$(ibmcloud sl subnet detail $PUBLICSUBNETID --output JSON | jq .cidr)

17. Set the IP address and CIDR for the public network:

$ PUB_IP_CIDR=$PRVN_PUB_IP/$PUBLICCIDR

18. Set the gateway for the public network:

$ PUB_GATEWAY=$(ibmcloud sl subnet detail $PUBLICSUBNETID --output JSON | jq .gateway -r)

19. Set the private IP address of the provisioner node:

$ PRVN_PRIV_IP=$(ibmcloud sl hardware detail $PRVN_HOST_ID --output JSON | \
jq .primaryBackendIpAddress -r)

20. Set the CIDR for the private network:

$ PRIVCIDR=$(ibmcloud sl subnet detail $PRIVSUBNETID --output JSON | jq .cidr)

21. Set the IP address and CIDR for the private network:

$ PRIV_IP_CIDR=$PRVN_PRIV_IP/$PRIVCIDR
22. Set the gateway for the private network:

```
$ PRIV_GATEWAY=$(ibmcloud sl subnet detail $PRIVSUBNETID --output JSON | jq .gateway -r)
```

23. Set up the bridges for the **baremetal** and **provisioning** networks:

```
$ sudo nohup bash -c "
   nmcli --get-values UUID con show | xargs -n 1 nmcli con delete
   nmcli connection add ifname provisioning type bridge con-name provisioning
   nmcli con add type bridge-slave ifname eth1 master provisioning
   nmcli connection add ifname baremetal type bridge con-name baremetal
   nmcli con add type bridge-slave ifname eth2 master baremetal
   nmcli connection modify baremetal ipv4.addresses $PUB_IP_CIDR ipv4.method manual
   ipv4.gateway $PUB_GATEWAY
   nmcli connection modify provisioning ipv4.addresses 172.22.0.1/24,$PRIV_IP_CIDR
   ipv4.method manual
   nmcli connection modify provisioning +ipv4.routes "10.0.0.0/8 $PRIV_GATEWAY"
   nmcli con down baremetal
   nmcli con up baremetal
   nmcli con down provisioning
   nmcli con up provisioning
   init 6
"
```

**NOTE**

For **eth1** and **eth2**, substitute the appropriate interface name, as needed.

24. If required, SSH back into the **provisioner** node:

```
# ssh kni@provisioner.<cluster-name>.<domain>
```

25. Verify the connection bridges have been properly created:

```
$ sudo nmcli con show
```

### Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>UUID</th>
<th>TYPE</th>
<th>DEVICE</th>
</tr>
</thead>
<tbody>
<tr>
<td>baremetal</td>
<td>4d5133a5-8351-4bb9-bfd4-3af264801530</td>
<td>bridge</td>
<td>baremetal</td>
</tr>
<tr>
<td>provisioning</td>
<td>43942805-017f-4d7d-a2c2-7cb3324482ed</td>
<td>bridge</td>
<td>provisioning</td>
</tr>
<tr>
<td>virbr0</td>
<td>d9bca40f-eee1-410b-8879-a2d4bb0465e7</td>
<td>bridge</td>
<td>virbr0</td>
</tr>
<tr>
<td>bridge-slave-eth1</td>
<td>76a8ed50-c7e5-4999-b416-6d9014dd0812</td>
<td>ethernet</td>
<td>eth1</td>
</tr>
<tr>
<td>bridge-slave-eth2</td>
<td>f31c3353-54b7-48de-893a-02d2b34c4736</td>
<td>ethernet</td>
<td>eth2</td>
</tr>
</tbody>
</table>

26. Create a **pull-secret.txt** file:

```
$ vim pull-secret.txt
```

In a web browser, navigate to [Install on Bare Metal with user-provisioned infrastructure](https://docs.openshift.com). In step 1, click **Download pull secret**. Paste the contents into the **pull-secret.txt** file and save the contents in the **kni** user’s home directory.
17.2.2. Configuring the public subnet

All of the OpenShift Container Platform cluster nodes must be on the public subnet. IBM Cloud Bare Metal (Classic) does not provide a DHCP server on the subnet. Set it up separately on the provisioner node.

You must reset the BASH variables defined when preparing the provisioner node. Rebooting the provisioner node after preparing it will delete the BASH variables previously set.

Procedure

1. Install **dnsmasq**:

   ```
   $ sudo dnf install dnsmasq
   ```

2. Open the **dnsmasq** configuration file:

   ```
   $ sudo vi /etc/dnsmasq.conf
   ```

3. Add the following configuration to the **dnsmasq** configuration file:

   ```
   interface=baremetal
   except-interface=lo
   bind-dynamic
   log-dhcp

   dhcp-range=<ip_addr>,<ip_addr>,<pub_cidr> 1
   dhcp-option=baremetal,121,0.0.0.0/0,<pub_gateway>,<prvn_priv_ip>,<prvn_pub_ip> 2

   dhcp-hostsfile=/var/lib/dnsmasq/dnsmasq.hostsfile
   ```

   **1** Set the DHCP range. Replace both instances of `<ip_addr>` with one unused IP address from the public subnet so that the dhcp-range for the baremetal network begins and ends with the same IP address. Replace `<pub_cidr>` with the CIDR of the public subnet.

   **2** Set the DHCP option. Replace `<pub_gateway>` with the IP address of the gateway for the baremetal network. Replace `<prvn_priv_ip>` with the IP address of the provisioner node’s private IP address on the provisioning network. Replace `<prvn_pub_ip>` with the IP address of the provisioner node’s public IP address on the baremetal network.

To retrieve the value for `<pub_cidr>`, execute:

```
$ ibmcloud sl subnet detail <publicsubnetid> --output JSON | jq .cidr
```

Replace `<publicsubnetid>` with the ID of the public subnet.

To retrieve the value for `<pub_gateway>`, execute:

```
$ ibmcloud sl subnet detail <publicsubnetid> --output JSON | jq .gateway -r
```

Replace `<publicsubnetid>` with the ID of the public subnet.
To retrieve the value for `<prvn_priv_ip>`, execute:

```
$ ibmcloud sl hardware detail <id> --output JSON | \ 
  jq .primaryBackendIpAddress -r
```

Replace `<id>` with the ID of the provisioner node.

To retrieve the value for `<prvn_pub_ip>`, execute:

```
$ ibmcloud sl hardware detail <id> --output JSON | jq .primaryIpAddress -r
```

Replace `<id>` with the ID of the provisioner node.

4. Obtain the list of hardware for the cluster:

```
$ ibmcloud sl hardware list
```

5. Obtain the MAC addresses and IP addresses for each node:

```
$ ibmcloud sl hardware detail <id> --output JSON | \ 
  jq ".networkComponents[] | \ 
  "(.primaryIpAddress) (.macAddress)"" | grep -v null
```

Replace `<id>` with the ID of the node.

**Example output**

```
"10.196.130.144 00:e0:ed:6a:ca:b4"
"141.125.65.215 00:e0:ed:6a:ca:b5"
```

Make a note of the MAC address and IP address of the public network. Make a separate note of the MAC address of the private network, which you will use later in the `install-config.yaml` file. Repeat this procedure for each node until you have all the public MAC and IP addresses for the public **baremetal** network, and the MAC addresses of the private **provisioning** network.

6. Add the MAC and IP address pair of the public **baremetal** network for each node into the `dnsmasq.hostsfile` file:

```
$ sudo vim /var/lib/dnsmasq/dnsmasq.hostsfile
```

**Example input**

```
00:e0:ed:6a:ca:b5,141.125.65.215,master-0
<mac>,<ip>,master-1
<mac>,<ip>,master-2
<mac>,<ip>,worker-0
<mac>,<ip>,worker-1
...
```

Replace `<mac>,<ip>` with the public MAC address and public IP address of the corresponding node name.

7. Start `dnsmasq`:  

---

2428
8. Enable **dnsmasq** so that it starts when booting the node:

   ```bash
   $ sudo systemctl start dnsmasq
   $ sudo systemctl enable dnsmasq
   ```

9. Verify **dnsmasq** is running:

   ```bash
   $ sudo systemctl status dnsmasq
   ```

**Example output**

```
● dnsmasq.service - DNS caching server.
Loaded: loaded (/usr/lib/systemd/system/dnsmasq.service; enabled; vendor preset: disabled)
Active: active (running) since Tue 2021-10-05 05:04:14 CDT; 49s ago
Main PID: 3101 (dnsmasq)
Tasks: 1 (limit: 204038)
Memory: 732.0K
CGroup: /system.slice/dnsmasq.service
└─ 3101 /usr/sbin/dnsmasq -k
```

10. Open ports **53** and **67** with UDP protocol:

    ```bash
    $ sudo firewall-cmd --add-port 53/udp --permanent
    $ sudo firewall-cmd --add-port 67/udp --permanent
    ```

11. Add **provisioning** to the external zone with masquerade:

    ```bash
    $ sudo firewall-cmd --change-zone=provisioning --zone=external --permanent
    ```

    This step ensures network address translation for IPMI calls to the management subnet.

12. Reload the **firewalld** configuration:

    ```bash
    $ sudo firewall-cmd --reload
    ```

### 17.2.3. Retrieving the OpenShift Container Platform installer

Use the **stable-4.x** version of the installation program and your selected architecture to deploy the generally available stable version of OpenShift Container Platform:

```bash
$ export VERSION=stable-4.14
$ export RELEASE_ARCH=<architecture>
$ export RELEASE_IMAGE=$(curl -s https://mirror.openshift.com/pub/openshift-v4/$RELEASE_ARCH/clients/ocp/$VERSION/release.txt | grep 'Pull From: quay.io' | awk -F ' ' '{print $3}')
```
17.2.4. Extracting the OpenShift Container Platform installer

After retrieving the installer, the next step is to extract it.

Procedure

1. Set the environment variables:

   ```bash
   $ export cmd=openshift-baremetal-install
   $ export pullsecret_file=~/.pull-secret.txt
   $ export extract_dir=$(pwd)
   ```

2. Get the oc binary:

   ```bash
   $ curl -s https://mirror.openshift.com/pub/openshift-v4/clients/ocp/$VERSION/openshift-client-linux.tar.gz | tar zxvf -
   ```

3. Extract the installer:

   ```bash
   $ sudo cp oc /usr/local/bin
   $ oc adm release extract --registry-config "${pullsecret_file}" --command=$cmd --to "${extract_dir}" ${RELEASE_IMAGE}
   $ sudo cp openshift-baremetal-install /usr/local/bin
   ```

17.2.5. Configuring the install-config.yaml file

The `install-config.yaml` file requires some additional details. Most of the information is teaching the installer and the resulting cluster enough about the available IBM Cloud® Bare Metal (Classic) hardware so that it is able to fully manage it. The material difference between installing on bare metal and installing on IBM Cloud® Bare Metal (Classic) is that you must explicitly set the privilege level for IPMI in the BMC section of the `install-config.yaml` file.

Procedure

1. Configure `install-config.yaml`. Change the appropriate variables to match the environment, including `pullSecret` and `sshKey`.

   ```yaml
   apiVersion: v1
   baseDomain: <domain>
   metadata:
     name: <cluster_name>
   networking:
     machineNetwork:
       - cidr: <public-cidr>
     networkType: OVNKubernetes
   compute:
     - name: worker
   replicas: 2
   ```
The `bmc.address` provides a `privilegelevel` configuration setting with the value set to `OPERATOR`. This is required for IBM Cloud® Bare Metal (Classic) infrastructure.

Add the MAC address of the private provisioning network NIC for the corresponding node.

**NOTE**

You can use the `ibmcloud` command-line utility to retrieve the password.

```
$ ibmcloud sl hardware detail <id> --output JSON | \n  jq "(.networkManagementIpAddress) (.remoteManagementAccounts[0].password)"
```

Replace `<id>` with the ID of the node.

2. Create a directory to store the cluster configuration:

```
$ mkdir ~/clusterconfigs
```
3. Copy the `install-config.yaml` file into the directory:

   ```
   $ cp install-config.yaml ~/clusterconfig
   ```

4. Ensure all bare metal nodes are powered off prior to installing the OpenShift Container Platform cluster:

   ```
   $ ipmitool -I lanplus -U <user> -P <password> -H <management_server_ip> power off
   ```

5. Remove old bootstrap resources if any are left over from a previous deployment attempt:

   ```
   for i in $(sudo virsh list | tail -n +3 | grep bootstrap | awk '{print $2}');
   do
   sudo virsh destroy $i;
   sudo virsh undefine $i;
   sudo virsh vol-delete $i --pool $i;
   sudo virsh vol-delete $i.ign --pool $i;
   sudo virsh pool-destroy $i;
   sudo virsh pool-undefine $i;
   done
   ```

17.2.6. Additional install-config parameters

See the following tables for the required parameters, the `hosts` parameter, and the `bmc` parameter for the `install-config.yaml` file.

**Table 17.2. Required parameters**

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>baseDomain</code></td>
<td></td>
<td>The domain name for the cluster. For example, <code>example.com</code>.</td>
</tr>
<tr>
<td><code>bootMode</code></td>
<td><code>UEFI</code></td>
<td>The boot mode for a node. Options are <code>legacy</code>, <code>UEFI</code>, and <code>UEFISecureBoot</code>. If <code>bootMode</code> is not set, Ironic sets it while inspecting the node.</td>
</tr>
<tr>
<td><code>bootstrapExternalStaticDNS</code></td>
<td></td>
<td>The static network DNS of the bootstrap node. This can be useful in environments without a DHCP server.</td>
</tr>
<tr>
<td><code>bootstrapExternalStaticIP</code></td>
<td></td>
<td>The static IP address for the bootstrap VM. You must set this value when deploying a cluster with static IP addresses when there is no DHCP server on the bare-metal network.</td>
</tr>
<tr>
<td><code>bootstrapExternalStaticGateway</code></td>
<td></td>
<td>The static IP address of the gateway for the bootstrap VM. You must set this value when deploying a cluster with static IP addresses when there is no DHCP server on the bare-metal network.</td>
</tr>
<tr>
<td>Parameters</td>
<td>Default</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>------------------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>sshKey</td>
<td></td>
<td>The <code>sshKey</code> configuration setting contains the key in the <code>~/.ssh/id_rsa.pub</code> file required to access the control plane nodes and worker nodes. Typically, this key is from the <code>provisioner</code> node.</td>
</tr>
<tr>
<td>pullSecret</td>
<td></td>
<td>The <code>pullSecret</code> configuration setting contains a copy of the pull secret downloaded from the [Install OpenShift on Bare Metal] page when preparing the provisioner node.</td>
</tr>
<tr>
<td>metadata:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>name:</td>
<td></td>
<td>The name to be given to the OpenShift Container Platform cluster. For example, <code>openshift</code>.</td>
</tr>
<tr>
<td>networking:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>machineNetwork:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>- cidr:</td>
<td></td>
<td>The public CIDR (Classless Inter-Domain Routing) of the external network. For example, <code>10.0.0.0/24</code>.</td>
</tr>
<tr>
<td>compute:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>- name: worker</td>
<td></td>
<td>The OpenShift Container Platform cluster requires a name be provided for worker (or compute) nodes even if there are zero nodes.</td>
</tr>
<tr>
<td>compute:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>replicas:</td>
<td>2</td>
<td>Replicas sets the number of worker (or compute) nodes in the OpenShift Container Platform cluster.</td>
</tr>
<tr>
<td>controlPlane:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>name: master</td>
<td></td>
<td>The OpenShift Container Platform cluster requires a name for control plane (master) nodes.</td>
</tr>
<tr>
<td>controlPlane:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>replicas:</td>
<td>3</td>
<td>Replicas sets the number of control plane (master) nodes included as part of the OpenShift Container Platform cluster.</td>
</tr>
<tr>
<td>provisioningNetworkInterface</td>
<td></td>
<td>The name of the network interface on nodes connected to the provisioning network. For OpenShift Container Platform 4.9 and later releases, use the <code>bootMACAddress</code> configuration setting to enable Ironic to identify the IP address of the NIC instead of using the <code>provisioningNetworkInterface</code> configuration setting to identify the name of the NIC.</td>
</tr>
<tr>
<td>defaultMachinePlatform</td>
<td></td>
<td>The default configuration used for machine pools without a platform configuration.</td>
</tr>
</tbody>
</table>
apiVIPs

(Optional) The virtual IP address for Kubernetes API communication.

This setting must either be provided in the `install-config.yaml` file as a reserved IP from the MachineNetwork or preconfigured in the DNS so that the default name resolves correctly. Use the virtual IP address and not the FQDN when adding a value to the `apiVIPs` configuration setting in the `install-config.yaml` file. The primary IP address must be from the IPv4 network when using dual stack networking. If not set, the installation program uses `api.<cluster_name>.<base_domain>` to derive the IP address from the DNS.

**NOTE**

Before OpenShift Container Platform 4.12, the cluster installation program only accepted an IPv4 address or an IPv6 address for the `apiVIP` configuration setting. From OpenShift Container Platform 4.12 or later, the `apiVIP` configuration setting is deprecated. Instead, use a list format for the `apiVIPs` configuration setting to specify an IPv4 address, an IPv6 address or both IP address formats.

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>disableCertificateVerification</td>
<td>False</td>
<td><code>redfish</code> and <code>redfish-virtualmedia</code> need this parameter to manage BMC addresses. The value should be <code>True</code> when using a self-signed certificate for BMC addresses.</td>
</tr>
</tbody>
</table>
### ingressVIPs

(Optional) The virtual IP address for ingress traffic.

This setting must either be provided in the `install-config.yaml` file as a reserved IP from the MachineNetwork or preconfigured in the DNS so that the default name resolves correctly. Use the virtual IP address and not the FQDN when adding a value to the `ingressVIPs` configuration setting in the `install-config.yaml` file. The primary IP address must be from the IPv4 network when using dual stack networking. If not set, the installation program uses `test.apps.<cluster_name>.<base_domain>` to derive the IP address from the DNS.

**NOTE**

Before OpenShift Container Platform 4.12, the cluster installation program only accepted an IPv4 address or an IPv6 address for the `ingressVIP` configuration setting. In OpenShift Container Platform 4.12 and later, the `ingressVIP` configuration setting is deprecated. Instead, use a list format for the `ingressVIPs` configuration setting to specify an IPv4 addresses, an IPv6 addresses or both IP address formats.

### Table 17.3. Optional Parameters

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>provisioningDHCPRange</code></td>
<td>172.22.0.10,172.22.0.100</td>
<td>Defines the IP range for nodes on the provisioning network.</td>
</tr>
<tr>
<td><code>provisioningNetworkCIDR</code></td>
<td>172.22.0.0/24</td>
<td>The CIDR for the network to use for provisioning. This option is required when not using the default address range on the provisioning network.</td>
</tr>
<tr>
<td><code>clusterProvisioningIP</code></td>
<td>The third IP address of the <code>provisioningNetworkCIDR</code></td>
<td>The IP address within the cluster where the provisioning services run. Defaults to the third IP address of the provisioning subnet. For example, <strong>172.22.0.3</strong>.</td>
</tr>
<tr>
<td><code>bootstrapProvisioningIP</code></td>
<td>The second IP address of the <code>provisioningNetworkCIDR</code></td>
<td>The IP address on the bootstrap VM where the provisioning services run while the installer is deploying the control plane (master) nodes. Defaults to the second IP address of the provisioning subnet. For example, <strong>172.22.0.2</strong> or <strong>2620:52:0:1307::2</strong>.</td>
</tr>
<tr>
<td><code>externalBridge</code></td>
<td>baremetal</td>
<td>The name of the bare-metal bridge of the hypervisor attached to the bare-metal network.</td>
</tr>
<tr>
<td>Parameters</td>
<td>Default</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>provisioningBridge</td>
<td>provisioning</td>
<td>The name of the provisioning bridge on the provisioner host attached to the provisioning network.</td>
</tr>
<tr>
<td>architecture</td>
<td></td>
<td>Defines the host architecture for your cluster. Valid values are amd64 or arm64.</td>
</tr>
<tr>
<td>defaultMachine Platform</td>
<td></td>
<td>The default configuration used for machine pools without a platform configuration.</td>
</tr>
<tr>
<td>bootstrapOSImage</td>
<td></td>
<td>A URL to override the default operating system image for the bootstrap node. The URL must contain a SHA-256 hash of the image. For example: <a href="https://mirror.openshift.com/rhcos-">https://mirror.openshift.com/rhcos-</a>&lt;version&gt;-qemu.qcow2.gz?sha256=&lt;uncompressed_sha256&gt;.</td>
</tr>
</tbody>
</table>
| provisioningNetwork      |            | The provisioningNetwork configuration setting determines whether the cluster uses the provisioning network. If it does, the configuration setting also determines if the cluster manages the network.  

**Disabled**: Set this parameter to Disabled to disable the requirement for a provisioning network. When set to Disabled, you must only use virtual media based provisioning, or bring up the cluster using the assisted installer. If Disabled and using power management, BMCs must be accessible from the bare-metal network. If Disabled, you must provide two IP addresses on the bare-metal network that are used for the provisioning services.

**Managed**: Set this parameter to Managed, which is the default, to fully manage the provisioning network, including DHCP, TFTP, and so on.

**Unmanaged**: Set this parameter to Unmanaged to enable the provisioning network but take care of manual configuration of DHCP. Virtual media provisioning is recommended but PXE is still available if required.

| httpProxy                |            | Set this parameter to the appropriate HTTP proxy used within your environment.                                                               |
| httpsProxy               |            | Set this parameter to the appropriate HTTPS proxy used within your environment.                                                                |
| noProxy                  |            | Set this parameter to the appropriate list of exclusions for proxy usage within your environment.                                               |

**Hosts**

The hosts parameter is a list of separate bare metal assets used to build the cluster.
Table 17.4. Hosts

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td></td>
<td>The name of the BareMetalHost resource to associate with the details. For example, openshift-master-0.</td>
</tr>
<tr>
<td>role</td>
<td></td>
<td>The role of the bare metal node. Either master or worker.</td>
</tr>
<tr>
<td>bmc</td>
<td></td>
<td>Connection details for the baseboard management controller. See the BMC addressing section for additional details.</td>
</tr>
<tr>
<td>bootMACAddress</td>
<td></td>
<td>The MAC address of the NIC that the host uses for the provisioning network. Ironic retrieves the IP address using the bootMACAddress configuration setting. Then, it binds to the host.</td>
</tr>
</tbody>
</table>

**NOTE**
You must provide a valid MAC address from the host if you disabled the provisioning network.

| networkConfig | Set this optional parameter to configure the network interface of a host. See "(Optional) Configuring host network interfaces" for additional details. |

17.2.7. Root device hints

The rootDeviceHints parameter enables the installer to provision the Red Hat Enterprise Linux CoreOS (RHCOS) image to a particular device. The installer examines the devices in the order it discovers them, and compares the discovered values with the hint values. The installer uses the first discovered device that matches the hint value. The configuration can combine multiple hints, but a device must match all hints for the installer to select it.

Table 17.5. Subfields

<table>
<thead>
<tr>
<th>Subfield</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>deviceName</td>
<td>A string containing a Linux device name such as /dev/vda or /dev/disk/by-path/. It is recommended to use the /dev/disk/by-path/&lt;device_path&gt; link to the storage location. The hint must match the actual value exactly.</td>
</tr>
<tr>
<td>hctl</td>
<td>A string containing a SCSI bus address like 0:0:0:0. The hint must match the actual value exactly.</td>
</tr>
<tr>
<td>Subfield</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>model</td>
<td>A string containing a vendor-specific device identifier. The hint can be a substring of the actual value.</td>
</tr>
<tr>
<td>vendor</td>
<td>A string containing the name of the vendor or manufacturer of the device. The hint can be a substring of the actual value.</td>
</tr>
<tr>
<td>serialNumber</td>
<td>A string containing the device serial number. The hint must match the actual value exactly.</td>
</tr>
<tr>
<td>minSizeGigabytes</td>
<td>An integer representing the minimum size of the device in gigabytes.</td>
</tr>
<tr>
<td>wwn</td>
<td>A string containing the unique storage identifier. The hint must match the actual value exactly.</td>
</tr>
<tr>
<td>wwnWithExtension</td>
<td>A string containing the unique storage identifier with the vendor extension appended. The hint must match the actual value exactly.</td>
</tr>
<tr>
<td>wwnVendorExtension</td>
<td>A string containing the unique vendor storage identifier. The hint must match the actual value exactly.</td>
</tr>
<tr>
<td>rotational</td>
<td>A boolean indicating whether the device should be a rotating disk (true) or not (false).</td>
</tr>
</tbody>
</table>

**Example usage**

```
- name: master-0
  role: master
  bmc:
    address: ipmi://10.10.0.3:6203
    username: admin
    password: redhat
  bootMACAddress: de:ad:be:ef:00:40
  rootDeviceHints:
    deviceName: "/dev/sda"
```

**17.2.8. Creating the OpenShift Container Platform manifests**

1. Create the OpenShift Container Platform manifests.

   ```bash
   $ ./openshift-baremetal-install --dir ~/clusterconfigs create manifests
   INFO Consuming Install Config from target directory
   ```
17.2.9. Deploying the cluster via the OpenShift Container Platform installer

Run the OpenShift Container Platform installer:

```
$ ./openshift-baremetal-install --dir ~/clusterconfigs --log-level debug create cluster
```

17.2.10. Following the installation

During the deployment process, you can check the installation’s overall status by issuing the `tail` command to the `.openshift_install.log` log file in the install directory folder:

```
$ tail -f /path/to/install-dir/.openshift_install.log
```
CHAPTER 18. INSTALLING ON IBM Z AND IBM LINUXONE

18.1. PREPARING TO INSTALL ON IBM Z AND IBM LINUXONE

18.1.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- Before you begin the installation process, you must clean the installation directory. This ensures that the required installation files are created and updated during the installation process.
- You provisioned persistent storage using OpenShift Data Foundation or other supported storage protocols for your cluster. To deploy a private image registry, you must set up persistent storage with ReadWriteMany access.
- If you use a firewall, you configured it to allow the sites that your cluster requires access to.

NOTE

While this document refers only to IBM Z®, all information in it also applies to IBM® LinuxONE.

18.1.2. Choosing a method to install OpenShift Container Platform on IBM Z or IBM LinuxONE

You can install OpenShift Container Platform with the Assisted Installer. This method requires no setup for the installer, and is ideal for connected environments like IBM Z®. See Installing an on-premise cluster using the Assisted Installer for additional details.

You can also install OpenShift Container Platform on infrastructure that you provide. If you do not use infrastructure that the installation program provisions, you must manage and maintain the cluster resources yourself.

See the Installation process for more information about Assisted Installer and user-provisioned installation processes.

IMPORTANT

The steps for performing a user-provisioned infrastructure installation are provided as an example only. Installing a cluster with infrastructure you provide requires knowledge of the IBM Z® platform and the installation process of OpenShift Container Platform. Use the user-provisioned infrastructure installation instructions as a guide; you are free to create the required resources through other methods.

18.1.2.1. User-provisioned infrastructure installation of OpenShift Container Platform on IBM Z

User-provisioned infrastructure requires the user to provision all resources required by OpenShift Container Platform.
• **Installing a cluster with z/VM on IBM Z® and IBM® LinuxONE** You can install OpenShift Container Platform with z/VM on IBM Z® or IBM® LinuxONE infrastructure that you provision.

• **Installing a cluster with z/VM on IBM Z® and IBM® LinuxONE in a restricted network** You can install OpenShift Container Platform with z/VM on IBM Z® or IBM® LinuxONE infrastructure that you provision in a restricted or disconnected network, by using an internal mirror of the installation release content. You can use this method to install a cluster that does not require an active internet connection to obtain the software components. You can also use this installation method to ensure that your clusters only use container images that satisfy your organizational controls on external content.

• **Installing a cluster with RHEL KVM on IBM Z® and IBM® LinuxONE** You can install OpenShift Container Platform with KVM on IBM Z® or IBM® LinuxONE infrastructure that you provision.

• **Installing a cluster with RHEL KVM on IBM Z® and IBM® LinuxONE in a restricted network** You can install OpenShift Container Platform with RHEL KVM on IBM Z® or IBM® LinuxONE infrastructure that you provision in a restricted or disconnected network, by using an internal mirror of the installation release content. You can use this method to install a cluster that does not require an active internet connection to obtain the software components. You can also use this installation method to ensure that your clusters only use container images that satisfy your organizational controls on external content.

### 18.2. INSTALLING A CLUSTER WITH Z/VM ON IBM Z AND IBM LINUXONE

In OpenShift Container Platform version 4.14, you can install a cluster on IBM Z® or IBM® LinuxONE infrastructure that you provision.

**NOTE**

While this document refers only to IBM Z®, all information in it also applies to IBM® LinuxONE.

**IMPORTANT**

Additional considerations exist for non-bare metal platforms. Review the information in the guidelines for deploying OpenShift Container Platform on non-tested platforms before you install an OpenShift Container Platform cluster.

### 18.2.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- Before you begin the installation process, you must clean the installation directory. This ensures that the required installation files are created and updated during the installation process.
- You provisioned persistent storage using OpenShift Data Foundation or other supported storage protocols for your cluster. To deploy a private image registry, you must set up persistent storage with ReadWriteMany access.
- If you use a firewall, you configured it to allow the sites that your cluster requires access to.
NOTE

Be sure to also review this site list if you are configuring a proxy.

18.2.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager Hybrid Cloud Console to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- Access Quay.io to obtain the packages that are required to install your cluster.

- Obtain the packages that are required to perform cluster updates.

IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

18.2.3. Requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

This section describes the requirements for deploying OpenShift Container Platform on user-provisioned infrastructure.

18.2.3.1. Required machines for cluster installation

The smallest OpenShift Container Platform clusters require the following hosts:

**Table 18.1. Minimum required hosts**

<table>
<thead>
<tr>
<th>Hosts</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>One temporary bootstrap machine</td>
<td>The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.</td>
</tr>
<tr>
<td>Three control plane machines</td>
<td>The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.</td>
</tr>
<tr>
<td>At least two compute machines, which are also known as worker machines.</td>
<td>The workloads requested by OpenShift Container Platform users run on the compute machines.</td>
</tr>
</tbody>
</table>
IMPORTANT

To improve high availability of your cluster, distribute the control plane machines over different z/VM instances on at least two physical machines.

The bootstrap, control plane, and compute machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 9.2 and inherits all of its hardware certifications and requirements. See Red Hat Enterprise Linux technology capabilities and limits.

18.2.3.2. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

Table 18.2. Minimum resource requirements

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS</td>
<td>2</td>
<td>8 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
</tbody>
</table>

1. One physical core (IFL) provides two logical cores (threads) when SMT-2 is enabled. The hypervisor can provide two or more vCPUs.

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

Additional resources

- Optimizing storage

18.2.3.3. Minimum IBM Z system environment

You can install OpenShift Container Platform version 4.14 on the following IBM® hardware:

- IBM® z16 (all models), IBM® z15 (all models), IBM® z14 (all models)
- IBM® LinuxONE 4 (all models), IBM® LinuxONE III (all models), IBM® LinuxONE Emperor II, IBM® LinuxONE Rockhopper II

Hardware requirements

- The equivalent of six Integrated Facilities for Linux (IFL), which are SMT2 enabled, for each cluster.
- At least one network connection to both connect to the LoadBalancer service and to serve data for traffic outside the cluster.
NOTE
You can use dedicated or shared IFLs to assign sufficient compute resources. Resource sharing is one of the key strengths of IBM Z®. However, you must adjust capacity correctly on each hypervisor layer and ensure sufficient resources for every OpenShift Container Platform cluster.

IMPORTANT
Since the overall performance of the cluster can be impacted, the LPARs that are used to set up the OpenShift Container Platform clusters must provide sufficient compute capacity. In this context, LPAR weight management, entitlements, and CPU shares on the hypervisor level play an important role.

Operating system requirements
- One instance of z/VM 7.2 or later

On your z/VM instance, set up:
- Three guest virtual machines for OpenShift Container Platform control plane machines
- Two guest virtual machines for OpenShift Container Platform compute machines
- One guest virtual machine for the temporary OpenShift Container Platform bootstrap machine

IBM Z network connectivity requirements
To install on IBM Z® under z/VM, you require a single z/VM virtual NIC in layer 2 mode. You also need:
- A direct-attached OSA or RoCE network adapter
- A z/VM VSwitch set up. For a preferred setup, use OSA link aggregation.

Disk storage for the z/VM guest virtual machines
- FICON attached disk storage (DASDs). These can be z/VM minidisks, fullpack minidisks, or dedicated DASDs, all of which must be formatted as CDL, which is the default. To reach the minimum required DASD size for Red Hat Enterprise Linux CoreOS (RHCOS) installations, you need extended address volumes (EAV). If available, use HyperPAV to ensure optimal performance.
- FCP attached disk storage

Storage / Main Memory
- 16 GB for OpenShift Container Platform control plane machines
- 8 GB for OpenShift Container Platform compute machines
- 16 GB for the temporary OpenShift Container Platform bootstrap machine

18.2.3.4. Preferred IBM Z system environment

Hardware requirements
- Three LPARS that each have the equivalent of six IFLs, which are SMT2 enabled, for each cluster.
- Two network connections to both connect to the **LoadBalancer** service and to serve data for traffic outside the cluster.

- HiperSockets, which are attached to a node either directly as a device or by bridging with one z/VM VSWITCH to be transparent to the z/VM guest. To directly connect HiperSockets to a node, you must set up a gateway to the external network via a RHEL 8 guest to bridge to the HiperSockets network.

**Operating system requirements**

- Two or three instances of z/VM 7.2 or later for high availability

On your z/VM instances, set up:

- Three guest virtual machines for OpenShift Container Platform control plane machines, one per z/VM instance.

- At least six guest virtual machines for OpenShift Container Platform compute machines, distributed across the z/VM instances.

- One guest virtual machine for the temporary OpenShift Container Platform bootstrap machine.

- To ensure the availability of integral components in an overcommitted environment, increase the priority of the control plane by using the CP command **SET SHARE**. Do the same for infrastructure nodes, if they exist. See **SET SHARE** in IBM® Documentation.

**IBM Z network connectivity requirements**

To install on IBM Z® under z/VM, you require a single z/VM virtual NIC in layer 2 mode. You also need:

- A direct-attached OSA or RoCE network adapter

- A z/VM VSwitch set up. For a preferred setup, use OSA link aggregation.

**Disk storage for the z/VM guest virtual machines**

- FICON attached disk storage (DASDs). These can be z/VM minidisks, fullpack minidisks, or dedicated DASDs, all of which must be formatted as CDL, which is the default. To reach the minimum required DASD size for Red Hat Enterprise Linux CoreOS (RHCOS) installations, you need extended address volumes (EAV). If available, use HyperPAV and High Performance FICON (zHPF) to ensure optimal performance.

- FCP attached disk storage

**Storage / Main Memory**

- 16 GB for OpenShift Container Platform control plane machines

- 8 GB for OpenShift Container Platform compute machines

- 16 GB for the temporary OpenShift Container Platform bootstrap machine

**18.2.3.5. Certificate signing requests management**

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The **kube-controller-manager** only approves the kubelet client CSRs. The **machine-approver** cannot guarantee the validity of a serving certificate that is requested by using...
kubelet credentials because it cannot confirm that the correct machine issued the request. You must
determine and implement a method of verifying the validity of the kubelet serving certificate requests
and approving them.

Additional resources

- See Bridging a HiperSockets LAN with a z/VM Virtual Switch in IBM® Documentation.
- See Scaling HyperPAV alias devices on Linux guests on z/VM for performance optimization.
- See Topics in LPAR performance for LPAR weight management and entitlements.
- Recommended host practices for IBM Z® & IBM® LinuxONE environments

18.2.3.6. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in
`initramfs` during boot to fetch their Ignition config files.

During the initial boot, the machines require an HTTP or HTTPS server to establish a network connection
to download their Ignition config files.

The machines are configured with static IP addresses. No DHCP server is required. Ensure that the
machines have persistent IP addresses and hostnames.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API
servers and worker nodes are in different zones, you can configure a default DNS search zone to allow
the API server to resolve the node names. Another supported approach is to always refer to hosts by
their fully-qualified domain names in both the node objects and all DNS requests.

18.2.3.6.1. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform
cluster components to communicate. Each machine must be able to resolve the hostnames of all other
machines in the cluster.

This section provides details about the ports that are required.

**IMPORTANT**

In connected OpenShift Container Platform environments, all nodes are required to have
internet access to pull images for platform containers and provide telemetry data to Red Hat.

### Table 18.3. Ports used for all-machine to all-machine communications

<table>
<thead>
<tr>
<th>Protocol</th>

</tbody>
</table>

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Port</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>2379-2380</td>
<td>etcd server and peer ports</td>
</tr>
</tbody>
</table>

**NTP configuration for user-provisioned infrastructure**

OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for *Configuring chrony time service*.

**Additional resources**

- [Configuring chrony time service](#)

**18.2.3.7. User-provisioned DNS requirements**
In OpenShift Container Platform deployments, DNS name resolution is required for the following components:

- The Kubernetes API
- The OpenShift Container Platform application wildcard
- The bootstrap, control plane, and compute machines

Reverse DNS resolution is also required for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the hostnames for all the nodes, unless the hostnames are provided by DHCP. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

The following DNS records are required for a user-provisioned OpenShift Container Platform cluster and they must be in place before installation. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>..

**Table 18.6. Required DNS records**

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes API</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the API load balancer. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td></td>
<td>api-int.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to internally identify the API load balancer. These records must be resolvable from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

The API server must be able to resolve the worker nodes by the hostnames that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.
<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Routes</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A wildcard DNS A/AAAA or CNAME record that refers to the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster. For example, <code>console-openshift-console.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;</code> is used as a wildcard route to the OpenShift Container Platform console.</td>
</tr>
<tr>
<td>Bootstrap machine</td>
<td>bootstrap.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Control plane machines</td>
<td>&lt;master&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Compute machines</td>
<td>&lt;worker&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**NOTE**

In OpenShift Container Platform 4.4 and later, you do not need to specify etcd host and SRV records in your DNS configuration.

**TIP**

You can use the `dig` command to verify name and reverse name resolution. See the section on Validating DNS resolution for user-provisioned infrastructure for detailed validation steps.

### 18.2.3.7.1. Example DNS configuration for user-provisioned clusters

This section provides A and PTR record configuration samples that meet the DNS requirements for deploying OpenShift Container Platform on user-provisioned infrastructure. The samples are not meant to provide advice for choosing one DNS solution over another.

In the examples, the cluster name is `ocp4` and the base domain is `example.com`.

**Example DNS A record configuration for a user-provisioned cluster**

The following example is a BIND zone file that shows sample A records for name resolution in a user-provisioned cluster.
Example 18.1. Sample DNS zone database

$TTL 1W
@ IN SOA ns1.example.com. root (2019070700 ; serial
3H ; refresh (3 hours)
30M ; retry (30 minutes)
2W ; expiry (2 weeks)
1W ) ; minimum (1 week)
IN NS ns1.example.com.
IN MX 10 smtp.example.com.
;
ns1.example.com. IN A 192.168.1.5
smtp.example.com. IN A 192.168.1.5
;
helper.example.com. IN A 192.168.1.5
helper.ocp4.example.com. IN A 192.168.1.5
;
api.ocp4.example.com. IN A 192.168.1.5 1
api-int.ocp4.example.com. IN A 192.168.1.5 2
;
*.apps.ocp4.example.com. IN A 192.168.1.5 3
;
bootstrap.ocp4.example.com. IN A 192.168.1.96 4
;
master0.ocp4.example.com. IN A 192.168.1.97 5
master1.ocp4.example.com. IN A 192.168.1.98 6
master2.ocp4.example.com. IN A 192.168.1.99 7
;
worker0.ocp4.example.com. IN A 192.168.1.11 8
worker1.ocp4.example.com. IN A 192.168.1.17 9
;
;EOF

1 Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer.

2 Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer and is used for internal cluster communications.

3 Provides name resolution for the wildcard routes. The record refers to the IP address of the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

NOTE

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.
Provides name resolution for the bootstrap machine.

Provides name resolution for the control plane machines.

Provides name resolution for the compute machines.

Example DNS PTR record configuration for a user-provisioned cluster

The following example BIND zone file shows sample PTR records for reverse name resolution in a user-provisioned cluster.

Example 18.2. Sample DNS zone database for reverse records

```plaintext
$TTL 1W
@ IN SOA ns1.example.com. root (2019070700 ; serial
3H ; refresh (3 hours)
30M ; retry (30 minutes)
2W ; expiry (2 weeks)
1W ) ; minimum (1 week)
IN NS ns1.example.com.
;
5.1.168.192.in-addr.arpa. IN PTR api.o cp4.example.com. 1
5.1.168.192.in-addr.arpa. IN PTR api-int.o cp4.example.com. 2
;
96.1.168.192.in-addr.arpa. IN PTR bootstrap.o cp4.example.com. 3
;
97.1.168.192.in-addr.arpa. IN PTR master0.o cp4.example.com. 4
98.1.168.192.in-addr.arpa. IN PTR master1.o cp4.example.com. 5
99.1.168.192.in-addr.arpa. IN PTR master2.o cp4.example.com. 6
;
11.1.168.192.in-addr.arpa. IN PTR worker0.o cp4.example.com. 7
7.1.168.192.in-addr.arpa. IN PTR worker1.o cp4.example.com. 8
;
;EOF
```

Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer.

Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer and is used for internal cluster communications.

Provides reverse DNS resolution for the bootstrap machine.

Provides reverse DNS resolution for the control plane machines.

Provides reverse DNS resolution for the compute machines.
NOTE
A PTR record is not required for the OpenShift Container Platform application wildcard.

18.2.3.8. Load balancing requirements for user-provisioned infrastructure

Before you install OpenShift Container Platform, you must provision the API and application Ingress load balancing infrastructure. In production scenarios, you can deploy the API and application Ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

NOTE
If you want to deploy the API and application Ingress load balancers with a Red Hat Enterprise Linux (RHEL) instance, you must purchase the RHEL subscription separately.

The load balancing infrastructure must meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.
   - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

**IMPORTANT**
Do not configure session persistence for an API load balancer. Configuring session persistence for a Kubernetes API server might cause performance issues from excess application traffic for your OpenShift Container Platform cluster and the Kubernetes API that runs inside the cluster.

Configure the following ports on both the front and back of the load balancers:

**Table 18.7. API load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the /readyz endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>
The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the `/readyz` endpoint to the removal of the API server instance from the pool. Within the time frame after `/readyz` returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application Ingress load balancer** Provides an ingress point for application traffic flowing in from outside the cluster. A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

**TIP**

If the true IP address of the client can be seen by the application Ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

Configure the following ports on both the front and back of the load balancers:

**Table 18.8. Application Ingress load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>

**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application Ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

**18.2.3.8.1. Example load balancer configuration for user-provisioned clusters**

This section provides an example API and application Ingress load balancer configuration that meets the load balancing requirements for user-provisioned clusters. The sample is an `/etc/haproxy/haproxy.cfg` configuration for an HAProxy load balancer. The example is not meant to provide advice for choosing
one load balancing solution over another.

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

NOTE

If you are using HAProxy as a load balancer and SELinux is set to enforcing, you must ensure that the HAProxy service can bind to the configured TCP port by running `setsebool -P haproxy_connect_any=1`.

Example 18.3. Sample API and application Ingress load balancer configuration

```
global
log 127.0.0.1 local2
pidfile /var/run/haproxy.pid
maxconn 4000
daemon
defaults
 mode http
 log global
 option dontlognull
 option http-server-close
 option redispatch
 retries 3
 timeout http-request 10s
 timeout queue 1m
 timeout connect 10s
 timeout client 1m
 timeout server 1m
 timeout http-keep-alive 10s
 timeout check 10s
 maxconn 3000
listen api-server-6443
  bind *:6443
  mode tcp
  server bootstrap bootstrap.ocp4.example.com:6443 check inter 1s backup
  server master0 master0.ocp4.example.com:6443 check inter 1s
  server master1 master1.ocp4.example.com:6443 check inter 1s
  server master2 master2.ocp4.example.com:6443 check inter 1s
listen machine-config-server-22623
  bind *:22623
  mode tcp
  server bootstrap bootstrap.ocp4.example.com:22623 check inter 1s backup
  server master0 master0.ocp4.example.com:22623 check inter 1s
  server master1 master1.ocp4.example.com:22623 check inter 1s
  server master2 master2.ocp4.example.com:22623 check inter 1s
listen ingress-router-443
  bind *:443
  mode tcp
  balance source
  server worker0 worker0.ocp4.example.com:443 check inter 1s
  server worker1 worker1.ocp4.example.com:443 check inter 1s
```

Port 6443 handles the Kubernetes API traffic and points to the control plane machines.

The bootstrap entries must be in place before the OpenShift Container Platform cluster installation and they must be removed after the bootstrap process is complete.

Port 22623 handles the machine config server traffic and points to the control plane machines.

Port 443 handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

Port 80 handles the HTTP traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application Ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

**TIP**

If you are using HAProxy as a load balancer, you can check that the haproxy process is listening on ports 6443, 22623, 443, and 80 by running `netstat -nltpue` on the HAProxy node.

### 18.2.4. Preparing the user-provisioned infrastructure

Before you install OpenShift Container Platform on user-provisioned infrastructure, you must prepare the underlying infrastructure.

This section provides details about the high-level steps required to set up your cluster infrastructure in preparation for an OpenShift Container Platform installation. This includes configuring IP networking and network connectivity for your cluster nodes, preparing a web server for the Ignition files, enabling the required ports through your firewall, and setting up the required DNS and load balancing infrastructure.

After preparation, your cluster infrastructure must meet the requirements outlined in the Requirements for a cluster with user-provisioned infrastructure section.

**Prerequisites**

- You have reviewed the OpenShift Container Platform 4.x Tested Integrations page.
- You have reviewed the infrastructure requirements detailed in the Requirements for a cluster with user-provisioned infrastructure section.
Procedure

1. Set up static IP addresses.

2. Set up an HTTP or HTTPS server to provide Ignition files to the cluster nodes.

3. Ensure that your network infrastructure provides the required network connectivity between the cluster components. See the Networking requirements for user-provisioned infrastructure section for details about the requirements.

4. Configure your firewall to enable the ports required for the OpenShift Container Platform cluster components to communicate. See Networking requirements for user-provisioned infrastructure section for details about the ports that are required.

   IMPORTANT
   
   By default, port 1936 is accessible for an OpenShift Container Platform cluster, because each control plane node needs access to this port.

   Avoid using the Ingress load balancer to expose this port, because doing so might result in the exposure of sensitive information, such as statistics and metrics, related to Ingress Controllers.

5. Setup the required DNS infrastructure for your cluster.
   a. Configure DNS name resolution for the Kubernetes API, the application wildcard, the bootstrap machine, the control plane machines, and the compute machines.
   b. Configure reverse DNS resolution for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines. See the User-provisioned DNS requirements section for more information about the OpenShift Container Platform DNS requirements.

6. Validate your DNS configuration.
   a. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses in the responses correspond to the correct components.
   b. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names in the responses correspond to the correct components. See the Validating DNS resolution for user-provisioned infrastructure section for detailed DNS validation steps.

7. Provision the required API and application ingress load balancing infrastructure. See the Load balancing requirements for user-provisioned infrastructure section for more information about the requirements.

   NOTE
   
   Some load balancing solutions require the DNS name resolution for the cluster nodes to be in place before the load balancing is initialized.

18.2.5. Validating DNS resolution for user-provisioned infrastructure
You can validate your DNS configuration before installing OpenShift Container Platform on user-provisioned infrastructure.

**IMPORTANT**

The validation steps detailed in this section must succeed before you install your cluster.

**Prerequisites**

- You have configured the required DNS records for your user-provisioned infrastructure.

**Procedure**

1. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses contained in the responses correspond to the correct components.

   a. Perform a lookup against the Kubernetes API record name. Check that the result points to the IP address of the API load balancer:

      ```
      $ dig +noall +answer @<nameserver_ip> api.<cluster_name>.<base_domain>
      ```

      Replace `<nameserver_ip>` with the IP address of the nameserver, `<cluster_name>` with your cluster name, and `<base_domain>` with your base domain name.

      Example output

      ```
      api.ocp4.example.com. 604800 IN A 192.168.1.5
      ```

   b. Perform a lookup against the Kubernetes internal API record name. Check that the result points to the IP address of the API load balancer:

      ```
      $ dig +noall +answer @<nameserver_ip> api-int.<cluster_name>.<base_domain>
      ```

      Example output

      ```
      api-int.ocp4.example.com. 604800 IN A 192.168.1.5
      ```

   c. Test an example `*.apps.<cluster_name>.<base_domain>` DNS wildcard lookup. All of the application wildcard lookups must resolve to the IP address of the application ingress load balancer:

      ```
      $ dig +noall +answer @<nameserver_ip> random.apps.<cluster_name>.<base_domain>
      ```

      Example output

      ```
      random.apps.ocp4.example.com. 604800 IN A 192.168.1.5
      ```
NOTE

In the example outputs, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

You can replace random with another wildcard value. For example, you can query the route to the OpenShift Container Platform console:

```
$ dig +noall +answer @<nameserver_ip> console-openshift-console.apps.<cluster_name>.<base_domain>
```

Example output

```
console-openshift-console.apps.ocp4.example.com. 604800 IN A 192.168.1.5
```

d. Run a lookup against the bootstrap DNS record name. Check that the result points to the IP address of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> bootstrap.<cluster_name>.<base_domain>
```

Example output

```
bootstrap.ocp4.example.com. 604800 IN A 192.168.1.96
```

e. Use this method to perform lookups against the DNS record names for the control plane and compute nodes. Check that the results correspond to the IP addresses of each node.

2. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names contained in the responses correspond to the correct components.

a. Perform a reverse lookup against the IP address of the API load balancer. Check that the response includes the record names for the Kubernetes API and the Kubernetes internal API:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.5
```

Example output

```
5.1.168.192.in-addr.arpa. 604800 IN PTR api-int.ocp4.example.com. 1
5.1.168.192.in-addr.arpa. 604800 IN PTR api.ocp4.example.com. 2
```

1. Provides the record name for the Kubernetes internal API.

2. Provides the record name for the Kubernetes API.
NOTE

A PTR record is not required for the OpenShift Container Platform application wildcard. No validation step is needed for reverse DNS resolution against the IP address of the application ingress load balancer.

b. Perform a reverse lookup against the IP address of the bootstrap node. Check that the result points to the DNS record name of the bootstrap node:

```bash
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.96
```

Example output

```
```

c. Use this method to perform reverse lookups against the IP addresses for the control plane and compute nodes. Check that the results correspond to the DNS record names of each node.

18.2.6. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the `core` user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user `core`. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N " " -f <path>/<file_name>
   ```

   Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.
NOTE

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   $ cat <path>/<file_name>.pub

   For example, run the following to view the ~/.ssh/id_ed25519.pub public key:

   $ cat ~/.ssh/id_ed25519.pub

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the ./openshift-install gather command.

   NOTE

   On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.

   a. If the ssh-agent process is not already running for your local user, start it as a background task:

      $ eval "$(ssh-agent -s)"

      Example output

      Agent pid 31874

   NOTE

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the ssh-agent:

   $ ssh-add <path>/<file_name> ①

   ① Specify the path and file name for your SSH private key, such as ~/.ssh/id_ed25519

   Example output

   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

Next steps
• When you install OpenShift Container Platform, provide the SSH public key to the installation program.

18.2.7. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on your provisioning machine.

Prerequisites

• You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space.

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```bash
$ tar -xvf openshift-install-linux.tar.gz
```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

18.2.8. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.
IMPORTANT

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of oc.

Installing the OpenShift CLI on Linux
You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure

2. Select the architecture from the Product Variant drop-down list.
3. Select the appropriate version from the Version drop-down list.
4. Click Download Now next to the OpenShift v4.14 Linux Client entry and save the file.
5. Unpack the archive:
   
   $ tar xvf <file>

6. Place the oc binary in a directory that is on your PATH.
   To check your PATH, execute the following command:
   
   $ echo $PATH

Verification

- After you install the OpenShift CLI, it is available using the oc command:
  
  $ oc <command>

Installing the OpenShift CLI on Windows
You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

Procedure

2. Select the appropriate version from the Version drop-down list.
3. Click Download Now next to the OpenShift v4.14 Windows Client entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the oc binary to a directory that is on your PATH.
   To check your PATH, open the command prompt and execute the following command:
   
   C:\> path

Verification
Installation the OpenShift CLI on macOS
You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.

Procedure
2. Select the appropriate version from the Version drop-down list.
3. Click Download Now next to the OpenShift v4.14 macOS Client entry and save the file.
   
   **NOTE**
   For macOS arm64, choose the OpenShift v4.14 macOS arm64 Client entry.
4. Unpack and unzip the archive.
5. Move the oc binary to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:

   `$ echo $PATH`

Verification
- After you install the OpenShift CLI, it is available using the oc command:

   `C:\> oc <command>`

18.2.9. Manually creating the installation configuration file

Prerequisites
- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.
- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure
1. Create an installation directory to store your required installation assets in:

   `$ mkdir <installation_directory>`
IMPORTANT

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample install-config.yaml file template that is provided and save it in the <installation_directory>.

NOTE
You must name this configuration file install-config.yaml.

NOTE
For some platform types, you can alternatively run ./openshift-install create install-config --dir <installation_directory> to generate an install-config.yaml file. You can provide details about your cluster configuration at the prompts.

3. Back up the install-config.yaml file so that you can use it to install multiple clusters.

IMPORTANT
The install-config.yaml file is consumed during the next step of the installation process. You must back it up now.

Additional resources

- Installation configuration parameters for IBM Z®

18.2.9.1. Sample install-config.yaml file for IBM Z

You can customize the install-config.yaml file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute:  
- hyperthreading: Enabled
  name: worker
  replicas: 0
  architecture: s390x
controlPlane:  
  hyperthreading: Enabled
  name: master
  replicas: 3
  architecture: s390x
metadata:
  name: test
```
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
    hostPrefix: 23
  networkType: OVNKubernetes
  serviceNetwork:
    - 172.30.0.0/16
platform:
  none: {}
  fips: false
  pullSecret: '{"auths": ...}'
  sshKey: 'ssh-ed25519 AAAAA...'

1. The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

2, 5. The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -, and the first line of the **controlPlane** section must not. Only one control plane pool is used.

3, 6. Specifies whether to enable or disable simultaneous multithreading (SMT), or hyperthreading. By default, SMT is enabled to increase the performance of the cores in your machines. You can disable it by setting the parameter value to **Disabled**. If you disable SMT, you must disable it in all cluster machines; this includes both control plane and compute machines.

**NOTE**
Simultaneous multithreading (SMT) is enabled by default. If SMT is not available on your OpenShift Container Platform nodes, the **hyperthreading** parameter has no effect.

**IMPORTANT**
If you disable **hyperthreading**, whether on your OpenShift Container Platform nodes or in the **install-config.yaml** file, ensure that your capacity planning accounts for the dramatically decreased machine performance.

4. You must set this value to 0 when you install OpenShift Container Platform on user-provisioned infrastructure. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. In user-provisioned installations, you must manually deploy the compute machines before you finish installing the cluster.

**NOTE**
If you are installing a three-node cluster, do not deploy any compute machines when you install the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

7. The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

8. The cluster name that you specified in your DNS records.
A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to

**NOTE**

Class E CIDR range is reserved for a future use. To use the Class E CIDR range, you must ensure your networking environment accepts the IP addresses within the Class E CIDR range.

The subnet prefix length to assign to each individual node. For example, if `hostPrefix` is set to **23**, then each node is assigned a /23 subnet out of the given `cidr`, which allows for 510 \(2^{(32 - 23)} - 2\) pod IP addresses. If you are required to provide access to nodes from an external network, configure load balancers and routers to manage the traffic.

The cluster network plugin to install. The supported values are **OVNKubernetes** and **OpenShiftSDN**. The default value is **OVNKubernetes**.

The IP address pool to use for service IP addresses. You can enter only one IP address pool. This block must not overlap with existing physical networks. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.

You must set the platform to **none**. You cannot provide additional platform configuration variables for IBM Z® infrastructure.

**IMPORTANT**

Clusters that are installed with the platform type **none** are unable to use some features, such as managing compute machines with the Machine API. This limitation applies even if the compute machines that are attached to the cluster are installed on a platform that would normally support the feature. This parameter cannot be changed after installation.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see [Installing the system in FIPS mode](#). When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures.

The pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

The SSH public key for the **core** user in Red Hat Enterprise Linux CoreOS (RHCOS).
NOTE
For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

18.2.9.2. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the install-config.yaml file.

Prerequisites

- You have an existing install-config.yaml file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the Proxy object’s spec.noProxy field to bypass the proxy if necessary.

NOTE
The Proxy object status.noProxy field is populated with the values of the networking.machineNetwork[].cidr, networking.clusterNetwork[].cidr, and networking.serviceNetwork[] fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object status.noProxy field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your install-config.yaml file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
     httpProxy: http://<username>:<pswd>@<ip>:<port>
     httpsProxy: https://<username>:<pswd>@<ip>:<port>
   noProxy: example.com
   additionalTrustBundle:
     -----BEGIN CERTIFICATE-----
     <MY_TRUSTED_CA_CERT>
     -----END CERTIFICATE-----
   additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle>
   ```

   1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.
   2 A proxy URL to use for creating HTTPS connections outside the cluster.
3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For

4. If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the `trustedCA` field of the `Proxy` object. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

5. Optional: The policy to determine the configuration of the `Proxy` object to reference the `user-ca-bundle` config map in the `trustedCA` field. The allowed values are `Proxyonly` and `Always`. Use `Proxyonly` to reference the `user-ca-bundle` config map only when http/https proxy is configured. Use `Always` to always reference the `user-ca-bundle` config map. The default value is `Proxyonly`.

**NOTE**

The installation program does not support the proxy `readinessEndpoints` field.

**NOTE**

If the installer times out, restart and then complete the deployment by using the `wait-for` command of the installer. For example:

```
$ ./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

**NOTE**

Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

18.2.9.3. Configuring a three-node cluster

Optionally, you can deploy zero compute machines in a minimal three node cluster that consists of three control plane machines only. This provides smaller, more resource efficient clusters for cluster administrators and developers to use for testing, development, and production.

In three-node OpenShift Container Platform environments, the three control plane machines are schedulable, which means that your application workloads are scheduled to run on them.

**Prerequisites**

- You have an existing `install-config.yaml` file.

**Procedure**
- Ensure that the number of compute replicas is set to `0` in your `install-config.yaml` file, as shown in the following `compute` stanza:

```
compute:
  - name: worker
    platform: {}
    replicas: 0
```

**NOTE**

You must set the value of the `replicas` parameter for the compute machines to `0` when you install OpenShift Container Platform on user-provisioned infrastructure, regardless of the number of compute machines you are deploying. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. This does not apply to user-provisioned installations, where the compute machines are deployed manually.

**NOTE**

The preferred resource for control plane nodes is six vCPUs and 21 GB. For three control plane nodes this is the memory + vCPU equivalent of a minimum five-node cluster. You should back the three nodes, each installed on a 120 GB disk, with three IFLs that are SMT2 enabled. The minimum tested setup is three vCPUs and 10 GB on a 120 GB disk for each control plane node.

For three-node cluster installations, follow these next steps:

- If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes. See the *Load balancing requirements for user-provisioned infrastructure* section for more information.

- When you create the Kubernetes manifest files in the following procedure, ensure that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file is set to `true`. This enables your application workloads to run on the control plane nodes.

- Do not deploy any compute nodes when you create the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

### 18.2.10. Cluster Network Operator configuration

The configuration for the cluster network is specified as part of the Cluster Network Operator (CNO) configuration and stored in a custom resource (CR) object that is named `cluster`. The CR specifies the fields for the `Network` API in the `operator.openshift.io` API group.

The CNO configuration inherits the following fields during cluster installation from the `Network` API in the `Network.config.openshift.io` API group and these fields cannot be changed:

- `clusterNetwork`
  - IP address pools from which pod IP addresses are allocated.
serviceNetwork
  IP address pool for services.

defaultNetwork.type
  Cluster network plugin, such as OpenShift SDN or OVN-Kubernetes.

You can specify the cluster network plugin configuration for your cluster by setting the fields for the defaultNetwork object in the CNO object named cluster.

18.2.10.1. Cluster Network Operator configuration object

The fields for the Cluster Network Operator (CNO) are described in the following table:

Table 18.9. Cluster Network Operator configuration object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>metadata.name</td>
<td>string</td>
<td>The name of the CNO object. This name is always cluster.</td>
</tr>
<tr>
<td>spec.clusterNetwork.array</td>
<td>array</td>
<td>A list specifying the blocks of IP addresses from which pod IP addresses are allocated and the subnet prefix length assigned to each individual node in the cluster. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>spec:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>clusterNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- cidr: 10.128.0.0/19</td>
</tr>
<tr>
<td></td>
<td></td>
<td>hostPrefix: 23</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- cidr: 10.128.32.0/19</td>
</tr>
<tr>
<td></td>
<td></td>
<td>hostPrefix: 23</td>
</tr>
<tr>
<td></td>
<td></td>
<td>You can customize this field only in the install-config.yaml file before you create the manifests. The value is read-only in the manifest file.</td>
</tr>
<tr>
<td>spec.serviceNetwork.array</td>
<td>array</td>
<td>A block of IP addresses for services. The OpenShift SDN and OVN-Kubernetes network plugins support only a single IP address block for the service network. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>spec:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>serviceNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- 172.30.0.0/14</td>
</tr>
<tr>
<td></td>
<td></td>
<td>You can customize this field only in the install-config.yaml file before you create the manifests. The value is read-only in the manifest file.</td>
</tr>
<tr>
<td>spec.defaultNetwork.object</td>
<td>object</td>
<td>Configures the network plugin for the cluster network.</td>
</tr>
<tr>
<td>spec.kubeProxy Config.object</td>
<td>object</td>
<td>The fields for this object specify the kube-proxy configuration. If you are using the OVN-Kubernetes cluster network plugin, the kube-proxy configuration has no effect.</td>
</tr>
</tbody>
</table>
defaultNetwork object configuration
The values for the defaultNetwork object are defined in the following table:

Table 18.10. defaultNetwork object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>string</td>
<td>Either OpenShiftSDN or OVNKubernetes. The Red Hat OpenShift Networking network plugin is selected during installation. This value cannot be changed after cluster installation.</td>
</tr>
<tr>
<td>openShiftSDNConfig</td>
<td>object</td>
<td>This object is only valid for the OpenShift SDN network plugin.</td>
</tr>
<tr>
<td>ovnKubernetesConfig</td>
<td>object</td>
<td>This object is only valid for the OVN-Kubernetes network plugin.</td>
</tr>
</tbody>
</table>

Configuration for the OpenShift SDN network plugin
The following table describes the configuration fields for the OpenShift SDN network plugin:

Table 18.11. openShiftSDNConfig object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mode</td>
<td>string</td>
<td>Configures the network isolation mode for OpenShift SDN. The default value is NetworkPolicy. The values Multitenant and Subnet are available for backwards compatibility with OpenShift Container Platform 3.x but are not recommended. This value cannot be changed after cluster installation.</td>
</tr>
</tbody>
</table>
**mtu**

- **Type:** integer
- **Description:** The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.

If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.

If your cluster requires different MTU values for different nodes, you must set this value to 50 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1450.

This value cannot be changed after cluster installation.

**vxlanPort**

- **Type:** integer
- **Description:** The port to use for all VXLAN packets. The default value is 4789. This value cannot be changed after cluster installation.

If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number.

On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port 9000 and port 9999.

### Example OpenShift SDN configuration

```yaml
defaultNetwork:
  type: OpenShiftSDN
  openshiftSDNConfig:
    mode: NetworkPolicy
    mtu: 1450
    vxlanPort: 4789
```

### Configuration for the OVN-Kubernetes network plugin

The following table describes the configuration fields for the OVN-Kubernetes network plugin:

**Table 18.12. ovnKubernetesConfig object**

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>defaultNetwork</td>
<td></td>
<td></td>

### CHAPTER 18. INSTALLING ON IBM Z AND IBM LINUXONE

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mtu</td>
<td>integer</td>
<td>The maximum transmission unit (MTU) for the Geneve (Generic Network Virtualization Encapsulation) overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU. If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes. If your cluster requires different MTU values for different nodes, you must set this value to 100 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1400.</td>
</tr>
<tr>
<td>genevePort</td>
<td>integer</td>
<td>The port to use for all Geneve packets. The default value is 6081. This value cannot be changed after cluster installation.</td>
</tr>
<tr>
<td>ipsecConfig</td>
<td>object</td>
<td>Specify an empty object to enable IPsec encryption.</td>
</tr>
<tr>
<td>policyAuditConfig</td>
<td>object</td>
<td>Specify a configuration object for customizing network policy audit logging. If unset, the defaults audit log settings are used.</td>
</tr>
<tr>
<td>gatewayConfig</td>
<td>object</td>
<td>Optional: Specify a configuration object for customizing how egress traffic is sent to the node gateway.</td>
</tr>
</tbody>
</table>

**NOTE**

While migrating egress traffic, you can expect some disruption to workloads and service traffic until the Cluster Network Operator (CNO) successfully rolls out the changes.
If your existing network infrastructure overlaps with the 100.64.0.0/16 IPv4 subnet, you can specify a different IP address range for internal use by OVN-Kubernetes. You must ensure that the IP address range does not overlap with any other subnet used by your OpenShift Container Platform installation. The IP address range must be larger than the maximum number of nodes that can be added to the cluster. For example, if the clusterNetwork.cidr value is 10.128.0.0/14 and the clusterNetwork.hostPrefix value is /23, then the maximum number of nodes is 2^(23-14)=512.

This field cannot be changed after installation.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>v4InternalSubnet</td>
<td></td>
<td>The default value is 100.64.0.0/16.</td>
</tr>
</tbody>
</table>
If your existing network infrastructure overlaps with the fd98::/48 IPv6 subnet, you can specify a different IP address range for internal use by OVN-Kubernetes. You must ensure that the IP address range does not overlap with any other subnet used by your OpenShift Container Platform installation. The IP address range must be larger than the maximum number of nodes that can be added to the cluster. This field cannot be changed after installation.

The default value is fd98::/48.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>v6InternalSubnet</td>
<td></td>
<td>If your existing network infrastructure overlaps with the fd98::/48 IPv6 subnet, you can specify a different IP address range for internal use by OVN-Kubernetes. You must ensure that the IP address range does not overlap with any other subnet used by your OpenShift Container Platform installation. The IP address range must be larger than the maximum number of nodes that can be added to the cluster. This field cannot be changed after installation.</td>
</tr>
</tbody>
</table>

**Table 18.13. policyAuditConfig object**

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rateLimit</td>
<td>integer</td>
<td>The maximum number of messages to generate every second per node. The default value is 20 messages per second.</td>
</tr>
<tr>
<td>maxFileSize</td>
<td>integer</td>
<td>The maximum size for the audit log in bytes. The default value is 50000000 or 50 MB.</td>
</tr>
</tbody>
</table>
destination | string | One of the following additional audit log targets:

**libc**
The libc `syslog()` function of the journald process on the host.

**udp:<host>:<port>**
A syslog server. Replace `<host>:<port>` with the host and port of the syslog server.

**unix:<file>**
A Unix Domain Socket file specified by `<file>`.

**null**
Do not send the audit logs to any additional target.

syslogFacility | string | The syslog facility, such as `kern`, as defined by RFC5424. The default value is `local0`.

Table 18.14. gatewayConfig object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| routingViaHost | boolean| Set this field to `true` to send egress traffic from pods to the host networking stack. For highly-specialized installations and applications that rely on manually configured routes in the kernel routing table, you might want to route egress traffic to the host networking stack. By default, egress traffic is processed in OVN to exit the cluster and is not affected by specialized routes in the kernel routing table. The default value is `false`.

This field has an interaction with the Open vSwitch hardware offloading feature. If you set this field to `true`, you do not receive the performance benefits of the offloading because egress traffic is processed by the host networking stack.

| ipForwarding   | object | You can control IP forwarding for all traffic on OVN-Kubernetes managed interfaces by using the `ipForwarding` specification in the `Network` resource. Specify `Restricted` to only allow IP forwarding for Kubernetes related traffic. Specify `Global` to allow forwarding of all IP traffic. For new installations, the default is `Restricted`. For updates to OpenShift Container Platform 4.14, the default is `Global`.

Example OVN-Kubernetes configuration with IPSec enabled

defaultNetwork:
  type: OVNKubernetes
  ovnKubernetesConfig:
    mtu: 1400
    genevePort: 6081
    ipsecConfig: {}
**kubeProxyConfig object configuration**

The values for the `kubeProxyConfig` object are defined in the following table:

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>iptablesSyncPeriod</code></td>
<td>string</td>
<td>The refresh period for <code>iptables</code> rules. The default value is <strong>30s</strong>. Valid suffixes include <code>s</code>, <code>m</code>, and <code>h</code> and are described in the <code>Go time</code> package documentation.</td>
</tr>
</tbody>
</table>
| `proxyArguments.iptables-min-sync-period` | array      | The minimum duration before refreshing `iptables` rules. This field ensures that the refresh does not happen too frequently. Valid suffixes include `s`, `m`, and `h` and are described in the `Go time` package. The default value is:  
```
kubeProxyConfig:
proxyArguments:
  iptables-min-sync-period:
- 0s
```  |

**NOTE**

Because of performance improvements introduced in OpenShift Container Platform 4.3 and greater, adjusting the `iptablesSyncPeriod` parameter is no longer necessary.

---

### 18.2.11. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.
IMPORTANT

- The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

NOTE

The installation program that generates the manifest and Ignition files is architecture specific and can be obtained from the client image mirror. The Linux version of the installation program runs on s390x only. This installer program is also available as a Mac OS version.

Prerequisites

- You obtained the OpenShift Container Platform installation program.
- You created the `install-config.yaml` installation configuration file.

Procedure

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

```
$ ./openshift-install create manifests --dir <installation_directory>
```

For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.

WARNING

If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.

IMPORTANT

When you configure control plane nodes from the default unschedulable to schedulable, additional subscriptions are required. This is because control plane nodes then become compute nodes.
2. Check that the `mastersSchedulable` parameter in the 
`<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest 
file is set to `false`. This setting prevents pods from being scheduled on the control plane 
machines:

   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.

   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.

   c. Save and exit the file.

3. To create the Ignition configuration files, run the following command from the directory that 
contains the installation program:

   ```bash
   $ ./openshift-install create ignition-configs --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the same installation directory.

   Ignition config files are created for the bootstrap, control plane, and compute nodes in the 
installation directory. The `kubeadmin-password` and `kubeconfig` files are created in the 
`./<installation_directory>/auth` directory:

   ```
   ├── auth
   │   ├── kubeadmin-password
   │   └── kubeconfig
   │       ├── bootstrap.ign
   │       └── master.ign
   │           └── metadata.json
   └── worker.ign
   ```

18.2.12. Configuring NBDE with static IP in an IBM Z or IBM LinuxONE environment

Enabling NBDE disk encryption in an IBM Z® or IBM® LinuxONE environment requires additional steps, 
which are described in detail in this section.

Prerequisites

- You have set up the External Tang Server. See Network-bound disk encryption for instructions.
- You have installed the `butane` utility.
- You have reviewed the instructions for how to create machine configs with Butane.

Procedure

1. Create Butane configuration files for the control plane and compute nodes. 
The following example of a Butane configuration for a control plane node creates a file named 
`master-storage.bu` for disk encryption:

   ```
   variant: openshift
   version: 4.14.0
   metadata:
       name: master-storage
   ```
The cipher option is only required if FIPS mode is enabled. Omit the entry if FIPS is disabled.

For installations on DASD-type disks, replace with `device: /dev/disk/by-label/root`.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

2. Create a customized initramfs file to boot the machine, by running the following command:

```
$ coreos-installer pxe customize \
/root/rhcos-bootfiles/rhcos-<release>-live-initramfs.s390x.img \
   --dest-device /dev/disk/by-id/scsi-<serial-number> --dest-karg-append \ 
   ip=<ip-address>::<gateway-ip>:<subnet-mask>::<network-device>:none \
   --dest-karg-append nameserver=<nameserver-ip> \
   --dest-karg-append rd.neednet=1 -o \
   /root/rhcos-bootfiles/<Node-name>-initramfs.s390x.img
```

NOTE

Before first boot, you must customize the initramfs for each node in the cluster, and add PXE kernel parameters.

3. Create a parameter file that includes `ignition.platform.id=metal` and `ignition.firstboot`.

Example kernel parameter file for the control plane machine:

```
rd.neednet=1
```
For installations on DASD-type disks, add `coreos.inst.install_dev=/dev/dasda`. Omit this value for FCP-type disks.

For installations on FCP-type disks, add `zfcp.allow_lun_scan=0`. Omit this value for DASD-type disks.

For installations on DASD-type disks, replace with `rd.dasd=0.0.3490` to specify the DASD device.

**NOTE**

Write all options in the parameter file as a single line and make sure you have no newline characters.

Additional resources

- Creating machine configs with Butane

### 18.2.13. Installing RHCOS and starting the OpenShift Container Platform bootstrap process

To install OpenShift Container Platform on IBM Z® infrastructure that you provision, you must install Red Hat Enterprise Linux CoreOS (RHCOS) on z/VM guest virtual machines. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS z/VM guest virtual machines have rebooted.

Complete the following steps to create the machines.

**Prerequisites**

- An HTTP or HTTPS server running on your provisioning machine that is accessible to the machines you create.

**Procedure**

1. Log in to Linux on your provisioning machine.
2. Obtain the Red Hat Enterprise Linux CoreOS (RHCOS) kernel, initramfs, and rootfs files from the RHCOS image mirror.

**IMPORTANT**

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate kernel, initramfs, and rootfs artifacts described in the following procedure.

The file names contain the OpenShift Container Platform version number. They resemble the following examples:

- **kernel**: `rhcos-<version>-live-kernel-<architecture>`
- **initramfs**: `rhcos-<version>-live-initramfs.<architecture>.img`
- **rootfs**: `rhcos-<version>-live-rootfs.<architecture>.img`

**NOTE**

The rootfs image is the same for FCP and DASD.

3. Create parameter files. The following parameters are specific for a particular virtual machine:

- **ip**=
  - i. The IP address for the machine.
  - ii. An empty string.
  - iii. The gateway.
  - iv. The netmask.
  - v. The machine host and domain name in the form `hostname.domainname`. Omit this value to let RHCOS decide.
  - vi. The network interface name. Omit this value to let RHCOS decide.
  - vii. If you use static IP addresses, specify `none`.

- **coreos.inst.ignition_url**=
  - For `bootstrap.ign`, `master.ign`, or `worker.ign`. Only HTTP and HTTPS protocols are supported.

- **coreos.live.rootfs_url**=
  - Specify the matching rootfs artifact for the kernel and initramfs you are booting. Only HTTP and HTTPS protocols are supported.

- **coreos.inst.install_dev**=
  - i. For `coreos.inst.install_dev`, specify `/dev/dasda`.
  - ii. Use `rd.dasd` to specify the DASD where RHCOS is to be installed.
  - iii. Leave all other parameters unchanged.
Example parameter file, `bootstrap-0.parm`, for the bootstrap machine:

```bash
rd.neednet=1 \nconsole=ttyscp0 \ncoreos.inst.install_dev=/dev/dasda \ncoreos.live.rootfs_url=http://cl1.provide.example.com:8080/assets/rhcos-live-rootfs.s390x.img \ncoreos.inst.ignition_url=http://cl1.provide.example.com:8080/ignition/bootstrap.ign \nip=172.18.78.2::172.18.78.1:255.255.255.0::none nameserver=172.18.78.1 \nrq.znet=qeth,0.0.bdf0,0.0.bdf1,0.0.bdf2,layer2=1.portno=0 \nzfcp.allow_lun_scan=0 \nrd.dasd=0.0.3490
```

Write all options in the parameter file as a single line and make sure you have no newline characters.

- For installations on FCP-type disks, complete the following tasks:
  
  i. Use `rd zfcp=<adapter>,<wwpn>,<lun>` to specify the FCP disk where RHCOS is to be installed. For multipathing repeat this step for each additional path.

  **NOTE**

  When you install with multiple paths, you must enable multipathing directly after the installation, not at a later point in time, as this can cause problems.

  ii. Set the install device as: `coreos.inst.install_dev=/dev/disk/by-id/scsi-<serial_number>`.

  **NOTE**

  If additional LUNs are configured with NPIV, FCP requires `zfcp.allow_lun_scan=0`. If you must enable `zfcp.allow_lun_scan=1` because you use a CSI driver, for example, you must configure your NPIV so that each node cannot access the boot partition of another node.

  iii. Leave all other parameters unchanged.

  **IMPORTANT**

  Additional postinstallation steps are required to fully enable multipathing. For more information, see "Enabling multipathing with kernel arguments on RHCOS" in Post-installation machine configuration tasks.

The following is an example parameter file `worker-1.parm` for a worker node with multipathing:

```bash
rd.neednet=1 \ncoreos.inst.install_dev=/dev/disk/by-id/scsi-<serial_number> \ncoreos.live.rootfs_url=http://cl1.provide.example.com:8080/assets/rhcos-live-```
Write all options in the parameter file as a single line and make sure you have no newline characters.

4. Transfer the initramfs, kernel, parameter files, and RHCOS images to z/VM, for example with FTP. For details about how to transfer the files with FTP and boot from the virtual reader, see Installing under Z/VM.

5. Punch the files to the virtual reader of the z/VM guest virtual machine that is to become your bootstrap node. See PUNCH in IBM Documentation.

   **TIP**

   You can use the CP PUNCH command or, if you use Linux, the vmur command to transfer files between two z/VM guest virtual machines.

7. IPL the bootstrap machine from the reader:

   ```
   $ ipl c
   ```

   See IPL in IBM Documentation.

8. Repeat this procedure for the other machines in the cluster.

### 18.2.13.1. Advanced RHCOS installation reference

This section illustrates the networking configuration and other advanced options that allow you to modify the Red Hat Enterprise Linux CoreOS (RHCOS) manual installation process. The following tables describe the kernel arguments and command-line options you can use with the RHCOS live installer and the `coreos-installer` command.

#### 18.2.13.1.1. Networking and bonding options for ISO installations

If you install RHCOS from an ISO image, you can add kernel arguments manually when you boot the image to configure networking for a node. If no networking arguments are specified, DHCP is activated in the initramfs when RHCOS detects that networking is required to fetch the Ignition config file.

**IMPORTANT**

When adding networking arguments manually, you must also add the `rd.neednet=1` kernel argument to bring the network up in the initramfs.
The following information provides examples for configuring networking and bonding on your RHCOS nodes for ISO installations. The examples describe how to use the `ip=`, `nameserver=`, and `bond=` kernel arguments.

**NOTE**

Ordering is important when adding the kernel arguments: `ip=`, `nameserver=`, and then `bond=`.

The networking options are passed to the `dracut` tool during system boot. For more information about the networking options supported by `dracut`, see the `dracut.cmdline` manual page.

The following examples are the networking options for ISO installation.

**Configuring DHCP or static IP addresses**

To configure an IP address, either use DHCP (`ip=dhcp`) or set an individual static IP address (`ip=<host_ip>`). If setting a static IP, you must then identify the DNS server IP address (`nameserver=<dns_ip>`) on each node. The following example sets:

- The node’s IP address to `10.10.10.2`
- The gateway address to `10.10.10.254`
- The netmask to `255.255.255.0`
- The hostname to `core0.example.com`
- The DNS server address to `4.4.4.41`
- The auto-configuration value to `none`. No auto-configuration is required when IP networking is configured statically.

```
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none
nameserver=4.4.4.41
```

**NOTE**

When you use DHCP to configure IP addressing for the RHCOS machines, the machines also obtain the DNS server information through DHCP. For DHCP-based deployments, you can define the DNS server address that is used by the RHCOS nodes through your DHCP server configuration.

**Configuring an IP address without a static hostname**

You can configure an IP address without assigning a static hostname. If a static hostname is not set by the user, it will be picked up and automatically set by a reverse DNS lookup. To configure an IP address without a static hostname refer to the following example:

- The node’s IP address to `10.10.10.2`
- The gateway address to `10.10.10.254`
- The netmask to `255.255.255.0`
- The DNS server address to `4.4.4.41`
The auto-configuration value to *none*. No auto-configuration is required when IP networking is configured statically.

Specifying multiple network interfaces
You can specify multiple network interfaces by setting multiple `ip=` entries.

NOTE
When you configure one or multiple networks, one default gateway is required. If the additional network gateway is different from the primary network gateway, the default gateway must be the primary network gateway.

- Run the following command to configure the default gateway:
  
  ```
ip=:10.10.10.254::
  ```

- Enter the following command to configure the route for the additional network:
  
  ```
rd.route=20.20.20.0/24:20.20.20.254:enp2s0
  ```

Disabling DHCP on a single interface
You can disable DHCP on a single interface, such as when there are two or more network interfaces and only one interface is being used. In the example, the `enp1s0` interface has a static networking configuration and DHCP is disabled for `enp2s0`, which is not used:

```
ip=:10.10.10.254::
```

Combining DHCP and static IP configurations
You can combine DHCP and static IP configurations on systems with multiple network interfaces, for example:

```
ip=enp1s0:dhcp
```

Configuring VLANS on individual interfaces
Optional: You can configure VLANS on individual interfaces by using the `vlan=` parameter.

- To configure a VLAN on a network interface and use a static IP address, run the following command:
  
  ```
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp2s0.100:enp2s0
  ```
To configure a VLAN on a network interface and to use DHCP, run the following command:

```
palin
ip=enp2s0.100:dhcp
vlan=enp2s0.100:enp2s0
```

**Providing multiple DNS servers**

You can provide multiple DNS servers by adding a `nameserver=` entry for each server, for example:

```
nameserver=1.1.1.1
nameserver=8.8.8.8
```

**Bonding multiple network interfaces to a single interface**

Optional: You can bond multiple network interfaces to a single interface by using the `bond=` option. Refer to the following examples:

- The syntax for configuring a bonded interface is: `bond=<name>[::<network_interfaces>][::<options>]`
  - `<name>` is the bonding device name (`bond0`), `<network_interfaces>` represents a comma-separated list of physical (ethernet) interfaces (`em1,em2`), and `<options>` is a comma-separated list of bonding options. Enter `modinfo bonding` to see available options.

- When you create a bonded interface using `bond=`, you must specify how the IP address is assigned and other information for the bonded interface.
  - To configure the bonded interface to use DHCP, set the bond’s IP address to `dhcp`. For example:
    ```
bond=bond0:em1,em2:mode=active-backup
ip=bond0:dhcp
```
    - To configure the bonded interface to use a static IP address, enter the specific IP address you want and related information. For example:
      ```
bond=bond0:em1,em2:mode=active-backup,fail_over_mac=1
ip=10.10.10.1::10.10.10.254:255.255.255.0:core0.example.com:bond0:none
```
  
  *Always set the `fail_over_mac=1` option in active-backup mode, to avoid problems when shared OSA/RoCE cards are used.*

- **Bonding multiple network interfaces to a single interface**
  Optional: You can configure VLANs on bonded interfaces by using the `vlan=` parameter and to use DHCP, for example:

  ```
ip=bond0.100:dhcp
bond=bond0:em1,em2:mode=active-backup
vlan=bond0.100:bond0
```

  Use the following example to configure the bonded interface with a VLAN and to use a static IP address:

  ```
ip=10.10.10.2::10.10.254:255.255.255.0:core0.example.com:bond0.100:none
bond=bond0:em1,em2:mode=active-backup
vlan=bond0.100:bond0
```

**Using network teaming**

---

**CHAPTER 18. INSTALLING ON IBM Z AND IBM LINUXONE**

2487
Optional: You can use a network teaming as an alternative to bonding by using the `team=` parameter:

- The syntax for configuring a team interface is: `team=name[:network_interfaces]`
  - `name` is the team device name (`team0`) and `network_interfaces` represents a comma-separated list of physical (ethernet) interfaces (`em1, em2`).

**NOTE**

Teaming is planned to be deprecated when RHCOS switches to an upcoming version of RHEL. For more information, see this [Red Hat Knowledgebase Article](#).

Use the following example to configure a network team:

```bash
team=team0:em1,em2
ip=team0:dhcp
```

### 18.2.14. Waiting for the bootstrap process to complete

The OpenShift Container Platform bootstrap process begins after the cluster nodes first boot into the persistent RHCOS environment that has been installed to disk. The configuration information provided through the Ignition config files is used to initialize the bootstrap process and install OpenShift Container Platform on the machines. You must wait for the bootstrap process to complete.

**Prerequisites**

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have obtained the installation program and generated the Ignition config files for your cluster.
- You installed RHCOS on your cluster machines and provided the Ignition config files that the OpenShift Container Platform installation program generated.
- Your machines have direct internet access or have an HTTP or HTTPS proxy available.

**Procedure**

1. Monitor the bootstrap process:

   ```bash
   $ ./openshift-install --dir <installation_directory> wait-for bootstrap-complete
   --log-level=info
   ```

   1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.
   2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

**Example output**

```
INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
```
The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After the bootstrap process is complete, remove the bootstrap machine from the load balancer.

**IMPORTANT**

You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the bootstrap machine itself.

18.2.15. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   ```

   **Example output**

   ```bash
   system:admin
   ```

18.2.16. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

**Prerequisites**
You added machines to your cluster.

Procedure

1. Confirm that the cluster recognizes the machines:

```bash
$ oc get nodes
```

**Example output**

```
NAME      STATUS    ROLES   AGE  VERSION
master-0  Ready     master  63m  v1.27.3
master-1  Ready     master  63m  v1.27.3
master-2  Ready     master  64m  v1.27.3
```

The output lists all of the machines that you created.

**NOTE**

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the `Pending` or `Approved` status for each machine that you added to the cluster:

```bash
$ oc get csr
```

**Example output**

```
NAME        AGE   REQUESTOR                                  CONDITION
csr-mddf5   20m   system:node:master-01.example.com   Approved,Issued
csr-z5rln   16m   system:node:worker-21.example.com   Approved,Issued
```

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in `Pending` status, approve the CSRs for your cluster machines:

**NOTE**

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the `machine-approver` if the Kubelet requests a new certificate with identical parameters.
NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the `oc exec`, `oc rsh`, and `oc logs` commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the `node-bootstrapper` service account in the `system:node` or `system:admin` groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

  ```bash
  $ oc adm certificate approve <csr_name>  
  ```

  `<csr_name>` is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

  ```bash
  $ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs --no-run-if-empty oc adm certificate approve
  ```

NOTE

Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```bash
$ oc get csr
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-c57lv</td>
<td>5m26s</td>
<td>system:node:ip-10-0-95-157.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

  ```bash
  $ oc adm certificate approve <csr_name>  
  ```

  `<csr_name>` is the name of a CSR from the list of current CSRs.
To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs oc adm certificate approve
```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>74m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>worker-0</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>worker-1</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.27.3</td>
</tr>
</tbody>
</table>

**NOTE**

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

**Additional information**

- For more information on CSRs, see [Certificate Signing Requests](#).

### 18.2.17. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

**Prerequisites**

- Your control plane has initialized.

**Procedure**

1. Watch the cluster components come online:

```
$ watch -n5 oc get clusteroperators
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
<th>SINCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>authentication</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>19m</td>
</tr>
<tr>
<td>baremetal</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>37m</td>
</tr>
<tr>
<td>cloud-credential</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>40m</td>
</tr>
<tr>
<td>cluster-autoscaler</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>37m</td>
</tr>
<tr>
<td>config-operator</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>38m</td>
</tr>
</tbody>
</table>
2. Configure the Operators that are not available.

**18.2.17.1. Image registry storage configuration**

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the **Recreate** rollout strategy during upgrades.

**18.2.17.1.1. Configuring registry storage for IBM Z**

As a cluster administrator, following installation you must configure your registry to use storage.

**Prerequisites**

- You have access to the cluster as a user with the **cluster-admin** role.
- You have a cluster on IBM Z®.
- You have provisioned persistent storage for your cluster, such as Red Hat OpenShift Data Foundation.
IMPORTANT

OpenShift Container Platform supports ReadWriteOnce access for image registry storage when you have only one replica. ReadWriteOnce access also requires that the registry uses the Recreate rollout strategy. To deploy an image registry that supports high availability with two or more replicas, ReadWriteMany access is required.

- Must have 100Gi capacity.

Procedure

1. To configure your registry to use storage, change the spec.storage.pvc in the configs.imageregistry/cluster resource.

   NOTE
   When you use shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

   $ oc get pod -n openshift-image-registry -l docker-registry=default

   Example output

   No resources found in openshift-image-registry namespace

   NOTE
   If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

   $ oc edit configs.imageregistry.operator.openshift.io

   Example output

   storage:
   pvc:
   claim:

   Leave the claim field blank to allow the automatic creation of an image-registry-storage PVC.

4. Check the clusteroperator status:

   $ oc get clusteroperator image-registry

   Example output
5. Ensure that your registry is set to managed to enable building and pushing of images.

   - Run:

     $ oc edit configs.imageregistry/cluster

     Then, change the line

     managementState: Removed

     to

     managementState: Managed

18.2.17.1.2. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set
the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

Procedure

- To set the image registry storage to an empty directory:

  $ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec":
  {"storage":{"emptyDir":{}}}}'

WARNING

Configure this option for only non-production clusters.

If you run this command before the Image Registry Operator initializes its components, the oc patch
command fails with the following error:

  Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found

Wait a few minutes and run the command again.

18.2.18. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure
that you provide.

Prerequisites
Your control plane has initialized.

You have completed the initial Operator configuration.

Procedure

1. Confirm that all the cluster components are online with the following command:

   ```bash
   $ watch -n5 oc get clusteroperators
   ```

Example output

<table>

</tr>
</tbody>
</table>

Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```bash
$ ./openshift-install --dir <installation_directory> wait-for install-complete
```

1 For `<installation_directory>`, specify the path to the directory that you stored the installation files in.
The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

2. Confirm that the Kubernetes API server is communicating with the pods.

   a. To view a list of all pods, use the following command:

   ```$ oc get pods --all-namespaces
   ```

   **Example output**

<table>
<thead>
<tr>
<th>NAMESPACE</th>
<th>NAME</th>

   b. View the logs for a pod that is listed in the output of the previous command by using the following command:

   ```$ oc logs <pod_name> -n <namespace>
   ```

   **Specify the pod name and namespace, as shown in the output of the previous command.**
If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation. See “Enabling multipathing with kernel arguments on RHCOS” in the Post-installation machine configuration tasks documentation for more information.

18.2.19. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager Hybrid Cloud Console.

After you confirm that your OpenShift Cluster Manager Hybrid Cloud Console inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service
- How to generate SOSREPORT within OpenShift4 nodes without SSH.

18.2.20. Next steps

- Enabling multipathing with kernel arguments on RHCOS.
- Customize your cluster.
- If necessary, you can opt out of remote health reporting.

18.3. INSTALLING A CLUSTER WITH Z/VM ON IBM Z AND IBM LINUXONE IN A RESTRICTED NETWORK

In OpenShift Container Platform version 4.14, you can install a cluster on IBM Z® or IBM® LinuxONE infrastructure that you provision in a restricted network.

NOTE

While this document refers to only IBM Z®, all information in it also applies to IBM® LinuxONE.

IMPORTANT

Additional considerations exist for non-bare metal platforms. Review the information in the guidelines for deploying OpenShift Container Platform on non-tested platforms before you install an OpenShift Container Platform cluster.

18.3.1. Prerequisites
You reviewed details about the OpenShift Container Platform installation and update processes.

You read the documentation on selecting a cluster installation method and preparing it for users.

You created a mirror registry for installation in a restricted network and obtained the `imageContentSources` data for your version of OpenShift Container Platform.

Before you begin the installation process, you must move or remove any existing installation files. This ensures that the required installation files are created and updated during the installation process.

IMPORTANT

Ensure that installation steps are done from a machine with access to the installation media.

You provisioned persistent storage using OpenShift Data Foundation or other supported storage protocols for your cluster. To deploy a private image registry, you must set up persistent storage with `ReadWriteMany` access.

If you use a firewall and plan to use the Telemetry service, you configured the firewall to allow the sites that your cluster requires access to.

NOTE

Be sure to also review this site list if you are configuring a proxy.

18.3.2. About installations in restricted networks

In OpenShift Container Platform 4.14, you can perform an installation that does not require an active connection to the internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service’s Route 53 DNS and IAM services, require internet access. Depending on your network, you might require less internet access for an installation on bare metal hardware, Nutanix, or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift image registry and contains the installation media. You can create this registry on a mirror host, which can access both the internet and your closed network, or by using other methods that meet your restrictions.

IMPORTANT

Because of the complexity of the configuration for user-provisioned installations, consider completing a standard user-provisioned infrastructure installation before you attempt a restricted network installation using user-provisioned infrastructure. Completing this test installation might make it easier to isolate and troubleshoot any issues that might arise during your installation in a restricted network.
18.3.2.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The `ClusterVersion` status includes an **Unable to retrieve available updates** error.
- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

18.3.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to obtain the images that are necessary to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager Hybrid Cloud Console](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

18.3.4. Requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

This section describes the requirements for deploying OpenShift Container Platform on user-provisioned infrastructure.

18.3.4.1. Required machines for cluster installation

The smallest OpenShift Container Platform clusters require the following hosts:

**Table 18.16. Minimum required hosts**

<table>
<thead>
<tr>
<th>Hosts</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>One temporary bootstrap machine</td>
<td>The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.</td>
</tr>
<tr>
<td>Three control plane machines</td>
<td>The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.</td>
</tr>
<tr>
<td>At least two compute machines, which are also known as worker machines.</td>
<td>The workloads requested by OpenShift Container Platform users run on the compute machines.</td>
</tr>
</tbody>
</table>
IMPORTANT

To improve high availability of your cluster, distribute the control plane machines over different z/VM instances on at least two physical machines.

The bootstrap, control plane, and compute machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 9.2 and inherits all of its hardware certifications and requirements. See Red Hat Enterprise Linux technology capabilities and limits.

18.3.4.2. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

Table 18.17. Minimum resource requirements

<table>
<thead>
<tr>
<th>Machine</th>
<th>Operating System</th>
<th>vCPU</th>
<th>Virtual RAM</th>
<th>Storage</th>
<th>Input/Output Per Second (IOPS)</th>
</tr>
</thead>
<tbody>
<tr>

<td>100 GB</td>
<td>N/A</td>
</tr>
</tbody>
</table>

1. One physical core (IFL) provides two logical cores (threads) when SMT-2 is enabled. The hypervisor can provide two or more vCPUs.

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

Additional resources

- Optimizing storage

18.3.4.3. Minimum IBM Z system environment

You can install OpenShift Container Platform version 4.14 on the following IBM® hardware:

- IBM® z16 (all models), IBM® z15 (all models), IBM® z14 (all models)
- IBM® LinuxONE 4 (all models), IBM® LinuxONE III (all models), IBM® LinuxONE Emperor II, IBM® LinuxONE Rockhopper II

Hardware requirements

- The equivalent of six Integrated Facilities for Linux (IFL), which are SMT2 enabled, for each cluster.
- At least one network connection to both connect to the LoadBalancer service and to serve data for traffic outside the cluster.
NOTE
You can use dedicated or shared IFLs to assign sufficient compute resources. Resource sharing is one of the key strengths of IBM Z®. However, you must adjust capacity correctly on each hypervisor layer and ensure sufficient resources for every OpenShift Container Platform cluster.

IMPORTANT
Since the overall performance of the cluster can be impacted, the LPARs that are used to set up the OpenShift Container Platform clusters must provide sufficient compute capacity. In this context, LPAR weight management, entitlements, and CPU shares on the hypervisor level play an important role.

Operating system requirements

- One instance of z/VM 7.2 or later

On your z/VM instance, set up:

- Three guest virtual machines for OpenShift Container Platform control plane machines
- Two guest virtual machines for OpenShift Container Platform compute machines
- One guest virtual machine for the temporary OpenShift Container Platform bootstrap machine

IBM Z network connectivity requirements

To install on IBM Z® under z/VM, you require a single z/VM virtual NIC in layer 2 mode. You also need:

- A direct-attached OSA or RoCE network adapter
- A z/VM VSwitch set up. For a preferred setup, use OSA link aggregation.

Disk storage for the z/VM guest virtual machines

- FICON attached disk storage (DASDs). These can be z/VM minidisks, fullpack minidisks, or dedicated DASDs, all of which must be formatted as CDL, which is the default. To reach the minimum required DASD size for Red Hat Enterprise Linux CoreOS (RHCOS) installations, you need extended address volumes (EAV). If available, use HyperPAV to ensure optimal performance.
- FCP attached disk storage

Storage / Main Memory

- 16 GB for OpenShift Container Platform control plane machines
- 8 GB for OpenShift Container Platform compute machines
- 16 GB for the temporary OpenShift Container Platform bootstrap machine

18.3.4.4. Preferred IBM Z system environment

Hardware requirements

- Three LPARS that each have the equivalent of six IFLs, which are SMT2 enabled, for each cluster.
• Two network connections to both connect to the LoadBalancer service and to serve data for traffic outside the cluster.

• HiperSockets, which are attached to a node either directly as a device or by bridging with one z/VM VSWITCH to be transparent to the z/VM guest. To directly connect HiperSockets to a node, you must set up a gateway to the external network via a RHEL 8 guest to bridge to the HiperSockets network.

Operating system requirements

• Two or three instances of z/VM 7.2 or later for high availability

On your z/VM instances, set up:

• Three guest virtual machines for OpenShift Container Platform control plane machines, one per z/VM instance.

• At least six guest virtual machines for OpenShift Container Platform compute machines, distributed across the z/VM instances.

• One guest virtual machine for the temporary OpenShift Container Platform bootstrap machine.

• To ensure the availability of integral components in an overcommitted environment, increase the priority of the control plane by using the CP command SET SHARE. Do the same for infrastructure nodes, if they exist. See SET SHARE in IBM® Documentation.

IBM Z network connectivity requirements
To install on IBM Z® under z/VM, you require a single z/VM virtual NIC in layer 2 mode. You also need:

• A direct-attached OSA or RoCE network adapter

• A z/VM VSwitch set up. For a preferred setup, use OSA link aggregation.

Disk storage for the z/VM guest virtual machines

• FICON attached disk storage (DASDs). These can be z/VM minidisks, fullpack minidisks, or dedicated DASDs, all of which must be formatted as CDL, which is the default. To reach the minimum required DASD size for Red Hat Enterprise Linux CoreOS (RHCOS) installations, you need extended address volumes (EAV). If available, use HyperPAV and High Performance FICON (zHPF) to ensure optimal performance.

• FCP attached disk storage

Storage / Main Memory

• 16 GB for OpenShift Container Platform control plane machines

• 8 GB for OpenShift Container Platform compute machines

• 16 GB for the temporary OpenShift Container Platform bootstrap machine

18.3.4.5. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The kube-controller-manager only approves the kubelet client CSRs. The machine-approver cannot guarantee the validity of a serving certificate that is requested by using
kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

Additional resources

- See Bridging a HiperSockets LAN with a z/VM Virtual Switch in IBM® Documentation.
- See Scaling HyperPAV alias devices on Linux guests on z/VM for performance optimization.
- See Topics in LPAR performance for LPAR weight management and entitlements.
- Recommended host practices for IBM Z® & IBM® LinuxONE environments

18.3.4.6. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in initramfs during boot to fetch their Ignition config files.

During the initial boot, the machines require an IP address configuration that is set either through a DHCP server or statically by providing the required boot options. After a network connection is established, the machines download their Ignition config files from an HTTP or HTTPS server. The Ignition config files are then used to set the exact state of each machine. The Machine Config Operator completes more changes to the machines, such as the application of new certificates or keys, after installation.

It is recommended to use a DHCP server for long-term management of the cluster machines. Ensure that the DHCP server is configured to provide persistent IP addresses, DNS server information, and hostnames to the cluster machines.

**NOTE**

If a DHCP service is not available for your user-provisioned infrastructure, you can instead provide the IP networking configuration and the address of the DNS server to the nodes at RHCOS install time. These can be passed as boot arguments if you are installing from an ISO image. See the Installing RHCOS and starting the OpenShift Container Platform bootstrap process section for more information about static IP provisioning and advanced networking options.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

18.3.4.6.1. Setting the cluster node hostnames through DHCP

On Red Hat Enterprise Linux CoreOS (RHCOS) machines, the hostname is set through NetworkManager. By default, the machines obtain their hostname through DHCP. If the hostname is not provided by DHCP, set statically through kernel arguments, or another method, it is obtained through a reverse DNS lookup. Reverse DNS lookup occurs after the network has been initialized on a node and can take time to resolve. Other system services can start prior to this and detect the hostname as localhost or similar. You can avoid this by using DHCP to provide the hostname for each cluster node.

Additionally, setting the hostnames through DHCP can bypass any manual DNS record name configuration errors in environments that have a DNS split-horizon implementation.
### 18.3.4.6.2. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

#### Table 18.18. Ports used for all-machine to all-machine communications

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Port</th>

</tbody>
</table>

**NTP configuration for user-provisioned infrastructure**

OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for *Configuring chrony time service*.

**Additional resources**

- Configuring chrony time service

**18.3.4.7. User-provisioned DNS requirements**

In OpenShift Container Platform deployments, DNS name resolution is required for the following components:

- The Kubernetes API
- The OpenShift Container Platform application wildcard
- The bootstrap, control plane, and compute machines

Reverse DNS resolution is also required for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the hostnames for all the nodes, unless the hostnames are provided by DHCP. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

The following DNS records are required for a user-provisioned OpenShift Container Platform cluster and they must be in place before installation. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>.

**Table 18.21. Required DNS records**

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes API</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the API load balancer. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Component</td>
<td>Record</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>---------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>api-int.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to internally identify the API load balancer. These records must be resolvable from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Routes</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A wildcard DNS A/AAAA or CNAME record that refers to the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster. For example, console-openshift-console.apps.&lt;cluster_name&gt;.&lt;base_domain&gt; is used as a wildcard route to the OpenShift Container Platform console.</td>
</tr>
<tr>
<td></td>
<td>bootstrap.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td></td>
<td>&lt;master&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td></td>
<td>&lt;worker&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**NOTE**

In OpenShift Container Platform 4.4 and later, you do not need to specify etcd host and SRV records in your DNS configuration.

**TIP**

You can use the `dig` command to verify name and reverse name resolution. See the section on *Validating DNS resolution for user-provisioned infrastructure* for detailed validation steps.
18.3.4.7.1. Example DNS configuration for user-provisioned clusters

This section provides A and PTR record configuration samples that meet the DNS requirements for deploying OpenShift Container Platform on user-provisioned infrastructure. The samples are not meant to provide advice for choosing one DNS solution over another.

In the examples, the cluster name is ocp4 and the base domain is example.com.

Example DNS A record configuration for a user-provisioned cluster

The following example is a BIND zone file that shows sample A records for name resolution in a user-provisioned cluster.

```plaintext
$TTL 1W
@ IN SOA ns1.example.com. root (2019070700 ; serial 3H ; refresh (3 hours)
30M ; retry (30 minutes)
2W ; expiry (2 weeks)
1W ) ; minimum (1 week)
IN NS ns1.example.com.
IN MX 10 smtp.example.com.

ns1.example.com. IN A 192.168.1.5
smtp.example.com. IN A 192.168.1.5

worker1.ocp4.example.com. IN A 192.168.1.17

;EOF
```

1. Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer.
2. Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer and is used for internal cluster communications.
3. Provides name resolution for the wildcard routes. The record refers to the IP address of the load balancer.
NOTE

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

4 Provides name resolution for the bootstrap machine.
5 6 7 Provides name resolution for the control plane machines.
8 9 Provides name resolution for the compute machines.

Example DNS PTR record configuration for a user-provisioned cluster

The following example BIND zone file shows sample PTR records for reverse name resolution in a user-provisioned cluster.

Example 18.5. Sample DNS zone database for reverse records

```
$TTL 1W
@ IN SOA ns1.example.com. root ( 2019070700 ; serial
3H ; refresh (3 hours)
30M ; retry (30 minutes)
2W ; expiry (2 weeks)
1W ) ; minimum (1 week)
IN NS ns1.example.com.
;
5.1.168.192.in-addr.arpa. IN PTR api.ocp4.example.com. 1
5.1.168.192.in-addr.arpa. IN PTR api-int.ocp4.example.com. 2
;
96.1.168.192.in-addr.arpa. IN PTR bootstrap.ocp4.example.com. 3
;
97.1.168.192.in-addr.arpa. IN PTR master0.ocp4.example.com. 4
98.1.168.192.in-addr.arpa. IN PTR master1.ocp4.example.com. 5
99.1.168.192.in-addr.arpa. IN PTR master2.ocp4.example.com. 6
;
11.1.168.192.in-addr.arpa. IN PTR worker0.ocp4.example.com. 7
7.1.168.192.in-addr.arpa. IN PTR worker1.ocp4.example.com. 8
;
;EOF
```

1 Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer.
2 Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer and is used for internal cluster communications.
3 Provides reverse DNS resolution for the bootstrap machine.
4 5 6 Provides reverse DNS resolution for the control plane machines.
Provides reverse DNS resolution for the compute machines.

NOTE

A PTR record is not required for the OpenShift Container Platform application wildcard.

18.3.4.8. Load balancing requirements for user-provisioned infrastructure

Before you install OpenShift Container Platform, you must provision the API and application Ingress load balancing infrastructure. In production scenarios, you can deploy the API and application Ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

NOTE

If you want to deploy the API and application Ingress load balancers with a Red Hat Enterprise Linux (RHEL) instance, you must purchase the RHEL subscription separately.

The load balancing infrastructure must meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:

   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.
   - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

   **IMPORTANT**

   Do not configure session persistence for an API load balancer. Configuring session persistence for a Kubernetes API server might cause performance issues from excess application traffic for your OpenShift Container Platform cluster and the Kubernetes API that runs inside the cluster.

Configure the following ports on both the front and back of the load balancers:

**Table 18.22. API load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the /readyz endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
</tbody>
</table>
Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>

**NOTE**

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the `/readyz` endpoint to the removal of the API server instance from the pool. Within the time frame after `/readyz` returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application Ingress load balancer**: Provides an ingress point for application traffic flowing in from outside the cluster. A working configuration for the Ingress router is required for an OpenShift Container Platform cluster.

Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

**TIP**

If the true IP address of the client can be seen by the application Ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

Configure the following ports on both the front and back of the load balancers:

**Table 18.23. Application Ingress load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>
If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application Ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

18.3.4.8.1. Example load balancer configuration for user-provisioned clusters

This section provides an example API and application Ingress load balancer configuration that meets the load balancing requirements for user-provisioned clusters. The sample is an `/etc/haproxy/haproxy.cfg` configuration for an HAProxy load balancer. The example is not meant to provide advice for choosing one load balancing solution over another.

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

If you are using HAProxy as a load balancer and SELinux is set to enforcing, you must ensure that the HAProxy service can bind to the configured TCP port by running `setsebool -P haproxy_connect_any=1`.

**Example 18.6. Sample API and application Ingress load balancer configuration**

```conf
global
log    127.0.0.1 local2
pidfile /var/run/haproxy.pid
maxconn 4000
daemon
defaults
mode                   http
log                     global
option                  dontlognull
option http-server-close
option                  redispatch
retries                 3
timeout http-request   10s
timeout queue          1m
timeout connect        10s
timeout client         1m
timeout server         1m
timeout http-keep-alive 10s
timeout check          10s
maxconn                 3000

listen api-server-6443 1
bind *:6443
mode tcp
server bootstrap bootstrap.ocp4.example.com:6443 check inter 1s backup
server master0 master0.ocp4.example.com:6443 check inter 1s
server master1 master1.ocp4.example.com:6443 check inter 1s
server master2 master2.ocp4.example.com:6443 check inter 1s
listen machine-config-server-22623 3
```
Port 6443 handles the Kubernetes API traffic and points to the control plane machines.

The bootstrap entries must be in place before the OpenShift Container Platform cluster installation and they must be removed after the bootstrap process is complete.

Port 22623 handles the machine config server traffic and points to the control plane machines.

Port 443 handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

Port 80 handles the HTTP traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application Ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

**TIP**

If you are using HAProxy as a load balancer, you can check that the `haproxy` process is listening on ports 6443, 22623, 443, and 80 by running `netstat -nltpu` on the HAProxy node.

### 18.3.5. Preparing the user-provisioned infrastructure

Before you install OpenShift Container Platform on user-provisioned infrastructure, you must prepare the underlying infrastructure.

This section provides details about the high-level steps required to set up your cluster infrastructure in preparation for an OpenShift Container Platform installation. This includes configuring IP networking and network connectivity for your cluster nodes, preparing a web server for the Ignition files, enabling
the required ports through your firewall, and setting up the required DNS and load balancing infrastructure.

After preparation, your cluster infrastructure must meet the requirements outlined in the Requirements for a cluster with user-provisioned infrastructure section.

Prerequisites

- You have reviewed the OpenShift Container Platform 4.x Tested Integrations page.
- You have reviewed the infrastructure requirements detailed in the Requirements for a cluster with user-provisioned infrastructure section.

Procedure

1. Set up static IP addresses.

2. Set up an HTTP or HTTPS server to provide Ignition files to the cluster nodes.

3. Ensure that your network infrastructure provides the required network connectivity between the cluster components. See the Networking requirements for user-provisioned infrastructure section for details about the requirements.

4. Configure your firewall to enable the ports required for the OpenShift Container Platform cluster components to communicate. See Networking requirements for user-provisioned infrastructure section for details about the ports that are required.

   **IMPORTANT**

   By default, port 1936 is accessible for an OpenShift Container Platform cluster, because each control plane node needs access to this port.

   Avoid using the Ingress load balancer to expose this port, because doing so might result in the exposure of sensitive information, such as statistics and metrics, related to Ingress Controllers.

5. Setup the required DNS infrastructure for your cluster.

   a. Configure DNS name resolution for the Kubernetes API, the application wildcard, the bootstrap machine, the control plane machines, and the compute machines.

   b. Configure reverse DNS resolution for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines. See the User-provisioned DNS requirements section for more information about the OpenShift Container Platform DNS requirements.

6. Validate your DNS configuration.

   a. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses in the responses correspond to the correct components.

   b. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names in the responses correspond to the correct components.
See the Validating DNS resolution for user-provisioned infrastructure section for detailed DNS validation steps.

7. Provision the required API and application ingress load balancing infrastructure. See the Load balancing requirements for user-provisioned infrastructure section for more information about the requirements.

**NOTE**

Some load balancing solutions require the DNS name resolution for the cluster nodes to be in place before the load balancing is initialized.

### 18.3.6. Validating DNS resolution for user-provisioned infrastructure

You can validate your DNS configuration before installing OpenShift Container Platform on user-provisioned infrastructure.

**IMPORTANT**

The validation steps detailed in this section must succeed before you install your cluster.

**Prerequisites**

- You have configured the required DNS records for your user-provisioned infrastructure.

**Procedure**

1. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses contained in the responses correspond to the correct components.

   a. Perform a lookup against the Kubernetes API record name. Check that the result points to the IP address of the API load balancer:

   ```
   $ dig +noall +answer @<nameserver_ip> api.<cluster_name>.<base_domain>
   
   api.ocp4.example.com.  604800 IN A 192.168.1.5
   ```

   Replace `<nameserver_ip>` with the IP address of the nameserver, `<cluster_name>` with your cluster name, and `<base_domain>` with your base domain name.

   **Example output**

   ```
   api.ocp4.example.com.  604800 IN A 192.168.1.5
   ```

   b. Perform a lookup against the Kubernetes internal API record name. Check that the result points to the IP address of the API load balancer:

   ```
   $ dig +noall +answer @<nameserver_ip> api-int.<cluster_name>.<base_domain>
   
   api-int.ocp4.example.com.  604800 IN A 192.168.1.5
   ```

   **Example output**

   ```
   api-int.ocp4.example.com.  604800 IN A 192.168.1.5
   ```
c. Test an example `*.apps.<cluster_name>.<base_domain>` DNS wildcard lookup. All of the application wildcard lookups must resolve to the IP address of the application ingress load balancer:

```
$ dig +noall +answer @<nameserver_ip> random.apps.<cluster_name>.<base_domain>
```

**Example output**

```
random.apps.ocp4.example.com. 604800 IN A 192.168.1.5
```

**NOTE**

In the example outputs, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

You can replace `random` with another wildcard value. For example, you can query the route to the OpenShift Container Platform console:

```
$ dig +noall +answer @<nameserver_ip> console-openshift-console.apps.<cluster_name>.<base_domain>
```

**Example output**

```
console-openshift-console.apps.ocp4.example.com. 604800 IN A 192.168.1.5
```

d. Run a lookup against the bootstrap DNS record name. Check that the result points to the IP address of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> bootstrap.<cluster_name>.<base_domain>
```

**Example output**

```
bootstrap.ocp4.example.com. 604800 IN A 192.168.1.96
```

e. Use this method to perform lookups against the DNS record names for the control plane and compute nodes. Check that the results correspond to the IP addresses of each node.

2. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names contained in the responses correspond to the correct components.

a. Perform a reverse lookup against the IP address of the API load balancer. Check that the response includes the record names for the Kubernetes API and the Kubernetes internal API:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.5
```

**Example output**
5.1.168.192.in-addr.arpa. 604800 IN PTR api-int.ocp4.example.com.

1. Provides the record name for the Kubernetes internal API.
2. Provides the record name for the Kubernetes API.

NOTE

A PTR record is not required for the OpenShift Container Platform application wildcard. No validation step is needed for reverse DNS resolution against the IP address of the application ingress load balancer.

b. Perform a reverse lookup against the IP address of the bootstrap node. Check that the result points to the DNS record name of the bootstrap node:

$ dig +noall +answer @<nameserver_ip> -x 192.168.1.96

Example output

18.3.7. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The ./openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:
Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

NOTE

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the `x86_64`, `ppc64le`, and `s390x` architectures, do not create a key that uses the `ed25519` algorithm. Instead, create a key that uses the `rsa` or `ecdsa` algorithm.

2. View the public SSH key:

   $ cat <path>/<file_name>.pub

   For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

   $ cat ~/.ssh/id_ed25519.pub

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `/openshift-install gather` command.

   NOTE

   On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

   a. If the `ssh-agent` process is not already running for your local user, start it as a background task:

      $ eval "$(ssh-agent -s)"

      Example output

      Agent pid 31874

      NOTE

      If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the `ssh-agent`:

   $ ssh-add <path>/<file_name>  

   Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`
Example output

- Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

18.3.8. Manually creating the installation configuration file

Prerequisites

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.
- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Create an installation directory to store your required installation assets in:

   $ mkdir <installation_directory>

   **IMPORTANT**

   You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample `install-config.yaml` file template that is provided and save it in the `<installation_directory>`.  

   **NOTE**

   You must name this configuration file `install-config.yaml`.

   **NOTE**

   For some platform types, you can alternatively run `./openshift-install create install-config --dir <installation_directory>` to generate an `install-config.yaml` file. You can provide details about your cluster configuration at the prompts.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.
IMPORTANT

The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.

Additional resources

- Installation configuration parameters for IBM Z

18.3.8.1. Sample install-config.yaml file for IBM Z

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute: 
  - hyperthreading: Enabled
    name: worker
    replicas: 0
    architecture: s390x
controlPlane: 
  hyperthreading: Enabled
  name: master
  replicas: 3
  architecture: s390x
metadata: 
  name: test
networking: 
  clusterNetwork: 
    - cidr: 10.128.0.0/14
    hostPrefix: 23
  networkType: OVNKubernetes
  serviceNetwork: 
    - 172.30.0.0/16
platform: 
  none: {}
fips: false
pullSecret: '{"auths":{"<local_registry>":{"auth": "<credentials>","email": "you@example.com"}}}'
sshKey: 'ssh-ed25519 AAAA...
additionalTrustBundle: |
  -----BEGIN CERTIFICATE-----
  ZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZ
  -----END CERTIFICATE-----
imageContentSources: 
  - mirrors: 
    - <local_repository>/ocp4/openshift4
    source: quay.io/openshift-release-dev/ocp-release
  - mirrors: 
    - <local_repository>/ocp4/openshift4
    source: quay.io/openshift-release-dev/ocp-v4.0-art-dev
```
The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -., and the first line of the **controlPlane** section must not. Only one control plane pool is used.

Specifies whether to enable or disable simultaneous multithreading (SMT), or hyperthreading. By default, SMT is enabled to increase the performance of the cores in your machines. You can disable it by setting the parameter value to **Disabled**. If you disable SMT, you must disable it in all cluster machines; this includes both control plane and compute machines.

**NOTE**

Simultaneous multithreading (SMT) is enabled by default. If SMT is not available on your OpenShift Container Platform nodes, the **hyperthreading** parameter has no effect.

**IMPORTANT**

If you disable **hyperthreading**, whether on your OpenShift Container Platform nodes or in the **install-config.yaml** file, ensure that your capacity planning accounts for the dramatically decreased machine performance.

You must set this value to **0** when you install OpenShift Container Platform on user-provisioned infrastructure. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. In user-provisioned installations, you must manually deploy the compute machines before you finish installing the cluster.

**NOTE**

If you are installing a three-node cluster, do not deploy any compute machines when you install the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

The cluster name that you specified in your DNS records.

A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to access the pods from an external network, you must configure load balancers and routers to manage the traffic.

**NOTE**

Class E CIDR range is reserved for a future use. To use the Class E CIDR range, you must ensure your networking environment accepts the IP addresses within the Class E CIDR range.
The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23, then each node is assigned a /23 subnet out of the given cidr, which allows for 510 \(2^{(32 - 23) - 2}\).

11 The cluster network plugin to install. The supported values are OVNKubernetes and OpenShiftSDN. The default value is OVNKubernetes.

12 The IP address pool to use for service IP addresses. You can enter only one IP address pool. This block must not overlap with existing physical networks. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.

13 You must set the platform to none. You cannot provide additional platform configuration variables for IBM Z® infrastructure.

**IMPORTANT**

Clusters that are installed with the platform type none are unable to use some features, such as managing compute machines with the Machine API. This limitation applies even if the compute machines that are attached to the cluster are installed on a platform that would normally support the feature. This parameter cannot be changed after installation.

14 Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see [Installing the system in FIPS mode](#). When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures.

15 For `<local_registry>`, specify the registry domain name, and optionally the port, that your mirror registry uses to serve content. For example, `registry.example.com` or `registry.example.com:5000`. For `<credentials>`, specify the base64-encoded user name and password for your mirror registry.

16 The SSH public key for the core user in Red Hat Enterprise Linux CoreOS (RHCOS).

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

17 Add the additionalTrustBundle parameter and value. The value must be the contents of the certificate file that you used for your mirror registry. The certificate file can be an existing, trusted certificate authority or the self-signed certificate that you generated for the mirror registry.
Provide the `imageContentSources` section according to the output of the command that you used to mirror the repository.

**IMPORTANT**

- When using the `oc adm release mirror` command, use the output from the `imageContentSources` section.

- When using `oc mirror` command, use the `repositoryDigestMirrors` section of the `ImageContentSourcePolicy` file that results from running the command.

- `ImageContentSourcePolicy` is deprecated. For more information see Configuring image registry repository mirroring.

### 18.3.8.2. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**Prerequisites**

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The `Proxy` object status.noProxy field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object status.noProxy field is also populated with the instance metadata endpoint (169.254.169.254).

**Procedure**

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port>
  httpsProxy: https://<username>:<pswd>@<ip>:<port>
  noProxy: example.com
additionalTrustBundle: |
-----BEGIN CERTIFICATE-----
```
A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.

A proxy URL to use for creating HTTPS connections outside the cluster.

A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with `.` to match subdomains only. For example, `.y.com` matches `x.y.com`, but not `y.com`. Use `*` to bypass the proxy for all destinations.

If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the `trustedCA` field of the `Proxy` object. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

Optional: The policy to determine the configuration of the `Proxy` object to reference the `user-ca-bundle` config map in the `trustedCA` field. The allowed values are `Proxyonly` and `Always`. Use `Proxyonly` to reference the `user-ca-bundle` config map only when `http/https` proxy is configured. Use `Always` to always reference the `user-ca-bundle` config map. The default value is `Proxyonly`.

NOTE

The installation program does not support the proxy `readinessEndpoints` field.

NOTE

If the installer times out, restart and then complete the deployment by using the `wait-for` command of the installer. For example:

```bash
$ ./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

NOTE

Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

18.3.8.3. Configuring a three-node cluster
Optionally, you can deploy zero compute machines in a minimal three node cluster that consists of three control plane machines only. This provides smaller, more resource efficient clusters for cluster administrators and developers to use for testing, development, and production.

In three-node OpenShift Container Platform environments, the three control plane machines are schedulable, which means that your application workloads are scheduled to run on them.

Prerequisites

- You have an existing `install-config.yaml` file.

Procedure

- Ensure that the number of compute replicas is set to 0 in your `install-config.yaml` file, as shown in the following `compute` stanza:

```yaml
compute:
  - name: worker
    platform: {}
    replicas: 0
```

**NOTE**

You must set the value of the `replicas` parameter for the compute machines to 0 when you install OpenShift Container Platform on user-provisioned infrastructure, regardless of the number of compute machines you are deploying. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. This does not apply to user-provisioned installations, where the compute machines are deployed manually.

**NOTE**

The preferred resource for control plane nodes is six vCPUs and 21 GB. For three control plane nodes this is the memory + vCPU equivalent of a minimum five-node cluster. You should back the three nodes, each installed on a 120 GB disk, with three IFLs that are SMT2 enabled. The minimum tested setup is three vCPUs and 10 GB on a 120 GB disk for each control plane node.

For three-node cluster installations, follow these next steps:

- If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes. See the *Load balancing requirements for user-provisioned infrastructure* section for more information.

- When you create the Kubernetes manifest files in the following procedure, ensure that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file is set to true. This enables your application workloads to run on the control plane nodes.

- Do not deploy any compute nodes when you create the Red Hat Enterprise Linux CoreOS (RHCOS) machines.
18.3.9. Cluster Network Operator configuration

The configuration for the cluster network is specified as part of the Cluster Network Operator (CNO) configuration and stored in a custom resource (CR) object that is named `cluster`. The CR specifies the fields for the `Network` API in the `operator.openshift.io` API group.

The CNO configuration inherits the following fields during cluster installation from the `Network` API in the `Network.config.openshift.io` API group and these fields cannot be changed:

- **clusterNetwork**: IP address pools from which pod IP addresses are allocated.
- **serviceNetwork**: IP address pool for services.
- **defaultNetwork.type**: Cluster network plugin, such as OpenShift SDN or OVN-Kubernetes.

You can specify the cluster network plugin configuration for your cluster by setting the fields for the `defaultNetwork` object in the CNO object named `cluster`.

18.3.9.1. Cluster Network Operator configuration object

The fields for the Cluster Network Operator (CNO) are described in the following table:

**Table 18.24. Cluster Network Operator configuration object**

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>metadata.name</td>
<td>string</td>
<td>The name of the CNO object. This name is always <code>cluster</code>.</td>
</tr>
<tr>
<td>spec.clusterNetwork</td>
<td>array</td>
<td>A list specifying the blocks of IP addresses from which pod IP addresses are allocated and the subnet prefix length assigned to each individual node in the cluster. For example:</td>
</tr>
</tbody>
</table>
|                      |            | spec:
|                      |            |   clusterNetwork:
|                      |            |     - cidr: 10.128.0.0/19
|                      |            |     hostPrefix: 23
|                      |            |     - cidr: 10.128.32.0/19
|                      |            |     hostPrefix: 23

You can customize this field only in the `install-config.yaml` file before you create the manifests. The value is read-only in the manifest file.
A block of IP addresses for services. The OpenShift SDN and OVN-Kubernetes network plugins support only a single IP address block for the service network. For example:

```
spec:
  serviceNetwork:
    - 172.30.0.0/14
```

You can customize this field only in the `install-config.yaml` file before you create the manifests. The value is read-only in the manifest file.

**defaultNetwork object configuration**

The values for the `defaultNetwork` object are defined in the following table:

**Table 18.25. defaultNetwork object**

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>string</td>
<td>Either OpenShiftSDN or OVNKubernetes. The Red Hat OpenShift Networking network plugin is selected during installation. This value cannot be changed after cluster installation.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>NOTE</strong> OpenShift Container Platform uses the OVN-Kubernetes network plugin by default.</td>
</tr>
<tr>
<td>openshiftSDNConfig</td>
<td>object</td>
<td>This object is only valid for the OpenShift SDN network plugin.</td>
</tr>
<tr>
<td>ovnKubernetesConfig</td>
<td>object</td>
<td>This object is only valid for the OVN-Kubernetes network plugin.</td>
</tr>
</tbody>
</table>

**Configuration for the OpenShift SDN network plugin**

The following table describes the configuration fields for the OpenShift SDN network plugin:

**Table 18.26. openshiftSDNConfig object**

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>spec.serviceNet work</td>
<td>array</td>
<td>A block of IP addresses for services. The OpenShift SDN and OVN-Kubernetes network plugins support only a single IP address block for the service network. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>spec: serviceNetwork: - 172.30.0.0/14</td>
</tr>
<tr>
<td>spec.defaultNet work</td>
<td>object</td>
<td>Configures the network plugin for the cluster network.</td>
</tr>
<tr>
<td>spec.kubeProxy Config</td>
<td>object</td>
<td>The fields for this object specify the kube-proxy configuration. If you are using the OVN-Kubernetes cluster network plugin, the kube-proxy configuration has no effect.</td>
</tr>
</tbody>
</table>
### Field | Type | Description
---|---|---
mode | string | Configures the network isolation mode for OpenShift SDN. The default value is **NetworkPolicy**.

The values **Multitenant** and **Subnet** are available for backwards compatibility with OpenShift Container Platform 3.x but are not recommended. This value cannot be changed after cluster installation.

mtu | integer | The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.

If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.

If your cluster requires different MTU values for different nodes, you must set this value to **50** less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of **9001**, and some have an MTU of **1500**, you must set this value to **1450**.

This value cannot be changed after cluster installation.

vxlanPort | integer | The port to use for all VXLAN packets. The default value is **4789**. This value cannot be changed after cluster installation.

If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number.

On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port **9000** and port **9999**.

---

**Example OpenShift SDN configuration**

```yaml
defaultNetwork:
  type: OpenShiftSDN
  openshiftSDNConfig:
    mode: NetworkPolicy
    mtu: 1450
    vxlanPort: 4789
```

**Configuration for the OVN-Kubernetes network plugin**

The following table describes the configuration fields for the OVN-Kubernetes network plugin:

<p>| Table 18.27. ovnKubernetesConfig object |</p>
<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mtu</td>
<td>integer</td>
<td>The maximum transmission unit (MTU) for the Geneve (Generic Network Virtualization Encapsulation) overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU. If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes. If your cluster requires different MTU values for different nodes, you must set this value to 100 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1400.</td>
</tr>
<tr>
<td>genevePort</td>
<td>integer</td>
<td>The port to use for all Geneve packets. The default value is 6081. This value cannot be changed after cluster installation.</td>
</tr>
<tr>
<td>ipsecConfig</td>
<td>object</td>
<td>Specify an empty object to enable IPsec encryption.</td>
</tr>
<tr>
<td>policyAuditConfig</td>
<td>object</td>
<td>Specify a configuration object for customizing network policy audit logging. If unset, the defaults audit log settings are used.</td>
</tr>
<tr>
<td>gatewayConfig</td>
<td>object</td>
<td>Optional: Specify a configuration object for customizing how egress traffic is sent to the node gateway.</td>
</tr>
</tbody>
</table>

**NOTE**

While migrating egress traffic, you can expect some disruption to workloads and service traffic until the Cluster Network Operator (CNO) successfully rolls out the changes.
If your existing network infrastructure overlaps with the 100.64.0.0/16 IPv4 subnet, you can specify a different IP address range for internal use by OVN-Kubernetes. You must ensure that the IP address range does not overlap with any other subnet used by your OpenShift Container Platform installation. The IP address range must be larger than the maximum number of nodes that can be added to the cluster. For example, if the `clusterNetwork.cidr` value is 10.128.0.0/14 and the `clusterNetwork.hostPrefix` value is /23, then the maximum number of nodes is $2^{(23-14)}=512$.

This field cannot be changed after installation.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>v4InternalSubnet</td>
<td></td>
<td>The default value is 100.64.0.0/16.</td>
</tr>
</tbody>
</table>
If your existing network infrastructure overlaps with the \texttt{fd98::/48} IPv6 subnet, you can specify a different IP address range for internal use by OVN-Kubernetes. You must ensure that the IP address range does not overlap with any other subnet used by your OpenShift Container Platform installation. The IP address range must be larger than the maximum number of nodes that can be added to the cluster.

This field cannot be changed after installation.

The default value is \texttt{fd98::/48}.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{v6InternalSubnet}</td>
<td></td>
<td>The default value is \texttt{fd98::/48}.</td>
</tr>
</tbody>
</table>

### Table 18.28. policyAuditConfig object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{rateLimit}</td>
<td>integer</td>
<td>The maximum number of messages to generate every second per node. The default value is 20 messages per second.</td>
</tr>
<tr>
<td>\texttt{maxFileSize}</td>
<td>integer</td>
<td>The maximum size for the audit log in bytes. The default value is 50000000 or 50 MB.</td>
</tr>
</tbody>
</table>
destination: string

One of the following additional audit log targets:

- libc
  The libc `syslog()` function of the journald process on the host.
- udp:<host>:<port>
  A syslog server. Replace `<host>:<port>` with the host and port of the syslog server.
- unix:<file>
  A Unix Domain Socket file specified by `<file>`.
- null
  Do not send the audit logs to any additional target.

syslogFacility: string

The syslog facility, such as `kern`, as defined by RFC5424. The default value is `local0`.

### Table 18.29. `gatewayConfig` object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>routingViaHost</td>
<td>boolean</td>
<td>Set this field to <code>true</code> to send egress traffic from pods to the host networking stack. For highly-specialized installations and applications that rely on manually configured routes in the kernel routing table, you might want to route egress traffic to the host networking stack. By default, egress traffic is processed in OVN to exit the cluster and is not affected by specialized routes in the kernel routing table. The default value is <code>false</code>. This field has an interaction with the Open vSwitch hardware offloading feature. If you set this field to <code>true</code>, you do not receive the performance benefits of the offloading because egress traffic is processed by the host networking stack.</td>
</tr>
<tr>
<td>ipForwarding</td>
<td>object</td>
<td>You can control IP forwarding for all traffic on OVN-Kubernetes managed interfaces by using the <code>ipForwarding</code> specification in the <code>Network</code> resource. Specify <code>Restricted</code> to only allow IP forwarding for Kubernetes related traffic. Specify <code>Global</code> to allow forwarding of all IP traffic. For new installations, the default is <code>Restricted</code>. For updates to OpenShift Container Platform 4.14, the default is <code>Global</code>.</td>
</tr>
</tbody>
</table>

### Example OVN-Kubernetes configuration with IPSec enabled

```yaml
defaultNetwork:
  type: OVNKubernetes
  ovnKubernetesConfig:
    mtu: 1400
    genevePort: 6081
    ipsecConfig: {}
```
kubeProxyConfig object configuration

The values for the kubeProxyConfig object are defined in the following table:

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>iptablesSyncPeriod</td>
<td>string</td>
<td>The refresh period for iptables rules. The default value is <strong>30s</strong>. Valid suffixes include s, m, and h and are described in the Go time package documentation.</td>
</tr>
<tr>
<td>proxyArguments.iptables-min-sync-period</td>
<td>array</td>
<td>The minimum duration before refreshing iptables rules. This field ensures that the refresh does not happen too frequently. Valid suffixes include s, m, and h and are described in the Go time package. The default value is: kubeProxyConfig: proxyArguments: iptables-min-sync-period: - 0s</td>
</tr>
</tbody>
</table>

**NOTE**

Because of performance improvements introduced in OpenShift Container Platform 4.3 and greater, adjusting the iptablesSyncPeriod parameter is no longer necessary.

18.3.10. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.
IMPORTANT

- The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

NOTE

The installation program that generates the manifest and Ignition files is architecture specific and can be obtained from the client image mirror. The Linux version of the installation program runs on s390x only. This installer program is also available as a Mac OS version.

Prerequisites

- You obtained the OpenShift Container Platform installation program. For a restricted network installation, these files are on your mirror host.

- You created the `install-config.yaml` installation configuration file.

Procedure

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

   ```
   $ ./openshift-install create manifests --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.

WARNING

If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.
IMPORTANT

When you configure control plane nodes from the default unschedulable to schedulable, additional subscriptions are required. This is because control plane nodes then become compute nodes.

2. Check that the mastersSchedulable parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to false. This setting prevents pods from being scheduled on the control plane machines:
   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.
   b. Locate the mastersSchedulable parameter and ensure that it is set to false.
   c. Save and exit the file.

3. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

```
$ ./openshift-install create ignition-configs --dir <installation_directory>
```

For `<installation_directory>`, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The kubadmin-password and kubeconfig files are created in the `<installation_directory>/auth` directory:

```
├── auth
│   ├── kubadmin-password
│   └── kubeconfig
├── bootstrap.ign
├── master.ign
├── metadata.json
└── worker.ign
```

18.3.11. Configuring NBDE with static IP in an IBM Z or IBM LinuxONE environment

Enabling NBDE disk encryption in an IBM Z® or IBM® LinuxONE environment requires additional steps, which are described in detail in this section.

Prerequisites

- You have set up the External Tang Server. See Network-bound disk encryption for instructions.
- You have installed the butane utility.
- You have reviewed the instructions for how to create machine configs with Butane.

Procedure

1. Create Butane configuration files for the control plane and compute nodes.
The following example of a Butane configuration for a control plane node creates a file named `master-storage.bu` for disk encryption:

```yaml
variant: openshift
version: 4.14.0
metadata:
  name: master-storage
labels:
  machineconfiguration.openshift.io/role: master
storage:
  luks:
    - clevis:
      tang:
        thumbprint: QcPr_NHFJammnRCA3ifFMVdNBwjs
        url: http://clevis.example.com:7500
    options: 
      --cipher
      aes-cbc-essiv:sha256
device: /dev/disk/by-partlabel/root
label: luks-root
name: root
wipe_volume: true
filesystems:
  - device: /dev/mapper/root
    format: xfs
    label: root
    wipe_filesystem: true
```

1. The cipher option is only required if FIPS mode is enabled. Omit the entry if FIPS is disabled.

2. For installations on DASD-type disks, replace with `device: /dev/disk/by-label/root`.

3. Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

2. Create a customized initramfs file to boot the machine, by running the following command:

```
$ coreos-installer pxe customize \
/root/rhcos-bootfiles/rhcos-<release>-live-initramfs.s390x.img \ 
--dest-device /dev/disk/by-id/scsi-<serial-number> --dest-karg-append \ 
ip=<ip-address> ::<gateway-ip> ::<subnet-mask> ::<network-device> ::none \ 
--dest-karg-append nameserver=<nameserver-ip> \ 
--dest-karg-append rd.neednet=1 -o \ 
/root/rhcos-bootfiles/<Node-name>-initramfs.s390x.img
```

**NOTE**

Before first boot, you must customize the initramfs for each node in the cluster, and add PXE kernel parameters.
3. Create a parameter file that includes `ignition.platform.id=metal` and `ignition.firstboot`.

Example kernel parameter file for the control plane machine:

```bash
rd.neednet=1 \ console=ttySCLP0 \ coreos.inst.install_dev=/dev/dasda \ ignition.firstboot ignition.platform.id=metal \ coreos.live.rootfs_url=http://10.19.17.25/redhat/ocp/rhcos-413.86.202302201445-0/rhcos-413.86.202302201445-0-live-rootfs.s390x.img \ coreos.inst.ignition_url=http://bastion.ocp-cluster1.example.com:8080/ignition/master.ign \ ip=10.19.17.2::10.19.17.1:255.255.255.0::enb0d0:none nameserver=10.19.17.1 \ zfcp.allow_lun_scan=0 \ rd.znet=qeth0.0.bdd0,0.0.bdd1,0.0.bdd2,layer2=1 \ rd.zfcps=0.0.5677,0x600606680g7f0056,0x034F000000000000 \ zfcp.allow_lun_scan=0 \ rd.znet=qeth0.0.bdd0,0.0.bdd1,0.0.bdd2,layer2=1 \ rd.zfcps=0.0.5677,0x600606680g7f0056,0x034F000000000000
```

1. For installations on DASD-type disks, add `coreos.inst.install_dev=/dev/dasda`. Omit this value for FCP-type disks.

2. For installations on FCP-type disks, add `zfcp.allow_lun_scan=0`. Omit this value for DASD-type disks.

3. For installations on DASD-type disks, replace with `rd.dasd=0.0.3490` to specify the DASD device.

**NOTE**

Write all options in the parameter file as a single line and make sure you have no newline characters.

### Additional resources

- [Creating machine configs with Butane](#)

### 18.3.12. Installing RHCOS and starting the OpenShift Container Platform bootstrap process

To install OpenShift Container Platform on IBM Z® infrastructure that you provision, you must install Red Hat Enterprise Linux CoreOS (RHCOS) on z/VM guest virtual machines. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS z/VM guest virtual machines have rebooted.

Complete the following steps to create the machines.

**Prerequisites**

- An HTTP or HTTPS server running on your provisioning machine that is accessible to the machines you create.
Procedure

1. Log in to Linux on your provisioning machine.

2. Obtain the Red Hat Enterprise Linux CoreOS (RHCOS) kernel, initramfs, and rootfs files from the RHCOS image mirror.

   **IMPORTANT**

   The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate kernel, initramfs, and rootfs artifacts described in the following procedure.

   The file names contain the OpenShift Container Platform version number. They resemble the following examples:

   - **kernel**: `rhcos-<version>-live-kernel-<architecture>`
   - **initramfs**: `rhcos-<version>-live-initramfs.<architecture>.img`
   - **rootfs**: `rhcos-<version>-live-rootfs.<architecture>.img`

   **NOTE**

   The rootfs image is the same for FCP and DASD.

3. Create parameter files. The following parameters are specific for a particular virtual machine:

   - For `ip=`, specify the following seven entries:
     i. The IP address for the machine.
     ii. An empty string.
     iii. The gateway.
     iv. The netmask.
     v. The machine host and domain name in the form `hostname.domainname`. Omit this value to let RHCOS decide.
     vi. The network interface name. Omit this value to let RHCOS decide.
     vii. If you use static IP addresses, specify `none`.

   - For `coreos.inst.ignition_url=`, specify the Ignition file for the machine role. Use `bootstrap.ign`, `master.ign`, or `worker.ign`. Only HTTP and HTTPS protocols are supported.

   - For `coreos.live.rootfs_url=`, specify the matching rootfs artifact for the kernel and initramfs you are booting. Only HTTP and HTTPS protocols are supported.

   - For installations on DASD-type disks, complete the following tasks:
     i. For `coreos.inst.install_dev=`, specify `/dev/dasda`. 
ii. Use `rd.dasd=` to specify the DASD where RH COS is to be installed.

iii. Leave all other parameters unchanged.

Example parameter file, `bootstrap-0.parm`, for the bootstrap machine:

```
rd.neednet=1 \ 
console=ttysclp0 \ 
coreos.inst.install_dev=/dev/dasda \ 
coreos.live.roots_url=http://c1.provide.example.com:8080/assets/rhcos-live-rootsfs.s390x.img \ 
coreos.inst.ignition_url=http://c1.provide.example.com:8080/ignition/bootstrap.ign \ 
ip=172.18.78.2::172.18.78.1:255.255.255.0::none nameserver=172.18.78.1 \ 
rd.znet=qeth,0.0.bdf0,0.0.bdf1,0.0.bdf2,layer2=1,portno=0 \ 
zfcp.allow_lun_scan=0 \ 
rd.dasd=0.0.3490
```

Write all options in the parameter file as a single line and make sure you have no newline characters.

- For installations on FCP-type disks, complete the following tasks:
  
  i. Use `rd.zfcp=<adapter>,<wwpn>,<lun>` to specify the FCP disk where RH COS is to be installed. For multipathing repeat this step for each additional path.

  **NOTE**

  When you install with multiple paths, you must enable multipathing directly after the installation, not at a later point in time, as this can cause problems.

  ii. Set the install device as: `coreos.inst.install_dev=/dev/disk/by-id/scsi-<serial_number>.

  **NOTE**

  If additional LUNs are configured with NPIV, FCP requires `zfcp.allow_lun_scan=0`. If you must enable `zfcp.allow_lun_scan=1` because you use a CSI driver, for example, you must configure your NPIV so that each node cannot access the boot partition of another node.

  iii. Leave all other parameters unchanged.

  **IMPORTANT**

  Additional postinstallation steps are required to fully enable multipathing. For more information, see “Enabling multipathing with kernel arguments on RH COS” in *Post-installation machine configuration tasks*.

The following is an example parameter file `worker-1.parm` for a worker node with multipathing:

```
rd.neednet=1 \ 
```
Write all options in the parameter file as a single line and make sure you have no newline characters.

4. Transfer the initramfs, kernel, parameter files, and RHCOS images to z/VM, for example with FTP. For details about how to transfer the files with FTP and boot from the virtual reader, see Installing under Z/VM.

5. Punch the files to the virtual reader of the z/VM guest virtual machine that is to become your bootstrap node.
   See PUNCH in IBM Documentation.

   **TIP**

   You can use the CP PUNCH command or, if you use Linux, the `vmur` command to transfer files between two z/VM guest virtual machines.

7. IPL the bootstrap machine from the reader:

   `$ ipl c`

   See IPL in IBM Documentation.

8. Repeat this procedure for the other machines in the cluster.

18.3.12.1. Advanced RHCOS installation reference

This section illustrates the networking configuration and other advanced options that allow you to modify the Red Hat Enterprise Linux CoreOS (RHCOS) manual installation process. The following tables describe the kernel arguments and command-line options you can use with the RHCOS live installer and the `coreos-installer` command.

18.3.12.1.1. Networking and bonding options for ISO installations

If you install RHCOS from an ISO image, you can add kernel arguments manually when you boot the image to configure networking for a node. If no networking arguments are specified, DHCP is activated in the initramfs when RHCOS detects that networking is required to fetch the Ignition config file.
IMPORTANT

When adding networking arguments manually, you must also add the `rd.neednet=1` kernel argument to bring the network up in the initramfs.

The following information provides examples for configuring networking and bonding on your RHCOS nodes for ISO installations. The examples describe how to use the `ip=`, `nameserver=`, and `bond=` kernel arguments.

NOTE

Ordering is important when adding the kernel arguments: `ip=`, `nameserver=`, and then `bond=`.

The networking options are passed to the `dracut` tool during system boot. For more information about the networking options supported by `dracut`, see the `dracut.cmdline` manual page.

The following examples are the networking options for ISO installation.

Configuring DHCP or static IP addresses
To configure an IP address, either use DHCP (`ip=dhcp`) or set an individual static IP address (`ip=<host_ip>`). If setting a static IP, you must then identify the DNS server IP address (`nameserver=<dns_ip>`) on each node. The following example sets:

- The node’s IP address to `10.10.10.2`
- The gateway address to `10.10.10.254`
- The netmask to `255.255.255.0`
- The hostname to `core0.example.com`
- The DNS server address to `4.4.4.41`
- The auto-configuration value to `none`. No auto-configuration is required when IP networking is configured statically.

```
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none
nameserver=4.4.4.41
```

NOTE

When you use DHCP to configure IP addressing for the RHCOS machines, the machines also obtain the DNS server information through DHCP. For DHCP-based deployments, you can define the DNS server address that is used by the RHCOS nodes through your DHCP server configuration.

Configuring an IP address without a static hostname
You can configure an IP address without assigning a static hostname. If a static hostname is not set by the user, it will be picked up and automatically set by a reverse DNS lookup. To configure an IP address without a static hostname refer to the following example:

- The node’s IP address to `10.10.10.2`
• The gateway address to **10.10.10.254**

• The netmask to **255.255.255.0**

• The DNS server address to **4.4.4.41**

• The auto-configuration value to **none**. No auto-configuration is required when IP networking is configured statically.

```console
ip=10.10.10.2::10.10.10.254:255.255.255.0::enp1s0:none
nameserver=4.4.4.41
```

**Specifying multiple network interfaces**

You can specify multiple network interfaces by setting multiple `ip=` entries.

```console
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none
ip=10.10.10.3::10.10.10.254:255.255.255.0:core0.example.com:enp2s0:none
```

**Configuring default gateway and route**

Optional: You can configure routes to additional networks by setting an `rd.route=` value.

**NOTE**

When you configure one or multiple networks, one default gateway is required. If the additional network gateway is different from the primary network gateway, the default gateway must be the primary network gateway.

• Run the following command to configure the default gateway:

  ```
  ip=::10.10.10.254::::
  ```

• Enter the following command to configure the route for the additional network:

  ```
  rd.route=20.20.20.0/24:20.20.20.254:enp2s0
  ```

**Disabling DHCP on a single interface**

You can disable DHCP on a single interface, such as when there are two or more network interfaces and only one interface is being used. In the example, the `enp1s0` interface has a static networking configuration and DHCP is disabled for `enp2s0`, which is not used:

```console
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none
ip=:core0.example.com:enp2s0:none
```

**Combining DHCP and static IP configurations**

You can combine DHCP and static IP configurations on systems with multiple network interfaces, for example:

```console
ip=enp1s0:dhcp
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp2s0:none
```

**Configuring VLANs on individual interfaces**

Optional: You can configure VLANs on individual interfaces by using the `vlan=` parameter.
To configure a VLAN on a network interface and use a static IP address, run the following command:

```bash
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp2s0.100:eno
vlan=enp2s0.100:enp2s0
```

To configure a VLAN on a network interface and to use DHCP, run the following command:

```bash
ip=enp2s0.100:dhcp
vlan=enp2s0.100:enp2s0
```

**Providing multiple DNS servers**
You can provide multiple DNS servers by adding a `nameserver=` entry for each server, for example:

```bash
nameserver=1.1.1.1
nameserver=8.8.8.8
```

**Bonding multiple network interfaces to a single interface**
Optional: You can bond multiple network interfaces to a single interface by using the `bond=` option. Refer to the following examples:

- The syntax for configuring a bonded interface is: `bond=<name>[::<network_interfaces>] [::options]`
  - `<name>` is the bonding device name (`bond0`), `<network_interfaces>` represents a comma-separated list of physical (ethernet) interfaces (`em1,em2`), and `options` is a comma-separated list of bonding options. Enter `modinfo bonding` to see available options.

- When you create a bonded interface using `bond=`, you must specify how the IP address is assigned and other information for the bonded interface.
  - To configure the bonded interface to use DHCP, set the bond’s IP address to `dhcp`. For example:
    ```bash
    bond=bond0:em1,em2:mode=active-backup
    ip=bond0:dhcp
    ```
  - To configure the bonded interface to use a static IP address, enter the specific IP address you want and related information. For example:

```bash
bond=bond0:em1,em2:mode=active-backup,fail_over_mac=1
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:bond0:none
```

Always set the `fail_over_mac=1` option in active-backup mode, to avoid problems when shared OSA/RoCE cards are used.

**Bonding multiple network interfaces to a single interface**
Optional: You can configure VLANs on bonded interfaces by using the `vlan=` parameter and to use DHCP, for example:

```bash
ip=bond0.100:dhcp
bond=bond0:em1,em2:mode=active-backup
vlan=bond0.100:bond0
```

Use the following example to configure the bonded interface with a VLAN and to use a static IP address:
Using network teaming
Optional: You can use a network teaming as an alternative to bonding by using the `team=` parameter:

- The syntax for configuring a team interface is: `team=name[:network_interfaces]`
  - `name` is the team device name (`team0`) and `network_interfaces` represents a comma-separated list of physical (ethernet) interfaces (`em1, em2`).

**NOTE**
Teaming is planned to be deprecated when RHCOS switches to an upcoming version of RHEL. For more information, see this Red Hat Knowledgebase Article.

Use the following example to configure a network team:

```bash
team=team0:em1,em2
ip=team0:dhcp
```

18.3.13. Waiting for the bootstrap process to complete

The OpenShift Container Platform bootstrap process begins after the cluster nodes first boot into the persistent RHCOS environment that has been installed to disk. The configuration information provided through the Ignition config files is used to initialize the bootstrap process and install OpenShift Container Platform on the machines. You must wait for the bootstrap process to complete.

**Prerequisites**

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have obtained the installation program and generated the Ignition config files for your cluster.
- You installed RHCOS on your cluster machines and provided the Ignition config files that the OpenShift Container Platform installation program generated.

**Procedure**

1. Monitor the bootstrap process:
   ```bash
   $ ./openshift-install --dir <installation_directory> wait-for bootstrap-complete
   --log-level=info
   ```
   **1** For `<installation_directory>`, specify the path to the directory that you stored the installation files in.
   **2** To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.  

Example output

INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
INFO API v1.27.3 up
INFO Waiting up to 30m0s for bootstrapping to complete...
INFO It is now safe to remove the bootstrap resources

The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After the bootstrap process is complete, remove the bootstrap machine from the load balancer.

IMPORTANT
You must remove the bootstrap machine from the load balancer at this point.
You can also remove or reformat the bootstrap machine itself.

18.3.14. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster kubeconfig file. The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the oc CLI.

Procedure

1. Export the kubeadmin credentials:

   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig

   1 For <installation_directory>, specify the path to the directory that you stored the installation files in.

2. Verify you can run oc commands successfully using the exported configuration:

   $ oc whoami

   Example output

   system:admin

18.3.15. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.
Prerequisites

- You added machines to your cluster.

Procedure

1. Confirm that the cluster recognizes the machines:

   ```
   $ oc get nodes
   ```

   **Example output**

   ```
   NAME      STATUS    ROLES   AGE  VERSION
   master-0  Ready     master  63m  v1.27.3
   master-1  Ready     master  63m  v1.27.3
   master-2  Ready     master  64m  v1.27.3
   ```

   The output lists all of the machines that you created.

   **NOTE**

   The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

   ```
   $ oc get csr
   ```

   **Example output**

   ```
   NAME        AGE     REQUESTOR                                                                   CONDITION
   csr-8b2br   15m     system:serviceaccount:openshift-machine-config-operator:node-bootstrapper   Pending
   csr-8vnps   15m     system:serviceaccount:openshift-machine-config-operator:node-bootstrapper   Pending
   ...            
   ```

   In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:
NOTE
Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine/approver** if the Kubelet requests a new certificate with identical parameters.

NOTE
For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the `oc exec`, `oc rsh`, and `oc logs` commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the `node-bootstrapper` service account in the `system:node` or `system:admin` groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

  ```
  $ oc adm certificate approve <csr_name>
  
  <csr_name> is the name of a CSR from the list of current CSRs.
  ```

- To approve all pending CSRs, run the following command:

  ```
  $ oc get csr -o go-template="{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs --no-run-if-empty oc adm certificate approve
  ```

NOTE
Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-c57lv</td>
<td>5m26s</td>
<td>system:node:ip-10-0-95-157.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td></td>
<td></td>
<td>...</td>
<td></td>
</tr>
</tbody>
</table>
5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

   - To approve them individually, run the following command for each valid CSR:
     
     ```
     $ oc adm certificate approve <csr_name>  
     ```

     `<csr_name>` is the name of a CSR from the list of current CSRs.

   - To approve all pending CSRs, run the following command:
     
     ```
     $ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs oc adm certificate approve  
     ```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes  
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>74m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>worker-0</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>worker-1</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.27.3</td>
</tr>
</tbody>
</table>

**NOTE**

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

**Additional information**

- For more information on CSRs, see [Certificate Signing Requests](#).

### 18.3.16. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

**Prerequisites**

- Your control plane has initialized.

**Procedure**

1. Watch the cluster components come online:

```
$ watch -n5 oc get clusteroperators  
```
Example output

<table>
<thead>
<tr>
<th>NAME</th>

2. Configure the Operators that are not available.

18.3.16.1. Disabling the default OperatorHub catalog sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

Procedure

- Disable the sources for the default catalogs by adding `disableAllDefaultSources: true` to the `OperatorHub` object:

  ```bash
  $ oc patch OperatorHub cluster --type json
  -p '(["op": "add", "path": "/spec/disableAllDefaultSources", "value": true])'
  ```
TIP

Alternatively, you can use the web console to manage catalog sources. From the Administration → Cluster Settings → Configuration → OperatorHub page, click the Sources tab, where you can create, update, delete, disable, and enable individual sources.

18.3.16.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the Recreate rollout strategy during upgrades.

18.3.16.2.1. Configuring registry storage for IBM Z

As a cluster administrator, following installation you must configure your registry to use storage.

Prerequisites

- You have access to the cluster as a user with the cluster-admin role.
- You have a cluster on IBM Z®.
- You have provisioned persistent storage for your cluster, such as Red Hat OpenShift Data Foundation.

IMPORTANT

OpenShift Container Platform supports ReadWriteOnce access for image registry storage when you have only one replica. ReadWriteOnce access also requires that the registry uses the Recreate rollout strategy. To deploy an image registry that supports high availability with two or more replicas, ReadWriteMany access is required.

- Must have 100Gi capacity.

Procedure

1. To configure your registry to use storage, change the spec.storage.pvc in the configs.imageregistry/cluster resource.

   NOTE

   When you use shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:
NOTE
If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

   $ oc edit configs.imageregistry.operator.openshift.io

   Example output

   storage:
   pvc:
     claim:

   Leave the claim field blank to allow the automatic creation of an image-registry-storage PVC.

4. Check the clusteroperator status:

   $ oc get clusteroperator image-registry

   Example output

   NAME             VERSION              AVAILABLE   PROGRESSING   DEGRADED   SINCE
   MESSAGE
   image-registry   4.14                 True        False         False      6h50m

5. Ensure that your registry is set to managed to enable building and pushing of images.
   - Run:

     $ oc edit configs.imageregistry/operator

     Then, change the line

     managementState: Removed

     to

     managementState: Managed

18.3.16.2.2. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.
Procedure

- To set the image registry storage to an empty directory:

  ```sh
  $ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec": {"storage": {"emptyDir": {}}}}'
  ```

**WARNING**

Configure this option for only non-production clusters.

If you run this command before the Image Registry Operator initializes its components, the `oc patch` command fails with the following error:

Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found

Wait a few minutes and run the command again.

18.3.17. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

**Prerequisites**

- Your control plane has initialized.
- You have completed the initial Operator configuration.

**Procedure**

1. Confirm that all the cluster components are online with the following command:

  ```sh
  $ watch -n5 oc get clusteroperators
  ```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
<th>SINCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>authentication</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>19m</td>
</tr>
<tr>
<td>baremetal</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>37m</td>
</tr>
<tr>
<td>cloud-credential</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>40m</td>
</tr>
<tr>
<td>cluster-autoscaler</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>37m</td>
</tr>
<tr>
<td>config-operator</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>38m</td>
</tr>
<tr>
<td>console</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>26m</td>
</tr>
<tr>
<td>csi-snapshot-controller</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>37m</td>
</tr>
<tr>
<td>dns</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>37m</td>
</tr>
<tr>
<td>etcd</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>36m</td>
</tr>
<tr>
<td>image-registry</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>31m</td>
</tr>
</tbody>
</table>
Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```
$ ./openshift-install --dir <installation_directory> wait-for install-complete
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

**Example output**

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for [Recovering from expired control plane certificates](#) for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.
2. Confirm that the Kubernetes API server is communicating with the pods.

   a. To view a list of all pods, use the following command:

   ```
   $ oc get pods --all-namespaces
   ```

   **Example output**

<table>
<thead>
<tr>
<th>NAMESPACE</th>

   b. View the logs for a pod that is listed in the output of the previous command by using the following command:

   ```
   $ oc logs <pod_name> -n <namespace> 1
   ```

   Specify the pod name and namespace, as shown in the output of the previous command.

   If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation.

   See "Enabling multipathing with kernel arguments on RHCOS" in the Post-installation machine configuration tasks documentation for more information.

4. Register your cluster on the Cluster registration page.

**Additional resources**

- How to generate SOSREPORT within OpenShift Container Platform version 4 nodes without SSH.

**18.3.18. Next steps**

- Customize your cluster.

- If the mirror registry that you used to install your cluster has a trusted CA, add it to the cluster by configuring additional trust stores.

- If necessary, you can opt out of remote health reporting.
18.4. INSTALLING A CLUSTER WITH RHEL KVM ON IBM Z AND IBM LINUXONE

In OpenShift Container Platform version 4.14, you can install a cluster on IBM Z® or IBM® LinuxONE infrastructure that you provision.

NOTE

While this document refers only to IBM Z®, all information in it also applies to IBM® LinuxONE.

IMPORTANT

Additional considerations exist for non-bare metal platforms. Review the information in the guidelines for deploying OpenShift Container Platform on non-tested platforms before you install an OpenShift Container Platform cluster.

18.4.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- Before you begin the installation process, you must clean the installation directory. This ensures that the required installation files are created and updated during the installation process.
- You provisioned persistent storage using OpenShift Data Foundation or other supported storage protocols for your cluster. To deploy a private image registry, you must set up persistent storage with ReadWriteMany access.
- If you use a firewall, you configured it to allow the sites that your cluster requires access to.

NOTE

Be sure to also review this site list if you are configuring a proxy.

- You provisioned a RHEL Kernel Virtual Machine (KVM) system that is hosted on the logical partition (LPAR) and based on RHEL 8.6 or later. See Red Hat Enterprise Linux 8 and 9 Life Cycle.

18.4.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager Hybrid Cloud Console to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
• Access Quay.io to obtain the packages that are required to install your cluster.

• Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 18.4.3. Machine requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

One or more KVM host machines based on RHEL 8.6 or later. Each RHEL KVM host machine must have libvirtd installed and running. The virtual machines are provisioned under each RHEL KVM host machine.

#### 18.4.3.1. Required machines

The smallest OpenShift Container Platform clusters require the following hosts:

**Table 18.31. Minimum required hosts**

<table>
<thead>
<tr>
<th>Hosts</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>One temporary bootstrap machine</td>
<td>The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.</td>
</tr>
<tr>
<td>Three control plane machines</td>
<td>The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.</td>
</tr>
<tr>
<td>At least two compute machines, which are also known as worker machines.</td>
<td>The workloads requested by OpenShift Container Platform users run on the compute machines.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

To improve high availability of your cluster, distribute the control plane machines over different RHEL instances on at least two physical machines.

The bootstrap, control plane, and compute machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system.

#### 18.4.3.2. Network connectivity requirements
The OpenShift Container Platform installer creates the Ignition files, which are necessary for all the Red Hat Enterprise Linux CoreOS (RHCOS) virtual machines. The automated installation of OpenShift Container Platform is performed by the bootstrap machine. It starts the installation of OpenShift Container Platform on each node, starts the Kubernetes cluster, and then finishes. During this bootstrap, the virtual machine must have an established network connection either through a Dynamic Host Configuration Protocol (DHCP) server or static IP address.

18.4.3.3. IBM Z network connectivity requirements

To install on IBM Z® under RHEL KVM, you need:

- A RHEL KVM host configured with an OSA or RoCE network adapter.
- Either a RHEL KVM host that is configured to use bridged networking in libvirt or MacVTap to connect the network to the guests.

See Types of virtual network connections.

18.4.3.4. Host machine resource requirements

The RHEL KVM host in your environment must meet the following requirements to host the virtual machines that you plan for the OpenShift Container Platform environment. See Getting started with virtualization.

You can install OpenShift Container Platform version 4.14 on the following IBM® hardware:

- IBM® z16 (all models), IBM® z15 (all models), IBM® z14 (all models)
- IBM® LinuxONE 4 (all models), IBM® LinuxONE III (all models), IBM® LinuxONE Emperor II, IBM® LinuxONE Rockhopper II

18.4.3.5. Minimum IBM Z system environment

Hardware requirements

- The equivalent of six Integrated Facilities for Linux (IFL), which are SMT2 enabled, for each cluster.
- At least one network connection to both connect to the LoadBalancer service and to serve data for traffic outside the cluster.

NOTE

You can use dedicated or shared IFLs to assign sufficient compute resources. Resource sharing is one of the key strengths of IBM Z®. However, you must adjust capacity correctly on each hypervisor layer and ensure sufficient resources for every OpenShift Container Platform cluster.

IMPORTANT

Since the overall performance of the cluster can be impacted, the LPARs that are used to set up the OpenShift Container Platform clusters must provide sufficient compute capacity. In this context, LPAR weight management, entitlements, and CPU shares on the hypervisor level play an important role.
• One LPAR running on RHEL 8.6 or later with KVM, which is managed by libvirt

On your RHEL KVM host, set up:

• Three guest virtual machines for OpenShift Container Platform control plane machines
• Two guest virtual machines for OpenShift Container Platform compute machines
• One guest virtual machine for the temporary OpenShift Container Platform bootstrap machine

18.4.3.6. Minimum resource requirements

Each cluster virtual machine must meet the following minimum requirements:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS</td>
<td>2</td>
<td>8 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
</tbody>
</table>

1. One physical core (IFL) provides two logical cores (threads) when SMT-2 is enabled. The hypervisor can provide two or more vCPUs.

18.4.3.7. Preferred IBM Z system environment

Hardware requirements

• Three LPARS that each have the equivalent of six IFLs, which are SMT2 enabled, for each cluster.

• Two network connections to both connect to the LoadBalancer service and to serve data for traffic outside the cluster.

Operating system requirements

• For high availability, two or three LPARs running on RHEL 8.6 or later with KVM, which are managed by libvirt.

On your RHEL KVM host, set up:

• Three guest virtual machines for OpenShift Container Platform control plane machines, distributed across the RHEL KVM host machines.

• At least six guest virtual machines for OpenShift Container Platform compute machines, distributed across the RHEL KVM host machines.

• One guest virtual machine for the temporary OpenShift Container Platform bootstrap machine.

• To ensure the availability of integral components in an overcommitted environment, increase the priority of the control plane by using cpu_shares. Do the same for infrastructure nodes, if they exist. See schedinfo in IBM® Documentation.
18.4.3.8. Preferred resource requirements

The preferred requirements for each cluster virtual machine are:

<table>
<thead>
<tr>
<th>Virtual Machine</th>
<th>Operating System</th>
<th>vCPU</th>
<th>Virtual RAM</th>
<th>Storage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>120 GB</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>8</td>
<td>16 GB</td>
<td>120 GB</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS</td>
<td>6</td>
<td>8 GB</td>
<td>120 GB</td>
</tr>
</tbody>
</table>

18.4.3.9. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The kube-controller-manager only approves the kubelet client CSRs. The machine-approver cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

Additional resources

- Recommended host practices for IBM Z® & IBM® LinuxONE environments

18.4.3.10. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in initramfs during boot to fetch their Ignition config files.

During the initial boot, the machines require an IP address configuration that is set either through a DHCP server or statically by providing the required boot options. After a network connection is established, the machines download their Ignition config files from an HTTP or HTTPS server. The Ignition config files are then used to set the exact state of each machine. The Machine Config Operator completes more changes to the machines, such as the application of new certificates or keys, after installation.

It is recommended to use a DHCP server for long-term management of the cluster machines. Ensure that the DHCP server is configured to provide persistent IP addresses, DNS server information, and hostnames to the cluster machines.

NOTE

If a DHCP service is not available for your user-provisioned infrastructure, you can instead provide the IP networking configuration and the address of the DNS server to the nodes at RHCOS install time. These can be passed as boot arguments if you are installing from an ISO image. See the Installing RHCOS and starting the OpenShift Container Platform bootstrap process section for more information about static IP provisioning and advanced networking options.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API
servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

18.4.3.10.1. Setting the cluster node hostnames through DHCP

On Red Hat Enterprise Linux CoreOS (RHCOS) machines, the hostname is set through NetworkManager. By default, the machines obtain their hostname through DHCP. If the hostname is not provided by DHCP, set statically through kernel arguments, or another method, it is obtained through a reverse DNS lookup. Reverse DNS lookup occurs after the network has been initialized on a node and can take time to resolve. Other system services can start prior to this and detect the hostname as localhost or similar. You can avoid this by using DHCP to provide the hostname for each cluster node.

Additionally, setting the hostnames through DHCP can bypass any manual DNS record name configuration errors in environments that have a DNS split-horizon implementation.

18.4.3.10.2. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

**IMPORTANT**

In connected OpenShift Container Platform environments, all nodes are required to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

**NOTE**

The RHEL KVM host must be configured to use bridged networking in libvirt or MacVTap to connect the network to the virtual machines. The virtual machines must have access to the network, which is attached to the RHEL KVM host. Virtual Networks, for example network address translation (NAT), within KVM are not a supported configuration.

Table 18.32. Ports used for all-machine to all-machine communications

Table 18.34. Ports used for control plane machine to control plane machine communications

TCP 2379-2380 etcd server and peer ports

NTP configuration for user-provisioned infrastructure

OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for Configuring chrony time service.

If a DHCP server provides NTP server information, the chrony time service on the Red Hat Enterprise Linux CoreOS (RHCOS) machines read the information and can sync the clock with the NTP servers.

Additional resources

- Configuring chrony time service

18.4.3.11. User-provisioned DNS requirements

In OpenShift Container Platform deployments, DNS name resolution is required for the following components:

- The Kubernetes API
The OpenShift Container Platform application wildcard

- The bootstrap, control plane, and compute machines

Reverse DNS resolution is also required for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the hostnames for all the nodes, unless the hostnames are provided by DHCP. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

The following DNS records are required for a user-provisioned OpenShift Container Platform cluster and they must be in place before installation. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>.

### Table 18.35. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes  API</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the API load balancer. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td></td>
<td>api-int.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to internally identify the API load balancer. These records must be resolvable from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Routes</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>A wildcard DNS A/AAAA or CNAME record that refers to the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster. For example, <code>console-openshift-console.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;</code> is used as a wildcard route to the OpenShift Container Platform console.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

The API server must be able to resolve the worker nodes by the hostnames that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.
### Component | Record | Description
--- | --- | ---
Bootstrap machine | bootstrap.<cluster_name>.<base_domain>. | A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.
Control plane machines | <master><n>.<cluster_name>.<base_domain>. | DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes. These records must be resolvable by the nodes within the cluster.
Compute machines | <worker><n>.<cluster_name>.<base_domain>. | DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.

**NOTE**

In OpenShift Container Platform 4.4 and later, you do not need to specify etcd host and SRV records in your DNS configuration.

**TIP**

You can use the `dig` command to verify name and reverse name resolution. See the section on **Validating DNS resolution for user-provisioned infrastructure** for detailed validation steps.

### 18.4.3.11.1. Example DNS configuration for user-provisioned clusters

This section provides A and PTR record configuration samples that meet the DNS requirements for deploying OpenShift Container Platform on user-provisioned infrastructure. The samples are not meant to provide advice for choosing one DNS solution over another.

In the examples, the cluster name is `ocp4` and the base domain is `example.com`.

**Example DNS A record configuration for a user-provisioned cluster**

The following example is a BIND zone file that shows sample A records for name resolution in a user-provisioned cluster.

**Example 18.7. Sample DNS zone database**

```
$TTL 1W  
@ IN SOA ns1.example.com. root ( 
  2019070700 ; serial 
  3H ; refresh (3 hours) 
  30M ; retry (30 minutes) 
  2W ; expiry (2 weeks) 
  1W ) ; minimum (1 week) 
IN NS ns1.example.com. 
IN MX 10 smtp.example.com. 
```
Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer.

Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer and is used for internal cluster communications.

Provides name resolution for the wildcard routes. The record refers to the IP address of the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

**NOTE**

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

Provides name resolution for the bootstrap machine.

Provides name resolution for the control plane machines.

Provides name resolution for the compute machines.

**Example DNS PTR record configuration for a user-provisioned cluster**

The following example BIND zone file shows sample PTR records for reverse name resolution in a user-provisioned cluster.
Example 18.8. Sample DNS zone database for reverse records

```dns
$TTL 1W
@ IN SOA ns1.example.com. root ( 2019070700 ; serial 3H ; refresh (3 hours) 30M ; retry (30 minutes) 2W ; expiry (2 weeks) 1W ) ; minimum (1 week)
IN NS ns1.example.com.
;
5.1.168.192.in-addr.arpa. IN PTR api.ocp4.example.com. 1
5.1.168.192.in-addr.arpa. IN PTR api-int.ocp4.example.com. 2
;
96.1.168.192.in-addr.arpa. IN PTR bootstrap.ocp4.example.com. 3
;
97.1.168.192.in-addr.arpa. IN PTR master0.ocp4.example.com. 4
98.1.168.192.in-addr.arpa. IN PTR master1.ocp4.example.com. 5
99.1.168.192.in-addr.arpa. IN PTR master2.ocp4.example.com. 6
;
11.1.168.192.in-addr.arpa. IN PTR worker0.ocp4.example.com. 7
7.1.168.192.in-addr.arpa. IN PTR worker1.ocp4.example.com. 8
EOF
```

1. Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer.
2. Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer and is used for internal cluster communications.
3. Provides reverse DNS resolution for the bootstrap machine.
4–6. Provides reverse DNS resolution for the control plane machines.
7–8. Provides reverse DNS resolution for the compute machines.

**NOTE**

A PTR record is not required for the OpenShift Container Platform application wildcard.

### 18.4.3.12. Load balancing requirements for user-provisioned infrastructure

Before you install OpenShift Container Platform, you must provision the API and application Ingress load balancing infrastructure. In production scenarios, you can deploy the API and application Ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

**NOTE**

If you want to deploy the API and application Ingress load balancers with a Red Hat Enterprise Linux (RHEL) instance, you must purchase the RHEL subscription separately.
The load balancing infrastructure must meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.
   - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

   **IMPORTANT**
   
   Do not configure session persistence for an API load balancer. Configuring session persistence for a Kubernetes API server might cause performance issues from excess application traffic for your OpenShift Container Platform cluster and the Kubernetes API that runs inside the cluster.

   Configure the following ports on both the front and back of the load balancers:

   **Table 18.36. API load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the /readyz endpoint for the API server health check probe.</td>
</tr>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
</tr>
</tbody>
</table>

   **NOTE**

   The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the /readyz endpoint to the removal of the API server instance from the pool. Within the time frame after /readyz returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application Ingress load balancer**: Provides an ingress point for application traffic flowing in from outside the cluster. A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. Configure the following conditions:
Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the ingress routes.

A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

**TIP**

If the true IP address of the client can be seen by the application Ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

Configure the following ports on both the front and back of the load balancers:

**Table 18.37. Application Ingress load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>

**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application Ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

**18.4.3.12.1. Example load balancer configuration for user-provisioned clusters**

This section provides an example API and application Ingress load balancer configuration that meets the load balancing requirements for user-provisioned clusters. The sample is an `/etc/haproxy/haproxy.cfg` configuration for an HAProxy load balancer. The example is not meant to provide advice for choosing one load balancing solution over another.

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

**NOTE**

If you are using HAProxy as a load balancer and SELinux is set to enforcing, you must ensure that the HAProxy service can bind to the configured TCP port by running `setsebool -P haproxy_connect_any=1`.

**Example 18.9. Sample API and application Ingress load balancer configuration**
Port 6443 handles the Kubernetes API traffic and points to the control plane machines.

The bootstrap entries must be in place before the OpenShift Container Platform cluster installation and they must be removed after the bootstrap process is complete.

Port 22623 handles the machine config server traffic and points to the control plane machines.

Port 443 handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.
pods. The Ingress Controller pods run on the compute machines by default.

Port 80 handles the HTTP traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

NOTE

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application Ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

TIP

If you are using HAProxy as a load balancer, you can check that the `haproxy` process is listening on ports 6443, 22623, 443, and 80 by running `netstat -nltpue` on the HAProxy node.

18.4.4. Preparing the user-provisioned infrastructure

Before you install OpenShift Container Platform on user-provisioned infrastructure, you must prepare the underlying infrastructure.

This section provides details about the high-level steps required to set up your cluster infrastructure in preparation for an OpenShift Container Platform installation. This includes configuring IP networking and network connectivity for your cluster nodes, enabling the required ports through your firewall, and setting up the required DNS and load balancing infrastructure.

After preparation, your cluster infrastructure must meet the requirements outlined in the Requirements for a cluster with user-provisioned infrastructure section.

Prerequisites

- You have reviewed the OpenShift Container Platform 4.x Tested Integrations page.
- You have reviewed the infrastructure requirements detailed in the Requirements for a cluster with user-provisioned infrastructure section.

Procedure

1. If you are using DHCP to provide the IP networking configuration to your cluster nodes, configure your DHCP service.
   a. Add persistent IP addresses for the nodes to your DHCP server configuration. In your configuration, match the MAC address of the relevant network interface to the intended IP address for each node.
   b. When you use DHCP to configure IP addressing for the cluster machines, the machines also obtain the DNS server information through DHCP. Define the persistent DNS server address that is used by the cluster nodes through your DHCP server configuration.
NOTE

If you are not using a DHCP service, you must provide the IP networking configuration and the address of the DNS server to the nodes at RHCOS install time. These can be passed as boot arguments if you are installing from an ISO image. See the Installing RHCOS and starting the OpenShift Container Platform bootstrap process section for more information about static IP provisioning and advanced networking options.

c. Define the hostnames of your cluster nodes in your DHCP server configuration. See the Setting the cluster node hostnames through DHCP section for details about hostname considerations.

NOTE

If you are not using a DHCP service, the cluster nodes obtain their hostname through a reverse DNS lookup.

2. Choose to perform either a fast track installation of Red Hat Enterprise Linux CoreOS (RHCOS) or a full installation of Red Hat Enterprise Linux CoreOS (RHCOS). For the full installation, you must set up an HTTP or HTTPS server to provide Ignition files and install images to the cluster nodes. For the fast track installation an HTTP or HTTPS server is not required, however, a DHCP server is required. See sections “Fast-track installation: Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines” and "Full installation: Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines".

3. Ensure that your network infrastructure provides the required network connectivity between the cluster components. See the Networking requirements for user-provisioned infrastructure section for details about the requirements.

4. Configure your firewall to enable the ports required for the OpenShift Container Platform cluster components to communicate. See Networking requirements for user-provisioned infrastructure section for details about the ports that are required.

IMPORTANT

By default, port 1936 is accessible for an OpenShift Container Platform cluster, because each control plane node needs access to this port.

Avoid using the Ingress load balancer to expose this port, because doing so might result in the exposure of sensitive information, such as statistics and metrics, related to Ingress Controllers.

5. Setup the required DNS infrastructure for your cluster.

   a. Configure DNS name resolution for the Kubernetes API, the application wildcard, the bootstrap machine, the control plane machines, and the compute machines.

   b. Configure reverse DNS resolution for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

   See the User-provisioned DNS requirements section for more information about the OpenShift Container Platform DNS requirements.

   6. Validate your DNS configuration.
a. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses in the responses correspond to the correct components.

b. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names in the responses correspond to the correct components. See the Validating DNS resolution for user-provisioned infrastructure section for detailed DNS validation steps.

7. Provision the required API and application ingress load balancing infrastructure. See the Load balancing requirements for user-provisioned infrastructure section for more information about the requirements.

NOTE

Some load balancing solutions require the DNS name resolution for the cluster nodes to be in place before the load balancing is initialized.

18.4.5. Validating DNS resolution for user-provisioned infrastructure

You can validate your DNS configuration before installing OpenShift Container Platform on user-provisioned infrastructure.

IMPORTANT

The validation steps detailed in this section must succeed before you install your cluster.

Prerequisites

- You have configured the required DNS records for your user-provisioned infrastructure.

Procedure

1. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses contained in the responses correspond to the correct components.

   a. Perform a lookup against the Kubernetes API record name. Check that the result points to the IP address of the API load balancer:

   ```
   $ dig +noall +answer @<nameserver_ip> api.<cluster_name>.<base_domain> 1
   
   Replace `<nameserver_ip>` with the IP address of the nameserver, `<cluster_name>` with your cluster name, and `<base_domain>` with your base domain name.
   ```

   Example output

   ```
   api.ocp4.example.com. 604800 IN A 192.168.1.5
   ```

   b. Perform a lookup against the Kubernetes internal API record name. Check that the result points to the IP address of the API load balancer:
c. Test an example `*.apps.<cluster_name>.<base_domain>` DNS wildcard lookup. All of the application wildcard lookups must resolve to the IP address of the application ingress load balancer:

```bash
$ dig +noall +answer @<nameserver_ip> random.apps.<cluster_name>.<base_domain>
```

Example output

```
random.apps.ocp4.example.com. 604800 IN A 192.168.1.5
```

NOTE

In the example outputs, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

You can replace `random` with another wildcard value. For example, you can query the route to the OpenShift Container Platform console:

```bash
$ dig +noall +answer @<nameserver_ip> console-openshift-console.apps.<cluster_name>.<base_domain>
```

Example output

```
console-openshift-console.apps.ocp4.example.com. 604800 IN A 192.168.1.5
```

d. Run a lookup against the bootstrap DNS record name. Check that the result points to the IP address of the bootstrap node:

```bash
$ dig +noall +answer @<nameserver_ip> bootstrap.<cluster_name>.<base_domain>
```

Example output

```
bootstrap.ocp4.example.com. 604800 IN A 192.168.1.96
```

e. Use this method to perform lookups against the DNS record names for the control plane and compute nodes. Check that the results correspond to the IP addresses of each node.

2. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names contained in the responses correspond to the correct components.

a. Perform a reverse lookup against the IP address of the API load balancer. Check that the response includes the record names for the Kubernetes API and the Kubernetes internal API:

```bash
$ dig +noall +answer @<nameserver_ip> api-int.<cluster_name>.<base_domain>
```

Example output

```
api-int.ocp4.example.com. 604800 IN A 192.168.1.5
```
API:

$ dig +noall +answer @<nameserver_ip> -x 192.168.1.5

Example output

1
5.1.168.192.in-addr.arpa. 604800 IN PTR api-int.ocp4.example.com.

2

1 Provides the record name for the Kubernetes internal API.
2 Provides the record name for the Kubernetes API.

NOTE

A PTR record is not required for the OpenShift Container Platform application wildcard. No validation step is needed for reverse DNS resolution against the IP address of the application ingress load balancer.

b. Perform a reverse lookup against the IP address of the bootstrap node. Check that the result points to the DNS record name of the bootstrap node:

$ dig +noall +answer @<nameserver_ip> -x 192.168.1.96

Example output

c. Use this method to perform reverse lookups against the IP addresses for the control plane and compute nodes. Check that the results correspond to the DNS record names of each node.

18.4.6. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The /openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.
Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>  
   ```

   Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   ```bash
   $ cat <path>/<file_name>.pub
   ```

   For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

   ```bash
   $ cat ~/.ssh/id_ed25519.pub
   ```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

   **NOTE**

   On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

   a. If the ssh-agent process is not already running for your local user, start it as a background task:

   ```bash
   $ eval "$(ssh-agent -s)"
   ```

   **Example output**

   ```bash
   Agent pid 31874
   ```

   **NOTE**

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the ssh-agent:
Specify the path and file name for your SSH private key, such as ~/.ssh/id_ed25519

Example output

Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

18.4.7. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on your provisioning machine.

Prerequisites

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space.

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

   **IMPORTANT**

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   **IMPORTANT**

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   $ tar -xvf openshift-install-linux.tar.gz
5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

18.4.8. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of oc.

**Installing the OpenShift CLI on Linux**

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

**Procedure**

2. Select the architecture from the Product Variant drop-down list.

3. Select the appropriate version from the Version drop-down list.

4. Click Download Now next to the OpenShift v4.14 Linux Client entry and save the file.

5. Unpack the archive:

   ```bash
   $ tar xvf <file>
   ```

6. Place the oc binary in a directory that is on your PATH.

   To check your PATH, execute the following command:

   ```bash
   $ echo $PATH
   ```

**Verification**

- After you install the OpenShift CLI, it is available using the oc command:

  ```bash
  $ oc <command>
  ```

**Installing the OpenShift CLI on Windows**

You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version from the Version drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 Windows Client** entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the `oc` binary to a directory that is on your **PATH**.
   To check your **PATH**, open the command prompt and execute the following command:
   ```
   C:\> path
   ```

**Verification**

- After you install the OpenShift CLI, it is available using the `oc` command:
  ```
  C:\> oc <command>
  ```

**Installing the OpenShift CLI on macOS**

You can install the OpenShift CLI (`oc`) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version from the **Version** drop-down list.

3. Click **Download Now** next to the **OpenShift v4.14 macOS Client** entry and save the file.

   **NOTE**

   For macOS arm64, choose the **OpenShift v4.14 macOS arm64 Client** entry.

4. Unpack and unzip the archive.

5. Move the `oc` binary to a directory on your PATH.
   To check your **PATH**, open a terminal and execute the following command:
   ```
   $ echo $PATH
   ```

**Verification**

- After you install the OpenShift CLI, it is available using the `oc` command:
  ```
  $ oc <command>
  ```

**18.4.9. Manually creating the installation configuration file**

**Prerequisites**

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.
You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Create an installation directory to store your required installation assets in:

   ```
   $ mkdir <installation_directory>
   ```

   **IMPORTANT**
   
   You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample `install-config.yaml` file template that is provided and save it in the `<installation_directory>`.  

   **NOTE**
   
   You must name this configuration file `install-config.yaml`.

   **NOTE**
   
   For some platform types, you can alternatively run `/openshift-install create install-config --dir <installation_directory>` to generate an `install-config.yaml` file. You can provide details about your cluster configuration at the prompts.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

   **IMPORTANT**
   
   The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.

**Additional resources**

- Installation configuration parameters for IBM Z®

**18.4.9.1. Sample install-config.yaml file for IBM Z**

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster's platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute: 2
  - hyperthreading: Enabled
name: worker
```
replicas: 0
architecture: s390x
controlPlane: 5
hyperthreading: Enabled 6
name: master
replicas: 3
architecture: s390x
metadata:
  name: test
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14 9
      hostPrefix: 23 10
  networkType: OVNKubernetes 11
serviceNetwork:
  - 172.30.0.0/16
platform:
  none: {} 13
fips: false 14
pullSecret: '{"auths": ...}' 15
sshKey: 'ssh-ed25519 AAAA...

1 The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

2 The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, -, and the first line of the controlPlane section must not. Only one control plane pool is used.

3 Specifies whether to enable or disable simultaneous multithreading (SMT), or hyperthreading. By default, SMT is enabled to increase the performance of the cores in your machines. You can disable it by setting the parameter value to Disabled. If you disable SMT, you must disable it in all cluster machines; this includes both control plane and compute machines.

NOTE

Simultaneous multithreading (SMT) is enabled by default. If SMT is not available on your OpenShift Container Platform nodes, the hyperthreading parameter has no effect.

IMPORTANT

If you disable hyperthreading, whether on your OpenShift Container Platform nodes or in the install-config.yaml file, ensure that your capacity planning accounts for the dramatically decreased machine performance.

4 You must set this value to 0 when you install OpenShift Container Platform on user-provisioned infrastructure. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. In user-provisioned installations, you must manually deploy the compute machines before you finish installing the cluster.
NOTE

If you are installing a three-node cluster, do not deploy any compute machines when you install the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

The cluster name that you specified in your DNS records.

A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to access the pods from an external network, you must configure load balancers and routers to manage the traffic.

NOTE

Class E CIDR range is reserved for a future use. To use the Class E CIDR range, you must ensure your networking environment accepts the IP addresses within the Class E CIDR range.

The subnet prefix length to assign to each individual node. For example, if `hostPrefix` is set to 23, then each node is assigned a /23 subnet out of the given `cidr`, which allows for 510 \(2^{32-23} - 2\) pod IP addresses. If you are required to provide access to nodes from an external network, configure load balancers and routers to manage the traffic.

The cluster network plugin to install. The supported values are `OVNKubernetes` and `OpenShiftSDN`. The default value is `OVNKubernetes`.

The IP address pool to use for service IP addresses. You can enter only one IP address pool. This block must not overlap with existing physical networks. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.

You must set the platform to `none`. You cannot provide additional platform configuration variables for IBM Z® infrastructure.

IMPORTANT

Clusters that are installed with the platform type `none` are unable to use some features, such as managing compute machines with the Machine API. This limitation applies even if the compute machines that are attached to the cluster are installed on a platform that would normally support the feature. This parameter cannot be changed after installation.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.
IMPORTANT

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see Installing the system in FIPS mode. When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures.

15 The pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

16 The SSH public key for the core user in Red Hat Enterprise Linux CoreOS (RHCOS).

NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

18.4.9.2. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the install-config.yaml file.

Prerequisites

- You have an existing install-config.yaml file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the Proxy object’s spec.noProxy field to bypass the proxy if necessary.

NOTE

The Proxy object status.noProxy field is populated with the values of the networking.machineNetwork[].cidr, networking.clusterNetwork[].cidr, and networking.serviceNetwork[] fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object status.noProxy field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your install-config.yaml file and add the proxy settings. For example:
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port>
  httpsProxy: https://<username>:<pswd>@<ip>:<port>
noProxy: example.com
additionalTrustBundle: |
  -----BEGIN CERTIFICATE-----
  <MY_TRUSTED_CA_CERT>
  -----END CERTIFICATE-----
additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle>

1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.
2. A proxy URL to use for creating HTTPS connections outside the cluster.
3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.
4. If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the trustedCA field of the Proxy object. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.
5. Optional: The policy to determine the configuration of the Proxy object to reference the user-ca-bundle config map in the trustedCA field. The allowed values are Proxyonly and Always. Use Proxyonly to reference the user-ca-bundle config map only when http/https proxy is configured. Use Always to always reference the user-ca-bundle config map. The default value is Proxyonly.

NOTE
The installation program does not support the proxy readinessEndpoints field.

NOTE
If the installer times out, restart and then complete the deployment by using the wait-for command of the installer. For example:

  $ ./openshift-install wait-for install-complete --log-level debug

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.
Only the Proxy object named cluster is supported, and no additional proxies can be created.

18.4.9.3. Configuring a three-node cluster

Optionally, you can deploy zero compute machines in a minimal three node cluster that consists of three control plane machines only. This provides smaller, more resource efficient clusters for cluster administrators and developers to use for testing, development, and production.

In three-node OpenShift Container Platform environments, the three control plane machines are schedulable, which means that your application workloads are scheduled to run on them.

Prerequisites

- You have an existing install-config.yaml file.

Procedure

- Ensure that the number of compute replicas is set to 0 in your install-config.yaml file, as shown in the following compute stanza:

```yaml
compute:
  - name: worker
    platform: {}
    replicas: 0
```

**NOTE**

You must set the value of the replicas parameter for the compute machines to 0 when you install OpenShift Container Platform on user-provisioned infrastructure, regardless of the number of compute machines you are deploying. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. This does not apply to user-provisioned installations, where the compute machines are deployed manually.

**NOTE**

The preferred resource for control plane nodes is six vCPUs and 21 GB. For three control plane nodes this is the memory + vCPU equivalent of a minimum five-node cluster. You should back the three nodes, each installed on a 120 GB disk, with three IFLs that are SMT2 enabled. The minimum tested setup is three vCPUs and 10 GB on a 120 GB disk for each control plane node.

For three-node cluster installations, follow these next steps:

- If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes. See the Load balancing requirements for user-provisioned infrastructure section for more information.
When you create the Kubernetes manifest files in the following procedure, ensure that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file is set to `true`. This enables your application workloads to run on the control plane nodes.

Do not deploy any compute nodes when you create the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

18.4.10. Cluster Network Operator configuration

The configuration for the cluster network is specified as part of the Cluster Network Operator (CNO) configuration and stored in a custom resource (CR) object that is named `cluster`. The CR specifies the fields for the `Network` API in the `operator.openshift.io` API group.

The CNO configuration inherits the following fields during cluster installation from the `Network` API in the `Network.config.openshift.io` API group and these fields cannot be changed:

- `clusterNetwork`: IP address pools from which pod IP addresses are allocated.
- `serviceNetwork`: IP address pool for services.
- `defaultNetwork.type`: Cluster network plugin, such as OpenShift SDN or OVN-Kubernetes.

You can specify the cluster network plugin configuration for your cluster by setting the fields for the `defaultNetwork` object in the CNO object named `cluster`.

18.4.10.1. Cluster Network Operator configuration object

The fields for the Cluster Network Operator (CNO) are described in the following table:

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>metadata.name</code></td>
<td>string</td>
<td>The name of the CNO object. This name is always <code>cluster</code>.</td>
</tr>
<tr>
<td><code>spec.clusterNetwork</code></td>
<td>array</td>
<td>A list specifying the blocks of IP addresses from which pod IP addresses are allocated and the subnet prefix length assigned to each individual node in the cluster. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>spec:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>clusterNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- cidr: 10.128.0.0/19</td>
</tr>
<tr>
<td></td>
<td></td>
<td>hostPrefix: 23</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- cidr: 10.128.32.0/19</td>
</tr>
<tr>
<td></td>
<td></td>
<td>hostPrefix: 23</td>
</tr>
</tbody>
</table>

You can customize this field only in the `install-config.yaml` file before you create the manifests. The value is read-only in the manifest file.
A block of IP addresses for services. The OpenShift SDN and OVN-Kubernetes network plugins support only a single IP address block for the service network. For example:

```yaml
spec:
  serviceNetwork:
    - 172.30.0.0/14
```

You can customize this field only in the `install-config.yaml` file before you create the manifests. The value is read-only in the manifest file.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>spec.serviceNet work</td>
<td>array</td>
<td>A block of IP addresses for services. The OpenShift SDN and OVN-Kubernetes network plugins support only a single IP address block for the service network. For example:</td>
</tr>
</tbody>
</table>

**spec.defaultNetwork** object configuration

The values for the `defaultNetwork` object are defined in the following table:

**Table 18.39. defaultNetwork object**

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>string</td>
<td>Either OpenShiftSDN or OVNKubernetes. The Red Hat OpenShift Networking network plugin is selected during installation. This value cannot be changed after cluster installation.</td>
</tr>
<tr>
<td>openshiftSDNConfig</td>
<td>object</td>
<td>This object is only valid for the OpenShift SDN network plugin.</td>
</tr>
<tr>
<td>ovnKubernetesConfig</td>
<td>object</td>
<td>This object is only valid for the OVN-Kubernetes network plugin.</td>
</tr>
</tbody>
</table>

**Configuration for the OpenShift SDN network plugin**

The following table describes the configuration fields for the OpenShift SDN network plugin:
### Table 18.40. openshiftSDNConfig object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mode</td>
<td>string</td>
<td>Configures the network isolation mode for OpenShift SDN. The default value is <strong>NetworkPolicy</strong>. The values <strong>Multitenant</strong> and <strong>Subnet</strong> are available for backwards compatibility with OpenShift Container Platform 3.x but are not recommended. This value cannot be changed after cluster installation.</td>
</tr>
<tr>
<td>mtu</td>
<td>integer</td>
<td>The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU. If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes. If your cluster requires different MTU values for different nodes, you must set this value to 50 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1450. This value cannot be changed after cluster installation.</td>
</tr>
<tr>
<td>vxlanPort</td>
<td>integer</td>
<td>The port to use for all VXLAN packets. The default value is 4789. This value cannot be changed after cluster installation. If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number. On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port 9000 and port 9999.</td>
</tr>
</tbody>
</table>

### Example OpenShift SDN configuration

```yaml
defaultNetwork:
  type: OpenShiftSDN
  openshiftSDNConfig:
    mode: NetworkPolicy
    mtu: 1450
    vxlanPort: 4789
```

### Configuration for the OVN-Kubernetes network plugin

The following table describes the configuration fields for the OVN-Kubernetes network plugin:
Table 18.41. `ovnKubernetesConfig` object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| `mtu`            | integer | The maximum transmission unit (MTU) for the Geneve (Generic Network Virtualization Encapsulation) overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.  
If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.  
If your cluster requires different MTU values for different nodes, you must set this value to 100 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1400. |
| `genevePort`     | integer | The port to use for all Geneve packets. The default value is 6081. This value cannot be changed after cluster installation.                                                                                                                                                                                                           |
| `ipsecConfig`    | object | Specify an empty object to enable IPsec encryption.                                                                                                                                                                                                                                                                                    |
| `policyAuditConf`| object | Specify a configuration object for customizing network policy audit logging. If unset, the defaults audit log settings are used.                                                                                                                                                                                                                     |
| `gatewayConfig`  | object | Optional: Specify a configuration object for customizing how egress traffic is sent to the node gateway.                                                                                                                                                                                                                                      |

**NOTE**

While migrating egress traffic, you can expect some disruption to workloads and service traffic until the Cluster Network Operator (CNO) successfully rolls out the changes.
If your existing network infrastructure overlaps with the 100.64.0.0/16 IPv4 subnet, you can specify a different IP address range for internal use by OVN-Kubernetes. You must ensure that the IP address range does not overlap with any other subnet used by your OpenShift Container Platform installation. The IP address range must be larger than the maximum number of nodes that can be added to the cluster. For example, if the clusterNetwork.cidr value is 10.128.0.0/14 and the clusterNetwork.hostPrefix value is /23, then the maximum number of nodes is $2^{23-14}=512$.

This field cannot be changed after installation.

The default value is 100.64.0.0/16.
If your existing network infrastructure overlaps with the fd98::/48 IPv6 subnet, you can specify a different IP address range for internal use by OVN-Kubernetes. You must ensure that the IP address range does not overlap with any other subnet used by your OpenShift Container Platform installation. The IP address range must be larger than the maximum number of nodes that can be added to the cluster. This field cannot be changed after installation.

The default value is **fd98::/48**.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>v6InternalSubnet</td>
<td></td>
<td>If your existing network infrastructure overlaps with the fd98::/48 IPv6 subnet, you can specify a different IP address range for internal use by OVN-Kubernetes. You must ensure that the IP address range does not overlap with any other subnet used by your OpenShift Container Platform installation. The IP address range must be larger than the maximum number of nodes that can be added to the cluster. This field cannot be changed after installation. The default value is <strong>fd98::/48</strong>.</td>
</tr>
</tbody>
</table>

**Table 18.42. policyAuditConfig object**

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rateLimit</td>
<td>integer</td>
<td>The maximum number of messages to generate every second per node. The default value is <strong>20</strong> messages per second.</td>
</tr>
<tr>
<td>maxFileSize</td>
<td>integer</td>
<td>The maximum size for the audit log in bytes. The default value is <strong>50000000</strong> or 50 MB.</td>
</tr>
</tbody>
</table>
destination

string

One of the following additional audit log targets:

**libc**

The libc `syslog()` function of the journald process on the host.

**udp:<host>::<port>**

A syslog server. Replace `<host>::<port>` with the host and port of the syslog server.

**unix:<file>**

A Unix Domain Socket file specified by `<file>`.

**null**

Do not send the audit logs to any additional target.

destination

syslogFacility

string

The syslog facility, such as `kern`, as defined by RFC5424. The default value is `local0`.

Table 18.43. gatewayConfig object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>routingViaHost</td>
<td>boolean</td>
<td>Set this field to <code>true</code> to send egress traffic from pods to the host networking stack. For highly-specialized installations and applications that rely on manually configured routes in the kernel routing table, you might want to route egress traffic to the host networking stack. By default, egress traffic is processed in OVN to exit the cluster and is not affected by specialized routes in the kernel routing table. The default value is <code>false</code>. This field has an interaction with the Open vSwitch hardware offloading feature. If you set this field to <code>true</code>, you do not receive the performance benefits of the offloading because egress traffic is processed by the host networking stack.</td>
</tr>
<tr>
<td>ipForwarding</td>
<td>object</td>
<td>You can control IP forwarding for all traffic on OVN-Kubernetes managed interfaces by using the <code>ipForwarding</code> specification in the <code>Network</code> resource. Specify <code>Restricted</code> to only allow IP forwarding for Kubernetes related traffic. Specify <code>Global</code> to allow forwarding of all IP traffic. For new installations, the default is <code>Restricted</code>. For updates to OpenShift Container Platform 4.14, the default is <code>Global</code>.</td>
</tr>
</tbody>
</table>

Example OVN-Kubernetes configuration with IPSec enabled

defaultNetwork:
  type: OVNKubernetes
  ovnKubernetesConfig:
**kubeProxyConfig object configuration**

The values for the `kubeProxyConfig` object are defined in the following table:

### Table 18.44. `kubeProxyConfig` object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>iptablesSyncPeriod</code></td>
<td>string</td>
<td>The refresh period for <code>iptables</code> rules. The default value is <strong>30s</strong>. Valid suffixes include <strong>s</strong>, <strong>m</strong>, and <strong>h</strong> and are described in the Go time package documentation.</td>
</tr>
<tr>
<td><code>proxyArguments.iptables-min-sync-period</code></td>
<td>array</td>
<td>The minimum duration before refreshing <code>iptables</code> rules. This field ensures that the refresh does not happen too frequently. Valid suffixes include <strong>s</strong>, <strong>m</strong>, and <strong>h</strong> and are described in the Go time package. The default value is:</td>
</tr>
</tbody>
</table>

```yaml
kubeProxyConfig:
  proxyArguments:
    iptables-min-sync-period: -0s
```

**NOTE**

Because of performance improvements introduced in OpenShift Container Platform 4.3 and greater, adjusting the `iptablesSyncPeriod` parameter is no longer necessary.

---

**18.4.11. Creating the Kubernetes manifest and Ignition config files**

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.
IMPORTANT

- The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

NOTE

The installation program that generates the manifest and Ignition files is architecture specific and can be obtained from the [client image mirror](#). The Linux version of the installation program runs on s390x only. This installer program is also available as a Mac OS version.

Prerequisites

- You obtained the OpenShift Container Platform installation program.
- You created the *install-config.yaml* installation configuration file.

Procedure

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

   ```bash
   $ ./openshift-install create manifests --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the installation directory that contains the *install-config.yaml* file you created.

   **WARNING**

   If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.

   **IMPORTANT**

   When you configure control plane nodes from the default unschedulable to schedulable, additional subscriptions are required. This is because control plane nodes then become compute nodes.
2. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:
   
a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.

b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.

c. Save and exit the file.

3. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

   $ ./openshift-install create ignition-configs --dir `<installation_directory>`

   For `<installation_directory>`, specify the same installation directory.

   Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The `kubeadmin-password` and `kubeconfig` files are created in the `./<installation_directory>/auth` directory:

   ├── auth
   │   └── kubeadmin-password
   │       └── kubeconfig
   │           └── bootstrap.ign
   │                   └── master.ign
   │                           └── metadata.json
   │                                   └── worker.ign

18.4.12. Installing RHCOS and starting the OpenShift Container Platform bootstrap process

To install OpenShift Container Platform on IBM Z® infrastructure that you provision, you must install Red Hat Enterprise Linux CoreOS (RHCOS) as Red Hat Enterprise Linux (RHEL) guest virtual machines. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS machines have rebooted.

You can perform a fast-track installation of RHCOS that uses a prepackaged QEMU copy-on-write (QCOW2) disk image. Alternatively, you can perform a full installation on a new QCOW2 disk image.

To add further security to your system, you can optionally install RHCOS using IBM® Secure Execution before proceeding to the fast-track installation.

18.4.12.1. Installing RHCOS using IBM Secure Execution

Before you install RHCOS using IBM® Secure Execution, you must prepare the underlying infrastructure.

Prerequisites

- IBM® z15 or later, or IBM® LinuxONE III or later.
Red Hat Enterprise Linux (RHEL) 8 or later.

- You have a bootstrap Ignition file. The file is not protected, enabling others to view and edit it.
- You have verified that the boot image has not been altered after installation.
- You must run all your nodes as IBM® Secure Execution guests.

**Procedure**

1. **Prepare your RHEL KVM host to support IBM® Secure Execution.**
   - By default, KVM hosts do not support guests in IBM® Secure Execution mode. To support guests in IBM® Secure Execution mode, KVM hosts must boot in LPAR mode with the kernel parameter specification `prot_virt=1`. To enable `prot_virt=1` on RHEL 8, follow these steps:
     a. Navigate to `/boot/loader/entries/` to modify your bootloader configuration file `.conf`.
     b. Add the kernel command line parameter `prot_virt=1`.
     c. Run the `zipl` command and reboot your system.
        KVM hosts that successfully start with support for IBM® Secure Execution for Linux issue the following kernel message:

        ```markdown
        prot_virt: Reserving <amount>MB as ultravisor base storage.
        ```
     d. To verify that the KVM host now supports IBM® Secure Execution, run the following command:

        ```bash
        # cat /sys/firmware/uv/prot_virt_host
        ```

        **Example output**

        ```
        1
        ```

        The value of this attribute is 1 for Linux instances that detect their environment as consistent with that of a secure host. For other instances, the value is 0.

2. **Add your host keys to the KVM guest via Ignition.**
   During the first boot, RHCOS looks for your host keys to re-encrypt itself with them. RHCOS searches for files starting with `ibm-z-hostkey-` in the `/etc/se-hostkeys` directory. All host keys, for each machine the cluster is running on, must be loaded into the directory by the administrator. After first boot, you cannot run the VM on any other machines.

   **NOTE**

   You need to prepare your Ignition file on a safe system. For example, another IBM® Secure Execution guest.

   For example:

   ```json
   { "ignition": { "version": "3.0.0" },
   ```
You can add as many host keys as required if you want your node to be able to run on multiple IBM Z® machines.

3. To generate the Base64 encoded string, run the following command:

   ```bash
   base64 <your-hostkey>.crt
   ```

   Compared to guests not running IBM® Secure Execution, the first boot of the machine is longer because the entire image is encrypted with a randomly generated LUKS passphrase before the Ignition phase.

4. Add Ignition protection

   To protect the secrets that are stored in the Ignition config file from being read or even modified, you must encrypt the Ignition config file.

   **NOTE**

   To achieve the desired security, Ignition logging and local login are disabled by default when running IBM® Secure Execution.

   a. Fetch the public GPG key for the `secex-qemu.qcow2` image and encrypt the Ignition config with the key by running the following command:

      ```bash
      gpg --recipient-file /path/to/ignition.gpg.pub --yes --output /path/to/config.ign.gpg --verbose --armor --encrypt /path/to/config.ign
      ```

5. Follow the fast-track installation of RHCOS to install nodes by using the IBM® Secure Execution QCOW image.
NOTE

Before you start the VM, replace `serial=ignition` with `serial=ignition_crypted`, and add the `launchSecurity` parameter.

Verification

When you have completed the fast-track installation of RHCOS and Ignition runs at the first boot, verify if decryption is successful.

- If the decryption is successful, you can expect an output similar to the following example:

  **Example output**

  ```
  [ 2.801433] systemd[1]: Starting coreos-ignition-setup-user.service - CoreOS Ignition User Config Setup...
  [ 2.803959] coreos-secex-ignition-decrypt[731]: gpg: key <key_name>: public key "Secure Execution (secex) 38.20230323.dev.0" imported
  [ 2.808874] coreos-secex-ignition-decrypt[740]: gpg: encrypted with rsa4096 key, ID <key_name>, created <yyyy-mm-dd>
  [  OK  ] Finished coreos-secex-ignition-decrypt...
  ```

  - If the decryption fails, you can expect an output similar to the following example:

  **Example output**

  ```
  Starting coreos-ignition-setup-user-config...
  [ 2.863675] coreos-secex-ignition-decrypt[729]: gpg: key <key_name>: public key "Secure Execution (secex) 38.20230323.dev.0" imported
  [ 2.869178] coreos-secex-ignition-decrypt[738]: gpg: encrypted with RSA key, ID <key_name>
  [ 2.870347] coreos-secex-ignition-decrypt[738]: gpg: public key decryption failed: No secret key
  [ 2.870371] coreos-secex-ignition-decrypt[738]: gpg: decryption failed: No secret key
  ```

18.4.12.2. Configuring NBDE with static IP in an IBM Z or IBM LinuxONE environment

Enabling NBDE disk encryption in an IBM Z® or IBM® LinuxONE environment requires additional steps, which are described in detail in this section.

Prerequisites

- You have set up the External Tang Server. See [Network-bound disk encryption](#) for instructions.
- You have installed the `butane` utility.
You have reviewed the instructions for how to create machine configs with Butane.

Procedure

1. Create Butane configuration files for the control plane and compute nodes.
   The following example of a Butane configuration for a control plane node creates a file named `master-storage.bu` for disk encryption:

   ```yaml
   variant: openshift
   version: 4.14.0
   metadata:
     name: master-storage
     labels:
       machineconfiguration.openshift.io/role: master
     storage:
       luks:
         - clevis:
           tang:
             - thumbprint: QcPr_NHFJammnRCA3fFMVdNBwjs
               url: http://clevis.example.com:7500
             options:
               --cipher
               --aes-cbc-essiv:sha256
       device: /dev/disk/by-partlabel/root
       label: luks-root
       name: root
       wipe_volume: true
   filesystems:
     - device: /dev/mapper/root
       format: xfs
       label: root
       wipe_filesystem: true
   openshift:
     fips: true
   
   1. The cipher option is only required if FIPS mode is enabled. Omit the entry if FIPS is disabled.
   
   2. Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

2. Create a customized initramfs file to boot the machine, by running the following command:

   ```bash
   $ coreos-installer pxe customize
   /root/rhcos-bootfiles/rhcos-<release>-live-initramfs.s390x.img
   --dest-device /dev/disk/by-id/scsi-<serial-number>
   --dest-karg-append ip=<ip-address>::<gateway-ip>::<subnet-mask>::<network-device>:none
   --dest-karg-append nameserver=<nameserver-ip>
   --dest-karg-append rd.neednet=1
   /root/rhcos-bootfiles/<Node-name>-initramfs.s390x.img
   ```
NOTE

Before first boot, you must customize the initramfs for each node in the cluster, and add PXE kernel parameters.

3. Create a parameter file that includes `ignition.platform.id=metal` and `ignition.firstboot`.

Example kernel parameter file for the control plane machine:

```bash
rd.neednet=1 \ 
console=ttyscp0 \ 
ignition.firstboot ignition.platform.id=metal \ 
coreos.live.roots_url=http://10.19.17.25/redhat/ocp/rhcos-413.86.202302201445-0/rhcos-413.86.202302201445-0-live-rootfs.s390x.img \ 
coreos.inst.ignition_url=http://bastion.ocp-cluster1.example.com:8080/ignition/master.ign \ 
ip=10.19.17.2::10.19.17.1:255.255.255.0::enbd0:none nameserver=10.19.17.1 \ 
zfcp.allow_lun_scan=0 \ 
rd.znet=qeth,0.0.bdd0,0.0.bdd1,0.0.bdd2,layer2=1 \ 
rd.zfcp=0.0.5677,0x600606680g7f0056,0x034F000000000000 
```

NOTE

Write all options in the parameter file as a single line and make sure you have no newline characters.

Additional resources

- Creating machine configs with Butane

18.4.12.3. **Fast-track installation by using a prepackaged QCOW2 disk image**

Complete the following steps to create the machines in a fast-track installation of Red Hat Enterprise Linux CoreOS (RHCOS), importing a prepackaged Red Hat Enterprise Linux CoreOS (RHCOS) QEMU copy-on-write (QCOW2) disk image.

**Prerequisites**

- At least one LPAR running on RHEL 8.6 or later with KVM, referred to as RHEL KVM host in this procedure.
- The KVM/QEMU hypervisor is installed on the RHEL KVM host.
- A domain name server (DNS) that can perform hostname and reverse lookup for the nodes.
- A DHCP server that provides IP addresses.

**Procedure**

1. Obtain the RHEL QEMU copy-on-write (QCOW2) disk image file from the Product Downloads page on the Red Hat Customer Portal or from the RHCOS image mirror page.
IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate RHCOS QCOW2 image described in the following procedure.

2. Download the QCOW2 disk image and Ignition files to a common directory on the RHEL KVM host.
   For example: `/var/lib/libvirt/images`

   **NOTE**
   The Ignition files are generated by the OpenShift Container Platform installer.

3. Create a new disk image with the QCOW2 disk image backing file for each KVM guest node.

   ```bash
   $ qemu-img create -f qcow2 -F qcow2 -b /var/lib/libvirt/images/{source_rhcos_qemu} /var/lib/libvirt/images/{vmname}.qcow2 {size}
   ```

4. Create the new KVM guest nodes using the Ignition file and the new disk image.

   ```bash
   $ virt-install --noautoconsole \
   --connect qemu:///system \
   --name {vm_name} \
   --memory {memory} \
   --vcpus {vcpus} \
   --disk {disk} \
   --launchSecurity type="s390-pv"  
   --import \
   --network network={network},mac={mac} \
   --disk path={ign_file},format=raw,readonly=on,serial=ignition,startup_policy=optional
   ```

   **1** If IBM® Secure Execution is enabled, add the `launchSecurity type="s390-pv"` parameter.
   **2** If IBM® Secure Execution is enabled, replace `serial=ignition` with `serial=ignition_crypted`.

### 18.4.12.4. Full installation on a new QCOW2 disk image

Complete the following steps to create the machines in a full installation on a new QEMU copy-on-write (QCOW2) disk image.

**Prerequisites**

- At least one LPAR running on RHEL 8.6 or later with KVM, referred to as RHEL KVM host in this procedure.
- The KVM/QEMU hypervisor is installed on the RHEL KVM host.
- A domain name server (DNS) that can perform hostname and reverse lookup for the nodes.
- An HTTP or HTTPS server is set up.
Procedure

1. Obtain the RHEL kernel, initramfs, and rootfs files from the Product Downloads page on the Red Hat Customer Portal or from the RHCOS image mirror page.

   **IMPORTANT**

   The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate RHCOS QCOW2 image described in the following procedure.

   The file names contain the OpenShift Container Platform version number. They resemble the following examples:

   - kernel: `rhcos-<version>-live-kernel-<architecture>`
   - initramfs: `rhcos-<version>-live-initramfs.<<architecture>>.img`
   - rootfs: `rhcos-<version>-live-rootfs.<<architecture>>.img`

2. Move the downloaded RHEL live kernel, initramfs, and rootfs as well as the Ignition files to an HTTP or HTTPS server before you launch virt-install.

   **NOTE**

   The Ignition files are generated by the OpenShift Container Platform installer.

3. Create the new KVM guest nodes using the RHEL kernel, initramfs, and Ignition files, the new disk image, and adjusted parm line arguments.

   - For `--location`, specify the location of the kernel/initrd on the HTTP or HTTPS server.
   - For `coreos.inst.ignition_url=`, specify the Ignition file for the machine role. Use bootstrap.ign, master.ign, or worker.ign. Only HTTP and HTTPS protocols are supported.
   - For `coreos.live.rootfs_url=`, specify the matching rootfs artifact for the kernel and initramfs you are booting. Only HTTP and HTTPS protocols are supported.

   ```bash
   $ virt-install \
   --connect qemu:///system \
   --name {vm_name} \
   --vcpus {vcpus} \
   --memory {memory_mb} \
   --disk {vm_name}.qcow2,size={image_size| default(10,true)} \
   --network network={virt_network_parm} \
   --boot hd \
   --location {media_location},kernel={rhcos_kernel},initrd={rhcos_initrd} \
   --extra-args "rd.neednet=1 coreos.inst.install_dev=/dev/vda coreos.live.rootfs_url=\ 
   {rhcos_liveos} ip={ip}::{default_gateway}:{subnet_mask_length}:{vm_name}:enc1:none: \ 
   {MTU} nameserver={dns} coreos.inst.ignition_url={rhcos_ign}" \
   --noautoconsole \ 
   --wait
   ```
18.4.12.5. Advanced RHCOS installation reference

This section illustrates the networking configuration and other advanced options that allow you to modify the Red Hat Enterprise Linux CoreOS (RHCOS) manual installation process. The following tables describe the kernel arguments and command-line options you can use with the RHCOS live installer and the `coreos-installer` command.

18.4.12.5.1. Networking options for ISO installations

If you install RHCOS from an ISO image, you can add kernel arguments manually when you boot the image to configure networking for a node. If no networking arguments are specified, DHCP is activated in the initramfs when RHCOS detects that networking is required to fetch the Ignition config file.

**IMPORTANT**

When adding networking arguments manually, you must also add the `rd.neednet=1` kernel argument to bring the network up in the initramfs.

The following information provides examples for configuring networking on your RHCOS nodes for ISO installations. The examples describe how to use the `ip=` and `nameserver=` kernel arguments.

**NOTE**

Ordering is important when adding the kernel arguments: `ip=` and `nameserver=`.

The networking options are passed to the `dracut` tool during system boot. For more information about the networking options supported by `dracut`, see the `dracut.cmdline` manual page.

The following examples are the networking options for ISO installation.

**Configuring DHCP or static IP addresses**

To configure an IP address, either use DHCP (`ip= dhcp`) or set an individual static IP address (`ip= <host_ip>`). If setting a static IP, you must then identify the DNS server IP address (`nameserver= <dns_ip>`) on each node. The following example sets:

- The node’s IP address to 10.10.10.2
- The gateway address to 10.10.10.254
- The netmask to 255.255.255.0
- The hostname to core0.example.com
- The DNS server address to 4.4.4.41
- The auto-configuration value to `none`. No auto-configuration is required when IP networking is configured statically.

```
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0: none
nameserver=4.4.4.41```

When you use DHCP to configure IP addressing for the RHCOS machines, the machines also obtain the DNS server information through DHCP. For DHCP-based deployments, you can define the DNS server address that is used by the RHCOS nodes through your DHCP server configuration.

### Configuring an IP address without a static hostname

You can configure an IP address without assigning a static hostname. If a static hostname is not set by the user, it will be picked up and automatically set by a reverse DNS lookup. To configure an IP address without a static hostname refer to the following example:

- The node's IP address to **10.10.10.2**
- The gateway address to **10.10.10.254**
- The netmask to **255.255.255.0**
- The DNS server address to **4.4.4.41**
- The auto-configuration value to **none**. No auto-configuration is required when IP networking is configured statically.

```sh
ip=10.10.10.2::10.10.10.254:255.255.255.0::enp1s0:none
nameserver=4.4.4.41
```

### Specifying multiple network interfaces

You can specify multiple network interfaces by setting multiple `ip=` entries.

```sh
ip=10.10.10.2::10.10.10.254:255.255.255.0::core0.example.com:enp1s0:none
ip=10.10.10.3::10.10.10.254:255.255.255.0::core0.example.com:enp2s0:none
```

### Configuring default gateway and route

Optional: You can configure routes to additional networks by setting an `rd.route=` value.

**NOTE**

When you configure one or multiple networks, one default gateway is required. If the additional network gateway is different from the primary network gateway, the default gateway must be the primary network gateway.

- Run the following command to configure the default gateway:

  ```sh
  ip=:10.10.10.254:::
  ```

- Enter the following command to configure the route for the additional network:

  ```sh
  rd.route=20.20.20.0/24:20.20.20.254:enp2s0
  ```

### Disabling DHCP on a single interface

You can disable DHCP on a single interface, such as when there are two or more network interfaces and only one interface is being used. In the example, the `enp1s0` interface has a static networking configuration and DHCP is disabled for `enp2s0`, which is not used.
Combining DHCP and static IP configurations
You can combine DHCP and static IP configurations on systems with multiple network interfaces, for example:

```
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp2s0:none
ip=:::core0.example.com:enp2s0:none
```

Configuring VLANs on individual interfaces
Optional: You can configure VLANs on individual interfaces by using the `vlan=` parameter.

- To configure a VLAN on a network interface and use a static IP address, run the following command:

  ```
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp2s0.100:none
vlan=enp2s0.100:enp2s0
```

- To configure a VLAN on a network interface and to use DHCP, run the following command:

  ```
ip=enp2s0.100:dhcp
vlan=enp2s0.100:enp2s0
```

Providing multiple DNS servers
You can provide multiple DNS servers by adding a `nameserver=` entry for each server, for example:

```
nameserver=1.1.1.1
nameserver=8.8.8.8
```

18.4.13. Waiting for the bootstrap process to complete
The OpenShift Container Platform bootstrap process begins after the cluster nodes first boot into the persistent RHCOS environment that has been installed to disk. The configuration information provided through the Ignition config files is used to initialize the bootstrap process and install OpenShift Container Platform on the machines. You must wait for the bootstrap process to complete.

Prerequisites
- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have obtained the installation program and generated the Ignition config files for your cluster.
- You installed RHCOS on your cluster machines and provided the Ignition config files that the OpenShift Container Platform installation program generated.
- Your machines have direct internet access or have an HTTP or HTTPS proxy available.

Procedure
1. Monitor the bootstrap process:
For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

### Example output

```
INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
INFO API v1.27.3 up
INFO Waiting up to 30m0s for bootstrapping to complete...
INFO It is now safe to remove the bootstrap resources
```

The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After the bootstrap process is complete, remove the bootstrap machine from the load balancer.

#### IMPORTANT

You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the bootstrap machine itself.

### 18.4.14. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

#### Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

#### Procedure

1. Export the `kubeadmin` credentials:

   ```
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```
   $ oc whoami
   ```
Example output

system:admin

18.4.15. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

Prerequisites

- You added machines to your cluster.

Procedure

1. Confirm that the cluster recognizes the machines:

   $ oc get nodes

   Example output

   NAME    STATUS    ROLES     AGE     VERSION
   master-0 Ready master 63m   v1.27.3
   master-1 Ready master 63m   v1.27.3
   master-2 Ready master 64m   v1.27.3

   The output lists all of the machines that you created.

   NOTE

   The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

   $ oc get csr

   Example output

   NAME    AGE     REQUESTOR                                                   CONDITION
   csr-mddf5 20m system:node:master-01.example.com   Approved,Issued
   csr-z5rln 16m system:node:worker-21.example.com   Approved,Issued

2. Review the pending CSRs and ensure that you see the client requests with the Pending or Approved status for each machine that you added to the cluster:

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in Pending status, approve the CSRs for your cluster machines:
Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the `machine approver` if the Kubelet requests a new certificate with identical parameters.

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the `oc exec`, `oc rsh`, and `oc logs` commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the `node-bootstrapper` service account in the `system:node` or `system:admin` groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

  ```
  $ oc adm certificate approve <csr_name>  
  ```

  * `<csr_name>` is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

  ```
  $ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve  
  ```

Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr  
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-c57lv</td>
<td>5m26s</td>
<td>system:node:ip-10-0-95-157.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
</tbody>
</table>
CHAPTER 18. INSTALLING ON IBM Z AND IBM LINUXONE

5. If the remaining CSRs are not approved, and are in the Pending status, approve the CSRs for
your cluster machines:
To approve them individually, run the following command for each valid CSR:
$ oc adm certificate approve <csr_name> 1
1

<csr_name> is the name of a CSR from the list of current CSRs.

To approve all pending CSRs, run the following command:
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}
{{end}}{{end}}' | xargs oc adm certificate approve
6. After all client and server CSRs have been approved, the machines have the Ready status.
Verify this by running the following command:
$ oc get nodes

Example output
NAME
master-0
master-1
master-2
worker-0
worker-1

STATUS ROLES AGE VERSION
Ready master 73m v1.27.3
Ready master 73m v1.27.3
Ready master 74m v1.27.3
Ready worker 11m v1.27.3
Ready worker 11m v1.27.3

NOTE
It can take a few minutes after approval of the server CSRs for the machines to
transition to the Ready status.
Additional information
For more information on CSRs, see Certificate Signing Requests .

18.4.16. Initial Operator configuration
After the control plane initializes, you must immediately configure some Operators so that they all
become available.
Prerequisites
Your control plane has initialized.
Procedure
1. Watch the cluster components come online:
$ watch -n5 oc get clusteroperators

2607


Example output

2. Configure the Operators that are not available.

18.4.16.1. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the **Recreate** rollout strategy during upgrades.

18.4.16.1.1. Configuring registry storage for IBM Z

As a cluster administrator, following installation you must configure your registry to use storage.
Prerequisites

- You have access to the cluster as a user with the `cluster-admin` role.
- You have a cluster on IBM Z®.
- You have provisioned persistent storage for your cluster, such as Red Hat OpenShift Data Foundation.

**IMPORTANT**

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. **ReadWriteOnce** access also requires that the registry uses the **Recreate** rollout strategy. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have 100Gi capacity.

Procedure

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

   **NOTE**

   When you use shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

   ```
   $ oc get pod -n openshift-image-registry -l docker-registry=default
   ```

   **Example output**

   No resources found in openshift-image-registry namespace

   **NOTE**

   If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

   ```
   $ oc edit configs.imageregistry.operator.openshift.io
   ```

   **Example output**

   ```
   storage:
   pvc:
   claim:
   ```
Leave the **claim** field blank to allow the automatic creation of an **image-registry-storage** PVC.

4. Check the **clusteroperator** status:

   $ oc get clusteroperator image-registry

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
<th>SINCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>image-registry</td>
<td>4.14</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>6h50m</td>
</tr>
</tbody>
</table>

5. Ensure that your registry is set to managed to enable building and pushing of images.

   - Run:

     $ oc edit configs.imageregistry/cluster

     Then, change the line

     ```
     managementState: Removed
     ```

     to

     ```
     managementState: Managed
     ```

18.4.16.1.2. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

**Procedure**

- To set the image registry storage to an empty directory:

  ```
  $ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec":{
  "storage":{"emptyDir":{}}}}'
  ```

  **WARNING**

  Configure this option for only non-production clusters.

  If you run this command before the Image Registry Operator initializes its components, the `oc patch` command fails with the following error:

  ```
  Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
  ```
Wait a few minutes and run the command again.

18.4.17. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

Prerequisites

- Your control plane has initialized.
- You have completed the initial Operator configuration.

Procedure

1. Confirm that all the cluster components are online with the following command:

```
$ watch -n5 oc get clusteroperators
```

Example output

</tbody>
</table>
Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```
$ ./openshift-install --dir <installation_directory> wait-for install-complete
```

1 For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

**Example output**

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

2. Confirm that the Kubernetes API server is communicating with the pods.
   a. To view a list of all pods, use the following command:

```
$ oc get pods --all-namespaces
```

**Example output**

```
<table>
<thead>
<tr>
<th>NAMESPACE</th>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>openshift-apiserver-operator</td>
<td>openshift-apiserver-operator-85cb746d55-zqhs8</td>
<td>1/1</td>
<td></td>
</tr>
<tr>
<td>Running 1</td>
<td>9m</td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apiserver-67b9g</td>
<td>1/1</td>
<td>Running 0</td>
</tr>
<tr>
<td>3m</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apiserver-ljcmx</td>
<td>1/1</td>
<td>Running 0</td>
</tr>
<tr>
<td>1m</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apiserver-z25h4</td>
<td>1/1</td>
<td>Running 0</td>
</tr>
<tr>
<td>2m</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-authentication-operator</td>
<td>authentication-operator-69d5d8bf84-vh2n8</td>
<td>1/1</td>
<td></td>
</tr>
<tr>
<td>Running 0</td>
<td>5m</td>
<td></td>
<td></td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```
b. View the logs for a pod that is listed in the output of the previous command by using the following command:

```
$ oc logs <pod_name> -n <namespace>
```

Specify the pod name and namespace, as shown in the output of the previous command.

If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation.

See "Enabling multipathing with kernel arguments on RHCOS" in the Post-installation machine configuration tasks documentation for more information.

### 18.4.18. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager Hybrid Cloud Console.

After you confirm that your OpenShift Cluster Manager Hybrid Cloud Console inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

#### Additional resources

- See About remote health monitoring for more information about the Telemetry service
- See How to generate SOSREPORT within OpenShift4 nodes without SSH.

### 18.4.19. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.

### 18.5. INSTALLING A CLUSTER WITH RHEL KVM ON IBM Z AND IBM LINUXONE IN A RESTRICTED NETWORK

In OpenShift Container Platform version 4.14, you can install a cluster on IBM Z® or IBM® LinuxONE infrastructure that you provision in a restricted network.

#### NOTE

While this document refers to only IBM Z®, all information in it also applies to IBM® LinuxONE.
18.5.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.

- You read the documentation on selecting a cluster installation method and preparing it for users.

- You created a registry on your mirror host and obtained the imageContentSources data for your version of OpenShift Container Platform.

- You must move or remove any existing installation files, before you begin the installation process. This ensures that the required installation files are created and updated during the installation process.

**IMPORTANT**

Ensure that installation steps are done from a machine with access to the installation media.

- You provisioned persistent storage using OpenShift Data Foundation or other supported storage protocols for your cluster. To deploy a private image registry, you must set up persistent storage with ReadWriteMany access.

- If you use a firewall, you configured it to allow the sites that your cluster requires access to.

**NOTE**

Be sure to also review this site list if you are configuring a proxy.

- You provisioned a RHEL Kernel Virtual Machine (KVM) system that is hosted on the logical partition (LPAR) and based on RHEL 8.6 or later. See Red Hat Enterprise Linux 8 and 9 Life Cycle.

18.5.2. About installations in restricted networks

In OpenShift Container Platform 4.14, you can perform an installation that does not require an active connection to the internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service’s Route 53 DNS and IAM services, require internet access. Depending on your network, you might require less internet access for an installation on bare metal hardware, Nutanix, or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift image registry and contains the installation media. You can create this registry on a mirror...
host, which can access both the internet and your closed network, or by using other methods that meet your restrictions.

**IMPORTANT**

Because of the complexity of the configuration for user-provisioned installations, consider completing a standard user-provisioned infrastructure installation before you attempt a restricted network installation using user-provisioned infrastructure. Completing this test installation might make it easier to isolate and troubleshoot any issues that might arise during your installation in a restricted network.

### 18.5.2.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The `ClusterVersion` status includes an **Unable to retrieve available updates** error.
- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

### 18.5.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to obtain the images that are necessary to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager Hybrid Cloud Console to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

### 18.5.4. Machine requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

One or more KVM host machines based on RHEL 8.6 or later. Each RHEL KVM host machine must have libvirt installed and running. The virtual machines are provisioned under each RHEL KVM host machine.

#### 18.5.4.1. Required machines

The smallest OpenShift Container Platform clusters require the following hosts:

**Table 18.45. Minimum required hosts**

<table>
<thead>
<tr>
<th>Hosts</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>One temporary bootstrap machine</td>
<td>The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.</td>
</tr>
</tbody>
</table>
Three control plane machines

The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.

At least two compute machines, which are also known as worker machines.

The workloads requested by OpenShift Container Platform users run on the compute machines.

**IMPORTANT**

To improve high availability of your cluster, distribute the control plane machines over different RHEL instances on at least two physical machines.

The bootstrap, control plane, and compute machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system.

See [Red Hat Enterprise Linux technology capabilities and limits](#).

### 18.5.4.2. Network connectivity requirements

The OpenShift Container Platform installer creates the Ignition files, which are necessary for all the Red Hat Enterprise Linux CoreOS (RHCOS) virtual machines. The automated installation of OpenShift Container Platform is performed by the bootstrap machine. It starts the installation of OpenShift Container Platform on each node, starts the Kubernetes cluster, and then finishes. During this bootstrap, the virtual machine must have an established network connection either through a Dynamic Host Configuration Protocol (DHCP) server or static IP address.

### 18.5.4.3. IBM Z network connectivity requirements

To install on IBM Z® under RHEL KVM, you need:

- A RHEL KVM host configured with an OSA or RoCE network adapter.
- Either a RHEL KVM host that is configured to use bridged networking in libvirt or MacVTap to connect the network to the guests.

See [Types of virtual network connections](#).

### 18.5.4.4. Host machine resource requirements

The RHEL KVM host in your environment must meet the following requirements to host the virtual machines that you plan for the OpenShift Container Platform environment. See [Getting started with virtualization](#).

You can install OpenShift Container Platform version 4.14 on the following IBM® hardware:

- IBM® z16 (all models), IBM® z15 (all models), IBM® z14 (all models)
- IBM® LinuxONE 4 (all models), IBM® LinuxONE III (all models), IBM® LinuxONE Emperor II, IBM® LinuxONE Rockhopper II

### 18.5.4.5. Minimum IBM Z system environment
Hardware requirements

- The equivalent of six Integrated Facilities for Linux (IFL), which are SMT2 enabled, for each cluster.
- At least one network connection to both connect to the LoadBalancer service and to serve data for traffic outside the cluster.

**NOTE**
You can use dedicated or shared IFLs to assign sufficient compute resources. Resource sharing is one of the key strengths of IBM Z®. However, you must adjust capacity correctly on each hypervisor layer and ensure sufficient resources for every OpenShift Container Platform cluster.

**IMPORTANT**
Since the overall performance of the cluster can be impacted, the LPARs that are used to set up the OpenShift Container Platform clusters must provide sufficient compute capacity. In this context, LPAR weight management, entitlements, and CPU shares on the hypervisor level play an important role.

Operating system requirements

- One LPAR running on RHEL 8.6 or later with KVM, which is managed by libvirt

On your RHEL KVM host, set up:

- Three guest virtual machines for OpenShift Container Platform control plane machines
- Two guest virtual machines for OpenShift Container Platform compute machines
- One guest virtual machine for the temporary OpenShift Container Platform bootstrap machine

18.5.4.6. Minimum resource requirements

Each cluster virtual machine must meet the following minimum requirements:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS</td>
<td>2</td>
<td>8 GB</td>
<td>100 GB</td>
<td>N/A</td>
</tr>
</tbody>
</table>

1. One physical core (IFL) provides two logical cores (threads) when SMT-2 is enabled. The hypervisor can provide two or more vCPUs.

18.5.4.7. Preferred IBM Z system environment

Hardware requirements
Three LPARs that each have the equivalent of six IFLs, which are SMT2 enabled, for each cluster.

Two network connections to both connect to the LoadBalancer service and to serve data for traffic outside the cluster.

Operating system requirements

For high availability, two or three LPARs running on RHEL 8.6 or later with KVM, which are managed by libvirt.

On your RHEL KVM host, set up:

- Three guest virtual machines for OpenShift Container Platform control plane machines, distributed across the RHEL KVM host machines.
- At least six guest virtual machines for OpenShift Container Platform compute machines, distributed across the RHEL KVM host machines.
- One guest virtual machine for the temporary OpenShift Container Platform bootstrap machine.
- To ensure the availability of integral components in an overcommitted environment, increase the priority of the control plane by using cpu_shares. Do the same for infrastructure nodes, if they exist. See schedinfo in IBM® Documentation.

18.5.4.8. Preferred resource requirements

The preferred requirements for each cluster virtual machine are:

<table>
<thead>
<tr>
<th>Virtual Machine</th>
<th>Operating System</th>
<th>vCPU</th>
<th>Virtual RAM</th>
<th>Storage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>120 GB</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>8</td>
<td>16 GB</td>
<td>120 GB</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS</td>
<td>6</td>
<td>8 GB</td>
<td>120 GB</td>
</tr>
</tbody>
</table>

18.5.4.9. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The kube-controller-manager only approves the kubelet client CSRs. The machine-approver cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

Additional resources

- Recommended host practices for IBM Z® & IBM® LinuxONE environments

18.5.4.10. Networking requirements for user-provisioned infrastructure
All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in `initramfs` during boot to fetch their Ignition config files.

During the initial boot, the machines require an IP address configuration that is set either through a DHCP server or statically by providing the required boot options. After a network connection is established, the machines download their Ignition config files from an HTTP or HTTPS server. The Ignition config files are then used to set the exact state of each machine. The Machine Config Operator completes more changes to the machines, such as the application of new certificates or keys, after installation.

It is recommended to use a DHCP server for long-term management of the cluster machines. Ensure that the DHCP server is configured to provide persistent IP addresses, DNS server information, and hostnames to the cluster machines.

**NOTE**

If a DHCP service is not available for your user-provisioned infrastructure, you can instead provide the IP networking configuration and the address of the DNS server to the nodes at RHCOS install time. These can be passed as boot arguments if you are installing from an ISO image. See the Installing RHCOS and starting the OpenShift Container Platform bootstrap process section for more information about static IP provisioning and advanced networking options.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

### 18.5.10.1. Setting the cluster node hostnames through DHCP

On Red Hat Enterprise Linux CoreOS (RHCOS) machines, the hostname is set through NetworkManager. By default, the machines obtain their hostname through DHCP. If the hostname is not provided by DHCP, set statically through kernel arguments, or another method, it is obtained through a reverse DNS lookup. Reverse DNS lookup occurs after the network has been initialized on a node and can take time to resolve. Other system services can start prior to this and detect the hostname as `localhost` or similar. You can avoid this by using DHCP to provide the hostname for each cluster node.

Additionally, setting the hostnames through DHCP can bypass any manual DNS record name configuration errors in environments that have a DNS split-horizon implementation.

### 18.5.10.2. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

**Table 18.46. Ports used for all-machine to all-machine communications**

<table>

<td>etcd server and peer ports</td>
</tr>
</tbody>
</table>

**NTP configuration for user-provisioned infrastructure**

OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for *Configuring chrony time service*.

If a DHCP server provides NTP server information, the chrony time service on the Red Hat Enterprise Linux CoreOS (RHCOS) machines read the information and can sync the clock with the NTP servers.

**Additional resources**
### 18.5.4.11. User-provisioned DNS requirements

In OpenShift Container Platform deployments, DNS name resolution is required for the following components:

- The Kubernetes API
- The OpenShift Container Platform application wildcard
- The bootstrap, control plane, and compute machines

Reverse DNS resolution is also required for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the hostnames for all the nodes, unless the hostnames are provided by DHCP. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

The following DNS records are required for a user-provisioned OpenShift Container Platform cluster and they must be in place before installation. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>`.

**Table 18.49. Required DNS records**

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes API</td>
<td><code>api.&lt;cluster_name&gt;.&lt;base_domain&gt;</code></td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the API load balancer. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td></td>
<td><code>api-int.&lt;cluster_name&gt;.&lt;base_domain&gt;</code></td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to internally identify the API load balancer. These records must be resolvable from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

The API server must be able to resolve the worker nodes by the hostnames that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.
<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Routes</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A wildcard DNS A/AAAA or CNAME record that refers to the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster. For example, <strong>console-openshift-console.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;</strong> is used as a wildcard route to the OpenShift Container Platform console.</td>
</tr>
<tr>
<td>Bootstrap machine</td>
<td>bootstrap.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Control plane</td>
<td>&lt;master&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Compute machines</td>
<td>&lt;worker&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**NOTE**

In OpenShift Container Platform 4.4 and later, you do not need to specify etcd host and SRV records in your DNS configuration.

**TIP**

You can use the `dig` command to verify name and reverse name resolution. See the section on Validating DNS resolution for user-provisioned infrastructure for detailed validation steps.

### 18.5.4.11.1. Example DNS configuration for user-provisioned clusters

This section provides A and PTR record configuration samples that meet the DNS requirements for deploying OpenShift Container Platform on user-provisioned infrastructure. The samples are not meant to provide advice for choosing one DNS solution over another.

In the examples, the cluster name is **ocp4** and the base domain is **example.com**.

**Example DNS A record configuration for a user-provisioned cluster**

The following example is a BIND zone file that shows sample A records for name resolution in a user-provisioned cluster.
Example 18.10. Sample DNS zone database

```dns
$TTL 1W
@ IN SOA ns1.example.com. root (2019070700 ; serial
3H ; refresh (3 hours)
30M ; retry (30 minutes)
2W ; expiry (2 weeks)
1W ) ; minimum (1 week)

; EOF
```

1. Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer.

2. Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer and is used for internal cluster communications.

3. Provides name resolution for the wildcard routes. The record refers to the IP address of the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

**NOTE**

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.
Provides name resolution for the bootstrap machine.

Provides name resolution for the control plane machines.

Provides name resolution for the compute machines.

Example DNS PTR record configuration for a user-provisioned cluster

The following example BIND zone file shows sample PTR records for reverse name resolution in a user-provisioned cluster.

Example 18.11. Sample DNS zone database for reverse records

```
$TTL 1W
@ IN SOA ns1.example.com. root (  
    2019070700 ; serial     
    3H ; refresh (3 hours)  
    30M ; retry (30 minutes)  
    2W ; expiry (2 weeks)    
    1W ) ; minimum (1 week) 
IN NS ns1.example.com. 
;  
;  
;  
97.1.168.192.in-addr.arpa. IN PTR master0.ocp4.example.com.  
;  
11.1.168.192.in-addr.arpa. IN PTR worker0.ocp4.example.com.  
;  
;.EOF
```

1 Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer.

2 Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer and is used for internal cluster communications.

3 Provides reverse DNS resolution for the bootstrap machine.

4 5 6 Provides reverse DNS resolution for the control plane machines.

7 8 Provides reverse DNS resolution for the compute machines.
A PTR record is not required for the OpenShift Container Platform application wildcard.

### 18.5.4.12. Load balancing requirements for user-provisioned infrastructure

Before you install OpenShift Container Platform, you must provision the API and application Ingress load balancing infrastructure. In production scenarios, you can deploy the API and application Ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

**NOTE**

If you want to deploy the API and application Ingress load balancers with a Red Hat Enterprise Linux (RHEL) instance, you must purchase the RHEL subscription separately.

The load balancing infrastructure must meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:

   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.

   - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

**IMPORTANT**

Do not configure session persistence for an API load balancer. Configuring session persistence for a Kubernetes API server might cause performance issues from excess application traffic for your OpenShift Container Platform cluster and the Kubernetes API that runs inside the cluster.

Configure the following ports on both the front and back of the load balancers:

#### Table 18.50. API load balancer

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the <code>/readyz</code> endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>
NOTE

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the /readyz endpoint to the removal of the API server instance from the pool. Within the time frame after /readyz returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application Ingress load balancer** Provides an ingress point for application traffic flowing in from outside the cluster. A working configuration for the Ingress router is required for an OpenShift Container Platform cluster.

Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

TIP

If the true IP address of the client can be seen by the application Ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

Configure the following ports on both the front and back of the load balancers:

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>

NOTE

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application Ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

**18.5.4.12.1. Example load balancer configuration for user-provisioned clusters**

This section provides an example API and application Ingress load balancer configuration that meets the load balancing requirements for user-provisioned clusters. The sample is an /etc/haproxy/haproxy.cfg configuration for an HAProxy load balancer. The example is not meant to provide advice for choosing
one load balancing solution over another.

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

**NOTE**

If you are using HAProxy as a load balancer and SELinux is set to enforcing, you must ensure that the HAProxy service can bind to the configured TCP port by running `setsebool -P haproxy_connect_any=1`.

Example 18.12. Sample API and application Ingress load balancer configuration

```
Example 18.12. Sample API and application Ingress load balancer configuration

global
  log  127.0.0.1 local2
  pidfile /var/run/haproxy.pid
  maxconn 4000
  daemon

defaults
  mode http
  log global
  option dontlognull
  option http-server-close
  option redispatch
  retries 3
  timeout http-request 10s
  timeout queue 1m
  timeout connect 10s
  timeout client 1m
  timeout server 1m
  timeout keepalive 10s
  timeout check 10s
  maxconn 3000

listen api-server-6443
  bind *:6443
  mode tcp
  server bootstrap bootstrap.ocp4.example.com:6443 check inter 1s backup
  server master0 master0.ocp4.example.com:6443 check inter 1s
  server master1 master1.ocp4.example.com:6443 check inter 1s
  server master2 master2.ocp4.example.com:6443 check inter 1s

listen machine-config-server-22623
  bind *:22623
  mode tcp
  server bootstrap bootstrap.ocp4.example.com:22623 check inter 1s backup
  server master0 master0.ocp4.example.com:22623 check inter 1s
  server master1 master1.ocp4.example.com:22623 check inter 1s
  server master2 master2.ocp4.example.com:22623 check inter 1s

listen ingress-router-443
  bind *:443
  mode tcp
  balance source
  server worker0 worker0.ocp4.example.com:443 check inter 1s
  server worker1 worker1.ocp4.example.com:443 check inter 1s
```
Port 6443 handles the Kubernetes API traffic and points to the control plane machines.

2 The bootstrap entries must be in place before the OpenShift Container Platform cluster installation and they must be removed after the bootstrap process is complete.

3 Port 22623 handles the machine config server traffic and points to the control plane machines.

4 Port 443 handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

5 Port 80 handles the HTTP traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

### NOTE

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application Ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

### TIP

If you are using HAProxy as a load balancer, you can check that the haproxy process is listening on ports 6443, 22623, 443, and 80 by running `netstat -nltupe` on the HAProxy node.

### 18.5.5. Preparing the user-provisioned infrastructure

Before you install OpenShift Container Platform on user-provisioned infrastructure, you must prepare the underlying infrastructure.

This section provides details about the high-level steps required to set up your cluster infrastructure in preparation for an OpenShift Container Platform installation. This includes configuring IP networking and network connectivity for your cluster nodes, enabling the required ports through your firewall, and setting up the required DNS and load balancing infrastructure.

After preparation, your cluster infrastructure must meet the requirements outlined in the Requirements for a cluster with user-provisioned infrastructure section.

### Prerequisites

- You have reviewed the OpenShift Container Platform 4.x Tested Integrations page.
- You have reviewed the infrastructure requirements detailed in the Requirements for a cluster with user-provisioned infrastructure section.
Procedure

1. If you are using DHCP to provide the IP networking configuration to your cluster nodes, configure your DHCP service.
   
   a. Add persistent IP addresses for the nodes to your DHCP server configuration. In your configuration, match the MAC address of the relevant network interface to the intended IP address for each node.

   b. When you use DHCP to configure IP addressing for the cluster machines, the machines also obtain the DNS server information through DHCP. Define the persistent DNS server address that is used by the cluster nodes through your DHCP server configuration.

   **NOTE**
   
   If you are not using a DHCP service, you must provide the IP networking configuration and the address of the DNS server to the nodes at RHCOS install time. These can be passed as boot arguments if you are installing from an ISO image. See the Installing RHCOS and starting the OpenShift Container Platform bootstrap process section for more information about static IP provisioning and advanced networking options.

   c. Define the hostnames of your cluster nodes in your DHCP server configuration. See the Setting the cluster node hostnames through DHCP section for details about hostname considerations.

   **NOTE**
   
   If you are not using a DHCP service, the cluster nodes obtain their hostname through a reverse DNS lookup.

2. Choose to perform either a fast track installation of Red Hat Enterprise Linux CoreOS (RHCOS) or a full installation of Red Hat Enterprise Linux CoreOS (RHCOS). For the full installation, you must set up an HTTP or HTTPS server to provide Ignition files and install images to the cluster nodes. For the fast track installation an HTTP or HTTPS server is not required, however, a DHCP server is required. See sections "Fast-track installation: Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines" and "Full installation: Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines".

3. Ensure that your network infrastructure provides the required network connectivity between the cluster components. See the Networking requirements for user-provisioned infrastructure section for details about the requirements.

4. Configure your firewall to enable the ports required for the OpenShift Container Platform cluster components to communicate. See Networking requirements for user-provisioned infrastructure section for details about the ports that are required.

   **IMPORTANT**
   
   By default, port 1936 is accessible for an OpenShift Container Platform cluster, because each control plane node needs access to this port.

   Avoid using the Ingress load balancer to expose this port, because doing so might result in the exposure of sensitive information, such as statistics and metrics, related to Ingress Controllers.
5. Setup the required DNS infrastructure for your cluster.
   a. Configure DNS name resolution for the Kubernetes API, the application wildcard, the bootstrap machine, the control plane machines, and the compute machines.
   b. Configure reverse DNS resolution for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.
   See the User-provisioned DNS requirements section for more information about the OpenShift Container Platform DNS requirements.

6. Validate your DNS configuration.
   a. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses in the responses correspond to the correct components.
   b. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names in the responses correspond to the correct components.
   See the Validating DNS resolution for user-provisioned infrastructure section for detailed DNS validation steps.

7. Provision the required API and application ingress load balancing infrastructure. See the Load balancing requirements for user-provisioned infrastructure section for more information about the requirements.

   NOTE

   Some load balancing solutions require the DNS name resolution for the cluster nodes to be in place before the load balancing is initialized.

**18.5.6. Validating DNS resolution for user-provisioned infrastructure**

You can validate your DNS configuration before installing OpenShift Container Platform on user-provisioned infrastructure.

**IMPORTANT**

The validation steps detailed in this section must succeed before you install your cluster.

**Prerequisites**

- You have configured the required DNS records for your user-provisioned infrastructure.

**Procedure**

1. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses contained in the responses correspond to the correct components.
   a. Perform a lookup against the Kubernetes API record name. Check that the result points to the IP address of the API load balancer:

   ```
   $ dig +noall +answer @<nameserver_ip> api.<cluster_name>.<base_domain>
   ```
1. Replace `<nameserver_ip>` with the IP address of the nameserver, `<cluster_name>` with your cluster name, and `<base_domain>` with your base domain name.

Example output

| api.ocp4.example.com | 604800 IN A 192.168.1.5 |

b. Perform a lookup against the Kubernetes internal API record name. Check that the result points to the IP address of the API load balancer:

```
$ dig +noall +answer @<nameserver_ip> api-int.<cluster_name>.<base_domain>
```

Example output

| api-int.ocp4.example.com | 604800 IN A 192.168.1.5 |

c. Test an example `*.apps.<cluster_name>.<base_domain>` DNS wildcard lookup. All of the application wildcard lookups must resolve to the IP address of the application ingress load balancer:

```
$ dig +noall +answer @<nameserver_ip> random.apps.<cluster_name>.<base_domain>
```

Example output

| random.apps.ocp4.example.com | 604800 IN A 192.168.1.5 |

**NOTE**

In the example outputs, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

You can replace `random` with another wildcard value. For example, you can query the route to the OpenShift Container Platform console:

```
$ dig +noall +answer @<nameserver_ip> console-openshift-console.apps.<cluster_name>.<base_domain>
```

Example output

| console-openshift-console.apps.ocp4.example.com | 604800 IN A 192.168.1.5 |

d. Run a lookup against the bootstrap DNS record name. Check that the result points to the IP address of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> bootstrap.<cluster_name>.<base_domain>
```

Example output
Use this method to perform lookups against the DNS record names for the control plane and compute nodes. Check that the results correspond to the IP addresses of each node.

2. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names contained in the responses correspond to the correct components.

   a. Perform a reverse lookup against the IP address of the API load balancer. Check that the response includes the record names for the Kubernetes API and the Kubernetes internal API:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.1.5
```

   Example output

```
5.1.168.192.in-addr.arpa. 604800 IN PTR api-int.ocp4.example.com. ①
5.1.168.192.in-addr.arpa. 604800 IN PTR api.ocp4.example.com. ②
```

   ① Provides the record name for the Kubernetes internal API.

   ② Provides the record name for the Kubernetes API.

   b. Perform a reverse lookup against the IP address of the bootstrap node. Check that the result points to the DNS record name of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.96
```

   Example output

```
```

c. Use this method to perform reverse lookups against the IP addresses for the control plane and compute nodes. Check that the results correspond to the DNS record names of each node.

18.5.7. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.
After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `.openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>
   ```

   Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

2. View the public SSH key:

   ```bash
   $ cat <path>/<file_name>.pub
   ```

   For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

   ```bash
   $ cat ~/.ssh/id_ed25519.pub
   ```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `.openshift-install gather` command.

   **NOTE**

   On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

   a. If the **ssh-agent** process is not already running for your local user, start it as a background task:
NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```bash
$ ssh-add <path>/<file_name>
```

Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

### 18.5.8. Manually creating the installation configuration file

**Prerequisites**

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.

- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Create an installation directory to store your required installation assets in:

```bash
$ mkdir <installation_directory>
```
IMPORTANT

You must create a directory. Some installation assets, like bootstrap X.509
certificates have short expiration intervals, so you must not reuse an installation
directory. If you want to reuse individual files from another cluster installation,
you can copy them into your directory. However, the file names for the
installation assets might change between releases. Use caution when copying
installation files from an earlier OpenShift Container Platform version.

2. Customize the sample `install-config.yaml` file template that is provided and save it in the
`<installation_directory>`.

NOTE

You must name this configuration file `install-config.yaml`.

NOTE

For some platform types, you can alternatively run `./openshift-install create
install-config --dir <installation_directory>` to generate an `install-config.yaml`
file. You can provide details about your cluster configuration at the prompts.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

IMPORTANT

The `install-config.yaml` file is consumed during the next step of the installation
process. You must back it up now.

Additional resources

- Installation configuration parameters for IBM Z®

18.5.8.1. Sample `install-config.yaml` file for IBM Z

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container
Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com  
compute:  
  - hyperthreading: Enabled
    name: worker
    replicas: 0
    architecture: s390x
controlPlane:  
  hyperthreading: Enabled
  name: master
  replicas: 3
  architecture: s390x
metadata:
  name: test
```
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
    - hostPrefix: 23
  networkType: OVNKubernetes
  serviceNetwork:
    - 172.30.0.0/16
platform:
  none: {}
  fips: false
pullSecret: {"auths":{"<local_registry>":{"auth": "<credentials>",”email": "you@example.com"}}}  
sshKey: ssh-ed25519 AAAA...
additionalTrustBundle: |
  -----BEGIN CERTIFICATE-----
  ZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZ
  -----END CERTIFICATE-----
imageContentSources:
  - mirrors:
    - <local_repository>/ocp4/openshift4
      source: quay.io/openshift-release-dev/ocp-release
    - mirrors:
      - <local_repository>/ocp4/openshift4
        source: quay.io/openshift-release-dev/ocp-v4.0-art-dev

1. The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

2. The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -, and the first line of the **controlPlane** section must not. Only one control plane pool is used.

3. Specifies whether to enable or disable simultaneous multithreading (SMT), or hyperthreading. By default, SMT is enabled to increase the performance of the cores in your machines. You can disable it by setting the parameter value to **Disabled**. If you disable SMT, you must disable it in all cluster machines; this includes both control plane and compute machines.

   **NOTE**
   Simultaneous multithreading (SMT) is enabled by default. If SMT is not available on your OpenShift Container Platform nodes, the **hyperthreading** parameter has no effect.

   **IMPORTANT**
   If you disable **hyperthreading**, whether on your OpenShift Container Platform nodes or in the **install-config.yaml** file, ensure that your capacity planning accounts for the dramatically decreased machine performance.

4. You must set this value to 0 when you install OpenShift Container Platform on user-provisioned infrastructure. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. In user-provisioned installations, you must manually deploy the compute machines before you finish installing the cluster.
NOTE
If you are installing a three-node cluster, do not deploy any compute machines when you install the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

7 The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

8 The cluster name that you specified in your DNS records.

9 A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to access the pods from an external network, you must configure load balancers and routers to manage the traffic.

NOTE
Class E CIDR range is reserved for a future use. To use the Class E CIDR range, you must ensure your networking environment accepts the IP addresses within the Class E CIDR range.

10 The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23, then each node is assigned a /23 subnet out of the given cidr, which allows for 510 \(2^{(32 - 23)} - 2\) pod IP addresses. If you are required to provide access to nodes from an external network, configure load balancers and routers to manage the traffic.

11 The cluster network plugin to install. The supported values are OVNKubernetes and OpenShiftSDN. The default value is OVNKubernetes.

12 The IP address pool to use for service IP addresses. You can enter only one IP address pool. This block must not overlap with existing physical networks. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.

13 You must set the platform to none. You cannot provide additional platform configuration variables for IBM Z® infrastructure.

IMPORTANT
Clusters that are installed with the platform type none are unable to use some features, such as managing compute machines with the Machine API. This limitation applies even if the compute machines that are attached to the cluster are installed on a platform that would normally support the feature. This parameter cannot be changed after installation.

14 Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.
IMPORTANT

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see Installing the system in FIPS mode. When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures.

For `<local_registry>`, specify the registry domain name, and optionally the port, that your mirror registry uses to serve content. For example, `registry.example.com` or `registry.example.com:5000`. For `<credentials>`, specify the base64-encoded user name and password for your mirror registry.

The SSH public key for the `core` user in Red Hat Enterprise Linux CoreOS (RHCOS).

NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

Add the `additionalTrustBundle` parameter and value. The value must be the contents of the certificate file that you used for your mirror registry. The certificate file can be an existing, trusted certificate authority or the self-signed certificate that you generated for the mirror registry.

Provide the `imageContentSources` section according to the output of the command that you used to mirror the repository.

IMPORTANT

- When using the `oc adm release mirror` command, use the output from the `imageContentSources` section.
- When using `oc mirror` command, use the `repositoryDigestMirrors` section of the `ImageContentSourcePolicy` file that results from running the command.
- `ImageContentSourcePolicy` is deprecated. For more information see Configuring image registry repository mirroring.

18.5.8.2. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

Prerequisites

- You have an existing `install-config.yaml` file.
You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[]`.cidr`, `networking.clusterNetwork[]`.cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

**Procedure**

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
     httpProxy: http://<username>:<pswd>@<ip>:<port> ¹
     httpsProxy: https://<username>:<pswd>@<ip>:<port> ²
     noProxy: example.com ³
   additionalTrustBundle: |
     -----BEGIN CERTIFICATE-----
     <MY_TRUSTED_CA_CERT>
     -----END CERTIFICATE-----
   additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> ⁵
   
   ¹ A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.
   
   ² A proxy URL to use for creating HTTPS connections outside the cluster.
   
   ³ A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.
   
   ⁴ If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the `trustedCA` field of the `Proxy` object. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.
   
   ⁵ Optional: The policy to determine the configuration of the `Proxy` object to reference the `user-ca-bundle` config map in the `trustedCA` field. The allowed values are `Proxyonly` and `Always`. Use `Proxyonly` to reference the `user-ca-bundle` config map only when http/https proxy is configured. Use `Always` to always reference the `user-ca-bundle` config map. The default value is `Proxyonly`. 
NOTE

The installation program does not support the proxy readinessEndpoints field.

NOTE

If the installer times out, restart and then complete the deployment by using the wait-for command of the installer. For example:

$ ./openshift-install wait-for install-complete --log-level debug

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

NOTE

Only the Proxy object named cluster is supported, and no additional proxies can be created.

18.5.8.3. Configuring a three-node cluster

Optionally, you can deploy zero compute machines in a minimal three node cluster that consists of three control plane machines only. This provides smaller, more resource efficient clusters for cluster administrators and developers to use for testing, development, and production.

In three-node OpenShift Container Platform environments, the three control plane machines are schedulable, which means that your application workloads are scheduled to run on them.

Prerequisites

- You have an existing install-config.yaml file.

Procedure

- Ensure that the number of compute replicas is set to 0 in your install-config.yaml file, as shown in the following compute stanza:

```
compute:
- name: worker
  platform: {}
  replicas: 0
```
NOTE

You must set the value of the `replicas` parameter for the compute machines to 0 when you install OpenShift Container Platform on user-provisioned infrastructure, regardless of the number of compute machines you are deploying. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. This does not apply to user-provisioned installations, where the compute machines are deployed manually.

NOTE

The preferred resource for control plane nodes is six vCPUs and 21 GB. For three control plane nodes this is the memory + vCPU equivalent of a minimum five-node cluster. You should back the three nodes, each installed on a 120 GB disk, with three IFLs that are SMT2 enabled. The minimum tested setup is three vCPUs and 10 GB on a 120 GB disk for each control plane node.

For three-node cluster installations, follow these next steps:

- If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes. See the Load balancing requirements for user-provisioned infrastructure section for more information.

- When you create the Kubernetes manifest files in the following procedure, ensure that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file is set to `true`. This enables your application workloads to run on the control plane nodes.

- Do not deploy any compute nodes when you create the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

18.5.9. Cluster Network Operator configuration

The configuration for the cluster network is specified as part of the Cluster Network Operator (CNO) configuration and stored in a custom resource (CR) object that is named `cluster`. The CR specifies the fields for the `Network` API in the `operator.openshift.io` API group.

The CNO configuration inherits the following fields during cluster installation from the `Network` API in the `Network.config.openshift.io` API group and these fields cannot be changed:

- `clusterNetwork`
  - IP address pools from which pod IP addresses are allocated.

- `serviceNetwork`
  - IP address pool for services.

- `defaultNetwork.type`
  - Cluster network plugin, such as OpenShift SDN or OVN-Kubernetes.

You can specify the cluster network plugin configuration for your cluster by setting the fields for the `defaultNetwork` object in the CNO object named `cluster`. 

### 18.5.9.1. Cluster Network Operator configuration object

The fields for the Cluster Network Operator (CNO) are described in the following table:

#### Table 18.52. Cluster Network Operator configuration object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>metadata.name</td>
<td>string</td>
<td>The name of the CNO object. This name is always <code>cluster</code>.</td>
</tr>
<tr>
<td>spec.clusterNetwork</td>
<td>array</td>
<td>A list specifying the blocks of IP addresses from which pod IP addresses are allocated and the subnet prefix length assigned to each individual node in the cluster. For example:</td>
</tr>
</tbody>
</table>

```yaml
spec:
  clusterNetwork:
    - cidr: 10.128.0.0/19
      hostPrefix: 23
    - cidr: 10.128.32.0/19
      hostPrefix: 23
```

You can customize this field only in the `install-config.yaml` file before you create the manifests. The value is read-only in the manifest file.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>spec.serviceNetwork</td>
<td>array</td>
<td>A block of IP addresses for services. The OpenShift SDN and OVN-Kubernetes network plugins support only a single IP address block for the service network. For example:</td>
</tr>
</tbody>
</table>

```yaml
spec:
  serviceNetwork:
    - 172.30.0.0/14
```

You can customize this field only in the `install-config.yaml` file before you create the manifests. The value is read-only in the manifest file.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>spec.defaultNetwork</td>
<td>object</td>
<td>Configures the network plugin for the cluster network.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>spec.kubeProxyConfig</td>
<td>object</td>
<td>The fields for this object specify the kube-proxy configuration. If you are using the OVN-Kubernetes cluster network plugin, the kube-proxy configuration has no effect.</td>
</tr>
</tbody>
</table>

#### defaultNetwork object configuration

The values for the `defaultNetwork` object are defined in the following table:

#### Table 18.53. defaultNetwork object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
Either OpenShiftSDN or OVNKubernetes. The Red Hat OpenShift Networking network plugin is selected during installation. This value cannot be changed after cluster installation.

**NOTE**
OpenShift Container Platform uses the OVN-Kubernetes network plugin by default.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>string</td>
<td>Either OpenShiftSDN or OVNKubernetes. The Red Hat OpenShift Networking network plugin is selected during installation. This value cannot be changed after cluster installation.</td>
</tr>
</tbody>
</table>

This object is only valid for the OpenShift SDN network plugin.

This object is only valid for the OVN-Kubernetes network plugin.

Configuration for the OpenShift SDN network plugin
The following table describes the configuration fields for the OpenShift SDN network plugin:

Table 18.54. openshiftSDNConfig object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mode</td>
<td>string</td>
<td>Configures the network isolation mode for OpenShift SDN. The default value is NetworkPolicy. The values Multitenant and Subnet are available for backwards compatibility with OpenShift Container Platform 3.x but are not recommended. This value cannot be changed after cluster installation.</td>
</tr>
<tr>
<td>mtu</td>
<td>integer</td>
<td>The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU. If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes. If your cluster requires different MTU values for different nodes, you must set this value to 50 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1450. This value cannot be changed after cluster installation.</td>
</tr>
</tbody>
</table>
The port to use for all VXLAN packets. The default value is 4789. This value cannot be changed after cluster installation.

If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number.

On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port 9000 and port 9999.

Example OpenShift SDN configuration

```yaml
defaultNetwork:
  type: OpenShiftSDN
  openshiftSDNConfig:
    mode: NetworkPolicy
    mtu: 1450
    vxlanPort: 4789
```

Configuration for the OVN-Kubernetes network plugin
The following table describes the configuration fields for the OVN-Kubernetes network plugin:

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>vxlanPort</td>
<td>integer</td>
<td>The port to use for all VXLAN packets. The default value is 4789. This value cannot be changed after cluster installation.</td>
</tr>
<tr>
<td>genevePort</td>
<td>integer</td>
<td>The port to use for all Geneve packets. The default value is 6081. This value cannot be changed after cluster installation.</td>
</tr>
<tr>
<td>ipsecConfig</td>
<td>object</td>
<td>Specify an empty object to enable IPsec encryption.</td>
</tr>
</tbody>
</table>

The maximum transmission unit (MTU) for the Geneve (Generic Network Virtualization Encapsulation) overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.

If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.

If your cluster requires different MTU values for different nodes, you must set this value to 100 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1400.

mtu

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>genevePort</td>
<td>integer</td>
<td>The port to use for all Geneve packets. The default value is 6081. This value cannot be changed after cluster installation.</td>
</tr>
<tr>
<td>ipsecConfig</td>
<td>object</td>
<td>Specify an empty object to enable IPsec encryption.</td>
</tr>
<tr>
<td>Field</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>--------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>policyAuditConfig</td>
<td>object</td>
<td>Specify a configuration object for customizing network policy audit logging. If unset, the defaults audit log settings are used.</td>
</tr>
<tr>
<td>gatewayConfig</td>
<td>object</td>
<td>Optional: Specify a configuration object for customizing how egress traffic is sent to the node gateway.</td>
</tr>
</tbody>
</table>

**NOTE**

While migrating egress traffic, you can expect some disruption to workloads and service traffic until the Cluster Network Operator (CNO) successfully rolls out the changes.
If your existing network infrastructure overlaps with the 100.64.0.0/16 IPv4 subnet, you can specify a different IP address range for internal use by OVN-Kubernetes. You must ensure that the IP address range does not overlap with any other subnet used by your OpenShift Container Platform installation. The IP address range must be larger than the maximum number of nodes that can be added to the cluster. For example, if the `clusterNetwork.cidr` value is 10.128.0.0/14 and the `clusterNetwork.hostPrefix` value is /23, then the maximum number of nodes is $2^{(23-14)}=512$.

This field cannot be changed after installation.

<table>
<thead>
<tr>
<th>Field</th>

<td>used by your OpenShift</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Container Platform</td>
<td></td>
</tr>
<tr>
<td></td>
<td>installation. The IP address</td>
<td></td>
</tr>
<tr>
<td></td>
<td>range must be larger than the</td>
<td></td>
</tr>
<tr>
<td></td>
<td>maximum number of nodes that</td>
<td></td>
</tr>
<tr>
<td></td>
<td>can be added to the cluster.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>For example, if the</td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>clusterNetwork.cidr</code> value</td>
<td></td>
</tr>
<tr>
<td></td>
<td>is 10.128.0.0/14 and the</td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>clusterNetwork.hostPrefix</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td>value is /23, then the</td>
<td></td>
</tr>
<tr>
<td></td>
<td>maximum number of nodes is</td>
<td></td>
</tr>
<tr>
<td></td>
<td>$2^{(23-14)}=512$.</td>
<td></td>
</tr>
</tbody>
</table>

This field cannot be changed after installation.
If your existing network infrastructure overlaps with the fd98::/48 IPv6 subnet, you can specify a different IP address range for internal use by OVN-Kubernetes. You must ensure that the IP address range does not overlap with any other subnet used by your OpenShift Container Platform installation. The IP address range must be larger than the maximum number of nodes that can be added to the cluster. This field cannot be changed after installation.

The default value is fd98::/48.

---

Table 18.56. policyAuditConfig object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rateLimit</td>
<td>integer</td>
<td>The maximum number of messages to generate every second per node. The default value is 20 messages per second.</td>
</tr>
<tr>
<td>maxFileSize</td>
<td>integer</td>
<td>The maximum size for the audit log in bytes. The default value is 50000000 or 50 MB.</td>
</tr>
</tbody>
</table>
One of the following additional audit log targets:

- **libc**
  - The libc `syslog()` function of the journald process on the host.

- **udp:<host>:<port>**
  - A syslog server. Replace `<host>:<port>` with the host and port of the syslog server.

- **unix:<file>**
  - A Unix Domain Socket file specified by `<file>`.

- **null**
  - Do not send the audit logs to any additional target.

---

The syslog facility, such as `kern`, as defined by RFC5424. The default value is `local0`.

---

**Table 18.57. gatewayConfig object**

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>routingViaHost</strong></td>
<td>boolean</td>
<td>Set this field to <strong>true</strong> to send egress traffic from pods to the host networking stack. For highly-specialized installations and applications that rely on manually configured routes in the kernel routing table, you might want to route egress traffic to the host networking stack. By default, egress traffic is processed in OVN to exit the cluster and is not affected by specialized routes in the kernel routing table. The default value is <strong>false</strong>. This field has an interaction with the Open vSwitch hardware offloading feature. If you set this field to <strong>true</strong>, you do not receive the performance benefits of the offloading because egress traffic is processed by the host networking stack.</td>
</tr>
<tr>
<td><strong>ipForwarding</strong></td>
<td>object</td>
<td>You can control IP forwarding for all traffic on OVN-Kubernetes managed interfaces by using the <strong>ipForwarding</strong> specification in the <strong>Network</strong> resource. Specify <strong>Restricted</strong> to only allow IP forwarding for Kubernetes related traffic. Specify <strong>Global</strong> to allow forwarding of all IP traffic. For new installations, the default is <strong>Restricted</strong>. For updates to OpenShift Container Platform 4.14, the default is <strong>Global</strong>.</td>
</tr>
</tbody>
</table>

---

**Example OVN-Kubernetes configuration with IPSec enabled**

```yaml
defaultNetwork:
  type: OVNKubernetes
  ovnKubernetesConfig:
    mtu: 1400
    genevePort: 6081
    ipsecConfig: {}
```
kubeProxyConfig object configuration

The values for the kubeProxyConfig object are defined in the following table:

Table 18.58. kubeProxyConfig object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>iptablesSyncPeriod</td>
<td>string</td>
<td>The refresh period for iptables rules. The default value is 30s. Valid suffixes include s, m, and h and are described in the Go time package documentation.</td>
</tr>
</tbody>
</table>
| proxyArguments.iptables-min-sync-period | array  | The minimum duration before refreshing iptables rules. This field ensures that the refresh does not happen too frequently. Valid suffixes include s, m, and h and are described in the Go time package. The default value is: kubeProxyConfig:
   proxyArguments:
       iptables-min-sync-period:
          - 0s |

NOTE

Because of performance improvements introduced in OpenShift Container Platform 4.3 and greater, adjusting the iptablesSyncPeriod parameter is no longer necessary.

18.5.10. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.
IMPORTANT

- The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

NOTE

The installation program that generates the manifest and Ignition files is architecture specific and can be obtained from the client image mirror. The Linux version of the installation program runs on s390x only. This installer program is also available as a Mac OS version.

Prerequisites

- You obtained the OpenShift Container Platform installation program. For a restricted network installation, these files are on your mirror host.

- You created the install-config.yaml installation configuration file.

Procedure

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

   ```
   $ ./openshift-install create manifests --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the installation directory that contains the install-config.yaml file you created.

   **WARNING**
   
   If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.
IMPORTANT

When you configure control plane nodes from the default unschedulable to schedulable, additional subscriptions are required. This is because control plane nodes then become compute nodes.

2. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:
   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.
   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.
   c. Save and exit the file.

3. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

   ```bash
   $ ./openshift-install create ignition-configs --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the same installation directory.

   Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The `kubeadmin-password` and `kubeconfig` files are created in the `<installation_directory>/auth` directory:

   ```
   ├── auth
   │   ├── kubeadmin-password
   │   └── kubeconfig
   │       ├── bootstrap.ign
   │       └── master.ign
   │           └── metadata.json
   └── worker.ign
   ```

18.5.11. Installing RHCOS and starting the OpenShift Container Platform bootstrap process

To install OpenShift Container Platform on IBM Z® infrastructure that you provision, you must install Red Hat Enterprise Linux CoreOS (RHCOS) as Red Hat Enterprise Linux (RHEL) guest virtual machines. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS machines have rebooted.

You can perform a fast-track installation of RHCOS that uses a prepackaged QEMU copy-on-write (QCOW2) disk image. Alternatively, you can perform a full installation on a new QCOW2 disk image.

To add further security to your system, you can optionally install RHCOS using IBM® Secure Execution before proceeding to the fast-track installation.

18.5.11.1. Installing RHCOS using IBM Secure Execution
Before you install RHCOS using IBM® Secure Execution, you must prepare the underlying infrastructure.

**Prerequisites**

- IBM® z15 or later, or IBM® LinuxONE III or later.
- Red Hat Enterprise Linux (RHEL) 8 or later.
- You have a bootstrap Ignition file. The file is not protected, enabling others to view and edit it.
- You have verified that the boot image has not been altered after installation.
- You must run all your nodes as IBM® Secure Execution guests.

**Procedure**

1. Prepare your RHEL KVM host to support IBM® Secure Execution.

   - By default, KVM hosts do not support guests in IBM® Secure Execution mode. To support guests in IBM® Secure Execution mode, KVM hosts must boot in LPAR mode with the kernel parameter specification `prot_virt=1`. To enable `prot_virt=1` on RHEL 8, follow these steps:
     
     a. Navigate to `/boot/loader/entries/` to modify your bootloader configuration file `*.conf`.
     
     b. Add the kernel command line parameter `prot_virt=1`.
     
     c. Run the `zipl` command and reboot your system.

     KVM hosts that successfully start with support for IBM® Secure Execution for Linux issue the following kernel message:

     ```
     prot_virt: Reserving <amount>MB as ultravisor base storage.
     ```

     d. To verify that the KVM host now supports IBM® Secure Execution, run the following command:

     ```
     # cat /sys/firmware/uv/prot_virt_host
     ```

     **Example output**

     ```
     1
     ```

     The value of this attribute is 1 for Linux instances that detect their environment as consistent with that of a secure host. For other instances, the value is 0.

2. Add your host keys to the KVM guest via Ignition.

   During the first boot, RHCOS looks for your host keys to re-encrypt itself with them. RHCOS searches for files starting with `ibm-z-hostkey-` in the `/etc/se-hostkeys` directory. All host keys, for each machine the cluster is running on, must be loaded into the directory by the administrator. After first boot, you cannot run the VM on any other machines.
You need to prepare your Ignition file on a safe system. For example, another IBM® Secure Execution guest.

For example:

```json
{
    "ignition": { "version": "3.0.0" },
    "storage": {
        "files": [
            {
                "path": "/etc/se-hostkeys/ibm-z-hostkey-<your-hostkey>.crt",
                "contents": {
                    "source": "data:;base64,<base64 encoded hostkey document>"
                },
                "mode": 420
            },
            {
                "path": "/etc/se-hostkeys/ibm-z-hostkey-<your-hostkey>.crt",
                "contents": {
                    "source": "data:;base64,<base64 encoded hostkey document>"
                },
                "mode": 420
            }
        ]
    }
}
```

You can add as many host keys as required if you want your node to be able to run on multiple IBM Z® machines.

3. To generate the Base64 encoded string, run the following command:

```
base64 <your-hostkey>.crt
```

Compared to guests not running IBM® Secure Execution, the first boot of the machine is longer because the entire image is encrypted with a randomly generated LUKS passphrase before the Ignition phase.

4. Add Ignition protection

   To protect the secrets that are stored in the Ignition config file from being read or even modified, you must encrypt the Ignition config file.

   To achieve the desired security, Ignition logging and local login are disabled by default when running IBM® Secure Execution.
a. Fetch the public GPG key for the `secex-qemu.qcow2` image and encrypt the Ignition config with the key by running the following command:

```
gpg --recipient-file /path/to/ignition.gpg.pub --yes --output /path/to/config.ign.gpg --verbose --armor --encrypt /path/to/config.ign
```

5. Follow the fast-track installation of RHCOS to install nodes by using the IBM® Secure Execution QCOW image.

**NOTE**

Before you start the VM, replace `serial=ignition` with `serial=ignition_crypted`, and add the `launchSecurity` parameter.

**Verification**

When you have completed the fast-track installation of RHCOS and Ignition runs at the first boot, verify if decryption is successful.

- If the decryption is successful, you can expect an output similar to the following example:

**Example output**

```
[ 2.801433] systemd[1]: Starting coreos-ignition-setup-user.service - CoreOS Ignition User Config Setup...

[ 2.803959] coreos-secex-ignition-decrypt[731]: gpg: key <key_name>: public key "Secure Execution (secex) 38.20230323.dev.0" imported
[ 2.808874] coreos-secex-ignition-decrypt[740]: gpg: encrypted with rsa4096 key, ID <key_name>, created <yyyy-mm-dd>
[ OK  ] Finished coreos-secex-ignition...S Secex Ignition Config Decryptor.
```

- If the decryption fails, you can expect an output similar to the following example:

**Example output**

```
Starting coreos-ignition-user-config-setup...  
[ 2.803959] coreos-secex-ignition-decrypt[731]: gpg: key <key_name>: public key "Secure Execution (secex) 38.20230323.dev.0" imported  
[ 2.808874] coreos-secex-ignition-decrypt[740]: gpg: encrypted with RSA key, ID <key_name>  
[ 2.870347] coreos-secex-ignition-decrypt[738]: gpg: public key decryption failed: No secret key  
[ 2.870371] coreos-secex-ignition-decrypt[738]: gpg: decryption failed: No secret key
```

18.5.11.2. Configuring NBDE with static IP in an IBM Z or IBM LinuxONE environment
Enabling NBDE disk encryption in an IBM Z® or IBM® LinuxONE environment requires additional steps, which are described in detail in this section.

**Prerequisites**

- You have set up the External Tang Server. See Network-bound disk encryption for instructions.
- You have installed the butane utility.
- You have reviewed the instructions for how to create machine configs with Butane.

**Procedure**

1. Create Butane configuration files for the control plane and compute nodes.
   The following example of a Butane configuration for a control plane node creates a file named `master-storage.bu` for disk encryption:

   ```yaml
   variant: openshift
   version: 4.14.0
   metadata:
     name: master-storage
     labels:
       machineconfiguration.openshift.io/role: master
   storage:
     luks:
       - clevis:
         tang:
           - thumbprint: QcPr_NHFJammnRCA3fFMVdNBwjs
             url: http://clevis.example.com:7500
         options:
           - --cipher
           - aes-cbc-essiv:sha256
         device: /dev/disk/by-partlabel/root
         label: luks-root
         name: root
         wipe_volume: true
   filesystems:
     - device: /dev/mapper/root
       format: xfs
       label: root
       wipe_filesystem: true
   openshift:
     fips: true
   
   1. The cipher option is only required if FIPS mode is enabled. Omit the entry if FIPS is disabled.
   2. Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

2. Create a customized initramfs file to boot the machine, by running the following command:
Before first boot, you must customize the initramfs for each node in the cluster, and add PXE kernel parameters.

3. Create a parameter file that includes `ignition.platform.id=metal` and `ignition.firstboot`.

**Example kernel parameter file for the control plane machine:**

```bash
$ coreos-installer pxe customize \
/root/rhcos-bootfiles/rhcos-<release>-live-initramfs.s390x.img \
--dest-device /dev/disk/by-id/scsi-<serial-number> --dest-karg-append \ 
ip=<ip-address>::<gateway-ip>::<subnet-mask>::<network-device>:none \ 
--dest-karg-append nameserver=<nameserver-ip> \ 
--dest-karg-append rd.neednet=1 -o \ 
/root/rhcos-bootfiles/<Node-name>-initramfs.s390x.img
```

NOTE

Write all options in the parameter file as a single line and make sure you have no newline characters.

Additional resources

- [Creating machine configs with Butane](#)

**18.5.11.3. Fast-track installation by using a prepackaged QCOW2 disk image**

Complete the following steps to create the machines in a fast-track installation of Red Hat Enterprise Linux CoreOS (RHCOS), importing a prepackaged Red Hat Enterprise Linux CoreOS (RHCOS) QEMU copy-on-write (QCOW2) disk image.

**Prerequisites**

- At least one LPAR running on RHEL 8.6 or later with KVM, referred to as RHEL KVM host in this procedure.
- The KVM/QEMU hypervisor is installed on the RHEL KVM host.
- A domain name server (DNS) that can perform hostname and reverse lookup for the nodes.
- A DHCP server that provides IP addresses.
Procedure

1. Obtain the RHEL QEMU copy-on-write (QCOW2) disk image file from the Product Downloads page on the Red Hat Customer Portal or from the RHCOS image mirror page.

   **IMPORTANT**

   The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate RHCOS QCOW2 image described in the following procedure.

2. Download the QCOW2 disk image and Ignition files to a common directory on the RHEL KVM host.
   
   For example: `/var/lib/libvirt/images`

   **NOTE**

   The Ignition files are generated by the OpenShift Container Platform installer.

3. Create a new disk image with the QCOW2 disk image backing file for each KVM guest node.

   ```bash
   $ qemu-img create -f qcow2 -F qcow2 -b /var/lib/libvirt/images/{source_rhcos_qemu} /var/lib/libvirt/images/{vmname}.qcow2 {size}
   ```

4. Create the new KVM guest nodes using the Ignition file and the new disk image.

   ```bash
   $ virt-install --noautoconsole \
   --connect qemu:///system \
   --name {vm_name} \
   --memory {memory} \
   --vcpus {vcpus} \
   --disk {disk} \
   --launchSecurity type="s390-pv" 1 \
   --import \
   --network network={network},mac={mac} \
   --disk path={ign_file},format=raw,readonly=on,serial=ignition,startup_policy=optional 2
   ```

   1. If IBM® Secure Execution is enabled, add the `launchSecurity type="s390-pv"` parameter.
   
   2. If IBM® Secure Execution is enabled, replace `serial=ignition` with `serial=ignition_crypted`.

18.5.11.4. Full installation on a new QCOW2 disk image

Complete the following steps to create the machines in a full installation on a new QEMU copy-on-write (QCOW2) disk image.

**Prerequisites**

- At least one LPAR running on RHEL 8.6 or later with KVM, referred to as RHEL KVM host in this procedure.
The KVM/QEMU hypervisor is installed on the RHEL KVM host.

A domain name server (DNS) that can perform hostname and reverse lookup for the nodes.

An HTTP or HTTPS server is set up.

**Procedure**

1. Obtain the RHEL kernel, initramfs, and rootfs files from the Product Downloads page on the Red Hat Customer Portal or from the RHCOS image mirror page.

   **IMPORTANT**

   The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate RHCOS QCOW2 image described in the following procedure.

   The file names contain the OpenShift Container Platform version number. They resemble the following examples:

   - **kernel**: `rhcos-<version>-live-kernel-<architecture>`
   - **initramfs**: `rhcos-<version>-live-initramfs.<architecture>.img`
   - **rootfs**: `rhcos-<version>-live-rootfs.<architecture>.img`

2. Move the downloaded RHEL live kernel, initramfs, and rootfs as well as the Ignition files to an HTTP or HTTPS server before you launch `virt-install`.

   **NOTE**

   The Ignition files are generated by the OpenShift Container Platform installer.

3. Create the new KVM guest nodes using the RHEL kernel, initramfs, and Ignition files, the new disk image, and adjusted parm line arguments.

   - For **--location**, specify the location of the kernel/initrd on the HTTP or HTTPS server.

   - For **coreos.inst.ignition_url**, specify the Ignition file for the machine role. Use `bootstrap.ign`, `master.ign`, or `worker.ign`. Only HTTP and HTTPS protocols are supported.

   - For **coreos.live.rootfs_url**, specify the matching rootfs artifact for the kernel and initramfs you are booting. Only HTTP and HTTPS protocols are supported.

   ```bash
   $ virt-install
   --connect qemu:///system
   --name {vm_name}
   --vcpus {vcpus}
   --memory {memory_mb}
   --disk {vm_name}.qcow2,size={image_size| default(10,true)}
   --network network={virt_network_parm}
   --boot hd
   --location {media_location},kernel={rhcos_kernel},initrd={rhcos_initrd}
   --extra-args "rd.neednet=1 coreos.inst.install_dev=/dev/vda coreos.live.rootfs_url=" 
   ```
18.5.11.5. Advanced RHCOS installation reference

This section illustrates the networking configuration and other advanced options that allow you to modify the Red Hat Enterprise Linux CoreOS (RHCOS) manual installation process. The following tables describe the kernel arguments and command-line options you can use with the RHCOS live installer and the `coreos-installer` command.

18.5.11.5.1. Networking options for ISO installations

If you install RHCOS from an ISO image, you can add kernel arguments manually when you boot the image to configure networking for a node. If no networking arguments are specified, DHCP is activated in the initramfs when RHCOS detects that networking is required to fetch the Ignition config file.

**IMPORTANT**

When adding networking arguments manually, you must also add the `rd.neednet=1` kernel argument to bring the network up in the initramfs.

The following information provides examples for configuring networking on your RHCOS nodes for ISO installations. The examples describe how to use the `ip=` and `nameserver=` kernel arguments.

**NOTE**

Ordering is important when adding the kernel arguments: `ip=` and `nameserver=`.

The networking options are passed to the `dracut` tool during system boot. For more information about the networking options supported by `dracut`, see the `dracut.cmdline` manual page.

The following examples are the networking options for ISO installation.

**Configuring DHCP or static IP addresses**

To configure an IP address, either use DHCP (`ip= dhcp`) or set an individual static IP address (`ip=<host_ip>`). If setting a static IP, you must then identify the DNS server IP address (`nameserver=<dns_ip>`) on each node. The following example sets:

- The node’s IP address to **10.10.10.2**
- The gateway address to **10.10.10.254**
- The netmask to **255.255.255.0**
- The hostname to **core0.example.com**
- The DNS server address to **4.4.4.41**
- The auto-configuration value to **none**. No auto-configuration is required when IP networking is configured statically.
When you use DHCP to configure IP addressing for the RHCOS machines, the machines also obtain the DNS server information through DHCP. For DHCP-based deployments, you can define the DNS server address that is used by the RHCOS nodes through your DHCP server configuration.

Configuring an IP address without a static hostname
You can configure an IP address without assigning a static hostname. If a static hostname is not set by the user, it will be picked up and automatically set by a reverse DNS lookup. To configure an IP address without a static hostname refer to the following example:

- The node’s IP address to `10.10.10.2`
- The gateway address to `10.10.10.254`
- The netmask to `255.255.255.0`
- The DNS server address to `4.4.4.41`
- The auto-configuration value to `none`. No auto-configuration is required when IP networking is configured statically.

Specifying multiple network interfaces
You can specify multiple network interfaces by setting multiple `ip=` entries.

```
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none
nameserver=4.4.4.41
```

Configuring default gateway and route
Optional: You can configure routes to additional networks by setting an `rd.route=` value.

```
ip=10.10.10.2::10.10.10.254:255.255.255.0::enp1s0:none
ip=10.10.10.3::10.10.10.254:255.255.255.0:core0.example.com:enp2s0:none
rd.route=20.20.20.0/24:20.20.20.254:enp2s0
```

Disabling DHCP on a single interface
You can disable DHCP on a single interface, such as when there are two or more network interfaces and

```
ip=::10.10.10.254::
rd.route=20.20.20.0/24:20.20.20.254:enp2s0
```
You can disable DHCP on a single interface, such as when there are two or more network interfaces and only one interface is being used. In the example, the `enp1s0` interface has a static networking configuration and DHCP is disabled for `enp2s0`, which is not used:

```
ip=10.10.10.2::10.10.255.255.255.0:core0.example.com:enp1s0:none
ip=:::core0.example.com:enp2s0:none
```

**Combining DHCP and static IP configurations**

You can combine DHCP and static IP configurations on systems with multiple network interfaces, for example:

```
ip=enp1s0:dhcp
ip=10.10.10.2::10.10.255.255.255.0:core0.example.com:enp2s0:none
```

**Configuring VLANs on individual interfaces**

Optional: You can configure VLANs on individual interfaces by using the `vlan=` parameter.

- To configure a VLAN on a network interface and use a static IP address, run the following command:

  ```
ip=10.10.10.2::10.10.254:255.255.255.0:core0.example.com:enp2s0.100:none
vlan=enp2s0.100:enp2s0
```

- To configure a VLAN on a network interface and to use DHCP, run the following command:

  ```
ip=enp2s0.100:dhcp
vlan=enp2s0.100:enp2s0
```

**Providing multiple DNS servers**

You can provide multiple DNS servers by adding a `nameserver=` entry for each server, for example:

```
nameserver=1.1.1.1
nameserver=8.8.8.8
```

**18.5.12. Waiting for the bootstrap process to complete**

The OpenShift Container Platform bootstrap process begins after the cluster nodes first boot into the persistent RHCOS environment that has been installed to disk. The configuration information provided through the Ignition config files is used to initialize the bootstrap process and install OpenShift Container Platform on the machines. You must wait for the bootstrap process to complete.

**Prerequisites**

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have obtained the installation program and generated the Ignition config files for your cluster.
- You installed RHCOS on your cluster machines and provided the Ignition config files that the OpenShift Container Platform installation program generated.
Procedure

1. Monitor the bootstrap process:

   $ ./openshift-install --dir <installation_directory> wait-for bootstrap-complete \  
   --log-level=info

1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

Example output

INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
INFO API v1.27.3 up
INFO Waiting up to 30m0s for bootstrapping to complete...
INFO It is now safe to remove the bootstrap resources

The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After the bootstrap process is complete, remove the bootstrap machine from the load balancer.

    IMPORTANT

    You must remove the bootstrap machine from the load balancer at this point.
    You can also remove or reformat the bootstrap machine itself.

18.5.13. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

Procedure

1. Export the `kubeadmin` credentials:

   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig

1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   2. Verify you can run `oc` commands successfully using the exported configuration:
18.5.14. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

**Prerequisites**

- You added machines to your cluster.

**Procedure**

1. Confirm that the cluster recognizes the machines:

   ```
   $ oc get nodes
   
   **Example output**
   
   NAME      STATUS    ROLES   AGE  VERSION
   master-0  Ready     master  63m  v1.27.3
   master-1  Ready     master  63m  v1.27.3
   master-2  Ready     master  64m  v1.27.3
   
   The output lists all of the machines that you created.
   
   **NOTE**
   
   The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

   ```
   $ oc get csr
   
   **Example output**
   
   NAME        AGE     REQUESTOR                                          CONDITION
   csr-8b2br   15m     system:serviceaccount:openshift-machine-config-operator:node-bootstrapper   Pending
   csr-8vnps   15m     system:serviceaccount:openshift-machine-config-operator:node-bootstrapper   Pending
   ...
In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

   **NOTE**

   Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approved** if the Kubelet requests a new certificate with identical parameters.

   **NOTE**

   For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrapper** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

   - To approve them individually, run the following command for each valid CSR:

     ```
     $ oc adm certificate approve <csr_name> 1
     
     1  \(<csr_name>\) is the name of a CSR from the list of current CSRs.
     ```

   - To approve all pending CSRs, run the following command:

     ```
     $ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
     ```

     **NOTE**

     Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

   ```
   $ oc get csr
   ```

   **Example output**
If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:
  ```
  $ oc adm certificate approve < csr_name >
  ```

  **< csr_name >** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:
  ```
  $ oc get csr -o go-template=’{{range .items}}{{if not .status}}{{.metadata.name}}{{“
”}}{{end}}{{end}}’ | xargs oc adm certificate approve
  ```

After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

### Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>74m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>worker-0</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>worker-1</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.27.3</td>
</tr>
</tbody>
</table>

**NOTE**

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

### Additional information

- For more information on CSRs, see [Certificate Signing Requests](#).

#### 18.5.15. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

**Prerequisites**

- Your control plane has initialized.
Procedure

1. Watch the cluster components come online:

   $ watch -n5 oc get clusteroperators

Example output

<table>
<thead>

2. Configure the Operators that are not available.

18.5.15.1. Disabling the default OperatorHub catalog sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

Procedure

- Disable the sources for the default catalogs by adding `disableAllDefaultSources: true` to the OperatorHub object:
TIP

Alternatively, you can use the web console to manage catalog sources. From the **Administration → Cluster Settings → Configuration → OperatorHub** page, click the **Sources** tab, where you can create, update, delete, disable, and enable individual sources.

18.5.15.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the **Recreate** rollout strategy during upgrades.

18.5.15.2.1. Configuring registry storage for IBM Z

As a cluster administrator, following installation you must configure your registry to use storage.

Prerequisites

- You have access to the cluster as a user with the **cluster-admin** role.
- You have a cluster on IBM Z®.
- You have provisioned persistent storage for your cluster, such as Red Hat OpenShift Data Foundation.

**IMPORTANT**

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. **ReadWriteOnce** access also requires that the registry uses the **Recreate** rollout strategy. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have 100Gi capacity.

Procedure

1. To configure your registry to use storage, change the **spec.storage.pvc** in the **configs.imageregistry/cluster** resource.
NOTE
When you use shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

$ oc get pod -n openshift-image-registry -l docker-registry=default

Example output
No resources found in openshift-image-registry namespace

NOTE
If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

$ oc edit configs.imageregistry.operator.openshift.io

Example output

<table>
<thead>
<tr>
<th>storage:</th>
</tr>
</thead>
<tbody>
<tr>
<td>pvc:</td>
</tr>
<tr>
<td>claim:</td>
</tr>
</tbody>
</table>

Leave the claim field blank to allow the automatic creation of an image-registry-storage PVC.

4. Check the clusteroperator status:

$ oc get clusteroperator image-registry

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
<th>SINCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>MESSAGE</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>image-registry</td>
<td>4.14</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>6h50m</td>
</tr>
</tbody>
</table>

5. Ensure that your registry is set to managed to enable building and pushing of images.

- Run:

  $ oc edit configs.imageregistry/cluster

  Then, change the line

  managementState: Removed

  to
18.5.15.2. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

Procedure

- To set the image registry storage to an empty directory:

  ```bash
  $ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec": {"storage": {"emptyDir": {}}}}'
  ```

  **WARNING**
  
  Configure this option for only non-production clusters.

  If you run this command before the Image Registry Operator initializes its components, the `oc patch` command fails with the following error:

  ```
  Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
  ```

  Wait a few minutes and run the command again.

18.5.16. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

Prerequisites

- Your control plane has initialized.
- You have completed the initial Operator configuration.

Procedure

1. Confirm that all the cluster components are online with the following command:

   ```bash
   $ watch -n5 oc get clusteroperators
   ```

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
<th>SINCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>authentication</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>19m</td>
</tr>
</tbody>
</table>
Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```
$ ./openshift-install --dir <installation_directory> wait-for install-complete
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

**Example output**

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.
IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

2. Confirm that the Kubernetes API server is communicating with the pods.
   a. To view a list of all pods, use the following command:

   ```bash
   $ oc get pods --all-namespaces
   ```

   **Example output**

<table>
<thead>
<tr>
<th>NAMESPACE</th>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>openshift-apiserver-operator</td>
<td>openshift-apiserver-operator-85cb746d55-zqhs8</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td></td>
<td>Running 1 9m</td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apiserver-67b9g</td>
<td>1/1</td>
<td>Running 3m</td>
</tr>
<tr>
<td></td>
<td>Running 0 3m</td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apiserver-ljcmx</td>
<td>1/1</td>
<td>Running 1m</td>
</tr>
<tr>
<td></td>
<td>Running 0 1m</td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apiserver-z25h4</td>
<td>1/1</td>
<td>Running 2m</td>
</tr>
<tr>
<td></td>
<td>Running 0 2m</td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-authentication-operator</td>
<td>authentication-operator-69d5d8bf84-vh2n8</td>
<td>1/1</td>
<td>Running 0 5m</td>
</tr>
<tr>
<td></td>
<td>Running 0 5m</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>...</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

   b. View the logs for a pod that is listed in the output of the previous command by using the following command:

   ```bash
   $ oc logs <pod_name> -n <namespace>
   ```

   1 Specify the pod name and namespace, as shown in the output of the previous command.

   If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation.

   See "Enabling multipathing with kernel arguments on RHcos" in the Post-installation machine configuration tasks documentation for more information.
4. Register your cluster on the Cluster registration page.

Additional resources

- How to generate SOSREPORT within OpenShift Container Platform version 4 nodes without SSH.

18.5.17. Next steps

- Customize your cluster.

- If the mirror registry that you used to install your cluster has a trusted CA, add it to the cluster by configuring additional trust stores.

- If necessary, you can opt out of remote health reporting.

- If necessary, see Registering your disconnected cluster

18.6. INSTALLATION CONFIGURATION PARAMETERS FOR IBM Z AND IBM LINUXONE

Before you deploy an OpenShift Container Platform cluster, you provide a customized install-config.yaml installation configuration file that describes the details for your environment.

**NOTE**

While this document refers only to IBM Z®, all information in it also applies to IBM® LinuxONE.

18.6.1. Available installation configuration parameters for IBM Z

The following tables specify the required, optional, and IBM Z-specific installation configuration parameters that you can set as part of the installation process.

**NOTE**

After installation, you cannot modify these parameters in the install-config.yaml file.

18.6.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Table 18.59. Required parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameter</td>
</tr>
<tr>
<td>apiVersion:</td>
</tr>
</tbody>
</table>
### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>baseDomain:</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the <code>baseDomain</code> and <code>metadata.name</code> parameter values that uses the <code>&lt;metadata.name&gt;</code>, <code>&lt;baseDomain&gt;</code> format.</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
</tr>
<tr>
<td>metadata:</td>
<td>Kubernetes resource <code>ObjectMeta</code>, from which only the <code>name</code> parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata: name:</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of <code>{{metadata.name}}.{{baseDomain}}</code>.</td>
<td>String of lowercase letters, hyphens (-), and periods (.), such as dev.</td>
</tr>
<tr>
<td>platform:</td>
<td>The configuration for the specific platform upon which to perform the installation: alibabacloud, aws, baremetal, azure, gcp, ibmcloud, nutanix, openstack, powervs, vsphere, or {}. For additional information about platform. <code>&lt;platform&gt;</code> parameters, consult the table for your specific platform that follows.</td>
<td>Object</td>
</tr>
</tbody>
</table>
pullSecret: Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.

```json
{
    "auths":{
        "cloud.openshift.com":{
            "auth":b3Blb=",
            "email":"you@example.com"
        },
        "quay.io":{
            "auth":b3Blb=",
            "email":"you@example.com"
        }
    }
}
```

### 18.6.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

- If you use the Red Hat OpenShift Networking OVN-Kubernetes network plugin, both IPv4 and IPv6 address families are supported.
- If you use the Red Hat OpenShift Networking OpenShift SDN network plugin, only the IPv4 address family is supported.

If you configure your cluster to use both IP address families, review the following requirements:

- Both IP families must use the same network interface for the default gateway.
- Both IP families must have the default gateway.
- You must specify IPv4 and IPv6 addresses in the same order for all network configuration parameters. For example, in the following configuration IPv4 addresses are listed before IPv6 addresses.

```yaml
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
      hostPrefix: 23
    - cidr: fd00:10:128::/56
      hostPrefix: 64
  serviceNetwork:
    - 172.30.0.0/16
    - fd00:172:16::/112
```

**NOTE**

Globalnet is not supported with Red Hat OpenShift Data Foundation disaster recovery solutions. For regional disaster recovery scenarios, ensure that you use a nonoverlapping range of private IP addresses for the cluster and service networks in each cluster.
<table>
<thead>
<tr>

<td>If you specify multiple IP kernel arguments, the <code>machineNetwork.cidr</code> value must be the CIDR of the primary network.</td>
<td>An IP network block in CIDR notation.</td>
</tr>
<tr>
<td></td>
<td>Required if you use <code>networking.machineNetwork</code>. An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt and IBM Power® Virtual Server. For libvirt, the default value is 192.168.126.0/24. For IBM Power® Virtual Server, the default value is 192.168.0.0/24.</td>
<td>For example, 10.0.0.0/16. An IP network block in CIDR notation.</td>
</tr>
</tbody>
</table>

**NOTE**

Set the `networking.machineNetwork` to match the CIDR that the preferred NIC resides in.

### 18.6.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

**Table 18.61. Optional parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle:</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>capabilities:</td>
<td>Controls the installation of optional core cluster components. You can reduce the footprint of your OpenShift Container Platform cluster by disabling optional components. For more information, see the &quot;Cluster capabilities&quot; page in Installing.</td>
<td>String array</td>
</tr>
<tr>
<td>baselineCapabilitySet:</td>
<td>Selects an initial set of optional capabilities to enable. Valid values are <code>None</code>, <code>v4.11</code>, <code>v4.12</code> and <code>vCurrent</code>. The default value is <code>vCurrent</code>.</td>
<td>String</td>
</tr>
</tbody>
</table>
### capabilities:

**additionalEnabledCapabilities:**

Extends the set of optional capabilities beyond what you specify in `baselineCapabilitySet`. You may specify multiple capabilities in this parameter.

**Values:**

String array

### cpuPartitioningMode:

Enables workload partitioning, which isolates OpenShift Container Platform services, cluster management workloads, and infrastructure pods to run on a reserved set of CPUs. Workload partitioning can only be enabled during installation and cannot be disabled after installation. While this field enables workload partitioning, it does not configure workloads to use specific CPUs. For more information, see the *Workload partitioning* page in the *Scalability and Performance* section.

**Values:**

None or AllNodes. None is the default value.

### compute:

The configuration for the machines that comprise the compute nodes.

**Values:**

Array of `MachinePool` objects.

### compute: architecture:

Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are `s390x` (the default).

**Values:**

String

### compute: hyperthreading:

Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.

**Values:**

Enabled or Disabled

### IMPORTANT

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.
<table>
<thead>
<tr>
<th>Parameter</th>

</tr>
<tr>
<td>fips:</td>
<td>Enable or disable FIPS mode. The default is <code>false</code> (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default</td>
<td>false or true</td>
</tr>
</tbody>
</table>
Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see [Installing the system in FIPS mode](#). When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures.

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>imageContentSources:</td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects. Includes a <em>source</em> and, optionally, <em>mirrors</em>, as described in the following rows of this table.</td>
</tr>
<tr>
<td>imageContentSources: source:</td>
<td>Required if you use <em>imageContentSources</em>. Specify the repository that users refer to, for example, in image pull specifications.</td>

<tr>
<td>publish:</td>
<td>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</td>
<td><em>Internal</em> or <em>External</em>. The default value is <em>External</em>. Setting this field to <em>Internal</em> is not supported on non-cloud platforms.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

If the value of the field is set to *Internal*, the cluster will become non-functional. For more information, refer to [BZ#1953035](#).
**sshKey:**

The SSH key to authenticate access to your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>sshKey:</td>
<td>The SSH key to authenticate access to your cluster machines.</td>
<td>For example, <strong>sshKey: ssh-ed25519 AAAA...</strong></td>
</tr>
</tbody>
</table>

1. Not all CCO modes are supported for all cloud providers. For more information about CCO modes, see the "Managing cloud provider credentials" entry in the *Authentication and authorization* content.
CHAPTER 19. INSTALLING ON IBM POWER

19.1. PREPARING TO INSTALL ON IBM POWER

19.1.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.

19.1.2. Choosing a method to install OpenShift Container Platform on IBM Power

You can install a cluster on IBM Power® infrastructure that you provision, by using one of the following methods:

- **Installing a cluster on IBM Power®**: You can install OpenShift Container Platform on IBM Power® infrastructure that you provision.
- **Installing a cluster on IBM Power® in a restricted network**: You can install OpenShift Container Platform on IBM Power® infrastructure that you provision in a restricted or disconnected network, by using an internal mirror of the installation release content. You can use this method to install a cluster that does not require an active internet connection to obtain the software components. You can also use this installation method to ensure that your clusters only use container images that satisfy your organizational controls on external content.

19.2. INSTALLING A CLUSTER ON IBM POWER

In OpenShift Container Platform version 4.14, you can install a cluster on IBM Power® infrastructure that you provision.

**IMPORTANT**

Additional considerations exist for non-bare metal platforms. Review the information in the guidelines for deploying OpenShift Container Platform on non-tested platforms before you install an OpenShift Container Platform cluster.

19.2.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- Before you begin the installation process, you must clean the installation directory. This ensures that the required installation files are created and updated during the installation process.
- You provisioned persistent storage using OpenShift Data Foundation or other supported storage protocols for your cluster. To deploy a private image registry, you must set up persistent storage with ReadWriteMany access.
If you use a firewall, you **configured it to allow the sites** that your cluster requires access to.

**NOTE**

Be sure to also review this site list if you are configuring a proxy.

## 19.2.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access **OpenShift Cluster Manager Hybrid Cloud Console** to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access **Quay.io** to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

## 19.2.3. Requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

This section describes the requirements for deploying OpenShift Container Platform on user-provisioned infrastructure.

### 19.2.3.1. Required machines for cluster installation

The smallest OpenShift Container Platform clusters require the following hosts:

**Table 19.1. Minimum required hosts**

<table>
<thead>
<tr>
<th>Hosts</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>One temporary bootstrap machine</td>
<td>The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.</td>
</tr>
<tr>
<td>Three control plane machines</td>
<td>The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.</td>
</tr>
</tbody>
</table>
At least two compute machines, which are also known as worker machines. The workloads requested by OpenShift Container Platform users run on the compute machines.

**IMPORTANT**

To maintain high availability of your cluster, use separate physical hosts for these cluster machines.

The bootstrap, control plane, and compute machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 9.2 and inherits all of its hardware certifications and requirements. See Red Hat Enterprise Linux technology capabilities and limits.

### 19.2.3.2. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

**Table 19.2. Minimum resource requirements**

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>2</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>2</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS</td>
<td>2</td>
<td>8 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
</tbody>
</table>

1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or hyperthreading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: (threads per core × cores) × sockets = vCPUs.

2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

**Additional resources**

- Optimizing storage

### 19.2.3.3. Minimum IBM Power requirements

You can install OpenShift Container Platform version 4.14 on the following IBM® hardware:
Hardware requirements
- Six logical partitions (LPARs) across multiple PowerVM servers

Operating system requirements
- One instance of an IBM Power®9 or Power10 processor-based system

On your IBM Power® instance, set up:
- Three LPARs for OpenShift Container Platform control plane machines
- Two LPARs for OpenShift Container Platform compute machines
- One LPAR for the temporary OpenShift Container Platform bootstrap machine

Disk storage for the IBM Power guest virtual machines
- Local storage, or storage provisioned by the Virtual I/O Server using vSCSI, NPIV (N-Port ID Virtualization) or SSP (shared storage pools)

Network for the PowerVM guest virtual machines
- Dedicated physical adapter, or SR-IOV virtual function
- Available by the Virtual I/O Server using Shared Ethernet Adapter
- Virtualized by the Virtual I/O Server using IBM® vNIC

Storage / main memory
- 100 GB / 16 GB for OpenShift Container Platform control plane machines
- 100 GB / 8 GB for OpenShift Container Platform compute machines
- 100 GB / 16 GB for the temporary OpenShift Container Platform bootstrap machine

19.2.3.4. Recommended IBM Power system requirements

Hardware requirements
- Six LPARs across multiple PowerVM servers

Operating system requirements
- One instance of an IBM Power®9 or IBM Power®10 processor-based system

On your IBM Power® instance, set up:
- Three LPARs for OpenShift Container Platform control plane machines
- Two LPARs for OpenShift Container Platform compute machines
- One LPAR for the temporary OpenShift Container Platform bootstrap machine

**Disk storage for the IBM Power guest virtual machines**
- Local storage, or storage provisioned by the Virtual I/O Server using vSCSI, NPIV (N-Port ID Virtualization) or SSP (shared storage pools)

**Network for the PowerVM guest virtual machines**
- Dedicated physical adapter, or SR-IOV virtual function
- Available by the Virtual I/O Server using Shared Ethernet Adapter
- Virtualized by the Virtual I/O Server using IBM® vNIC

**Storage / main memory**
- 120 GB / 32 GB for OpenShift Container Platform control plane machines
- 120 GB / 32 GB for OpenShift Container Platform compute machines
- 120 GB / 16 GB for the temporary OpenShift Container Platform bootstrap machine

**19.2.3.5. Certificate signing requests management**

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The `kube-controller-manager` only approves the kubelet client CSRs. The `machine-approver` cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

**19.2.3.6. Networking requirements for user-provisioned infrastructure**

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in `initramfs` during boot to fetch their Ignition config files.

During the initial boot, the machines require an IP address configuration that is set either through a DHCP server or statically by providing the required boot options. After a network connection is established, the machines download their Ignition config files from an HTTP or HTTPS server. The Ignition config files are then used to set the exact state of each machine. The Machine Config Operator completes more changes to the machines, such as the application of new certificates or keys, after installation.

It is recommended to use a DHCP server for long-term management of the cluster machines. Ensure that the DHCP server is configured to provide persistent IP addresses, DNS server information, and hostnames to the cluster machines.
NOTE

If a DHCP service is not available for your user-provisioned infrastructure, you can instead provide the IP networking configuration and the address of the DNS server to the nodes at RH COS install time. These can be passed as boot arguments if you are installing from an ISO image. See the Installing RH COS and starting the OpenShift Container Platform bootstrap process section for more information about static IP provisioning and advanced networking options.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

19.2.3.6.1. Setting the cluster node hostnames through DHCP

On Red Hat Enterprise Linux CoreOS (RHCOS) machines, the hostname is set through NetworkManager. By default, the machines obtain their hostname through DHCP. If the hostname is not provided by DHCP, set statically through kernel arguments, or another method, it is obtained through a reverse DNS lookup. Reverse DNS lookup occurs after the network has been initialized on a node and can take time to resolve. Other system services can start prior to this and detect the hostname as localhost or similar. You can avoid this by using DHCP to provide the hostname for each cluster node.

Additionally, setting the hostnames through DHCP can bypass any manual DNS record name configuration errors in environments that have a DNS split-horizon implementation.

19.2.3.6.2. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

IMPORTANT

In connected OpenShift Container Platform environments, all nodes are required to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

Table 19.3. Ports used for all-machine to all-machine communications

<table>

### NTP configuration for user-provisioned infrastructure

OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for *Configuring chrony time service*.

If a DHCP server provides NTP server information, the chrony time service on the Red Hat Enterprise Linux CoreOS (RHCOS) machines read the information and can sync the clock with the NTP servers.

### Additional resources

- [Configuring chrony time service](#)

### 19.2.3.7. User-provisioned DNS requirements

In OpenShift Container Platform deployments, DNS name resolution is required for the following components:
The Kubernetes API

- The Kubernetes API
- The OpenShift Container Platform application wildcard
- The bootstrap, control plane, and compute machines

Reverse DNS resolution is also required for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the hostnames for all the nodes, unless the hostnames are provided by DHCP. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

**NOTE**

It is recommended to use a DHCP server to provide the hostnames to each cluster node. See the *DHCP recommendations for user-provisioned infrastructure* section for more information.

The following DNS records are required for a user-provisioned OpenShift Container Platform cluster and they must be in place before installation. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>..<cluster_name>..<base_domain>`.

**Table 19.6. Required DNS records**

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes API</td>
<td>api..&lt;cluster_name&gt;..&lt;base_domain&gt;</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the API load balancer. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td></td>
<td>api-int..&lt;cluster_name&gt;..&lt;base_domain&gt;</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to internally identify the API load balancer. These records must be resolvable from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

The API server must be able to resolve the worker nodes by the hostnames that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.
<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Routes</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A wildcard DNS A/AAAA or CNAME record that refers to the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster. For example, console-openshift-console.apps.&lt;cluster_name&gt;.&lt;base_domain&gt; is used as a wildcard route to the OpenShift Container Platform console.</td>
</tr>
<tr>
<td>Bootstrap machine</td>
<td>bootstrap.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Control plane machines</td>
<td>&lt;master&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Compute machines</td>
<td>&lt;worker&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**NOTE**

In OpenShift Container Platform 4.4 and later, you do not need to specify etcd host and SRV records in your DNS configuration.

**TIP**

You can use the `dig` command to verify name and reverse name resolution. See the section on Validating DNS resolution for user-provisioned infrastructure for detailed validation steps.

19.2.3.7.1. Example DNS configuration for user-provisioned clusters

This section provides A and PTR record configuration samples that meet the DNS requirements for deploying OpenShift Container Platform on user-provisioned infrastructure. The samples are not meant to provide advice for choosing one DNS solution over another.

In the examples, the cluster name is `ocp4` and the base domain is `example.com`.

**Example DNS A record configuration for a user-provisioned cluster**

The following example is a BIND zone file that shows sample A records for name resolution in a user-provisioned cluster.

---
Example 19.1. Sample DNS zone database

```
$TTL 1W
@ IN SOA ns1.example.com. root ( 2019070700 ; serial 
3H ; refresh (3 hours) 
30M ; retry (30 minutes) 
2W ; expiry (2 weeks) 
1W ) ; minimum (1 week)
IN NS ns1.example.com.
IN MX 10 smtp.example.com.
;
ns1.example.com. IN A 192.168.1.5

worker1.ocp4.example.com. IN A 192.168.1.17
;
;EOF
```

1. Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer.
2. Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer and is used for internal cluster communications.
3. Provides name resolution for the wildcard routes. The record refers to the IP address of the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

**NOTE**

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.
Provides name resolution for the bootstrap machine.

Provides name resolution for the control plane machines.

Provides name resolution for the compute machines.

Example DNS PTR record configuration for a user-provisioned cluster

The following example BIND zone file shows sample PTR records for reverse name resolution in a user-provisioned cluster.

Example 19.2. Sample DNS zone database for reverse records

```
$TTL 1W
@ IN SOA ns1.example.com. root ( 
  2019070700 ; serial 
  3H ; refresh (3 hours) 
  30M ; retry (30 minutes) 
  2W ; expiry (2 weeks) 
  1W ) ; minimum (1 week)
IN NS ns1.example.com.
;
5.1.168.192.in-addr.arpa. IN PTR api.ocp4.example.com. 1
5.1.168.192.in-addr.arpa. IN PTR api-int.ocp4.example.com. 2
;
96.1.168.192.in-addr.arpa. IN PTR bootstrap.ocp4.example.com. 3
;
97.1.168.192.in-addr.arpa. IN PTR master0.ocp4.example.com. 4
98.1.168.192.in-addr.arpa. IN PTR master1.ocp4.example.com. 5
99.1.168.192.in-addr.arpa. IN PTR master2.ocp4.example.com. 6
;
11.1.168.192.in-addr.arpa. IN PTR worker0.ocp4.example.com. 7
7.1.168.192.in-addr.arpa. IN PTR worker1.ocp4.example.com. 8
;
;EOF
```

1 Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer.

2 Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer and is used for internal cluster communications.

3 Provides reverse DNS resolution for the bootstrap machine.

4, 5, 6 Provides reverse DNS resolution for the control plane machines.

7, 8 Provides reverse DNS resolution for the compute machines.
A PTR record is not required for the OpenShift Container Platform application wildcard.

**19.2.3.8. Load balancing requirements for user-provisioned infrastructure**

Before you install OpenShift Container Platform, you must provision the API and application Ingress load balancing infrastructure. In production scenarios, you can deploy the API and application Ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

If you want to deploy the API and application Ingress load balancers with a Red Hat Enterprise Linux (RHEL) instance, you must purchase the RHEL subscription separately.

The load balancing infrastructure must meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.
   - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

   **IMPORTANT**
   
   Do not configure session persistence for an API load balancer. Configuring session persistence for a Kubernetes API server might cause performance issues from excess application traffic for your OpenShift Container Platform cluster and the Kubernetes API that runs inside the cluster.

Configure the following ports on both the front and back of the load balancers:

**Table 19.7. API load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the <code>/readyz</code> endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>
NOTE

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the /readyz endpoint to the removal of the API server instance from the pool. Within the time frame after /readyz returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application Ingress load balancer** Provides an ingress point for application traffic flowing in from outside the cluster. A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

TIP

If the true IP address of the client can be seen by the application Ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

Configure the following ports on both the front and back of the load balancers:

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>

NOTE

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application Ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

19.2.3.8.1. Example load balancer configuration for user-provisioned clusters

This section provides an example API and application Ingress load balancer configuration that meets the load balancing requirements for user-provisioned clusters. The sample is an /etc/haproxy/haproxy.cfg configuration for an HAPerxy load balancer. The example is not meant to provide advice for choosing
one load balancing solution over another.

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

NOTE

If you are using HAProxy as a load balancer and SELinux is set to enforcing, you must ensure that the HAProxy service can bind to the configured TCP port by running `setsebool -P haproxy_connect_any=1`.

Example 19.3. Sample API and application Ingress load balancer configuration

```
global
  log 127.0.0.1 local2
  pidfile /var/run/haproxy.pid
  maxconn 4000
daemon
defaults
  mode http
  log global
  option dontlognull
  option http-server-close
  option redispatch
  retries 3
  timeout http-request 10s
  timeout queue 1m
  timeout connect 10s
  timeout client 1m
  timeout server 1m
  timeout http-keep-alive 10s
  timeout check 10s
  maxconn 3000
listen api-server-6443
  bind *:6443
  mode tcp
  server bootstrap bootstrap.ocp4.example.com:6443 check inter 1s backup
  server master0 master0.ocp4.example.com:6443 check inter 1s
  server master1 master1.ocp4.example.com:6443 check inter 1s
  server master2 master2.ocp4.example.com:6443 check inter 1s
listen machine-config-server-22623
  bind *:22623
  mode tcp
  server bootstrap bootstrap.ocp4.example.com:22623 check inter 1s backup
  server master0 master0.ocp4.example.com:22623 check inter 1s
  server master1 master1.ocp4.example.com:22623 check inter 1s
  server master2 master2.ocp4.example.com:22623 check inter 1s
listen ingress-router-443
  bind *:443
  mode tcp
  balance source
  server worker0 worker0.ocp4.example.com:443 check inter 1s
  server worker1 worker1.ocp4.example.com:443 check inter 1s
```
Port 6443 handles the Kubernetes API traffic and points to the control plane machines.

The bootstrap entries must be in place before the OpenShift Container Platform cluster installation and they must be removed after the bootstrap process is complete.

Port 22623 handles the machine config server traffic and points to the control plane machines.

Port 443 handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

Port 80 handles the HTTP traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

NOTE
If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application Ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

TIP
If you are using HAProxy as a load balancer, you can check that the haproxy process is listening on ports 6443, 22623, 443, and 80 by running netstat -nltupe on the HAProxy node.

19.2.4. Preparing the user-provisioned infrastructure

Before you install OpenShift Container Platform on user-provisioned infrastructure, you must prepare the underlying infrastructure.

This section provides details about the high-level steps required to set up your cluster infrastructure in preparation for an OpenShift Container Platform installation. This includes configuring IP networking and network connectivity for your cluster nodes, enabling the required ports through your firewall, and setting up the required DNS and load balancing infrastructure.

After preparation, your cluster infrastructure must meet the requirements outlined in the Requirements for a cluster with user-provisioned infrastructure section.

Prerequisites

- You have reviewed the OpenShift Container Platform 4.x Tested Integrations page.
- You have reviewed the infrastructure requirements detailed in the Requirements for a cluster with user-provisioned infrastructure section.
Procedure

1. If you are using DHCP to provide the IP networking configuration to your cluster nodes, configure your DHCP service.
   a. Add persistent IP addresses for the nodes to your DHCP server configuration. In your configuration, match the MAC address of the relevant network interface to the intended IP address for each node.
   b. When you use DHCP to configure IP addressing for the cluster machines, the machines also obtain the DNS server information through DHCP. Define the persistent DNS server address that is used by the cluster nodes through your DHCP server configuration.
      
      **NOTE**
      
      If you are not using a DHCP service, you must provide the IP networking configuration and the address of the DNS server to the nodes at RHCOS install time. These can be passed as boot arguments if you are installing from an ISO image. See the Installing RHCOS and starting the OpenShift Container Platform bootstrap process section for more information about static IP provisioning and advanced networking options.

   c. Define the hostnames of your cluster nodes in your DHCP server configuration. See the Setting the cluster node hostnames through DHCP section for details about hostname considerations.
      
      **NOTE**
      
      If you are not using a DHCP service, the cluster nodes obtain their hostname through a reverse DNS lookup.

2. Ensure that your network infrastructure provides the required network connectivity between the cluster components. See the Networking requirements for user-provisioned infrastructure section for details about the requirements.

3. Configure your firewall to enable the ports required for the OpenShift Container Platform cluster components to communicate. See Networking requirements for user-provisioned infrastructure section for details about the ports that are required.
   
   **IMPORTANT**
   
   By default, port 1936 is accessible for an OpenShift Container Platform cluster, because each control plane node needs access to this port.

   Avoid using the Ingress load balancer to expose this port, because doing so might result in the exposure of sensitive information, such as statistics and metrics, related to Ingress Controllers.

4. Setup the required DNS infrastructure for your cluster.
   a. Configure DNS name resolution for the Kubernetes API, the application wildcard, the bootstrap machine, the control plane machines, and the compute machines.
   b. Configure reverse DNS resolution for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.
See the *User-provisioned DNS requirements* section for more information about the OpenShift Container Platform DNS requirements.

5. Validate your DNS configuration.
   a. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses in the responses correspond to the correct components.
   b. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names in the responses correspond to the correct components.
      See the *Validating DNS resolution for user-provisioned infrastructure* section for detailed DNS validation steps.

6. Provision the required API and application ingress load balancing infrastructure. See the *Load balancing requirements for user-provisioned infrastructure* section for more information about the requirements.

NOTE
Some load balancing solutions require the DNS name resolution for the cluster nodes to be in place before the load balancing is initialized.

19.2.5. Validating DNS resolution for user-provisioned infrastructure

You can validate your DNS configuration before installing OpenShift Container Platform on user-provisioned infrastructure.

IMPORTANT
The validation steps detailed in this section must succeed before you install your cluster.

Prerequisites
- You have configured the required DNS records for your user-provisioned infrastructure.

Procedure

1. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses contained in the responses correspond to the correct components.
   a. Perform a lookup against the Kubernetes API record name. Check that the result points to the IP address of the API load balancer:

   ```
   $ dig +noall +answer @<nameserver_ip> api.<cluster_name>.<base_domain>
   ```

   Replace `<nameserver_ip>` with the IP address of the nameserver, `<cluster_name>` with your cluster name, and `<base_domain>` with your base domain name.

Example output

```
api.ocp4.example.com. 604800 IN A 192.168.1.5
```
Perform a lookup against the Kubernetes internal API record name. Check that the result points to the IP address of the API load balancer:

```
$ dig +noall +answer @<nameserver_ip> api-int.<cluster_name>.<base_domain>
```

**Example output**

```
api-int.ocp4.example.com. 604800 IN A 192.168.1.5
```

c. Test an example `*.apps.<cluster_name>.<base_domain>` DNS wildcard lookup. All of the application wildcard lookups must resolve to the IP address of the application ingress load balancer:

```
$ dig +noall +answer @<nameserver_ip> random.apps.<cluster_name>.<base_domain>
```

**Example output**

```
random.apps.ocp4.example.com. 604800 IN A 192.168.1.5
```

**NOTE**

In the example outputs, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

You can replace `random` with another wildcard value. For example, you can query the route to the OpenShift Container Platform console:

```
$ dig +noall +answer @<nameserver_ip> console-openshift-console.apps.<cluster_name>.<base_domain>
```

**Example output**

```
console-openshift-console.apps.ocp4.example.com. 604800 IN A 192.168.1.5
```

d. Run a lookup against the bootstrap DNS record name. Check that the result points to the IP address of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> bootstrap.<cluster_name>.<base_domain>
```

**Example output**

```
bootstrap.ocp4.example.com. 604800 IN A 192.168.1.96
```

e. Use this method to perform lookups against the DNS record names for the control plane and compute nodes. Check that the results correspond to the IP addresses of each node.
2. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names contained in the responses correspond to the correct components.

a. Perform a reverse lookup against the IP address of the API load balancer. Check that the response includes the record names for the Kubernetes API and the Kubernetes internal API:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.5
```

**Example output**

```
5.1.168.192.in-addr.arpa. 604800 IN PTR api-int.ocp4.example.com.  
```

1. Provides the record name for the Kubernetes internal API.
2. Provides the record name for the Kubernetes API.

![NOTE]

A PTR record is not required for the OpenShift Container Platform application wildcard. No validation step is needed for reverse DNS resolution against the IP address of the application ingress load balancer.

b. Perform a reverse lookup against the IP address of the bootstrap node. Check that the result points to the DNS record name of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.96
```

**Example output**

```
```

c. Use this method to perform reverse lookups against the IP addresses for the control plane and compute nodes. Check that the results correspond to the DNS record names of each node.

**19.2.6. Generating a key pair for cluster node SSH access**

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the `core` user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH into the RHCOS nodes as the user `core`. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.
If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N " -f <path>/<file_name>
   ```

   Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

   **NOTE**
   
   If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the `x86_64`, `ppc64le`, and `s390x` architectures, do not create a key that uses the `ed25519` algorithm. Instead, create a key that uses the `rsa` or `ecdsa` algorithm.

2. View the public SSH key:

   ```bash
   $ cat <path>/<file_name>.pub
   ```

   For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

   ```bash
   $ cat ~/.ssh/id_ed25519.pub
   ```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

   **NOTE**
   
   On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.
a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

   ```
   $ eval "$(ssh-agent -s)"
   ```

   **Example output**
   ```
   Agent pid 31874
   ```

   **NOTE**

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

   ```
   $ ssh-add <path>/<file_name>
   ```

   Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

   **Example output**
   ```
   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
   ```

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

**19.2.7. Obtaining the installation program**

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

**Prerequisites**

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

**Procedure**

1. Access the **Infrastructure Provider** page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.
IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

19.2.8. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

IMPORTANT

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of oc.

Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure

2. Select the architecture from the Product Variant drop-down list.

3. Select the appropriate version from the Version drop-down list.

4. Click Download Now next to the OpenShift v4.14 Linux Client entry and save the file.

5. Unpack the archive:

```
$ tar xvf <file>
```

6. Place the oc binary in a directory that is on your PATH.
To check your PATH, execute the following command:

```
$ echo $PATH
```

**Verification**

- After you install the OpenShift CLI, it is available using the `oc` command:

```
$ oc <command>
```

**Installing the OpenShift CLI on Windows**

You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version from the Version drop-down list.
3. Click Download Now next to the OpenShift v4.14 Windows Client entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the `oc` binary to a directory that is on your PATH.

To check your PATH, open the command prompt and execute the following command:

```
C:\> path
```

**Verification**

- After you install the OpenShift CLI, it is available using the `oc` command:

```
C:\> oc <command>
```

**Installing the OpenShift CLI on macOS**

You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version from the Version drop-down list.
3. Click Download Now next to the OpenShift v4.14 macOS Client entry and save the file.

   **NOTE**

   For macOS arm64, choose the OpenShift v4.14 macOS arm64 Client entry.

4. Unpack and unzip the archive.
5. Move the `oc` binary to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:
   
   ```
   $ echo $PATH
   ```

   **Verification**

   - After you install the OpenShift CLI, it is available using the `oc` command:
     
     ```
     $ oc <command>
     ```

   **19.2.9. Manually creating the installation configuration file**

   **Prerequisites**

   - You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.
   - You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

   **Procedure**

   1. Create an installation directory to store your required installation assets in:
      
      ```
      $ mkdir <installation_directory>
      ```

      **IMPORTANT**

      You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

   2. Customize the sample `install-config.yaml` file template that is provided and save it in the `<installation_directory>`.
      
      **NOTE**

      You must name this configuration file `install-config.yaml`.

      **NOTE**

      For some platform types, you can alternatively run `./openshift-install create install-config --dir <installation_directory>` to generate an `install-config.yaml` file. You can provide details about your cluster configuration at the prompts.

   3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.
IMPORTANT

The install-config.yaml file is consumed during the next step of the installation process. You must back it up now.

Additional resources

- Installation configuration parameters for IBM Power®

19.2.9.1. Sample install-config.yaml file for IBM Power

You can customize the install-config.yaml file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute:
  - hyperthreading: Enabled
    name: worker
    replicas: 0
    architecture: ppc64le
controlPlane:
  hyperthreading: Enabled
  name: master
  replicas: 3
  architecture: ppc64le
metadata:
  name: test
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
  hostPrefix: 23
  networkType: OVNKubernetes
  serviceNetwork:
    - 172.30.0.0/16
platform:
  none: {}
fips: false
pullSecret: '{"auths": ...}"
sshKey: 'ssh-ed25519 AAAA...'
```

1. The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

2. The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, -, and the first line of the controlPlane section must not. Only one control plane pool is used.

3. Specifies whether to enable or disable simultaneous multithreading (SMT), or hyperthreading. By default, SMT is enabled to increase the performance of the cores in your machines. You can disable it by setting the parameter value to Disabled. If you disable SMT, you must disable it in all cluster machines; this includes both control plane and compute machines.
Simultaneous multithreading (SMT) is enabled by default. If SMT is not enabled in your BIOS settings, the `hyperthreading` parameter has no effect.

**IMPORTANT**

If you disable `hyperthreading`, whether in the BIOS or in the `install-config.yaml` file, ensure that your capacity planning accounts for the dramatically decreased machine performance.

You must set this value to **0** when you install OpenShift Container Platform on user-provisioned infrastructure. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. In user-provisioned installations, you must manually deploy the compute machines before you finish installing the cluster.

**NOTE**

If you are installing a three-node cluster, do not deploy any compute machines when you install the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

The cluster name that you specified in your DNS records.

A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to access the pods from an external network, you must configure load balancers and routers to manage the traffic.

**NOTE**

Class E CIDR range is reserved for a future use. To use the Class E CIDR range, you must ensure your networking environment accepts the IP addresses within the Class E CIDR range.

The subnet prefix length to assign to each individual node. For example, if `hostPrefix` is set to **23**, then each node is assigned a `/23` subnet out of the given `cidr`, which allows for 510 \(2^{(32 - 23)} - 2\) pod IP addresses. If you are required to provide access to nodes from an external network, configure load balancers and routers to manage the traffic.

The cluster network plugin to install. The supported values are `OVNKubernetes` and `OpenShiftSDN`. The default value is `OVNKubernetes`.

The IP address pool to use for service IP addresses. You can enter only one IP address pool. This block must not overlap with existing physical networks. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.

You must set the platform to **none**. You cannot provide additional platform configuration variables for IBM Power® infrastructure.
IMPORTANT

Clusters that are installed with the platform type **none** are unable to use some features, such as managing compute machines with the Machine API. This limitation applies even if the compute machines that are attached to the cluster are installed on a platform that would normally support the feature. This parameter cannot be changed after installation.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

IMPORTANT

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see [Installing the system in FIPS mode](#). When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures.

The pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

The SSH public key for the **core** user in Red Hat Enterprise Linux CoreOS (RHCOS).

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

19.2.9.2. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

**Prerequisites**

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object’s **spec.noProxy** field to bypass the proxy if necessary.
NOTE

The Proxy object status.noProxy field is populated with the values of the networking.machineNetwork[].cidr, networking.clusterNetwork[].cidr, and networking.serviceNetwork[] fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object status.noProxy field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your install-config.yaml file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port> 1
  httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
  noProxy: example.com 3
additionalTrustBundle: |
  -----BEGIN CERTIFICATE-----
  <MY_TRUSTED_CA_CERT>
  -----END CERTIFICATE-----
additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> 5
```

1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.

2. A proxy URL to use for creating HTTPS connections outside the cluster.

3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.

4. If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the trustedCA field of the Proxy object. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

5. Optional: The policy to determine the configuration of the Proxy object to reference the user-ca-bundle config map in the trustedCA field. The allowed values are Proxyonly and Always. Use Proxyonly to reference the user-ca-bundle config map only when http/https proxy is configured. Use Always to always reference the user-ca-bundle config map. The default value is Proxyonly.

NOTE

The installation program does not support the proxy readinessEndpoints field.
NOTE

If the installer times out, restart and then complete the deployment by using the wait-for command of the installer. For example:

```
$ ./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

NOTE

Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

19.2.9.3. Configuring a three-node cluster

Optionally, you can deploy zero compute machines in a bare metal cluster that consists of three control plane machines only. This provides smaller, more resource efficient clusters for cluster administrators and developers to use for testing, development, and production.

In three-node OpenShift Container Platform environments, the three control plane machines are schedulable, which means that your application workloads are scheduled to run on them.

Prerequisites

- You have an existing `install-config.yaml` file.

Procedure

- Ensure that the number of compute replicas is set to **0** in your `install-config.yaml` file, as shown in the following `compute` stanza:

```yaml
compute:
- name: worker
  platform: {}
  replicas: 0
```

NOTE

You must set the value of the `replicas` parameter for the compute machines to **0** when you install OpenShift Container Platform on user-provisioned infrastructure, regardless of the number of compute machines you are deploying. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. This does not apply to user-provisioned installations, where the compute machines are deployed manually.

For three-node cluster installations, follow these next steps:
● If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes. See the Load balancing requirements for user-provisioned infrastructure section for more information.

● When you create the Kubernetes manifest files in the following procedure, ensure that the mastersSchedulable parameter in the <installation_directory>/manifests/cluster-scheduler-02-config.yaml file is set to true. This enables your application workloads to run on the control plane nodes.

● Do not deploy any compute nodes when you create the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

19.2.10. Cluster Network Operator configuration

The configuration for the cluster network is specified as part of the Cluster Network Operator (CNO) configuration and stored in a custom resource (CR) object that is named cluster. The CR specifies the fields for the Network API in the operator.openshift.io API group.

The CNO configuration inherits the following fields during cluster installation from the Network API in the Network.config.openshift.io API group and these fields cannot be changed:

clusterNetwork
   IP address pools from which pod IP addresses are allocated.

serviceNetwork
   IP address pool for services.

defaultNetwork.type
   Cluster network plugin, such as OpenShift SDN or OVN-Kubernetes.

You can specify the cluster network plugin configuration for your cluster by setting the fields for the defaultNetwork object in the CNO object named cluster.

19.2.10.1. Cluster Network Operator configuration object

The fields for the Cluster Network Operator (CNO) are described in the following table:

Table 19.9. Cluster Network Operator configuration object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>metadata.name</td>
<td>string</td>
<td>The name of the CNO object. This name is always cluster.</td>
</tr>
</tbody>
</table>
spec.clusterNetwork

A list specifying the blocks of IP addresses from which pod IP addresses are allocated and the subnet prefix length assigned to each individual node in the cluster. For example:

```yaml
spec:
  clusterNetwork:
    - cidr: 10.128.0.0/19
      hostPrefix: 23
    - cidr: 10.128.32.0/19
      hostPrefix: 23
```

You can customize this field only in the `install-config.yaml` file before you create the manifests. The value is read-only in the manifest file.

spec.serviceNetwork

A block of IP addresses for services. The OpenShift SDN and OVN-Kubernetes network plugins support only a single IP address block for the service network. For example:

```yaml
spec:
  serviceNetwork:
    - 172.30.0.0/14
```

You can customize this field only in the `install-config.yaml` file before you create the manifests. The value is read-only in the manifest file.

defaultNetwork object configuration

The values for the `defaultNetwork` object are defined in the following table:

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>spec.defaultNetwork</td>
<td>object</td>
<td>Configures the network plugin for the cluster network.</td>
</tr>
<tr>
<td>spec.kubeProxyConfig</td>
<td>object</td>
<td>The fields for this object specify the kube-proxy configuration. If you are using the OVN-Kubernetes cluster network plugin, the kube-proxy configuration has no effect.</td>
</tr>
</tbody>
</table>
Either **OpenShiftSDN** or **OVN Kubernetes**. The Red Hat OpenShift Networking network plugin is selected during installation. This value cannot be changed after cluster installation.

**NOTE**

OpenShift Container Platform uses the OVN-Kubernetes network plugin by default.

The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.

If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.

If your cluster requires different MTU values for different nodes, you must set this value to 50 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1450.

This value cannot be changed after cluster installation.

The port to use for all VXLAN packets. The default value is 4789. This value cannot be changed after cluster installation.

If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number.

On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port 9000 and port 9999.

Example OpenShift SDN configuration

defaultNetwork:
    type: OpenShiftSDN
    openshiftSDNConfig:
        mode: NetworkPolicy
        mtu: 1450
        vxlanPort: 4789

Configuration for the OVN–Kubernetes network plugin

### Field

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| mtu           | integer| The maximum transmission unit (MTU) for the Geneve (Generic Network Virtualization Encapsulation) overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.  
If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.  
If your cluster requires different MTU values for different nodes, you must set this value to 100 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1400. |
| genevePort    | integer| The port to use for all Geneve packets. The default value is 6081. This value cannot be changed after cluster installation.                   |
| ipsecConfig   | object | Specify an empty object to enable IPsec encryption.                                                                                         |
| policyAuditConfg | object  | Specify a configuration object for customizing network policy audit logging. If unset, the defaults audit log settings are used.           |
| gatewayConfig | object | Optional: Specify a configuration object for customizing how egress traffic is sent to the node gateway.                                     |

**NOTE**

While migrating egress traffic, you can expect some disruption to workloads and service traffic until the Cluster Network Operator (CNO) successfully rolls out the changes.
If your existing network infrastructure overlaps with the **100.64.0.0/16** IPv4 subnet, you can specify a different IP address range for internal use by OVN-Kubernetes. You must ensure that the IP address range does not overlap with any other subnet used by your OpenShift Container Platform installation. The IP address range must be larger than the maximum number of nodes that can be added to the cluster. For example, if the `clusterNetwork.cidr` value is **10.128.0.0/14** and the `clusterNetwork.hostPrefix` value is /23, then the maximum number of nodes is $2^{(23-14)}=512$.

This field cannot be changed after installation.

</tr>
</tbody>
</table>
IMPORTANT

- The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

NOTE

The installation program that generates the manifest and Ignition files is architecture specific and can be obtained from the client image mirror. The Linux version of the installation program (without an architecture postfix) runs on ppc64le only. This installer program is also available as a Mac OS version.

Prerequisites

- You obtained the OpenShift Container Platform installation program.
- You created the install-config.yaml installation configuration file.

Procedure

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

   ```bash
   $ ./openshift-install create manifests --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the installation directory that contains the install-config.yaml file you created.

   WARNING

   If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.

   IMPORTANT

   When you configure control plane nodes from the default unschedulable to schedulable, additional subscriptions are required. This is because control plane nodes then become compute nodes.
2. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:

   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.

   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.

   c. Save and exit the file.

3. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

   ```bash
   $ ./openshift-install create ignition-configs --dir <installation_directory>  
   ``

   For `<installation_directory>`, specify the same installation directory.

   Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The `kubeadmin-password` and `kubeconfig` files are created in the `./<installation_directory>/auth` directory:

   ```
   ├── auth
   │   └── kubeadmin-password
   │   └── kubeconfig
   ├── bootstrap.ign
   ├── master.ign
   ├── metadata.json
   └── worker.ign
   ```

19.2.12. Installing RHCOS and starting the OpenShift Container Platform bootstrap process

To install OpenShift Container Platform on IBM Power® infrastructure that you provision, you must install Red Hat Enterprise Linux CoreOS (RHCOS) on the machines. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS machines have rebooted.

Follow either the steps to use an ISO image or network PXE booting to install RHCOS on the machines.

19.2.12.1. Installing RHCOS by using an ISO image

You can use an ISO image to install RHCOS on the machines.

**Prerequisites**

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
You have an HTTP server that can be accessed from your computer, and from the machines that you create.

You have reviewed the Advanced RHCOS installation configuration section for different ways to configure features, such as networking and disk partitioning.

Procedure

1. Obtain the SHA512 digest for each of your Ignition config files. For example, you can use the following on a system running Linux to get the SHA512 digest for your bootstrap.ign Ignition config file:

   ```bash
   $ sha512sum <installation_directory>/bootstrap.ign
   ```

   The digests are provided to the coreos-installer in a later step to validate the authenticity of the Ignition config files on the cluster nodes.

2. Upload the bootstrap, control plane, and compute node Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

   IMPORTANT

   You can add or change configuration settings in your Ignition configs before saving them to your HTTP server. If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

3. From the installation host, validate that the Ignition config files are available on the URLs. The following example gets the Ignition config file for the bootstrap node:

   ```bash
   $ curl -k http://<HTTP_server>/bootstrap.ign
   ```

   Example output

   
<table>
<thead>
<tr>
<th>% Total</th>
<th>% Received</th>
<th>% Xferd</th>
<th>Average Speed</th>
<th>Time</th>
<th>Time</th>
<th>Time</th>
<th>Current</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>
   
   Replace bootstrap.ign with master.ign or worker.ign in the command to validate that the Ignition config files for the control plane and compute nodes are also available.

4. Although it is possible to obtain the RHCOS images that are required for your preferred method of installing operating system instances from the RHCOS image mirror page, the recommended way to obtain the correct version of your RHCOS images are from the output of openshift-install command:

   ```bash
   $ openshift-install coreos print-stream-json | grep ".iso[^.]"
   ```

   Example output

   "location": "<url>/art/storage/releases/rhcos-4.14-aarch64/<release>/aarch64/rhcos-<release>-live.aarch64.iso",
   "location": "<url>/art/storage/releases/rhcos-4.14-ppc64le/<release>/ppc64le/rhcos-..."
IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available. Use only ISO images for this procedure. RHCOS qcow2 images are not supported for this installation type.

ISO file names resemble the following example:

```
rhcos-<version>-live.<architecture>.iso
```

5. Use the ISO to start the RHCOS installation. Use one of the following installation options:
   - Burn the ISO image to a disk and boot it directly.
   - Use ISO redirection by using a lights-out management (LOM) interface.

6. Boot the RHCOS ISO image without specifying any options or interrupting the live boot sequence. Wait for the installer to boot into a shell prompt in the RHCOS live environment.

   **NOTE**

   It is possible to interrupt the RHCOS installation boot process to add kernel arguments. However, for this ISO procedure you should use the `coreos-installer` command as outlined in the following steps, instead of adding kernel arguments.

7. Run the `coreos-installer` command and specify the options that meet your installation requirements. At a minimum, you must specify the URL that points to the Ignition config file for the node type, and the device that you are installing to:

   ```bash
   $ sudo coreos-installer install --ignition-url=http://<HTTP_server>/<node_type>.ign <device> --ignition-hash=sha512-<digest>  
   ```

   1. You must run the `coreos-installer` command by using `sudo`, because the `core` user does not have the required root privileges to perform the installation.

   2. The `--ignition-hash` option is required when the Ignition config file is obtained through an HTTP URL to validate the authenticity of the Ignition config file on the cluster node. `<digest>` is the Ignition config file SHA512 digest obtained in a preceding step.

   **NOTE**

   If you want to provide your Ignition config files through an HTTPS server that uses TLS, you can add the internal certificate authority (CA) to the system trust store before running `coreos-installer`.
The following example initializes a bootstrap node installation to the /dev/sda device. The Ignition config file for the bootstrap node is obtained from an HTTP web server with the IP address 192.168.1.2:

```bash
$ sudo coreos-installer install --ignition-url=http://192.168.1.2:80/installation_directory/bootstrap.ign /dev/sda --ignition-hash=sha512-a5a2d43879223273c9b60af66b44202a1d1248fc01cf156c46d4a79f552b6bad47bc8cc78ddf0116e80c59d2ea9e32ba53bc807afbca581aa059311def2c3e3b
```

8. Monitor the progress of the RHCOS installation on the console of the machine.

```
**IMPORTANT**
Be sure that the installation is successful on each node before commencing with the OpenShift Container Platform installation. Observing the installation process can also help to determine the cause of RHCOS installation issues that might arise.
```

9. After RHCOS installs, you must reboot the system. During the system reboot, it applies the Ignition config file that you specified.

10. Check the console output to verify that Ignition ran.

**Example command**

```
Ignition: ran on 2022/03/14 14:48:33 UTC (this boot)
Ignition: user-provided config was applied
```

11. Continue to create the other machines for your cluster.

```
**IMPORTANT**
You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, also create at least two compute machines before you install OpenShift Container Platform.
```

If the required network, DNS, and load balancer infrastructure are in place, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS nodes have rebooted.

```
**NOTE**
RHCOS nodes do not include a default password for the **core** user. You can access the nodes by running `ssh core@<node>.<cluster_name>.<base_domain>` as a user with access to the SSH private key that is paired to the public key that you specified in your `install_config.yaml` file. OpenShift Container Platform 4 cluster nodes running RHCOS are immutable and rely on Operators to apply cluster changes. Accessing cluster nodes by using SSH is not recommended. However, when investigating installation issues, if the OpenShift Container Platform API is not available, or the kubelet is not properly functioning on a target node, SSH access might be required for debugging or disaster recovery.
```
19.2.12.1. Advanced RHCOS installation reference

This section illustrates the networking configuration and other advanced options that allow you to modify the Red Hat Enterprise Linux CoreOS (RHCOS) manual installation process. The following tables describe the kernel arguments and command-line options you can use with the RHCOS live installer and the `coreos-installer` command.

19.2.12.1.1. Networking and bonding options for ISO installations

If you install RHCOS from an ISO image, you can add kernel arguments manually when you boot the image to configure networking for a node. If no networking arguments are specified, DHCP is activated in the initramfs when RHCOS detects that networking is required to fetch the Ignition config file.

**IMPORTANT**

When adding networking arguments manually, you must also add the `rd.neednet=1` kernel argument to bring the network up in the initramfs.

The following information provides examples for configuring networking and bonding on your RHCOS nodes for ISO installations. The examples describe how to use the `ip=`, `nameserver=`, and `bond=` kernel arguments.

**NOTE**

Ordering is important when adding the kernel arguments: `ip=`, `nameserver=`, and then `bond=`.

The networking options are passed to the `dracut` tool during system boot. For more information about the networking options supported by `dracut`, see the `dracut.cmdline` manual page.

The following examples are the networking options for ISO installation.

Configuring DHCP or static IP addresses

To configure an IP address, either use DHCP (`ip= dhcp`) or set an individual static IP address (`ip= <host_ip>`). If setting a static IP, you must then identify the DNS server IP address (`nameserver= <dns_ip>`) on each node. The following example sets:

- The node’s IP address to 10.10.10.2
- The gateway address to 10.10.10.254
- The netmask to 255.255.255.0
- The hostname to `core0.example.com`
- The DNS server address to 4.4.4.41
- The auto-configuration value to none. No auto-configuration is required when IP networking is configured statically.

```
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none
nameserver=4.4.4.41
dracut --force --always --reboot
```
When you use DHCP to configure IP addressing for the RHCOS machines, the machines also obtain the DNS server information through DHCP. For DHCP-based deployments, you can define the DNS server address that is used by the RHCOS nodes through your DHCP server configuration.

Configuring an IP address without a static hostname
You can configure an IP address without assigning a static hostname. If a static hostname is not set by the user, it will be picked up and automatically set by a reverse DNS lookup. To configure an IP address without a static hostname refer to the following example:

- The node’s IP address to **10.10.10.2**
- The gateway address to **10.10.10.254**
- The netmask to **255.255.255.0**
- The DNS server address to **4.4.4.41**
- The auto-configuration value to **none**. No auto-configuration is required when IP networking is configured statically.

```text
ip=10.10.10.2::10.10.10.254:255.255.255.0::enp1s0:none
nameserver=4.4.4.41
```

Specifying multiple network interfaces
You can specify multiple network interfaces by setting multiple `ip=` entries.

```text
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none
ip=10.10.10.3::10.10.10.254:255.255.255.0:core0.example.com:enp2s0:none
```

Configuring default gateway and route
Optional: You can configure routes to additional networks by setting an `rd.route=` value.

```text
NOTE
When you configure one or multiple networks, one default gateway is required. If the additional network gateway is different from the primary network gateway, the default gateway must be the primary network gateway.
```

- Run the following command to configure the default gateway:
  ```text
  ip=:10.10.10.254:::
  ```
- Enter the following command to configure the route for the additional network:
  ```text
  rd.route=20.20.20.0/24:20.20.20.254:enp2s0
  ```

Disabling DHCP on a single interface
You can disable DHCP on a single interface, such as when there are two or more network interfaces and only one interface is being used. In the example, the `enp1s0` interface has a static networking configuration and DHCP is disabled for `enp2s0`, which is not used:

```text
```
Combining DHCP and static IP configurations
You can combine DHCP and static IP configurations on systems with multiple network interfaces, for example:

```
ip=enp1s0:dhcp
ip=10.10.10.2::10.10.254:255.255.255.0:core0.example.com:enp2s0:0
```

Configuring VLANs on individual interfaces
Optional: You can configure VLANs on individual interfaces by using the `vlan=` parameter.

- To configure a VLAN on a network interface and use a static IP address, run the following command:

```
ip=10.10.2::10.10.254:255.255.255.0:core0.example.com:enp2s0.100:0
vlan=enp2s0.100:enp2s0
```

- To configure a VLAN on a network interface and to use DHCP, run the following command:

```
ip=enp2s0.100:dhcp
vlan=enp2s0.100:enp2s0
```

Providing multiple DNS servers
You can provide multiple DNS servers by adding a `nameserver=` entry for each server, for example:

```
nameserver=1.1.1.1
nameserver=8.8.8.8
```

Bonding multiple network interfaces to a single interface
Optional: You can bond multiple network interfaces to a single interface by using the `bond=` option. Refer to the following examples:

- The syntax for configuring a bonded interface is: `bond=<name>[:<network_interfaces>][:options]`
  `<name>` is the bonding device name (`bond0`), `<network_interfaces>` represents a comma-separated list of physical (ethernet) interfaces (`em1,em2`), and `options` is a comma-separated list of bonding options. Enter `modinfo bonding` to see available options.

- When you create a bonded interface using `bond=`, you must specify how the IP address is assigned and other information for the bonded interface.
  - To configure the bonded interface to use DHCP, set the bond’s IP address to `dhcp`. For example:

    ```
bond=bond0:em1,em2:mode=active-backup
ip=bond0:dhcp
```

  - To configure the bonded interface to use a static IP address, enter the specific IP address you want and related information. For example:

    ```
bond=bond0:em1,em2:mode=active-backup
ip=10.10.10.2::10.10.254:255.255.255.0:core0.example.com:bond0:0
```
Bonding multiple SR-IOV network interfaces to a dual port NIC interface

**IMPORTANT**

Support for Day 1 operations associated with enabling NIC partitioning for SR-IOV devices is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see [Technology Preview Features Support Scope](#).

Optional: You can bond multiple SR-IOV network interfaces to a dual port NIC interface by using the `bond=` option.

On each node, you must perform the following tasks:

1. Create the SR-IOV virtual functions (VFs) following the guidance in [Managing SR-IOV devices](#). Follow the procedure in the "Attaching SR-IOV networking devices to virtual machines" section.

2. Create the bond, attach the desired VFs to the bond and set the bond link state up following the guidance in [Configuring network bonding](#). Follow any of the described procedures to create the bond.

The following examples illustrate the syntax you must use:

- The syntax for configuring a bonded interface is `bond=<name>[::<network_interfaces>] [::<options>]`. `<name>` is the bonding device name (`bond0`), `<network_interfaces>` represents the virtual functions (VFs) by their known name in the kernel and shown in the output of the `ip link` command (`eno1f0`, `eno2f0`), and `options` is a comma-separated list of bonding options. Enter `modinfo bonding` to see available options.

- When you create a bonded interface using `bond=`, you must specify how the IP address is assigned and other information for the bonded interface.
  - To configure the bonded interface to use DHCP, set the bond’s IP address to `dhcp`. For example:
    ```
    bond=bond0:eno1f0,eno2f0:mode=active-backup
    ip=bond0:dhcp
    ```
  - To configure the bonded interface to use a static IP address, enter the specific IP address you want and related information. For example:
    ```
    bond=bond0:eno1f0,eno2f0:mode=active-backup
    ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:bond0:none
    ```

**19.2.12.2. Installing RHCOS by using PXE booting**

You can use PXE booting to install RHCOS on the machines.
Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have configured suitable PXE infrastructure.
- You have an HTTP server that can be accessed from your computer, and from the machines that you create.
- You have reviewed the Advanced RHCOS installation configuration section for different ways to configure features, such as networking and disk partitioning.

Procedure

1. Upload the bootstrap, control plane, and compute node Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

   **IMPORTANT**
   
   You can add or change configuration settings in your Ignition configs before saving them to your HTTP server. If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

2. From the installation host, validate that the Ignition config files are available on the URLs. The following example gets the Ignition config file for the bootstrap node:

   ```
   $ curl -k http://<HTTP_server>/bootstrap.ign
   ```

   Replace `bootstrap.ign` with `master.ign` or `worker.ign` in the command to validate that the Ignition config files for the control plane and compute nodes are also available.

3. Although it is possible to obtain the RHCOS kernel, initramfs and rootfs files that are required for your preferred method of installing operating system instances from the RHCOS image mirror page, the recommended way to obtain the correct version of your RHCOS files are from the output of openshift-install command:

   ```
   $ openshift-install coreos print-stream-json | grep -Eo "https.*kernel-|initramfs.|rootfs.
   ```

   Replace `bootstrap.ign` with `coreos print-stream-json` in the command to validate that the Ignition config files for the control plane and compute nodes are also available.
"<url>/art/storage/releases/rhcos-4.14-aarch64/<release>/aarch64/rhcos-<release>-live-rootfs.aarch64.img"
"<url>/art/storage/releases/rhcos-4.14-ppc64le/49.84.202110081256-0/ppc64le/rhcos-<release>-live-kernel-ppc64le" 
"<url>/art/storage/releases/rhcos-4.14-ppc64le/<release>/ppc64le/rhcos-<release>-live-initramfs.ppc64le.img"
"<url>/art/storage/releases/rhcos-4.14-ppc64le/<release>/ppc64le/rhcos-<release>-live-rootfs.ppc64le.img"
"<url>/art/storage/releases/rhcos-4.14-s390x/<release>/s390x/rhcos-<release>-live-kernel-s390x"
"<url>/art/storage/releases/rhcos-4.14-s390x/<release>/s390x/rhcos-<release>-live-initramfs.s390x.img"
"<url>/art/storage/releases/rhcos-4.14-s390x/<release>/s390x/rhcos-<release>-live-rootfs.s390x.img"
"<url>/art/storage/releases/rhcos-4.14/<release>/x86_64/rhcos-<release>-live-kernel-x86_64" 
"<url>/art/storage/releases/rhcos-4.14/<release>/x86_64/rhcos-<release>-live-initramfs.x86_64.img"
"<url>/art/storage/releases/rhcos-4.14/<release>/x86_64/rhcos-<release>-live-rootfs.x86_64.img"

### IMPORTANT

The RHCOS artifacts might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate kernel, initramfs, and rootfs artifacts described below for this procedure. RHCOS QCOW2 images are not supported for this installation type.

The file names contain the OpenShift Container Platform version number. They resemble the following examples:

- **kernel**: `rhcos-<version>-live-kernel-<architecture>`
- **initramfs**: `rhcos-<version>-live-initramfs.<architecture>.img`
- **rootfs**: `rhcos-<version>-live-rootfs.<architecture>.img`

4. Upload the **rootfs**, **kernel**, and **initramfs** files to your HTTP server.

### IMPORTANT

If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

5. Configure the network boot infrastructure so that the machines boot from their local disks after RHCOS is installed on them.

6. Configure PXE installation for the RHCOS images and begin the installation.

Modify the following example menu entry for your environment and verify that the image and Ignition files are properly accessible:

```
DEFAULT pxeboot
```
TIMEOUT 20  
PROMPT 0  
LABEL pxeboot  

KERNEL http://<HTTP_server>/rhcos-<version>-live-kernel-<architecture>  
APPEND initrd=http://<HTTP_server>/rhcos-<version>-live-initramfs.<architecture>.img  
coreos.inst.install_dev=/dev/sda  
coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign  

1. Specify the location of the live kernel file that you uploaded to your HTTP server. The URL must be HTTP, TFTP, or FTP; HTTPS and NFS are not supported.

2. If you use multiple NICs, specify a single interface in the ip option. For example, to use DHCP on a NIC that is named eno1, set ip=eno1:dhcp.

3. Specify the locations of the RHCOS files that you uploaded to your HTTP server. The initrd parameter value is the location of the initramfs file, the coreos.live.roots_url parameter value is the location of the rootfs file, and the coreos.inst.ignition_url parameter value is the location of the bootstrap Ignition config file. You can also add more kernel arguments to the APPEND line to configure networking or other boot options.

NOTE

This configuration does not enable serial console access on machines with a graphical console. To configure a different console, add one or more console= arguments to the APPEND line. For example, add console=tty0 console=ttyS0 to set the first PC serial port as the primary console and the graphical console as a secondary console. For more information, see How does one set up a serial terminal and/or console in Red Hat Enterprise Linux? and "Enabling the serial console for PXE and ISO installation" in the "Advanced RHCOS installation configuration" section.

7. Monitor the progress of the RHCOS installation on the console of the machine.

IMPORTANT

Be sure that the installation is successful on each node before commencing with the OpenShift Container Platform installation. Observing the installation process can also help to determine the cause of RHCOS installation issues that might arise.

8. After RHCOS installs, the system reboots. During reboot, the system applies the Ignition config file that you specified.

9. Check the console output to verify that Ignition ran.

Example command

Ignition: ran on 2022/03/14 14:48:33 UTC (this boot)  
Ignition: user-provided config was applied

10. Continue to create the machines for your cluster.
IMPORTANT

You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, also create at least two compute machines before you install the cluster.

If the required network, DNS, and load balancer infrastructure are in place, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS nodes have rebooted.

NOTE

RHCOS nodes do not include a default password for the core user. You can access the nodes by running `ssh core@<node>.<cluster_name>.<base_domain>` as a user with access to the SSH private key that is paired to the public key that you specified in your `install_config.yaml` file. OpenShift Container Platform 4 cluster nodes running RHCOS are immutable and rely on Operators to apply cluster changes. Accessing cluster nodes by using SSH is not recommended. However, when investigating installation issues, if the OpenShift Container Platform API is not available, or the kubelet is not properly functioning on a target node, SSH access might be required for debugging or disaster recovery.

19.2.12.3. Enabling multipathing with kernel arguments on RHCOS

In OpenShift Container Platform version 4.14, during installation, you can enable multipathing for provisioned nodes. RHCOS supports multipathing on the primary disk. Multipathing provides added benefits of stronger resilience to hardware failure to achieve higher host availability.

During the initial cluster creation, you might want to add kernel arguments to all master or worker nodes. To add kernel arguments to master or worker nodes, you can create a `MachineConfig` object and inject that object into the set of manifest files used by Ignition during cluster setup.

Procedure

1. Change to the directory that contains the installation program and generate the Kubernetes manifests for the cluster:

   ```
   $ ./openshift-install create manifests --dir <installation_directory>
   ```

2. Decide if you want to add kernel arguments to worker or control plane nodes.
   - Create a machine config file. For example, create a `99-master-kargs-mpath.yaml` that instructs the cluster to add the `master` label and identify the multipath kernel argument:

     ```yaml
     apiVersion: machineconfiguration.openshift.io/v1
     kind: MachineConfig
     metadata:
       labels:
         machineconfiguration.openshift.io/role: "master"
     name: 99-master-kargs-mpath
     spec:
       kernelArguments:
         - 'rd.multipath=default'
         - 'root=/dev/disk/by-label/dm-mpath-root'
     ```
3. To enable multipathing on worker nodes:

- Create a machine config file. For example, create a **99-worker-kargs-mpath.yaml** that instructs the cluster to add the **worker** label and identify the multipath kernel argument:

```yaml
apiVersion: machineconfiguration.openshift.io/v1
kind: MachineConfig
metadata:
  labels:
    machineconfiguration.openshift.io/role: "worker"
name: 99-worker-kargs-mpath
spec:
  kernelArguments:
  - 'rd.multipath=default'
  - 'root=/dev/disk/by-label/dm-mpath-root'
```

You can now continue on to create the cluster.

**IMPORTANT**

Additional postinstallation steps are required to fully enable multipathing. For more information, see "Enabling multipathing with kernel arguments on RHCOS" in *Postinstallation machine configuration tasks*.

In case of MPIO failure, use the bootlist command to update the boot device list with alternate logical device names. The command displays a boot list and it designates the possible boot devices for when the system is booted in normal mode.

a. To display a boot list and specify the possible boot devices if the system is booted in normal mode, enter the following command:

```
$ bootlist -m normal -o
sda
```

b. To update the boot list for normal mode and add alternate device names, enter the following command:

```
$ bootlist -m normal -o /dev/sdc /dev/sdd /dev/sde
sdc
sdd
sde
```

If the original boot disk path is down, the node reboots from the alternate device registered in the normal boot device list.

### 19.2.13. Waiting for the bootstrap process to complete

The OpenShift Container Platform bootstrap process begins after the cluster nodes first boot into the persistent RHCOS environment that has been installed to disk. The configuration information provided through the Ignition config files is used to initialize the bootstrap process and install OpenShift Container Platform on the machines. You must wait for the bootstrap process to complete.

**Prerequisites**
• You have created the Ignition config files for your cluster.
• You have configured suitable network, DNS and load balancing infrastructure.
• You have obtained the installation program and generated the Ignition config files for your cluster.
• You installed RHCOS on your cluster machines and provided the Ignition config files that the OpenShift Container Platform installation program generated.
• Your machines have direct internet access or have an HTTP or HTTPS proxy available.

Procedure

1. Monitor the bootstrap process:

   ```bash
   $ ./openshift-install --dir <installation_directory> wait-for bootstrap-complete \ 
   --log-level=info
   ```

   1 For `<installation_directory>`, specify the path to the directory that you stored the installation files in.
   2 To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

   Example output

   ```
   INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
   INFO API v1.27.3 up
   INFO Waiting up to 30m0s for bootstrapping to complete...
   INFO It is now safe to remove the bootstrap resources
   ```

   The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After the bootstrap process is complete, remove the bootstrap machine from the load balancer.

   **IMPORTANT**

   You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the bootstrap machine itself.

19.2.14. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

• You deployed an OpenShift Container Platform cluster.
• You installed the `oc` CLI.
Procedure

1. Export the `kubeadmin` credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   ```

   **Example output**

   ```
   system:admin
   ```

19.2.15. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

**Prerequisites**

- You added machines to your cluster.

**Procedure**

1. Confirm that the cluster recognizes the machines:

   ```bash
   $ oc get nodes
   ```

   **Example output**

   ```
   NAME      STATUS    ROLES   AGE VERSION
   master-0  Ready     master  63m v1.27.3
   master-1  Ready     master  63m v1.27.3
   master-2  Ready     master  64m v1.27.3
   ```

   The output lists all of the machines that you created.

   **NOTE**

   The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

   ```bash
   $ oc get csr
   ```
Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-8b2br</td>
<td>15m</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-8vnps</td>
<td>15m</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Pending</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in Pending status, approve the CSRs for your cluster machines:

**NOTE**

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

**NOTE**

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the `oc exec`, `oc rsh`, and `oc logs` commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the node-bootstrapper service account in the `system:node` or `system:admin` groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

  ```bash
  $ oc adm certificate approve <csr_name> 1
  ```

1  `<csr_name>` is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

  ```bash
  $ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
  ```
NOTE
Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

   $ oc get csr

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-c57lv</td>
<td>5m26s</td>
<td>system:node:ip-10-0-95-157.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
</tbody>
</table>

5. If the remaining CSRs are not approved, and are in the Pending status, approve the CSRs for your cluster machines:

   - To approve them individually, run the following command for each valid CSR:

     $ oc adm certificate approve <csr_name> ¹

     ¹ <csr_name> is the name of a CSR from the list of current CSRs.

   - To approve all pending CSRs, run the following command:

     $ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs oc adm certificate approve

6. After all client and server CSRs have been approved, the machines have the Ready status. Verify this by running the following command:

   $ oc get nodes

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>74m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>worker-0</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>worker-1</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.27.3</td>
</tr>
</tbody>
</table>

NOTE
It can take a few minutes after approval of the server CSRs for the machines to transition to the Ready status.
19.2.16. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

**Prerequisites**

- Your control plane has initialized.

**Procedure**

1. Watch the cluster components come online:

   ```
   $ watch -n5 oc get clusteroperators
   ```

   **Example output**

<table>
<thead>
<tr>

2. Configure the Operators that are not available.

19.2.16.1. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the *Recreate* rollout strategy during upgrades.

19.2.16.1.1. Configuring registry storage for IBM Power

As a cluster administrator, following installation you must configure your registry to use storage.

**Prerequisites**

- You have access to the cluster as a user with the *cluster-admin* role.
- You have a cluster on IBM Power®.
- You have provisioned persistent storage for your cluster, such as Red Hat OpenShift Data Foundation.

**IMPORTANT**

OpenShift Container Platform supports *ReadWriteOnce* access for image registry storage when you have only one replica. *ReadWriteOnce* access also requires that the registry uses the *Recreate* rollout strategy. To deploy an image registry that supports high availability with two or more replicas, *ReadWriteMany* access is required.

- Must have 100Gi capacity.

**Procedure**

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

   **NOTE**

   When you use shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

   ```
   $ oc get pod -n openshift-image-registry -l docker-registry=default
   ```

   **Example output**
3. Check the registry configuration:

```
$ oc edit configs.imageregistry.operator.openshift.io
```

Example output

```
storage:
pvc:
  claim:

Leave the claim field blank to allow the automatic creation of an image-registry-storage PVC.
```

4. Check the clusteroperator status:

```
$ oc get clusteroperator image-registry
```

Example output

```
NAME             VERSION              AVAILABLE   PROGRESSING   DEGRADED   SINCE
MESSAGE
image-registry   4.14                 True        False         False      6h50m
```

5. Ensure that your registry is set to managed to enable building and pushing of images.

- Run:

```
$ oc edit configs.imageregistry/cluster
```

Then, change the line

```
managementState: Removed
```

to

```
managementState: Managed
```

19.2.16.1.2. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

Procedure

- To set the image registry storage to an empty directory:
$ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec": {"storage": {"emptyDir": {}}}}'

**WARNING**

Configure this option for only non-production clusters.

If you run this command before the Image Registry Operator initializes its components, the `oc patch` command fails with the following error:

```
Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
```

Wait a few minutes and run the command again.

### 19.2.17. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

**Prerequisites**

- Your control plane has initialized.
- You have completed the initial Operator configuration.

**Procedure**

1. Confirm that all the cluster components are online with the following command:

   ```
   $ watch -n5 oc get clusteroperators
   ```

**Example output**

<table>
<thead>
<tr>

</tr>
<tr>
<td>kube-apiserver</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>26m</td>
</tr>
</tbody>
</table>
Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```
$ ./openshift-install --dir <installation_directory> wait-for install-complete
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

**Example output**

INFO Waiting up to 30m0s for the cluster to initialize...

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

2. Confirm that the Kubernetes API server is communicating with the pods.
a. To view a list of all pods, use the following command:

```
$ oc get pods --all-namespaces
```

**Example output**

```
NAMESPACE                         NAME                                            READY   STATUS      RESTARTS   AGE
openshift-apiserver-operator      openshift-apiserver-operator-85cb746d55-zqhs8  1/1  Running     1          9m
openshift-apiserver               apiserver-67b9g                                 1/1  Running     0          3m
openshift-apiserver               apiserver-ljcmx                                 1/1  Running     0          1m
openshift-apiserver               apiserver-z25h4                                 1/1  Running     0          2m
openshift-authentication-operator authentication-operator-69d5d8bf84-vh2n8        1/1  Running     0          5m
```

b. View the logs for a pod that is listed in the output of the previous command by using the following command:

```
$ oc logs <pod_name> -n <namespace>  
```

Specify the pod name and namespace, as shown in the output of the previous command.

If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. Additional steps are required to enable multipathing. Do not enable multipathing during installation.

   See "Enabling multipathing with kernel arguments on RHCOS" in the *Post-installation machine configuration tasks* documentation for more information.

### 19.2.18. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager Hybrid Cloud Console](https://example.com).

After you confirm that your [OpenShift Cluster Manager Hybrid Cloud Console](https://example.com) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use [subscription watch](https://example.com) to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- See [About remote health monitoring](https://example.com) for more information about the Telemetry service

### 19.2.19. Next steps
Enabling multipathing with kernel arguments on RHCOS.

Customize your cluster.

If necessary, you can opt out of remote health reporting.

19.3. INSTALLING A CLUSTER ON IBM POWER IN A RESTRICTED NETWORK

In OpenShift Container Platform version 4.14, you can install a cluster on IBM Power® infrastructure that you provision in a restricted network.

**IMPORTANT**

Additional considerations exist for non-bare metal platforms. Review the information in the guidelines for deploying OpenShift Container Platform on non-tested platforms before you install an OpenShift Container Platform cluster.

19.3.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.

- You read the documentation on selecting a cluster installation method and preparing it for users.

- You created a mirror registry for installation in a restricted network and obtained the imageContentSources data for your version of OpenShift Container Platform.

- Before you begin the installation process, you must move or remove any existing installation files. This ensures that the required installation files are created and updated during the installation process.

**IMPORTANT**

Ensure that installation steps are performed on a machine with access to the installation media.

- You provisioned persistent storage using OpenShift Data Foundation or other supported storage protocols for your cluster. To deploy a private image registry, you must set up persistent storage with ReadWriteMany access.

- If you use a firewall and plan to use the Telemetry service, you configured the firewall to allow the sites that your cluster requires access to.

**NOTE**

Be sure to also review this site list if you are configuring a proxy.

19.3.2. About installations in restricted networks

In OpenShift Container Platform 4.14, you can perform an installation that does not require an active connection to the internet to obtain software components. Restricted network installations can be
completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift image registry and contains the installation media. You can create this registry on a mirror host, which can access both the internet and your closed network, or by using other methods that meet your restrictions.

**IMPORTANT**

Because of the complexity of the configuration for user-provisioned installations, consider completing a standard user-provisioned infrastructure installation before you attempt a restricted network installation using user-provisioned infrastructure. Completing this test installation might make it easier to isolate and troubleshoot any issues that might arise during your installation in a restricted network.

19.3.2.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The `ClusterVersion` status includes an *Unable to retrieve available updates* error.

- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

19.3.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to obtain the images that are necessary to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager Hybrid Cloud Console](https://example.com) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- Access [Quay.io](https://example.com) to obtain the packages that are required to install your cluster.

- Obtain the packages that are required to perform cluster updates.

19.3.4. Requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

This section describes the requirements for deploying OpenShift Container Platform on user-provisioned infrastructure.

19.3.4.1. Required machines for cluster installation

The smallest OpenShift Container Platform clusters require the following hosts:

**Table 19.16. Minimum required hosts**
Hosts | Description
--- | ---
One temporary bootstrap machine | The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.
Three control plane machines | The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.
At least two compute machines, which are also known as worker machines. | The workloads requested by OpenShift Container Platform users run on the compute machines.

**IMPORTANT**

To maintain high availability of your cluster, use separate physical hosts for these cluster machines.

The bootstrap, control plane, and compute machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 9.2 and inherits all of its hardware certifications and requirements. See [Red Hat Enterprise Linux technology capabilities and limits](#).

**19.3.4.2. Minimum resource requirements for cluster installation**

Each cluster machine must meet the following minimum requirements:

**Table 19.17. Minimum resource requirements**

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>2</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>2</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS</td>
<td>2</td>
<td>8 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
</tbody>
</table>

1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or hyperthreading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: (threads per core × cores) ÷ sockets = vCPUs.

2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate...
storage volume to obtain sufficient performance.

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

Additional resources

- Optimizing storage

19.3.4.3. Minimum IBM Power requirements

You can install OpenShift Container Platform version 4.14 on the following IBM® hardware:

- IBM Power®9 or IBM Power®10 processor-based systems

NOTE

Support for RHCOS functionality for all IBM Power®8 models, IBM Power® AC922, IBM Power® IC922, and IBM Power® LC922 is deprecated in OpenShift Container Platform 4.14. Red Hat recommends that you use later hardware models.

Hardware requirements

- Six logical partitions (LPARs) across multiple PowerVM servers

Operating system requirements

- One instance of an IBM Power®9 or Power10 processor-based system

On your IBM Power® instance, set up:

- Three LPARs for OpenShift Container Platform control plane machines
- Two LPARs for OpenShift Container Platform compute machines
- One LPAR for the temporary OpenShift Container Platform bootstrap machine

Disk storage for the IBM Power guest virtual machines

- Local storage, or storage provisioned by the Virtual I/O Server using vSCSI, NPIV (N-Port ID Virtualization) or SSP (shared storage pools)

Network for the PowerVM guest virtual machines

- Dedicated physical adapter, or SR-IOV virtual function
- Available by the Virtual I/O Server using Shared Ethernet Adapter
- Virtualized by the Virtual I/O Server using IBM® vNIC

Storage / main memory

- 100 GB / 16 GB for OpenShift Container Platform control plane machines
- 100 GB / 8 GB for OpenShift Container Platform compute machines
- 100 GB / 16 GB for the temporary OpenShift Container Platform bootstrap machine
19.3.4.4. Recommended IBM Power system requirements

Hardware requirements
- Six LPARs across multiple PowerVM servers

Operating system requirements
- One instance of an IBM Power®9 or IBM Power®10 processor-based system

On your IBM Power® instance, set up:
- Three LPARs for OpenShift Container Platform control plane machines
- Two LPARs for OpenShift Container Platform compute machines
- One LPAR for the temporary OpenShift Container Platform bootstrap machine

Disk storage for the IBM Power guest virtual machines
- Local storage, or storage provisioned by the Virtual I/O Server using vSCSI, NPIV (N-Port ID Virtualization) or SSP (shared storage pools)

Network for the PowerVM guest virtual machines
- Dedicated physical adapter, or SR-IOV virtual function
- Available by the Virtual I/O Server using Shared Ethernet Adapter
- Virtualized by the Virtual I/O Server using IBM® vNIC

Storage / main memory
- 120 GB / 32 GB for OpenShift Container Platform control plane machines
- 120 GB / 32 GB for OpenShift Container Platform compute machines
- 120 GB / 16 GB for the temporary OpenShift Container Platform bootstrap machine

19.3.4.5. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The kube-controller-manager only approves the kubelet client CSRs. The machine-approver cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

19.3.4.6. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in initramfs during boot to fetch their Ignition config files.

During the initial boot, the machines require an IP address configuration that is set either through a DHCP server or statically by providing the required boot options. After a network connection is established, the machines download their Ignition config files from an HTTP or HTTPS server. The
Ignition config files are then used to set the exact state of each machine. The Machine Config Operator completes more changes to the machines, such as the application of new certificates or keys, after installation.

It is recommended to use a DHCP server for long-term management of the cluster machines. Ensure that the DHCP server is configured to provide persistent IP addresses, DNS server information, and hostnames to the cluster machines.

**NOTE**

If a DHCP service is not available for your user-provisioned infrastructure, you can instead provide the IP networking configuration and the address of the DNS server to the nodes at RHCOS install time. These can be passed as boot arguments if you are installing from an ISO image. See the *Installing RHCOS and starting the OpenShift Container Platform bootstrap process* section for more information about static IP provisioning and advanced networking options.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

19.3.4.6.1. Setting the cluster node hostnames through DHCP

On Red Hat Enterprise Linux CoreOS (RHCOS) machines, the hostname is set through NetworkManager. By default, the machines obtain their hostname through DHCP. If the hostname is not provided by DHCP, set statically through kernel arguments, or another method, it is obtained through a reverse DNS lookup. Reverse DNS lookup occurs after the network has been initialized on a node and can take time to resolve. Other system services can start prior to this and detect the hostname as localhost or similar. You can avoid this by using DHCP to provide the hostname for each cluster node.

Additionally, setting the hostnames through DHCP can bypass any manual DNS record name configuration errors in environments that have a DNS split-horizon implementation.

19.3.4.6.2. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

**Table 19.18. Ports used for all-machine to all-machine communications**

**NTP configuration for user-provisioned infrastructure**

OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for Configuring chrony time service.

If a DHCP server provides NTP server information, the chrony time service on the Red Hat Enterprise Linux CoreOS (RHCOS) machines read the information and can sync the clock with the NTP servers.

**Additional resources**

- Configuring chrony time service

**19.3.4.7. User-provisioned DNS requirements**
In OpenShift Container Platform deployments, DNS name resolution is required for the following components:

- The Kubernetes API
- The OpenShift Container Platform application wildcard
- The bootstrap, control plane, and compute machines

Reverse DNS resolution is also required for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the hostnames for all the nodes, unless the hostnames are provided by DHCP. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

**NOTE**

It is recommended to use a DHCP server to provide the hostnames to each cluster node. See the DHCP recommendations for user-provisioned infrastructure section for more information.

The following DNS records are required for a user-provisioned OpenShift Container Platform cluster and they must be in place before installation. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>`.

### Table 19.21. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the API load balancer. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td></td>
<td>api-int.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to internally identify the API load balancer. These records must be resolvable from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

The API server must be able to resolve the worker nodes by the hostnames that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.
<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Routes</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>A wildcard DNS A/AAAA or CNAME record that refers to the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster. For example, console-openshift-console.apps.&lt;cluster_name&gt;.&lt;base_domain&gt; is used as a wildcard route to the OpenShift Container Platform console.</td>
</tr>
<tr>
<td>Bootstrap machine</td>
<td>bootstrap.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Control plane machines</td>
<td>&lt;master&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Compute machines</td>
<td>&lt;worker&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**NOTE**

In OpenShift Container Platform 4.4 and later, you do not need to specify etcd host and SRV records in your DNS configuration.

**TIP**

You can use the `dig` command to verify name and reverse name resolution. See the section on Validating DNS resolution for user-provisioned infrastructure for detailed validation steps.

19.3.4.7.1. Example DNS configuration for user-provisioned clusters

This section provides A and PTR record configuration samples that meet the DNS requirements for deploying OpenShift Container Platform on user-provisioned infrastructure. The samples are not meant to provide advice for choosing one DNS solution over another.

In the examples, the cluster name is `ocp4` and the base domain is `example.com`.

**Example DNS A record configuration for a user-provisioned cluster**
The following example is a BIND zone file that shows sample A records for name resolution in a user-provisioned cluster.

Example 19.4. Sample DNS zone database

```
$TTL 1W
@ IN SOA ns1.example.com. root (2019070700 ; serial
3H ; refresh (3 hours)
30M ; retry (30 minutes)
2W ; expiry (2 weeks)
1W ) ; minimum (1 week)
IN NS ns1.example.com.
IN MX 10 smtp.example.com.
;
ns1.example.com.  IN A 192.168.1.5
smtp.example.com.  IN A 192.168.1.5
;
helper.example.com.  IN A 192.168.1.5
helper.ocp4.example.com. IN A 192.168.1.5
;
api.ocp4.example.com. IN A 192.168.1.5 1
api-int.ocp4.example.com. IN A 192.168.1.5 2
;
*.apps.ocp4.example.com. IN A 192.168.1.5 3
;
bootstrap.ocp4.example.com. IN A 192.168.1.96 4

master0.ocp4.example.com. IN A 192.168.1.97 5
master1.ocp4.example.com. IN A 192.168.1.98 6
master2.ocp4.example.com. IN A 192.168.1.99 7
;
worker0.ocp4.example.com. IN A 192.168.1.11 8
worker1.ocp4.example.com. IN A 192.168.1.7 9
;
:EOF
```

1. Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer.

2. Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer and is used for internal cluster communications.

3. Provides name resolution for the wildcard routes. The record refers to the IP address of the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.
NOTE

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

4 Provides name resolution for the bootstrap machine.
5 6 7 Provides name resolution for the control plane machines.
8 9 Provides name resolution for the compute machines.

Example DNS PTR record configuration for a user-provisioned cluster

The following example BIND zone file shows sample PTR records for reverse name resolution in a user-provisioned cluster.

Example 19.5. Sample DNS zone database for reverse records

```
$TTL 1W
@ IN SOA ns1.example.com. root (2019070700 ; serial
3H ; refresh (3 hours)
30M ; retry (30 minutes)
2W ; expiry (2 weeks)
1W ) ; minimum (1 week)
IN NS ns1.example.com.
;
5.1.168.192.in-addr.arpa. IN PTR api.ocp4.example.com. 1
5.1.168.192.in-addr.arpa. IN PTR api-int.ocp4.example.com. 2
;
96.1.168.192.in-addr.arpa. IN PTR bootstrap.ocp4.example.com. 3
;
97.1.168.192.in-addr.arpa. IN PTR master0.ocp4.example.com. 4
98.1.168.192.in-addr.arpa. IN PTR master1.ocp4.example.com. 5
99.1.168.192.in-addr.arpa. IN PTR master2.ocp4.example.com. 6
;
11.1.168.192.in-addr.arpa. IN PTR worker0.ocp4.example.com. 7
7.1.168.192.in-addr.arpa. IN PTR worker1.ocp4.example.com. 8
;
;EOF
```

1 Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer.
2 Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer and is used for internal cluster communications.
3 Provides reverse DNS resolution for the bootstrap machine.
4 5 6 Provides reverse DNS resolution for the control plane machines.
Provides reverse DNS resolution for the compute machines.

**NOTE**

A PTR record is not required for the OpenShift Container Platform application wildcard.

19.3.4.8. Load balancing requirements for user-provisioned infrastructure

Before you install OpenShift Container Platform, you must provision the API and application Ingress load balancing infrastructure. In production scenarios, you can deploy the API and application Ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

**NOTE**

If you want to deploy the API and application Ingress load balancers with a Red Hat Enterprise Linux (RHEL) instance, you must purchase the RHEL subscription separately.

The load balancing infrastructure must meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.
   - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

   **IMPORTANT**

   Do not configure session persistence for an API load balancer. Configuring session persistence for a Kubernetes API server might cause performance issues from excess application traffic for your OpenShift Container Platform cluster and the Kubernetes API that runs inside the cluster.

Configure the following ports on both the front and back of the load balancers:

**Table 19.22. API load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the /readyz endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
</tbody>
</table>
22623
Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>

**NOTE**

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the `/readyz` endpoint to the removal of the API server instance from the pool. Within the time frame after `/readyz` returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application Ingress load balancer**: Provides an ingress point for application traffic flowing in from outside the cluster. A working configuration for the Ingress router is required for an OpenShift Container Platform cluster.

Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

**TIP**

If the true IP address of the client can be seen by the application Ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

Configure the following ports on both the front and back of the load balancers:

**Table 19.23. Application Ingress load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>
If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application Ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

19.3.4.8.1. Example load balancer configuration for user-provisioned clusters

This section provides an example API and application Ingress load balancer configuration that meets the load balancing requirements for user-provisioned clusters. The sample is an `/etc/haproxy/haproxy.cfg` configuration for an HAProxy load balancer. The example is not meant to provide advice for choosing one load balancing solution over another.

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

If you are using HAProxy as a load balancer and SELinux is set to enforcing, you must ensure that the HAProxy service can bind to the configured TCP port by running `setsebool -P haproxy_connect_any=1`.

Example 19.6. Sample API and application Ingress load balancer configuration

```plaintext
global
  log       127.0.0.1 local2
  pidfile   /var/run/haproxy.pid
  maxconn   4000
daemon
defaults
  mode          http
  log           global
  option        dontlognull
  option        http-server-close
  option        redispatch
  retries       3
  timeout http-request 10s
  timeout queue  1m
  timeout connect 10s
  timeout client 1m
  timeout server 1m
  timeout http-keep-alive 10s
  timeout check  10s
  maxconn       3000
listen api-server-6443 1
  bind *:6443
  mode tcp
  server bootstrap bootstrap.ocp4.example.com:6443 check inter 1s backup 2
  server master0 master0.ocp4.example.com:6443 check inter 1s
  server master1 master1.ocp4.example.com:6443 check inter 1s
  server master2 master2.ocp4.example.com:6443 check inter 1s
listen machine-config-server-22623 3
```
Port 6443 handles the Kubernetes API traffic and points to the control plane machines.

The bootstrap entries must be in place before the OpenShift Container Platform cluster installation and they must be removed after the bootstrap process is complete.

Port 22623 handles the machine config server traffic and points to the control plane machines.

Port 443 handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

Port 80 handles the HTTP traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

NOTE

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application Ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

TIP

If you are using HAProxy as a load balancer, you can check that the haproxy process is listening on ports 6443, 22623, 443, and 80 by running netstat -nltupe on the HAProxy node.

19.3.5. Preparing the user-provisioned infrastructure

Before you install OpenShift Container Platform on user-provisioned infrastructure, you must prepare the underlying infrastructure.

This section provides details about the high-level steps required to set up your cluster infrastructure in preparation for an OpenShift Container Platform installation. This includes configuring IP networking and network connectivity for your cluster nodes, enabling the required ports through your firewall, and
setting up the required DNS and load balancing infrastructure.

After preparation, your cluster infrastructure must meet the requirements outlined in the *Requirements for a cluster with user-provisioned infrastructure* section.

**Prerequisites**

- You have reviewed the [OpenShift Container Platform 4.x Tested Integrations](#) page.
- You have reviewed the infrastructure requirements detailed in the *Requirements for a cluster with user-provisioned infrastructure* section.

**Procedure**

1. If you are using DHCP to provide the IP networking configuration to your cluster nodes, configure your DHCP service.
   
   a. Add persistent IP addresses for the nodes to your DHCP server configuration. In your configuration, match the MAC address of the relevant network interface to the intended IP address for each node.

   b. When you use DHCP to configure IP addressing for the cluster machines, the machines also obtain the DNS server information through DHCP. Define the persistent DNS server address that is used by the cluster nodes through your DHCP server configuration.

   **NOTE**

   If you are not using a DHCP service, you must provide the IP networking configuration and the address of the DNS server to the nodes at RHCOS install time. These can be passed as boot arguments if you are installing from an ISO image. See the *Installing RHCOS and starting the OpenShift Container Platform bootstrap process* section for more information about static IP provisioning and advanced networking options.

   c. Define the hostnames of your cluster nodes in your DHCP server configuration. See the *Setting the cluster node hostnames through DHCP* section for details about hostname considerations.

   **NOTE**

   If you are not using a DHCP service, the cluster nodes obtain their hostname through a reverse DNS lookup.

2. Ensure that your network infrastructure provides the required network connectivity between the cluster components. See the *Networking requirements for user-provisioned infrastructure* section for details about the requirements.

3. Configure your firewall to enable the ports required for the OpenShift Container Platform cluster components to communicate. See *Networking requirements for user-provisioned infrastructure* section for details about the ports that are required.
4. Set up the required DNS infrastructure for your cluster.
   a. Configure DNS name resolution for the Kubernetes API, the application wildcard, the bootstrap machine, the control plane machines, and the compute machines.
   b. Configure reverse DNS resolution for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.
      See the User-provisioned DNS requirements section for more information about the OpenShift Container Platform DNS requirements.

5. Validate your DNS configuration.
   a. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses in the responses correspond to the correct components.
   b. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names in the responses correspond to the correct components.
      See the Validating DNS resolution for user-provisioned infrastructure section for detailed DNS validation steps.

6. Provision the required API and application ingress load balancing infrastructure. See the Load balancing requirements for user-provisioned infrastructure section for more information about the requirements.

   **NOTE**

   Some load balancing solutions require the DNS name resolution for the cluster nodes to be in place before the load balancing is initialized.

19.3.6. Validating DNS resolution for user-provisioned infrastructure

You can validate your DNS configuration before installing OpenShift Container Platform on user-provisioned infrastructure.

**IMPORTANT**

The validation steps detailed in this section must succeed before you install your cluster.

**Prerequisites**

- You have configured the required DNS records for your user-provisioned infrastructure.

**Procedure**
1. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses contained in the responses correspond to the correct components.

   a. Perform a lookup against the Kubernetes API record name. Check that the result points to the IP address of the API load balancer:

   ```
   $ dig +noall +answer @<nameserver_ip> api.<cluster_name>.<base_domain>
   # Replace <nameserver_ip> with the IP address of the nameserver, <cluster_name> with your cluster name, and <base_domain> with your base domain name.
   ```

   **Example output**

   ```
   api.ocp4.example.com. 604800 IN A 192.168.1.5
   ```

   b. Perform a lookup against the Kubernetes internal API record name. Check that the result points to the IP address of the API load balancer:

   ```
   $ dig +noall +answer @<nameserver_ip> api-int.<cluster_name>.<base_domain>
   ```

   **Example output**

   ```
   api-int.ocp4.example.com. 604800 IN A 192.168.1.5
   ```

   c. Test an example *.apps.<cluster_name>.<base_domain> DNS wildcard lookup. All of the application wildcard lookups must resolve to the IP address of the application ingress load balancer:

   ```
   $ dig +noall +answer @<nameserver_ip> random.apps.<cluster_name>.<base_domain>
   ```

   **Example output**

   ```
   random.apps.ocp4.example.com. 604800 IN A 192.168.1.5
   ```

   **NOTE**

   In the example outputs, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

   You can replace random with another wildcard value. For example, you can query the route to the OpenShift Container Platform console:

   ```
   $ dig +noall +answer @<nameserver_ip> console-openshift-console.apps.<cluster_name>.<base_domain>
   ```

   **Example output**

   ```
   console-openshift-console.apps.o cp4.example.com. 604800 IN A 192.168.1.5
   ```
d. Run a lookup against the bootstrap DNS record name. Check that the result points to the IP address of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> bootstrap.<cluster_name>.<base_domain>
```

**Example output**

```
bootstrap.ocp4.example.com. 604800 IN A 192.168.1.96
```

e. Use this method to perform lookups against the DNS record names for the control plane and compute nodes. Check that the results correspond to the IP addresses of each node.

2. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names contained in the responses correspond to the correct components.

a. Perform a reverse lookup against the IP address of the API load balancer. Check that the response includes the record names for the Kubernetes API and the Kubernetes internal API:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.5
```

**Example output**

```
5.1.168.192.in-addr.arpa. 604800 IN PTR api-int.ocp4.example.com. 1
5.1.168.192.in-addr.arpa. 604800 IN PTR api.ocp4.example.com. 2
```

1. Provides the record name for the Kubernetes internal API.

2. Provides the record name for the Kubernetes API.

**NOTE**

A PTR record is not required for the OpenShift Container Platform application wildcard. No validation step is needed for reverse DNS resolution against the IP address of the application ingress load balancer.

b. Perform a reverse lookup against the IP address of the bootstrap node. Check that the result points to the DNS record name of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.96
```

**Example output**

```
```

c. Use this method to perform reverse lookups against the IP addresses for the control plane and compute nodes. Check that the results correspond to the DNS record names of each node.
19.3.7. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The ./openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>```

   Specify the path and file name, such as ~/.ssh/id_ed25519, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   ```$ cat <path>/<file_name>.pub```

   For example, run the following to view the ~/.ssh/id_ed25519.pub public key:

   ```$ cat ~/.ssh/id_ed25519.pub```
3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

**NOTE**

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

a. If the `ssh-agent` process is not already running for your local user, start it as a background task:

```bash
$ eval "$(ssh-agent -s)"
```

**Example output**

```
Agent pid 31874
```

**NOTE**

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the `ssh-agent`:

```bash
$ ssh-add <path>/<file_name>
```

Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

**Example output**

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

19.3.8. Manually creating the installation configuration file

**Prerequisites**

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.

- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**
1. Create an installation directory to store your required installation assets in:

   `$ mkdir <installation_directory>`

   **IMPORTANT**

   You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample `install-config.yaml` file template that is provided and save it in the `<installation_directory>`.

   **NOTE**

   You must name this configuration file `install-config.yaml`.

   **NOTE**

   For some platform types, you can alternatively run `./openshift-install create install-config --dir <installation_directory>` to generate an `install-config.yaml` file. You can provide details about your cluster configuration at the prompts.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

   **IMPORTANT**

   The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.

**Additional resources**

- Installation configuration parameters for IBM Power®

**19.3.8.1. Sample install-config.yaml file for IBM Power**

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute:
  - hyperthreading: Enabled
    name: worker
    replicas: 0
    architecture: ppc64le
    controlPlane:
      hyperthreading: Enabled
      name: master
```
The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, -, and the first line of the controlPlane section must not. Only one control plane pool is used.

Specifies whether to enable or disable simultaneous multithreading (SMT), or hyperthreading. By default, SMT is enabled to increase the performance of the cores in your machines. You can disable it by setting the parameter value to Disabled. If you disable SMT, you must disable it in all cluster machines; this includes both control plane and compute machines.

NOTE

Simultaneous multithreading (SMT) is enabled by default. If SMT is not enabled in your BIOS settings, the hyperthreading parameter has no effect.

IMPORTANT

If you disable hyperthreading, whether in the BIOS or in the install-config.yaml file, ensure that your capacity planning accounts for the dramatically decreased machine performance.

You must set this value to 0 when you install OpenShift Container Platform on user-provisioned
NOTE
If you are installing a three-node cluster, do not deploy any compute machines when you install the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

7 The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

8 The cluster name that you specified in your DNS records.

9 A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to access the pods from an external network, you must configure load balancers and routers to manage the traffic.

NOTE
Class E CIDR range is reserved for a future use. To use the Class E CIDR range, you must ensure your networking environment accepts the IP addresses within the Class E CIDR range.

10 The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23, then each node is assigned a /23 subnet out of the given cidr, which allows for 510 \(2^{(32 - 23)} - 2\) pod IP addresses. If you are required to provide access to nodes from an external network, configure load balancers and routers to manage the traffic.

11 The cluster network plugin to install. The supported values are OVNKubernetes and OpenShiftSDN. The default value is OVNKubernetes.

12 The IP address pool to use for service IP addresses. You can enter only one IP address pool. This block must not overlap with existing physical networks. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.

13 You must set the platform to none. You cannot provide additional platform configuration variables for IBM Power® infrastructure.

IMPORTANT
Clusters that are installed with the platform type none are unable to use some features, such as managing compute machines with the Machine API. This limitation applies even if the compute machines that are attached to the cluster are installed on a platform that would normally support the feature. This parameter cannot be changed after installation.

14 Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.
IMPORTANT

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see Installing the system in FIPS mode. When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures.

For `<local_registry>`, specify the registry domain name, and optionally the port, that your mirror registry uses to serve content. For example, `registry.example.com` or `registry.example.com:5000`. For `<credentials>`, specify the base64-encoded user name and password for your mirror registry.

The SSH public key for the `core` user in Red Hat Enterprise Linux CoreOS (RHCOS).

NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

Provide the contents of the certificate file that you used for your mirror registry.

Provide the `imageContentSources` section according to the output of the command that you used to mirror the repository.

IMPORTANT

- When using the `oc adm release mirror` command, use the output from the `imageContentSources` section.
- When using `oc mirror` command, use the `repositoryDigestMirrors` section of the `ImageContentSourcePolicy` file that results from running the command.
- `ImageContentSourcePolicy` is deprecated. For more information see Configuring image registry repository mirroring.

19.3.8.2. Configuring the cluster–wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

Prerequisites

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to
hosting cloud provider APIs. You added sites to the Proxy object’s spec.noProxy field to bypass the proxy if necessary.

**NOTE**

The Proxy object status.noProxy field is populated with the values of the networking.machineNetwork[].cidr, networking.clusterNetwork[].cidr, and networking.serviceNetwork[] fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object status.noProxy field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your install-config.yaml file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port>  # 1
  httpsProxy: https://<username>:<pswd>@<ip>:<port>  # 2
  noProxy: example.com  # 3
additionalTrustBundle: |
  -----BEGIN CERTIFICATE-----<MY_TRUSTED_CA_CERT>-----END CERTIFICATE-----
additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle>  # 5
```

1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.

2. A proxy URL to use for creating HTTPS connections outside the cluster.

3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.

4. If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the trustedCA field of the Proxy object. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

5. Optional: The policy to determine the configuration of the Proxy object to reference the user-ca-bundle config map in the trustedCA field. The allowed values are Proxyonly and Always. Use Proxyonly to reference the user-ca-bundle config map only when http/https proxy is configured. Use Always to always reference the user-ca-bundle config map. The default value is Proxyonly.
NOTE
The installation program does not support the proxy `readinessEndpoints` field.

NOTE
If the installer times out, restart and then complete the deployment by using the `wait-for` command of the installer. For example:

```bash
$ ./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

NOTE
Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

### 19.3.8.3. Configuring a three-node cluster

Optionally, you can deploy zero compute machines in a bare metal cluster that consists of three control plane machines only. This provides smaller, more resource efficient clusters for cluster administrators and developers to use for testing, development, and production.

In three-node OpenShift Container Platform environments, the three control plane machines are schedulable, which means that your application workloads are scheduled to run on them.

#### Prerequisites

- You have an existing `install-config.yaml` file.

#### Procedure

- Ensure that the number of compute replicas is set to 0 in your `install-config.yaml` file, as shown in the following `compute` stanza:

```yaml
compute:
  - name: worker
    platform: {}
    replicas: 0
```
NOTE

You must set the value of the `replicas` parameter for the compute machines to 0 when you install OpenShift Container Platform on user-provisioned infrastructure, regardless of the number of compute machines you are deploying. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. This does not apply to user-provisioned installations, where the compute machines are deployed manually.

For three-node cluster installations, follow these next steps:

- If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes. See the *Load balancing requirements for user-provisioned infrastructure* section for more information.

- When you create the Kubernetes manifest files in the following procedure, ensure that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file is set to `true`. This enables your application workloads to run on the control plane nodes.

- Do not deploy any compute nodes when you create the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

### 19.3.9. Cluster Network Operator configuration

The configuration for the cluster network is specified as part of the Cluster Network Operator (CNO) configuration and stored in a custom resource (CR) object that is named `cluster`. The CR specifies the fields for the `Network` API in the `operator.openshift.io` API group.

The CNO configuration inherits the following fields during cluster installation from the `Network` API in the `Network.config.openshift.io` API group and these fields cannot be changed:

- `clusterNetwork`
  - IP address pools from which pod IP addresses are allocated.

- `serviceNetwork`
  - IP address pool for services.

- `defaultNetwork.type`
  - Cluster network plugin, such as OpenShift SDN or OVN-Kubernetes.

You can specify the cluster network plugin configuration for your cluster by setting the fields for the `defaultNetwork` object in the CNO object named `cluster`.

### 19.3.9.1. Cluster Network Operator configuration object

The fields for the Cluster Network Operator (CNO) are described in the following table:

<p>| Table 19.24. Cluster Network Operator configuration object |</p>
<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>metadata.name</td>
<td>string</td>
<td>The name of the CNO object. This name is always <code>cluster</code>.</td>
</tr>
<tr>
<td>spec.clusterNetwork</td>
<td>array</td>
<td>A list specifying the blocks of IP addresses from which pod IP addresses are allocated and the subnet prefix length assigned to each individual node in the cluster. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>spec:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>clusterNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- cidr: 10.128.0.0/19</td>
</tr>
<tr>
<td></td>

<td>The fields for this object specify the kube-proxy configuration. If you are using the OVN-Kubernetes cluster network plugin, the kube-proxy configuration has no effect.</td>
</tr>
</tbody>
</table>
Either **OpenShiftSDN** or **OVNKubernetes**. The Red Hat OpenShift Networking network plugin is selected during installation. This value cannot be changed after cluster installation.

**NOTE**

OpenShift Container Platform uses the OVN-Kubernetes network plugin by default.

**Configuration for the OpenShift SDN network plugin**

The following table describes the configuration fields for the OpenShift SDN network plugin:

### Table 19.26. openshiftSDNConfig object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>type</strong></td>
<td>string</td>
<td>Either <strong>OpenShiftSDN</strong> or <strong>OVNKubernetes</strong>. The Red Hat OpenShift Networking network plugin is selected during installation. This value cannot be changed after cluster installation.</td>
</tr>
</tbody>
</table>

**NOTE**

OpenShift Container Platform uses the OVN-Kubernetes network plugin by default.

**Configuration for the OpenShift SDN network plugin**

The following table describes the configuration fields for the OpenShift SDN network plugin:

### Table 19.26. openshiftSDNConfig object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>mode</strong></td>
<td>string</td>
<td>Configures the network isolation mode for OpenShift SDN. The default value is <strong>NetworkPolicy</strong>. The values <strong>Multitenant</strong> and <strong>Subnet</strong> are available for backwards compatibility with OpenShift Container Platform 3.x but are not recommended. This value cannot be changed after cluster installation.</td>
</tr>
</tbody>
</table>
The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.

If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.

If your cluster requires different MTU values for different nodes, you must set this value to 50 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1450.

This value cannot be changed after cluster installation.

The port to use for all VXLAN packets. The default value is 4789. This value cannot be changed after cluster installation.

If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number.

On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port 9000 and port 9999.

Example OpenShift SDN configuration

```
defaultNetwork:
  type: OpenShiftSDN
  openshiftSDNConfig:
    mode: NetworkPolicy
    mtu: 1450
    vxlanPort: 4789
```

Configuration for the OVN-Kubernetes network plugin

The following table describes the configuration fields for the OVN-Kubernetes network plugin:

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ovnKubernetesConfig</td>
<td>object</td>
<td></td>
</tr>
</tbody>
</table>

Table 19.27. ovnKubernetesConfig object
### OpenShift Container Platform 4.14 Installing

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mtu</td>
<td>integer</td>
<td>The maximum transmission unit (MTU) for the Geneve (Generic Network Virtualization Encapsulation) overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU. If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes. If your cluster requires different MTU values for different nodes, you must set this value to 100 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1400.</td>
</tr>
<tr>
<td>genevePort</td>
<td>integer</td>
<td>The port to use for all Geneve packets. The default value is 6081. This value cannot be changed after cluster installation.</td>
</tr>
<tr>
<td>ipsecConfig</td>
<td>object</td>
<td>Specify an empty object to enable IPsec encryption.</td>
</tr>
<tr>
<td>policyAuditConfig</td>
<td>object</td>
<td>Specify a configuration object for customizing network policy audit logging. If unset, the defaults audit log settings are used.</td>
</tr>
<tr>
<td>gatewayConfig</td>
<td>object</td>
<td>Optional: Specify a configuration object for customizing how egress traffic is sent to the node gateway.</td>
</tr>
</tbody>
</table>

**NOTE**

While migrating egress traffic, you can expect some disruption to workloads and service traffic until the Cluster Network Operator (CNO) successfully rolls out the changes.
If your existing network infrastructure overlaps with the 100.64.0.0/16 IPv4 subnet, you can specify a different IP address range for internal use by OVN-Kubernetes. You must ensure that the IP address range does not overlap with any other subnet used by your OpenShift Container Platform installation. The IP address range must be larger than the maximum number of nodes that can be added to the cluster. For example, if the `clusterNetwork.cidr` value is 10.128.0.0/14 and the `clusterNetwork.hostPrefix` value is /23, then the maximum number of nodes is $2^{23-14}=512$.

This field cannot be changed after installation.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>v4InternalSubnet</td>
<td>If your existing network infrastructure overlaps with the 100.64.0.0/16 IPv4 subnet, you can specify a different IP address range for internal use by OVN-Kubernetes. You must ensure that the IP address range does not overlap with any other subnet used by your OpenShift Container Platform installation. The IP address range must be larger than the maximum number of nodes that can be added to the cluster. For example, if the <code>clusterNetwork.cidr</code> value is 10.128.0.0/14 and the <code>clusterNetwork.hostPrefix</code> value is /23, then the maximum number of nodes is $2^{23-14}=512$. This field cannot be changed after installation.</td>
<td>The default value is 100.64.0.0/16.</td>
</tr>
</tbody>
</table>
If your existing network infrastructure overlaps with the fd98::/48 IPv6 subnet, you can specify a different IP address range for internal use by OVN-Kubernetes. You must ensure that the IP address range does not overlap with any other subnet used by your OpenShift Container Platform installation. The IP address range must be larger than the maximum number of nodes that can be added to the cluster. This field cannot be changed after installation.

**Table 19.28. policyAuditConfig object**

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rateLimit</td>
<td>integer</td>
<td>The maximum number of messages to generate every second per node. The default value is 20 messages per second.</td>
</tr>
<tr>
<td>maxFileSize</td>
<td>integer</td>
<td>The maximum size for the audit log in bytes. The default value is 50000000 or 50 MB.</td>
</tr>
</tbody>
</table>
One of the following additional audit log targets:

- **libc**
  - The libc `syslog()` function of the journald process on the host.
- **udp:<host>:<port>**
  - A syslog server. Replace `<host>:<port>` with the host and port of the syslog server.
- **unix:<file>**
  - A Unix Domain Socket file specified by `<file>`.
- **null**
  - Do not send the audit logs to any additional target.

The syslog facility, such as kern, as defined by RFC5424. The default value is local0.

### Table 19.29. gatewayConfig object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>routingViaHost</td>
<td>boolean</td>
<td>Set this field to <code>true</code> to send egress traffic from pods to the host networking stack. For highly-specialized installations and applications that rely on manually configured routes in the kernel routing table, you might want to route egress traffic to the host networking stack. By default, egress traffic is processed in OVN to exit the cluster and is not affected by specialized routes in the kernel routing table. The default value is <code>false</code>. This field has an interaction with the Open vSwitch hardware offloading feature. If you set this field to <code>true</code>, you do not receive the performance benefits of the offloading because egress traffic is processed by the host networking stack.</td>
</tr>
<tr>
<td>ipForwarding</td>
<td>object</td>
<td>You can control IP forwarding for all traffic on OVN-Kubernetes managed interfaces by using the <code>ipForwarding</code> specification in the Network resource. Specify <strong>Restricted</strong> to only allow IP forwarding for Kubernetes related traffic. Specify <strong>Global</strong> to allow forwarding of all IP traffic. For new installations, the default is <strong>Restricted</strong>. For updates to OpenShift Container Platform 4.14, the default is <strong>Global</strong>.</td>
</tr>
</tbody>
</table>

**Example OVN-Kubernetes configuration with IPSec enabled**

```yaml
defaultNetwork:
  type: OVNKubernetes
  ovnKubernetesConfig:
    mtu: 1400
    genevePort: 6081
    ipsecConfig: {}
```
kubeProxyConfig object configuration

The values for the kubeProxyConfig object are defined in the following table:

Table 19.30. kubeProxyConfig object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>iptablesSyncPeriod</td>
<td>string</td>
<td>The refresh period for iptables rules. The default value is <strong>30s</strong>. Valid suffixes include <strong>s</strong>, <strong>m</strong>, and <strong>h</strong> and are described in the Go time package documentation.</td>
</tr>
</tbody>
</table>
| proxyArguments.iptables-min-sync-period | array | The minimum duration before refreshing iptables rules. This field ensures that the refresh does not happen too frequently. Valid suffixes include **s**, **m**, and **h** and are described in the Go time package. The default value is:  
```
kubeProxyConfig:  
proxyArguments:  
  iptables-min-sync-period:  
    - 0s  
```

NOTE

Because of performance improvements introduced in OpenShift Container Platform 4.3 and greater, adjusting the iptablesSyncPeriod parameter is no longer necessary.

19.3.10. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.
The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

The installation program that generates the manifest and Ignition files is architecture specific and can be obtained from the client image mirror. The Linux version of the installation program (without an architecture postfix) runs on ppc64le only. This installer program is also available as a Mac OS version.

Prerequisites

- You obtained the OpenShift Container Platform installation program. For a restricted network installation, these files are on your mirror host.
- You created the install-config.yaml installation configuration file.

Procedure

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

   ```
   $ ./openshift-install create manifests --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the installation directory that contains the install-config.yaml file you created.

   **WARNING**

   If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.
IMPORTANT

When you configure control plane nodes from the default unschedulable to schedulable, additional subscriptions are required. This is because control plane nodes then become compute nodes.

2. Check that the `mastersSchedulable` parameter in the 
   `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:
   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.
   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.
   c. Save and exit the file.

3. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

   ```
   $ ./openshift-install create ignition-configs --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the same installation directory.

   Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The `kubeadmin-password` and `kubeconfig` files are created in the `./<installation_directory>/auth` directory:

   ```
   ├── auth
   │   └── kubeadmin-password
   │       └── kubeconfig
   │           └── bootstrap.ign
   │                   └── master.ign
   │                           └── metadata.json
   │                                   └── worker.ign
   ```

19.3.11. Installing RHCOS and starting the OpenShift Container Platform bootstrap process

To install OpenShift Container Platform on IBM Power® infrastructure that you provision, you must install Red Hat Enterprise Linux CoreOS (RHCOS) on the machines. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS machines have rebooted.

Follow either the steps to use an ISO image or network PXE booting to install RHCOS on the machines.

19.3.11.1. Installing RHCOS by using an ISO image

You can use an ISO image to install RHCOS on the machines.
Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have an HTTP server that can be accessed from your computer, and from the machines that you create.
- You have reviewed the Advanced RHCOS installation configuration section for different ways to configure features, such as networking and disk partitioning.

Procedure

1. Obtain the SHA512 digest for each of your Ignition config files. For example, you can use the following on a system running Linux to get the SHA512 digest for your `bootstrap.ign` Ignition config file:

   ```
   $ sha512sum <installation_directory>/bootstrap.ign
   ``

   The digests are provided to the `coreos-installer` in a later step to validate the authenticity of the Ignition config files on the cluster nodes.

2. Upload the bootstrap, control plane, and compute node Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

   **IMPORTANT**

   You can add or change configuration settings in your Ignition configs before saving them to your HTTP server. If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

3. From the installation host, validate that the Ignition config files are available on the URLs. The following example gets the Ignition config file for the bootstrap node:

   ```
   $ curl -k http://<HTTP_server>/bootstrap.ign
   ``

   **Example output**

   ```
   % Total    % Received % Xferd  Average Speed   Time    Time     Time  Current
   Dload  Upload   Total   Spent    Left  Speed
   0  0  0  0  0  0  0  0 --:--:-- --:--:-- --:--:--     0

   "ignition": {
     "version": "3.2.0",
     "passwd": {
       "users": [
         "name": "core",
         "sshAuthorizedKeys": ["ssh-rsa...
   ```

   Replace `bootstrap.ign` with `master.ign` or `worker.ign` in the command to validate that the Ignition config files for the control plane and compute nodes are also available.

4. Although it is possible to obtain the RHCOS images that are required for your preferred method of installing operating system instances from the **RHCOS image mirror** page, the recommended way to obtain the correct version of your RHCOS images are from the output of `openshift-install` command:

   ```
   $ openshift-install coreos print-stream-json | grep ".iso[^\]"
   ```
Example output

"location": "<url>/art/storage/releases/rhcos-4.14-aarch64/<release>/aarch64/rhcos-<release>-live.aarch64.iso",
"location": "<url>/art/storage/releases/rhcos-4.14-ppc64le/<release>/ppc64le/rhcos-<release>-live.ppc64le.iso",
"location": "<url>/art/storage/releases/rhcos-4.14-s390x/<release>/s390x/rhcos-<release>-live.s390x.iso",
"location": "<url>/art/storage/releases/rhcos-4.14/<release>/x86_64/rhcos-<release>-live.x86_64.iso",

IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available. Use only ISO images for this procedure. RHCOS qcow2 images are not supported for this installation type.

ISO file names resemble the following example:

rhcos-<version>-live.<architecture>.iso

5. Use the ISO to start the RHCOS installation. Use one of the following installation options:

- Burn the ISO image to a disk and boot it directly.
- Use ISO redirection by using a lights-out management (LOM) interface.

6. Boot the RHCOS ISO image without specifying any options or interrupting the live boot sequence. Wait for the installer to boot into a shell prompt in the RHCOS live environment.

NOTE

It is possible to interrupt the RHCOS installation boot process to add kernel arguments. However, for this ISO procedure you should use the `coreos-installer` command as outlined in the following steps, instead of adding kernel arguments.

7. Run the `coreos-installer` command and specify the options that meet your installation requirements. At a minimum, you must specify the URL that points to the Ignition config file for the node type, and the device that you are installing to:

   $ sudo coreos-installer install --ignition-url=http://<HTTP_server>/<node_type>.ign <device> --ignition-hash=sha512-<digest>

   1 You must run the `coreos-installer` command by using `sudo`, because the core user does not have the required root privileges to perform the installation.

   2 The `--ignition-hash` option is required when the Ignition config file is obtained through an HTTP URL to validate the authenticity of the Ignition config file on the cluster node. `<digest>` is the Ignition config file SHA512 digest obtained in a preceding step.
NOTE

If you want to provide your Ignition config files through an HTTPS server that uses TLS, you can add the internal certificate authority (CA) to the system trust store before running `coreos-installer`.

The following example initializes a bootstrap node installation to the `/dev/sda` device. The Ignition config file for the bootstrap node is obtained from an HTTP web server with the IP address 192.168.1.2:

```
$ sudo coreos-installer install --ignition-url=http://192.168.1.2:80/installation_directory/bootstrap.ign /dev/sda --ignition-hash=sha512-a5a2d43879223273c9b60af66b44202a1d1248fc01cf156c46d4a79f552b6bad47bc8cc78ddf0116e80c59d2ea9e32ba53bc807afbca581aa059311def2c3e3b
```

8. Monitor the progress of the RHCOS installation on the console of the machine.

IMPORTANT

Be sure that the installation is successful on each node before commencing with the OpenShift Container Platform installation. Observing the installation process can also help to determine the cause of RHCOS installation issues that might arise.

9. After RHCOS installs, you must reboot the system. During the system reboot, it applies the Ignition config file that you specified.

10. Check the console output to verify that Ignition ran.

Example command

```
Ignition: ran on 2022/03/14 14:48:33 UTC (this boot)
Ignition: user-provided config was applied
```

11. Continue to create the other machines for your cluster.

IMPORTANT

You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, also create at least two compute machines before you install OpenShift Container Platform.

If the required network, DNS, and load balancer infrastructure are in place, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS nodes have rebooted.
NOTE

RHCOS nodes do not include a default password for the core user. You can access the nodes by running `ssh core@<node>.<cluster_name>.<base_domain>` as a user with access to the SSH private key that is paired to the public key that you specified in your `install_config.yaml` file. OpenShift Container Platform 4 cluster nodes running RHCOS are immutable and rely on Operators to apply cluster changes. Accessing cluster nodes by using SSH is not recommended. However, when investigating installation issues, if the OpenShift Container Platform API is not available, or the kubelet is not properly functioning on a target node, SSH access might be required for debugging or disaster recovery.

19.3.11.1. Advanced RHCOS installation reference

This section illustrates the networking configuration and other advanced options that allow you to modify the Red Hat Enterprise Linux CoreOS (RHCOS) manual installation process. The following tables describe the kernel arguments and command-line options you can use with the RHCOS live installer and the `coreos-installer` command.

19.3.11.1.1. Networking and bonding options for ISO installations

If you install RHCOS from an ISO image, you can add kernel arguments manually when you boot the image to configure networking for a node. If no networking arguments are specified, DHCP is activated in the initramfs when RHCOS detects that networking is required to fetch the Ignition config file.

IMPORTANT

When adding networking arguments manually, you must also add the `rd.neednet=1` kernel argument to bring the network up in the initramfs.

The following information provides examples for configuring networking and bonding on your RHCOS nodes for ISO installations. The examples describe how to use the `ip=`, `nameserver=`, and `bond=` kernel arguments.

NOTE

Ordering is important when adding the kernel arguments: `ip=`, `nameserver=`, and then `bond=`.

The networking options are passed to the `dracut` tool during system boot. For more information about the networking options supported by `dracut`, see the `dracut.cmdline` manual page.

The following examples are the networking options for ISO installation.

Configuring DHCP or static IP addresses

To configure an IP address, either use DHCP (`ip=dhcp`) or set an individual static IP address (`ip=<host_ip>`). If setting a static IP, you must then identify the DNS server IP address (`nameserver=<dns_ip>`) on each node. The following example sets:

- The node’s IP address to 10.10.10.2
- The gateway address to 10.10.10.254
- The netmask to 255.255.255.0
The hostname to core0.example.com

The DNS server address to 4.4.4.41

The auto-configuration value to none. No auto-configuration is required when IP networking is configured statically.

```
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none
nameserver=4.4.4.41
```

NOTE

When you use DHCP to configure IP addressing for the RHCOS machines, the machines also obtain the DNS server information through DHCP. For DHCP-based deployments, you can define the DNS server address that is used by the RHCOS nodes through your DHCP server configuration.

Configuring an IP address without a static hostname

You can configure an IP address without assigning a static hostname. If a static hostname is not set by the user, it will be picked up and automatically set by a reverse DNS lookup. To configure an IP address without a static hostname refer to the following example:

- The node's IP address to 10.10.10.2
- The gateway address to 10.10.10.254
- The netmask to 255.255.255.0
- The DNS server address to 4.4.4.41
- The auto-configuration value to none. No auto-configuration is required when IP networking is configured statically.

```
ip=10.10.10.2::10.10.10.254:255.255.255.0:enp1s0:none
nameserver=4.4.4.41
```

Specifying multiple network interfaces

You can specify multiple network interfaces by setting multiple `ip=` entries.

```
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none
ip=10.10.10.3::10.10.10.254:255.255.255.0:core0.example.com:enp2s0:none
```

Configuring default gateway and route

Optional: You can configure routes to additional networks by setting an `rd.route=` value.

NOTE

When you configure one or multiple networks, one default gateway is required. If the additional network gateway is different from the primary network gateway, the default gateway must be the primary network gateway.

- Run the following command to configure the default gateway:
Disabling DHCP on a single interface
You can disable DHCP on a single interface, such as when there are two or more network interfaces and only one interface is being used. In the example, the `enp1s0` interface has a static networking configuration and DHCP is disabled for `enp2s0`, which is not used:

```
ip=10.10.10.2::10.10.254:255.255.255.0:core0.example.com:enp1s0:none
ip=:::core0.example.com:enp2s0:none
```

Combining DHCP and static IP configurations
You can combine DHCP and static IP configurations on systems with multiple network interfaces, for example:

```
ip=enp1s0:dhcp
ip=10.10.10.2::10.10.254:255.255.255.0:core0.example.com:enp2s0:none
```

Configuring VLANs on individual interfaces
Optional: You can configure VLANs on individual interfaces by using the `vlan=` parameter.

- To configure a VLAN on a network interface and use a static IP address, run the following command:

```
ip=10.10.10.2::10.10.254:255.255.255.0:core0.example.com:enp2s0.100:enp2s0
vlan=enp2s0.100:enp2s0
```

- To configure a VLAN on a network interface and to use DHCP, run the following command:

```
ip=enp2s0.100:dhcp
vlan=enp2s0.100:enp2s0
```

Providing multiple DNS servers
You can provide multiple DNS servers by adding a `nameserver=` entry for each server, for example:

```
nameserver=1.1.1.1
nameserver=8.8.8.8
```

Bonding multiple network interfaces to a single interface
Optional: You can bond multiple network interfaces to a single interface by using the `bond=` option. Refer to the following examples:

- The syntax for configuring a bonded interface is: `bond=<name>[:<network_interfaces>][:options]`
  
  `<name>` is the bonding device name (`bond0`), `<network_interfaces>` represents a comma-separated list of physical (ethernet) interfaces (`em1,em2`), and `options` is a comma-separated list of bonding options. Enter `modinfo bonding` to see available options.

- When you create a bonded interface using `bond=`, you must specify how the IP address is assigned and other information for the bonded interface.
To configure the bonded interface to use DHCP, set the bond’s IP address to `dhcp`. For example:

```
bond=bond0:em1,em2:mode=active-backup
ip=bond0:dhcp
```

To configure the bonded interface to use a static IP address, enter the specific IP address you want and related information. For example:

```
bond=bond0:em1,em2:mode=active-backup
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:bond0:none
```

Bonding multiple SR-IOV network interfaces to a dual port NIC interface

**IMPORTANT**

Support for Day 1 operations associated with enabling NIC partitioning for SR-IOV devices is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see [Technology Preview Features Support Scope](#).

Optional: You can bond multiple SR-IOV network interfaces to a dual port NIC interface by using the `bond=` option.

On each node, you must perform the following tasks:

1. Create the SR-IOV virtual functions (VFs) following the guidance in [Managing SR-IOV devices](#). Follow the procedure in the "Attaching SR-IOV networking devices to virtual machines" section.

2. Create the bond, attach the desired VFs to the bond and set the bond link state up following the guidance in [Configuring network bonding](#). Follow any of the described procedures to create the bond.

The following examples illustrate the syntax you must use:

- The syntax for configuring a bonded interface is `bond=<name>[:<network_interfaces>] [:options]`. 
  `<name>` is the bonding device name (`bond0`), `<network_interfaces>` represents the virtual functions (VFs) by their known name in the kernel and shown in the output of the `ip link` command (`eno1f0`, `eno2f0`), and `options` is a comma-separated list of bonding options. Enter `modinfo bonding` to see available options.

- When you create a bonded interface using `bond=`, you must specify how the IP address is assigned and other information for the bonded interface.

  - To configure the bonded interface to use DHCP, set the bond’s IP address to `dhcp`. For example:

    ```
    bond=bond0:eno1f0,eno2f0:mode=active-backup
    ip=bond0:dhcp
    ```
To configure the bonded interface to use a static IP address, enter the specific IP address you want and related information. For example:

```
bond=bond0:eno1f0,eno2f0:mode=active-backup
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:bond0:none
```

19.3.11.2. Installing RHCOS by using PXE booting

You can use PXE booting to install RHCOS on the machines.

Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have configured suitable PXE infrastructure.
- You have an HTTP server that can be accessed from your computer, and from the machines that you create.
- You have reviewed the Advanced RHCOS installation configuration section for different ways to configure features, such as networking and disk partitioning.

Procedure

1. Upload the bootstrap, control plane, and compute node Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

   **IMPORTANT**

   You can add or change configuration settings in your Ignition configs before saving them to your HTTP server. If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

2. From the installation host, validate that the Ignition config files are available on the URLs. The following example gets the Ignition config file for the bootstrap node:

   ```bash
   $ curl -k http://<HTTP_server>/bootstrap.ign
   ```

   **Example output**

   Replace `bootstrap.ign` with `master.ign` or `worker.ign` in the command to validate that the Ignition config files for the control plane and compute nodes are also available.

3. Although it is possible to obtain the RHCOS kernel, initramfs and rootfs files that are required for your preferred method of installing operating system instances from the RHCOS image mirror page, the recommended way to obtain the correct version of your RHCOS files are from
the output of `openshift-install` command:

```
$ openshift-install coreos print-stream-json | grep -Eo "https.*\(kernel-|initramfs.|rootfs.)\w+ (.\img)\n"
```

**Example output**

```
"<url>/art/storage/releases/rhcos-4.14-aarch64/<release>/aarch64/rhcos-<release>-live-kernel-aarch64"
"<url>/art/storage/releases/rhcos-4.14-aarch64/<release>/aarch64/rhcos-<release>-live-initramfs.aarch64.img"
"<url>/art/storage/releases/rhcos-4.14-aarch64/<release>/aarch64/rhcos-<release>-live-rootfs.aarch64.img"
"<url>/art/storage/releases/rhcos-4.14-ppc64le/49.84.202110081256-0/ppc64le/rhcos-<release>-live-kernel-ppc64le"
"<url>/art/storage/releases/rhcos-4.14-ppc64le/<release>/ppc64le/rhcos-<release>-live-initramfs.ppc64le.img"
"<url>/art/storage/releases/rhcos-4.14-ppc64le/<release>/ppc64le/rhcos-<release>-live-rootfs.ppc64le.img"
"<url>/art/storage/releases/rhcos-4.14-s390x/<release>/s390x/rhcos-<release>-live-kernel-s390x"
"<url>/art/storage/releases/rhcos-4.14-s390x/<release>/s390x/rhcos-<release>-live-initramfs.s390x.img"
"<url>/art/storage/releases/rhcos-4.14-s390x/<release>/s390x/rhcos-<release>-live-rootfs.s390x.img"
"<url>/art/storage/releases/rhcos-4.14-<release>/x86_64/rhcos-<release>-live-kernel-x86_64"
"<url>/art/storage/releases/rhcos-4.14-<release>/x86_64/rhcos-<release>-live-initramfs.x86_64.img"
"<url>/art/storage/releases/rhcos-4.14-<release>/x86_64/rhcos-<release>-live-rootfs.x86_64.img"
```

**IMPORTANT**

The RHCOS artifacts might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate `kernel`, `initramfs`, and `rootfs` artifacts described below for this procedure. RHCOS QCOW2 images are not supported for this installation type.

The file names contain the OpenShift Container Platform version number. They resemble the following examples:

- **kernel**: `rhcos-<version>-live-kernel-<architecture>`
- **initramfs**: `rhcos-<version>-live-initramfs.<architecture>.img`
- **rootfs**: `rhcos-<version>-live-rootfs.<architecture>.img`

4. Upload the `rootfs`, `kernel`, and `initramfs` files to your HTTP server.
IMPORTANT

If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

5. Configure the network boot infrastructure so that the machines boot from their local disks after RHCOS is installed on them.

6. Configure PXE installation for the RHCOS images and begin the installation.

   Modify the following example menu entry for your environment and verify that the image and Ignition files are properly accessible:

   ```
   DEFAULT pxeboot
   TIMEOUT 20
   PROMPT 0
   LABEL pxeboot
   KERNEL http://<HTTP_server>/rhcos-<version>-live-kernel-<architecture>
   APPEND initrd=http://<HTTP_server>/rhcos-<version>-live-initramfs.<architecture>.img
   coreos.inst.install_dev=/dev/sda coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign
   ```

1. Specify the location of the live kernel file that you uploaded to your HTTP server. The URL must be HTTP, TFTP, or FTP; HTTPS and NFS are not supported.

2. If you use multiple NICs, specify a single interface in the `ip` option. For example, to use DHCP on a NIC that is named `eno1`, set `ip=eno1:dhcp`.

3. Specify the locations of the RHCOS files that you uploaded to your HTTP server. The `initrd` parameter value is the location of the initramfs file, the `coreos.live.roots_url` parameter value is the location of the `rootfs` file, and the `coreos.inst.ignition_url` parameter value is the location of the bootstrap Ignition config file. You can also add more kernel arguments to the `APPEND` line to configure networking or other boot options.

NOTE

This configuration does not enable serial console access on machines with a graphical console. To configure a different console, add one or more `console=` arguments to the `APPEND` line. For example, add `console=ttys0 console=ttys0` to set the first PC serial port as the primary console and the graphical console as a secondary console. For more information, see How does one set up a serial terminal and/or console in Red Hat Enterprise Linux? and “Enabling the serial console for PXE and ISO installation” in the “Advanced RHCOS installation configuration” section.

7. Monitor the progress of the RHCOS installation on the console of the machine.

IMPORTANT

Be sure that the installation is successful on each node before commencing with the OpenShift Container Platform installation. Observing the installation process can also help to determine the cause of RHCOS installation issues that might arise.
8. After RHCOS installs, the system reboots. During reboot, the system applies the Ignition config file that you specified.

9. Check the console output to verify that Ignition ran.

**Example command**

```
Ignition: ran on 2022/03/14 14:48:33 UTC (this boot)
Ignition: user-provided config was applied
```

10. Continue to create the machines for your cluster.

**IMPORTANT**

You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, also create at least two compute machines before you install the cluster.

If the required network, DNS, and load balancer infrastructure are in place, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS nodes have rebooted.

**NOTE**

RHCOS nodes do not include a default password for the `core` user. You can access the nodes by running `ssh core@<node>.<cluster_name>.<base_domain>` as a user with access to the SSH private key that is paired to the public key that you specified in your `install_config.yaml` file. OpenShift Container Platform 4 cluster nodes running RHCOS are immutable and rely on Operators to apply cluster changes. Accessing cluster nodes by using SSH is not recommended. However, when investigating installation issues, if the OpenShift Container Platform API is not available, or the kubelet is not properly functioning on a target node, SSH access might be required for debugging or disaster recovery.

19.3.11.3. Enabling multipathing with kernel arguments on RHCOS

In OpenShift Container Platform version 4.14, during installation, you can enable multipathing for provisioned nodes. RHCOS supports multipathing on the primary disk. Multipathing provides added benefits of stronger resilience to hardware failure to achieve higher host availability.

During the initial cluster creation, you might want to add kernel arguments to all master or worker nodes. To add kernel arguments to master or worker nodes, you can create a `MachineConfig` object and inject that object into the set of manifest files used by Ignition during cluster setup.

**Procedure**

1. Change to the directory that contains the installation program and generate the Kubernetes manifests for the cluster:

   ```
   $ ./openshift-install create manifests --dir <installation_directory>
   ```

2. Decide if you want to add kernel arguments to worker or control plane nodes.
Create a machine config file. For example, create a `99-master-kargs-mpath.yaml` that instructs the cluster to add the `master` label and identify the multipath kernel argument:

```yaml
apiVersion: machineconfiguration.openshift.io/v1
kind: MachineConfig
metadata:
  labels:
    machineconfiguration.openshift.io/role: "master"
name: 99-master-kargs-mpath
spec:
  kernelArguments:
  - 'rd.multipath=default'
  - 'root=/dev/disk/by-label/dm-mpath-root'
```

3. To enable multipathing on worker nodes:

Create a machine config file. For example, create a `99-worker-kargs-mpath.yaml` that instructs the cluster to add the `worker` label and identify the multipath kernel argument:

```yaml
apiVersion: machineconfiguration.openshift.io/v1
kind: MachineConfig
metadata:
  labels:
    machineconfiguration.openshift.io/role: "worker"
name: 99-worker-kargs-mpath
spec:
  kernelArguments:
  - 'rd.multipath=default'
  - 'root=/dev/disk/by-label/dm-mpath-root'
```

You can now continue on to create the cluster.

**IMPORTANT**

Additional postinstallation steps are required to fully enable multipathing. For more information, see “Enabling multipathing with kernel arguments on RHCOS” in Postinstallation machine configuration tasks.

In case of MPIO failure, use the bootlist command to update the boot device list with alternate logical device names. The command displays a boot list and it designates the possible boot devices for when the system is booted in normal mode.

a. To display a boot list and specify the possible boot devices if the system is booted in normal mode, enter the following command:

```
$ bootlist -m normal -o
sda
```

b. To update the boot list for normal mode and add alternate device names, enter the following command:

```
$ bootlist -m normal -o /dev/sdc /dev/sdd /dev/sde
sdc
sdd
```
If the original boot disk path is down, the node reboots from the alternate device registered in the normal boot device list.

### 19.3.12. Waiting for the bootstrap process to complete

The OpenShift Container Platform bootstrap process begins after the cluster nodes first boot into the persistent RHCOS environment that has been installed to disk. The configuration information provided through the Ignition config files is used to initialize the bootstrap process and install OpenShift Container Platform on the machines. You must wait for the bootstrap process to complete.

**Prerequisites**

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have obtained the installation program and generated the Ignition config files for your cluster.
- You installed RHCOS on your cluster machines and provided the Ignition config files that the OpenShift Container Platform installation program generated.

**Procedure**

1. Monitor the bootstrap process:

   ```bash
   $ ./openshift-install --dir <installation_directory> wait-for bootstrap-complete \
   --log-level=info
   ```

   - **1** For `<installation_directory>`, specify the path to the directory that you stored the installation files in.
   - **2** To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

   **Example output**

   ```text
   INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
   INFO API v1.27.3 up
   INFO Waiting up to 30m0s for bootstrapping to complete...
   INFO It is now safe to remove the bootstrap resources
   ```

   The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After the bootstrap process is complete, remove the bootstrap machine from the load balancer.

   **IMPORTANT**

   You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the bootstrap machine itself.
19.3.13. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   system:admin
   ```

19.3.14. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

**Prerequisites**

- You added machines to your cluster.

**Procedure**

1. Confirm that the cluster recognizes the machines:

   ```bash
   $ oc get nodes
   ```

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>64m</td>
<td>v1.27.3</td>
</tr>
</tbody>
</table>
The output lists all of the machines that you created.

NOTE

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

   ```
   $ oc get csr
   
   Example output
   ```

   ```
   NAME    AGE     REQUESTOR                                                                 CONDITION
   csr-8b2br 15m  system:serviceaccount:openshift-machine-config-operator:node-bootstrapper   Pending
   csr-8vnps 15m  system:serviceaccount:openshift-machine-config-operator:node-bootstrapper   Pending
   ...
   ```

   In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

NOTE

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kublet serving certificate requests (CSRs). If a request is not approved, then the `oc exec`, `oc rsh`, and `oc logs` commands cannot succeed, because a serving certificate is required when the API server connects to the kublet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the `node-bootstrapper` service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:
$ oc adm certificate approve <csr_name> ①

① <csr_name> is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs --no-run-if-empty oc adm certificate approve
```

**NOTE**

Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-c57lv</td>
<td>5m26s</td>
<td>system:node:ip-10-0-95-157.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> ①

① <csr_name> is the name of a CSR from the list of current CSRs.
```

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs oc adm certificate approve
```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.27.3</td>
</tr>
</tbody>
</table>
NOTE

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

Additional information

- For more information on CSRs, see [Certificate Signing Requests](#).

### 19.3.15. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

**Prerequisites**

- Your control plane has initialized.

**Procedure**

1. Watch the cluster components come online:

   ```bash
   $ watch -n5 oc get clusteroperators
   ```

**Example output**

<table>
<thead>
<tr>

19.3.15.1. Disabling the default OperatorHub catalog sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

**Procedure**

- Disable the sources for the default catalogs by adding `disableAllDefaultSources: true` to the `OperatorHub` object:

  ```bash
  $ oc patch OperatorHub cluster --type json
  -p '{"op": "add", "path": "/spec/disableAllDefaultSources", "value": true}'
  ```

**TIP**

Alternatively, you can use the web console to manage catalog sources. From the Administration → Cluster Settings → Configuration → OperatorHub page, click the Sources tab, where you can create, update, delete, disable, and enable individual sources.

19.3.15.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the *Recreate* rollout strategy during upgrades.

19.3.15.2.1. Changing the image registry’s management state

To start the image registry, you must change the Image Registry Operator configuration’s `managementState` from **Removed** to **Managed**.

**Procedure**

1. Configure the Operators that are not available.
- Change **managementState** Image Registry Operator configuration from **Removed** to **Managed**. For example:

```
$ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec": {"managementState":"Managed"}}'
```

### 19.3.15.2.2. Configuring registry storage for IBM Power

As a cluster administrator, following installation you must configure your registry to use storage.

**Prerequisites**

- You have access to the cluster as a user with the `cluster-admin` role.
- You have a cluster on IBM Power®.
- You have provisioned persistent storage for your cluster, such as Red Hat OpenShift Data Foundation.

**IMPORTANT**

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. **ReadWriteOnce** access also requires that the registry uses the **Recreate** rollout strategy. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have 100Gi capacity.

**Procedure**

1. To configure your registry to use storage, change the **spec.storage.pvc** in the `configs.imageregistry/cluster` resource.

```
NOTE
When you use shared storage, review your security settings to prevent outside access.
```

2. Verify that you do not have a registry pod:

```
$ oc get pod -n openshift-image-registry -l docker-registry=default
```

**Example output**

```
No resources found in openshift-image-registry namespace
```

**NOTE**

If you do have a registry pod in your output, you do not need to continue with this procedure.
3. Check the registry configuration:

```
$ oc edit configs.imagerepository.operator.openshift.io
```

**Example output**

```
storage:
  pvc:
    claim:
```

Leave the `claim` field blank to allow the automatic creation of an `image-registry-storage` PVC.

4. Check the `clusteroperator` status:

```
$ oc get clusteroperator image-registry
```

**Example output**

```
NAME             VERSION              AVAILABLE   PROGRESSING   DEGRADED   SINCE
MESSAGE
image-registry   4.14                 True        False         False      6h50m
```

5. Ensure that your registry is set to managed to enable building and pushing of images.

- Run:

```
$ oc edit configs.imagerepository/operator.openshift.io
```

Then, change the line

```
managementState: Removed
```

to

```
managementState: Managed
```

### 19.3.15.2.3. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

**Procedure**

- To set the image registry storage to an empty directory:

```
$ oc patch configs.imagerepository.operator.openshift.io cluster --type merge --patch '{"spec": {"storage":{"emptyDir":{}}}}'
```
WARNING

Configure this option for only non-production clusters.

If you run this command before the Image Registry Operator initializes its components, the `oc patch` command fails with the following error:

```
Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
```

Wait a few minutes and run the command again.

19.3.16. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

Prerequisites

- Your control plane has initialized.
- You have completed the initial Operator configuration.

Procedure

1. Confirm that all the cluster components are online with the following command:

```
$ watch -n5 oc get clusteroperators
```

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
<th>SINCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>authentication</td>
<td>4.14.0</td>
<td>True</td>

<td>True</td>
<td>False</td>
<td>False</td>
<td>31m</td>
</tr>
<tr>
<td>ingress</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>30m</td>
</tr>
<tr>
<td>insights</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>31m</td>
</tr>
<tr>
<td>kube-apiserver</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>26m</td>
</tr>
<tr>
<td>kube-controller-manager</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>36m</td>
</tr>
<tr>
<td>kube-scheduler</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>36m</td>
</tr>
<tr>
<td>kube-storage-version-migrator</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>37m</td>
</tr>
<tr>
<td>machine-api</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>29m</td>
</tr>
</tbody>
</table>
Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```
$ ./openshift-install --dir <installation_directory> wait-for install-complete
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

**Example output**

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

2. Confirm that the Kubernetes API server is communicating with the pods.
   a. To view a list of all pods, use the following command:

```
$ oc get pods --all-namespaces
```
Example output

```
<table>
<thead>
<tr>
<th>NAMESPACE</th>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>openshift-apiserver-operator</td>
<td>openshift-apiserver-operator-85cb746d55-zqhs8</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td></td>
<td>Running 9m</td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apiserver-67b9g</td>

<td>Running</td>
</tr>
<tr>
<td></td>
<td>Running 0m</td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apiserver-ljcmx</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td></td>
<td>Running 0m</td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apiserver-z25h4</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td></td>
<td>Running 0m</td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-authentication-operator</td>
<td>authentication-operator-69d5d8bf84-vh2n8</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td></td>
<td>Running 0m</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

b. View the logs for a pod that is listed in the output of the previous command by using the following command:

```
$ oc logs <pod_name> -n <namespace>
```

1 Specify the pod name and namespace, as shown in the output of the previous command.

If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. Additional steps are required to enable multipathing. Do not enable multipathing during installation.
   See “Enabling multipathing with kernel arguments on RHCOS” in the Post-installation machine configuration tasks documentation for more information.

4. Register your cluster on the Cluster registration page.

19.3.17. Next steps

- Enabling multipathing with kernel arguments on RHCOS.
- Customize your cluster.
- If the mirror registry that you used to install your cluster has a trusted CA, add it to the cluster by configuring additional trust stores.
- If necessary, you can opt out of remote health reporting.
- If necessary, see Registering your disconnected cluster.

19.4. INSTALLATION CONFIGURATION PARAMETERS FOR IBM POWER

Before you deploy an OpenShift Container Platform cluster, you provide a customized install-config.yaml installation configuration file that describes the details for your environment.
19.4.1. Available installation configuration parameters for IBM Power

The following tables specify the required, optional, and IBM Power-specific installation configuration parameters that you can set as part of the installation process.

**NOTE**

After installation, you cannot modify these parameters in the `install-config.yaml` file.

19.4.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

**Table 19.31. Required parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion:</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is <code>v1</code>. The installation program may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>baseDomain:</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the <code>baseDomain</code> and <code>metadata.name</code> parameter values that uses the <code>&lt;metadata.name&gt;.&lt;baseDomain&gt;</code> format.</td>
<td>A fully-qualified domain or subdomain name, such as <code>example.com</code>.</td>
</tr>
<tr>
<td>metadata:</td>
<td>Kubernetes resource <code>ObjectMeta</code>, from which only the <code>name</code> parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata:</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of <code>{{.metadata.name}}</code>. <code>{{.baseDomain}}</code>.</td>
<td>String of lowercase letters, hyphens (-), and periods (.), such as <code>dev</code>.</td>
</tr>
</tbody>
</table>
The configuration for the specific platform upon which to perform the installation: `alibabacloud`, `aws`, `baremetal`, `azure`, `gcp`, `ibmcloud`, `nutanix`, `openstack`, `powers`, `vsphere`, or `{}`. For additional information about platform parameters, consult the table for your specific platform that follows.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>platform:</td>
<td>The configuration for the specific platform upon which to perform the installation: <code>alibabacloud</code>, <code>aws</code>, <code>baremetal</code>, <code>azure</code>, <code>gcp</code>, <code>ibmcloud</code>, <code>nutanix</code>, <code>openstack</code>, <code>powers</code>, <code>vsphere</code>, or <code>{}</code>.</td>
<td>Object</td>
</tr>
<tr>
<td>pullSecret:</td>
<td>Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.</td>
<td></td>
</tr>
</tbody>
</table>

```
{
  "auths":{
    "cloud.openshift.com":{
      "auth":"b3Blb=",

    },
    "quay.io":{
      "auth":"b3Blb=",
      "email":"you@example.com"
    }
  }
}
```

### 19.4.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

- If you use the Red Hat OpenShift Networking OVN–Kubernetes network plugin, both IPv4 and IPv6 address families are supported.
- If you use the Red Hat OpenShift Networking OpenShift SDN network plugin, only the IPv4 address family is supported.

If you configure your cluster to use both IP address families, review the following requirements:

- Both IP families must use the same network interface for the default gateway.
- Both IP families must have the default gateway.
- You must specify IPv4 and IPv6 addresses in the same order for all network configuration parameters. For example, in the following configuration IPv4 addresses are listed before IPv6 addresses.

```
networking:
  clusterNetwork:
```
Globalnet is not supported with Red Hat OpenShift Data Foundation disaster recovery solutions. For regional disaster recovery scenarios, ensure that you use a nonoverlapping range of private IP addresses for the cluster and service networks in each cluster.

Table 19.32. Network parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking:</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>

<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td></td>
<td>An IPv4 network.</td>
<td></td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td>networking: clusterNetwork: hostPrefix:</td>
<td>The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given cidr. A hostPrefix value of 23 provides 510 (2^8 - 2) pod IP addresses.</td>
<td>A subnet prefix. The default value is 23.</td>
</tr>
<tr>
<td>networking: serviceNetwork:</td>
<td>The IP address block for services. The default value is 172.30.0.0/16. The OpenShift SDN and OVN-Kubernetes network plugins support only a single IP address block for the service network.</td>
<td>An array with an IP address block in CIDR format. For example: networking: serviceNetwork: - 172.30.0.0/16</td>
</tr>
<tr>
<td>networking: machineNetwork:</td>
<td>The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap. If you specify multiple IP kernel arguments, the machineNetwork.cidr value must be the CIDR of the primary network.</td>
<td>An array of objects. For example: networking: machineNetwork: - cidr: 10.0.0.0/16</td>
</tr>
<tr>
<td>networking: machineNetwork: cidr:</td>
<td>Required if you use networking.machineNetwork. An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt and IBM Power® Virtual Server. For libvirt, the default value is 192.168.126.0/24. For IBM Power® Virtual Server, the default value is 192.168.0.0/24.</td>
<td>An IP network block in CIDR notation. For example, 10.0.0.0/16.</td>
</tr>
</tbody>
</table>

**NOTE**

Set the networking.machineNetwork to match the CIDR that the preferred NIC resides in.

### 19.4.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

Table 19.33. Optional parameters
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle:</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes' trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>capabilities:</td>
<td>Controls the installation of optional core cluster components. You can reduce the footprint of your OpenShift Container Platform cluster by disabling optional components. For more information, see the &quot;Cluster capabilities&quot; page in <em>Installing</em>.</td>
<td>String array</td>
</tr>
<tr>
<td>baselineCapabilitySet:</td>
<td>Selects an initial set of optional capabilities to enable. Valid values are <em>None</em>, <em>v4.11</em>, <em>v4.12</em> and <em>vCurrent</em>. The default value is <em>vCurrent</em>.</td>
<td>String</td>
</tr>
<tr>
<td>capabilities:</td>
<td>Extends the set of optional capabilities beyond what you specify in <em>baselineCapabilitySet</em>. You may specify multiple capabilities in this parameter.</td>
<td>String array</td>
</tr>
<tr>
<td>cpuPartitioningMode:</td>
<td>Enables workload partitioning, which isolates OpenShift Container Platform services, cluster management workloads, and infrastructure pods to run on a reserved set of CPUs. Workload partitioning can only be enabled during installation and cannot be disabled after installation. While this field enables workload partitioning, it does not configure workloads to use specific CPUs. For more information, see the <em>Workload partitioning</em> page in the <em>Scalability and Performance</em> section.</td>
<td><em>None</em> or <em>AllNodes</em>. <em>None</em> is the default value.</td>

<td><code>false</code> or <code>true</code></td>
</tr>
</tbody>
</table>

**IMPORTANT**

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see [Installing the system in FIPS mode](#). When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures.

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.
<table>
<thead>

<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>imageContentSources:</td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects. Includes a source and, optionally, mirrors, as described in the following rows of this table.</td>
</tr>
<tr>
<td>imageContentSources: source:</td>
<td>Required if you use imageContentSources. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td>imageContentSources: mirrors:</td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
<tr>
<td>publish:</td>
<td>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</td>
<td>Internal or External. The default value is External. Setting this field to Internal is not supported on non-cloud platforms. IMPORTANT If the value of the field is set to Internal, the cluster will become non-functional. For more information, refer to BZ#1953035.</td>
</tr>
<tr>
<td>sshKey:</td>
<td>The SSH key to authenticate access to your cluster machines.</td>
<td>For example, sshKey: ssh-ed25519 AAAA...</td>
</tr>
</tbody>
</table>

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.
1. Not all CCO modes are supported for all cloud providers. For more information about CCO modes, see the "Managing cloud provider credentials" entry in the Authentication and authorization content.
CHAPTER 20. INSTALLING ON IBM POWER VIRTUAL SERVER

20.1. PREPARING TO INSTALL ON IBM POWER VIRTUAL SERVER

The installation workflows documented in this section are for IBM Power® Virtual Server infrastructure environments.

20.1.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.

IMPORTANT

IBM Power® Virtual Server using installer-provisioned infrastructure is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see Technology Preview Features Support Scope.

20.1.2. Requirements for installing OpenShift Container Platform on IBM Power Virtual Server

Before installing OpenShift Container Platform on IBM Power® Virtual Server you must create a service account and configure an IBM Cloud® account. See Configuring an IBM Cloud® account for details about creating an account, configuring DNS and supported IBM Power® Virtual Server regions.

You must manually manage your cloud credentials when installing a cluster to IBM Power® Virtual Server. Do this by configuring the Cloud Credential Operator (CCO) for manual mode before you install the cluster.

20.1.3. Choosing a method to install OpenShift Container Platform on IBM Power Virtual Server

You can install OpenShift Container Platform on IBM Power® Virtual Server using installer-provisioned infrastructure. This process involves using an installation program to provision the underlying infrastructure for your cluster. Installing OpenShift Container Platform on IBM Power® Virtual Server using user-provisioned infrastructure is not supported at this time.

See Installation process for more information about installer-provisioned installation processes.

20.1.3.1. Installing a cluster on installer-provisioned infrastructure

You can install a cluster on IBM Power® Virtual Server infrastructure that is provisioned by the OpenShift Container Platform installation program by using one of the following methods:
• **Installing a customized cluster on IBM Power® Virtual Server** You can install a customized cluster on IBM Power® Virtual Server infrastructure that the installation program provisions. The installation program allows for some customization to be applied at the installation stage. Many other customization options are available post-installation.

• **Installing a cluster on IBM Power® Virtual Server into an existing VPC** You can install OpenShift Container Platform on IBM Power® Virtual Server into an existing Virtual Private Cloud (VPC). You can use this installation method if you have constraints set by the guidelines of your company, such as limits when creating new accounts or infrastructure.

• **Installing a private cluster on IBM Power® Virtual Server** You can install a private cluster on IBM Power® Virtual Server. You can use this method to deploy OpenShift Container Platform on an internal network that is not visible to the internet.

• **Installing a cluster on IBM Power® Virtual Server in a restricted network** You can install OpenShift Container Platform on IBM Power® Virtual Server on installer-provisioned infrastructure by using an internal mirror of the installation release content. You can use this method to install a cluster that does not require an active internet connection to obtain the software components.

### 20.1.4. Configuring the Cloud Credential Operator utility

The Cloud Credential Operator (CCO) manages cloud provider credentials as Kubernetes custom resource definitions (CRDs). To install a cluster on IBM Power® Virtual Server, you must set the CCO to manual mode as part of the installation process.

To create and manage cloud credentials from outside of the cluster when the Cloud Credential Operator (CCO) is operating in manual mode, extract and prepare the CCO utility (ccoctl) binary.

**NOTE**

The ccoctl utility is a Linux binary that must run in a Linux environment.

**Prerequisites**

- You have access to an OpenShift Container Platform account with cluster administrator access.
- You have installed the OpenShift CLI (oc).

**Procedure**

1. Obtain the OpenShift Container Platform release image by running the following command:

   ```
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
   ```

2. Obtain the CCO container image from the OpenShift Container Platform release image by running the following command:

   ```
   $ CCO_IMAGE=$(oc adm release info --image-for='cloud-credential-operator' $RELEASE_IMAGE -a ~/.pull-secret)
   ```
NOTE

Ensure that the architecture of the $RELEASE_IMAGE matches the architecture of the environment in which you will use the ccoctl tool.

3. Extract the ccoctl binary from the CCO container image within the OpenShift Container Platform release image by running the following command:

   $ oc image extract $CCO_IMAGE --file="/usr/bin/ccoctl" -a ~/.pull-secret

4. Change the permissions to make ccoctl executable by running the following command:

   $ chmod 775 ccoctl

Verification

- To verify that ccoctl is ready to use, display the help file by running the following command:

   $ ccoctl --help

Output of ccoctl --help

OpenShift credentials provisioning tool

Usage:
   ccoctl [command]

Available Commands:
   alibabacloud Manage credentials objects for alibaba cloud
   aws Manage credentials objects for AWS cloud
   azure Manage credentials objects for Azure
   gcp Manage credentials objects for Google cloud
   help Help about any command
   ibmcloud Manage credentials objects for IBM Cloud
   nutanix Manage credentials objects for Nutanix

Flags:
   -h, --help help for ccoctl

Use "ccoctl [command] --help" for more information about a command.

Additional resources

- Rotating API keys

20.1.5. Next steps

- Configuring an IBM Cloud® account

20.2. CONFIGURING AN IBM CLOUD ACCOUNT

Before you can install OpenShift Container Platform, you must configure an IBM Cloud® account.
IMPORTANT

IBM Power Virtual Server using installer-provisioned infrastructure is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see Technology Preview Features Support Scope.

20.2.1. Prerequisites

- You have an IBM Cloud® account with a subscription. You cannot install OpenShift Container Platform on a free or on a trial IBM Cloud® account.

20.2.2. Quotas and limits on IBM Power Virtual Server

The OpenShift Container Platform cluster uses several IBM Cloud® and IBM Power® Virtual Server components, and the default quotas and limits affect your ability to install OpenShift Container Platform clusters. If you use certain cluster configurations, deploy your cluster in certain regions, or run multiple clusters from your account, you might need to request additional resources for your IBM Cloud® account.

For a comprehensive list of the default IBM Cloud® quotas and service limits, see the IBM Cloud® documentation for Quotas and service limits.

Virtual Private Cloud
Each OpenShift Container Platform cluster creates its own Virtual Private Cloud (VPC). The default quota of VPCs per region is 10. If you have 10 VPCs created, you will need to increase your quota before attempting an installation.

Application load balancer
By default, each cluster creates two application load balancers (ALBs):

- Internal load balancer for the control plane API server
- External load balancer for the control plane API server

You can create additional LoadBalancer service objects to create additional ALBs. The default quota of VPC ALBs are 50 per region. To have more than 50 ALBs, you must increase this quota.

VPC ALBs are supported. Classic ALBs are not supported for IBM Power® Virtual Server.

Cloud connections
There is a limit of two cloud connections per IBM Power® Virtual Server instance. It is recommended that you have only one cloud connection in your IBM Power® Virtual Server instance to serve your cluster.

NOTE

Cloud Connections are no longer supported in dal10. A transit gateway is used instead.

Dynamic Host Configuration Protocol Service
There is a limit of one Dynamic Host Configuration Protocol (DHCP) service per IBM Power® Virtual Server instance.

**Networking**
Due to networking limitations, there is a restriction of one OpenShift cluster installed through IPI per zone per account. This is not configurable.

**Virtual Server Instances**
By default, a cluster creates server instances with the following resources:

- 0.5 CPUs
- 32 GB RAM
- System Type: s922
- Processor Type: uncapped, shared
- Storage Tier: Tier-3

The following nodes are created:

- One bootstrap machine, which is removed after the installation is complete
- Three control plane nodes
- Three compute nodes

For more information, see Creating a Power Systems Virtual Server in the IBM Cloud® documentation.

20.2.3. Configuring DNS resolution

How you configure DNS resolution depends on the type of OpenShift Container Platform cluster you are installing:

- If you are installing a public cluster, you use IBM Cloud® Internet Services (CIS).
- If you are installing a private cluster, you use IBM Cloud® DNS Services (DNS Services).

20.2.4. Using IBM Cloud Internet Services for DNS resolution

The installation program uses IBM Cloud® Internet Services (CIS) to configure cluster DNS resolution and provide name lookup for a public cluster.

**NOTE**

This offering does not support IPv6, so dual stack or IPv6 environments are not possible.

You must create a domain zone in CIS in the same account as your cluster. You must also ensure the zone is authoritative for the domain. You can do this using a root domain or subdomain.

**Prerequisites**

- You have installed the IBM Cloud® CLI.
- You have an existing domain and registrar. For more information, see the IBM® documentation.
Procedure

1. Create a CIS instance to use with your cluster:
   a. Install the CIS plugin:
      
      $ ibmcloud plugin install cis
   
   b. Log in to IBM Cloud® by using the CLI:
      
      $ ibmcloud login
   
   c. Create the CIS instance:
      
      $ ibmcloud cis instance-create <instance_name> standard

   At a minimum, a **Standard** plan is required for CIS to manage the cluster subdomain and its DNS records.

2. Connect an existing domain to your CIS instance:
   a. Set the context instance for CIS:
      
      $ ibmcloud cis instance-set <instance_CRN>

   The instance CRN (Cloud Resource Name). For example: `ibmcloud cis instance-set crn:v1:bluemix:public:power-iaas:osa21:a/65b64c1f1c29460d8c2e4bbfbd893c2c:c09233ac-48a5-4ccb-a051-d1cfd3fc7eb5:`

   b. Add the domain for CIS:
      
      $ ibmcloud cis domain-add <domain_name>

   The fully qualified domain name. You can use either the root domain or subdomain value as the domain name, depending on which you plan to configure.

   **NOTE**

3. Open the **CIS web console**, navigate to the **Overview** page, and note your CIS name servers. These name servers will be used in the next step.

4. Configure the name servers for your domains or subdomains at the domain's registrar or DNS provider. For more information, see the IBM Cloud® documentation.

**20.2.5. IBM Cloud IAM Policies and API Key**
To install OpenShift Container Platform into your IBM Cloud® account, the installation program requires an IAM API key, which provides authentication and authorization to access IBM Cloud® service APIs. You can use an existing IAM API key that contains the required policies or create a new one.

For an IBM Cloud® IAM overview, see the IBM Cloud® documentation.

### 20.2.5.1. Pre-requisite permissions

#### Table 20.1. Pre-requisite permissions

<table>
<thead>
<tr>
<th>Role</th>
<th>Access</th>
</tr>
</thead>
<tbody>
<tr>
<td>Viewer, Operator, Editor, Administrator, Reader, Writer, Manager</td>
<td>Internet Services service in <code>&lt;resource_group&gt;</code> resource group</td>
</tr>
<tr>
<td>Viewer, Operator, Editor, Administrator, User API key creator, Service ID creator</td>
<td>IAM Identity Service service</td>
</tr>
<tr>
<td>Viewer, Operator, Administrator, Editor, Reader, Writer, Manager, Console Administrator</td>
<td>VPC Infrastructure Services service in <code>&lt;resource_group&gt;</code> resource group</td>
</tr>
</tbody>
</table>
| Viewer | Resource Group: Access to view the resource group itself. The resource type should equal `Resource group`, with a value of `<your_resource_group_name>`.

### 20.2.5.2. Cluster-creation permissions

#### Table 20.2. Cluster-creation permissions

<table>
<thead>
<tr>
<th>Role</th>
<th>Access</th>
</tr>
</thead>
<tbody>
<tr>
<td>Viewer</td>
<td><code>&lt;resource_group&gt;</code> (Resource Group Created for Your Team)</td>
</tr>
<tr>
<td>Viewer, Operator, Editor, Reader, Writer, Manager</td>
<td>All service in Default resource group</td>
</tr>
<tr>
<td>Viewer, Reader</td>
<td>Internet Services service</td>
</tr>
<tr>
<td>Viewer, Operator, Reader, Writer, Manager, Content Reader, Object Reader, Object Writer, Editor</td>
<td>Cloud Object Storage service</td>
</tr>
<tr>
<td>Viewer</td>
<td>Default resource group: The resource type should equal <code>Resource group</code>, with a value of <code>Default</code>. If your account administrator changed your account’s default resource group to something other than Default, use that value instead.</td>
</tr>
</tbody>
</table>
### 20.2.5.3. Access policy assignment

In IBM Cloud® IAM, access policies can be attached to different subjects:

- Access group (Recommended)
- Service ID
- User

The recommended method is to define IAM access policies in an access group. This helps organize all the access required for OpenShift Container Platform and enables you to onboard users and service IDs to this group. You can also assign access to users and service IDs directly, if desired.

### 20.2.5.4. Creating an API key

You must create a user API key or a service ID API key for your IBM Cloud® account.

**Prerequisites**

- You have assigned the required access policies to your IBM Cloud® account.
- You have attached your IAM access policies to an access group, or other appropriate resource.

**Procedure**

- Create an API key, depending on how you defined your IAM access policies.
  
  For example, if you assigned your access policies to a user, you must create a user API key. If you assigned your access policies to a service ID, you must create a service ID API key. If your access policies are assigned to an access group, you can use either API key type. For more information on IBM Cloud® API keys, see Understanding API keys.

### 20.2.6. Supported IBM Power Virtual Server regions and zones

You can deploy an OpenShift Container Platform cluster to the following regions:

- dal (Dallas, USA)
You might optionally specify the IBM Cloud® region in which the installer will create any VPC components. Supported regions in IBM Cloud® are:

- **us-east** (Washington DC, USA)
  - us-east

- **eu-de** (Frankfurt, Germany)
  - eu-de-1
  - eu-de-2

- **lon** (London, UK)
  - lon04
  - lon06

- **osa** (Osaka, Japan)
  - osa21

- **sao** (Sao Paulo, Brazil)
  - sao01

- **syd** (Sydney, Australia)
  - syd04

- **tok** (Tokyo, Japan)
  - tok04

- **tor** (Toronto, Canada)
  - tor01
20.2.7. Next steps

- Creating an IBM Power® Virtual Server workspace

20.3. CREATING AN IBM POWER VIRTUAL SERVER WORKSPACE

**IMPORTANT**

IBM Power® Virtual Server using installer-provisioned infrastructure is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see Technology Preview Features Support Scope.

20.3.1. Creating an IBM Power Virtual Server workspace

Use the following procedure to create an IBM Power® Virtual Server workspace.

**Procedure**

1. To create an IBM Power® Virtual Server workspace, complete step 1 to step 5 from the IBM Cloud® documentation for Creating an IBM Power® Virtual Server.

2. After it has finished provisioning, retrieve the 32-character alphanumeric Globally Unique Identifier (GUID) of your new workspace by entering the following command:

   $ ibmcloud resource service-instance <workspace name>

20.3.2. Next steps

- Installing a cluster on IBM Power® Virtual Server with customizations

20.4. INSTALLING A CLUSTER ON IBM POWER VIRTUAL SERVER WITH CUSTOMIZATIONS

In OpenShift Container Platform version 4.14, you can install a customized cluster on infrastructure that the installation program provisions on IBM Power Virtual Server. To customize the installation, you modify parameters in the `install-config.yaml` file before you install the cluster.
20.4.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You configured an IBM Cloud® account to host the cluster.
- If you use a firewall, you configured it to allow the sites that your cluster requires access to.
- You configured the `ccoctl` utility before you installed the cluster. For more information, see Configuring the Cloud Credential Operator utility.

20.4.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager Hybrid Cloud Console to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

20.4.3. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added
to the `~/.ssh/authorized_keys` list for the `core` user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user `core`. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>  
   ```

   **Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.**

2. View the public SSH key:

   ```
   $ cat <path>/<file_name>.pub
   ```

   For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

   ```
   $ cat ~/.ssh/id_ed25519.pub
   ```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

   **NOTE**

   On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

   a. If the `ssh-agent` process is not already running for your local user, start it as a background task:
4. Add your SSH private key to the `ssh-agent`:

```bash
$ ssh-add <path>/<file_name>
```

Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

**Example output**

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

### 20.4.4. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

**Prerequisites**

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

**Procedure**

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.
Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 20.4.5. Exporting the API key

You must set the API key you created as a global variable; the installation program ingests the variable during startup to set the API key.

**Prerequisites**

- You have created either a user API key or service ID API key for your IBM Cloud® account.

**Procedure**

- Export your API key for your account as a global variable:

```
$ export IBMCloud_API_KEY=<api_key>
```

**IMPORTANT**

You must set the variable name exactly as specified; the installation program expects the variable name to be present during startup.

### 20.4.6. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on

**Prerequisites**

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Create the `install-config.yaml` file.

   a. Change to the directory that contains the installation program and run the following command:
For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

When specifying the directory:

- Verify that the directory has the `execute` permission. This permission is required to run Terraform binaries under the installation directory.

- Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

**NOTE**

Always delete the `~/.powervs` directory to avoid reusing a stale configuration. Run the following command:

```
$ rm -rf ~/.powervs
```

b. At the prompts, provide the configuration details for your cloud:

i. Optional: Select an SSH key to use to access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

ii. Select `powervs` as the platform to target.

iii. Select the region to deploy the cluster to.

iv. Select the zone to deploy the cluster to.

v. Select the base domain to deploy the cluster to. The base domain corresponds to the public DNS zone that you created for your cluster.

vi. Enter a descriptive name for your cluster.

2. Modify the `install-config.yaml` file. You can find more information about the available parameters in the "Installation configuration parameters" section.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.
IMPORTANT

The **install-config.yaml** file is consumed during the installation process. If you want to reuse the file, you must back it up now.

Additional resources

- Installation configuration parameters for IBM Power® Virtual Server

### 20.4.6.1. Sample customized install-config.yaml file for IBM Power Virtual Server

You can customize the **install-config.yaml** file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

**IMPORTANT**

This sample YAML file is provided for reference only. You must obtain your **install-config.yaml** file by using the installation program and modify it.

```yaml
apiVersion: v1
baseDomain: example.com
compute:
- architecture: ppc64le
  hyperthreading: Enabled
  name: worker
  platform: {}
  replicas: 3
controlPlane:
- architecture: ppc64le
  hyperthreading: Enabled
  name: master
  platform: {}
  replicas: 3
metadata:
  creationTimestamp: null
  name: example-cluster-name
networking:
  clusterNetwork:
  - cidr: 10.128.0.0/14
    hostPrefix: 23
  machineNetwork:
  - cidr: 192.168.0.0/24
  networkType: OVNKubernetes
  serviceNetwork:
  - 172.30.0.0/16
platform:
powervs:
  userID: ibm-user-id
  region: powervs-region
  zone: powervs-zone
  powervsResourceGroup: "ibmcloud-resource-group"
  serviceInstanceID: "powervs-region-service-instance-id"
vpcRegion : vpc-region
```

---

OpenShift Container Platform 4.14 Installing

---

2832
If you do not provide these parameters and values, the installation program provides the default value.

The `controlPlane` section is a single mapping, but the `compute` section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the `compute` section must begin with a hyphen, `-`, and the first line of the `controlPlane` section must not. Although both sections currently define a single machine pool, it is possible that OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading, or hyperthreading. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to `Disabled`. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.

The cluster network plugin to install. The supported values are `OVNKubernetes` and `OpenShiftSDN`. The default value is `OVNKubernetes`.

The name of an existing resource group.

Required. The installation program prompts you for this value.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

### 20.4.6.2. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**Prerequisites**

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.
NOTE

The Proxy object status.noProxy field is populated with the values of the networking.machineNetwork[].cidr, networking.clusterNetwork[].cidr, and networking.serviceNetwork[] fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object status.noProxy field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your install-config.yaml file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
     httpProxy: http://<username>:<pswd>@<ip>:<port>
     httpsProxy: https://<username>:<pswd>@<ip>:<port>
     noProxy: example.com
     additionalTrustBundle:
       -----BEGIN CERTIFICATE-----
       <MY_TRUSTED_CA_CERT>
       -----END CERTIFICATE-----
     additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle>
   ```

   1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.
   2. A proxy URL to use for creating HTTPS connections outside the cluster.
   3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.
   4. If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the trustedCA field of the Proxy object. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.
   5. Optional: The policy to determine the configuration of the Proxy object to reference the user-ca-bundle config map in the trustedCA field. The allowed values are Proxyonly and Always. Use Proxyonly to reference the user-ca-bundle config map only when http/https proxy is configured. Use Always to always reference the user-ca-bundle config map. The default value is Proxyonly.

NOTE

The installation program does not support the proxy readinessEndpoints field.
NOTE

If the installer times out, restart and then complete the deployment by using the `wait-for` command of the installer. For example:

```
$ ./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

NOTE

Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

20.4.7. Manually creating IAM

Installing the cluster requires that the Cloud Credential Operator (CCO) operate in manual mode. While the installation program configures the CCO for manual mode, you must specify the identity and access management secrets for your cloud provider.

You can use the Cloud Credential Operator (CCO) utility (`ccocctl`) to create the required IBM Cloud® resources.

Prerequisites

- You have configured the `ccocctl` binary.
- You have an existing `install-config.yaml` file.

Procedure

1. Edit the `install-config.yaml` configuration file so that it contains the `credentialsMode` parameter set to `Manual`.

   **Example `install-config.yaml` configuration file**

   ```yaml
   apiVersion: v1
   baseDomain: cluster1.example.com
   credentialsMode: Manual
   compute:
     - architecture: ppc64le
       hyperthreading: Enabled
   
   1 This line is added to set the `credentialsMode` parameter to `Manual`.
   ```

2. To generate the manifests, run the following command from the directory that contains the installation program:
$ openshift-install create manifests --dir <installation_directory>

3. From the directory that contains the installation program, set a $RELEASE_IMAGE variable with the release image from your installation file by running the following command:

   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')

4. Extract the list of CredentialsRequest custom resources (CRs) from the OpenShift Container Platform release image by running the following command:

   $ oc adm release extract \
   --from=$RELEASE_IMAGE \
   --credentials-requests \
   --included \ 1
   --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \ 2
   --to=<path_to_directory_for_credentials_requests> \ 3

   The --included parameter includes only the manifests that your specific cluster configuration requires.

   Specify the location of the install-config.yaml file.

   Specify the path to the directory where you want to store the CredentialsRequest objects. If the specified directory does not exist, this command creates it.

This command creates a YAML file for each CredentialsRequest object.

Sample CredentialsRequest object

```yaml
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
  labels:
    controller-tools.k8s.io: "1.0"
name: openshift-image-registry-ibmcos
namespace: openshift-image-registry-ibmcos-operator
spec:
  secretRef:
    name: installer-cloud-credentials
    namespace: openshift-image-registry
  providerSpec:
    apiVersion: cloudcredential.openshift.io/v1
    kind: IBMCloudProviderSpec
    policies:
      - attributes:
          - name: serviceName
            value: cloud-object-storage
        roles:
          - crn: v1:bluemix:public:iam:::role:Viewer
          - crn: v1:bluemix:public:iam:::role:Operator
          - crn: v1:bluemix:public:iam:::role:Editor
          - crn: v1:bluemix:public:iam:::serviceRole:Reader
          - crn: v1:bluemix:public:iam:::serviceRole:Writer
```
5. Create the service ID for each credential request, assign the policies defined, create an API key, and generate the secret:

```bash
$ ccoctl ibmcloud create-service-id \
   --credentials-requests-dir=<path_to_credential_requests_directory> \
   --name=<cluster_name> \
   --output-dir=<installation_directory> \
   --resource-group-name=<resource_group_name>
```

1. Specify the directory containing the files for the component `CredentialsRequest` objects.
2. Specify the name of the OpenShift Container Platform cluster.
3. Optional: Specify the directory in which you want the `ccoctl` utility to create objects. By default, the utility creates objects in the directory in which the commands are run.
4. Optional: Specify the name of the resource group used for scoping the access policies.

**NOTE**

If your cluster uses Technology Preview features that are enabled by the `TechPreviewNoUpgrade` feature set, you must include the `--enable-tech-preview` parameter.

If an incorrect resource group name is provided, the installation fails during the bootstrap phase. To find the correct resource group name, run the following command:

```bash
$ grep resourceGroup <installation_directory>/manifests/cluster-infrastructure-02-config.yml
```

**Verification**

- Ensure that the appropriate secrets were generated in your cluster’s `manifests` directory.

### 20.4.8. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

**Prerequisites**
• You have configured an account with the cloud platform that hosts your cluster.

• You have the OpenShift Container Platform installation program and the pull secret for your cluster.

• You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.

Procedure

• Change to the directory that contains the installation program and initialize the cluster deployment:

```
$ ./openshift-install create cluster --dir <installation_directory> \ 
   --log-level=info
```

1. For `<installation_directory>`, specify the location of your customized `.install-config.yaml` file.

2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

Verification

When the cluster deployment completes successfully:

• The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the `kubeadmin` user.

• Credential information also outputs to `<installation_directory>/openshift_install.log`.

   IMPORTANT

   Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

Example output

```
... INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export
KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```
20.4.9. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (\texttt{oc}) to interact with OpenShift Container Platform from a command-line interface. You can install \texttt{oc} on Linux, Windows, or macOS.

\section*{IMPORTANT}

If you installed an earlier version of \texttt{oc}, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of \texttt{oc}.

\subsection*{Installing the OpenShift CLI on Linux}

You can install the OpenShift CLI (\texttt{oc}) binary on Linux by using the following procedure.

\section*{Procedure}

2. Select the architecture from the Product Variant drop-down list.

3. Select the appropriate version from the Version drop-down list.

4. Click Download Now next to the OpenShift v4.14 Linux Client entry and save the file.

5. Unpack the archive:

\begin{verbatim}
$ tar xvf <file>
\end{verbatim}

6. Place the \texttt{oc} binary in a directory that is on your \texttt{PATH}.

To check your \texttt{PATH}, execute the following command:

\begin{verbatim}
$ echo $PATH
\end{verbatim}

\section*{Verification}

After you install the OpenShift CLI, it is available using the \texttt{oc} command:

\begin{verbatim}
$ oc <command>
\end{verbatim}
Installing the OpenShift CLI on Windows
You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

Procedure

2. Select the appropriate version from the Version drop-down list.

3. Click Download Now next to the OpenShift v4.14 Windows Client entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the oc binary to a directory that is on your PATH.
   To check your PATH, open the command prompt and execute the following command:

   ```
   C:\> path
   ```

Verification

- After you install the OpenShift CLI, it is available using the oc command:

  ```
  C:\> oc <command>
  ```

Installing the OpenShift CLI on macOS
You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.

Procedure

2. Select the appropriate version from the Version drop-down list.

3. Click Download Now next to the OpenShift v4.14 macOS Client entry and save the file.

4. Unpack and unzip the archive.

5. Move the oc binary to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:

   ```
   $ echo $PATH
   ```

Verification

- After you install the OpenShift CLI, it is available using the oc command:
20.4.10. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

   ```
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig  
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```
   $ oc whoami
   ```

   **Example output**

   ```
   system:admin
   ```

**Additional resources**

- [Accessing the web console](#)

20.4.11. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager Hybrid Cloud Console](#).

After you confirm that your [OpenShift Cluster Manager Hybrid Cloud Console](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use `subscription watch` to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- [About remote health monitoring](#)
20.4.12. Next steps

- Customize your cluster
- If necessary, you can opt out of remote health reporting

**20.5. INSTALLING A CLUSTER ON IBM POWER VIRTUAL SERVER INTO AN EXISTING VPC**

In OpenShift Container Platform version 4.14, you can install a cluster into an existing Virtual Private Cloud (VPC) on IBM Cloud®. The installation program provisions the rest of the required infrastructure, which you can then further customize. To customize the installation, you modify parameters in the `install-config.yaml` file before you install the cluster.

IMPORTANT

IBM Power® Virtual Server using installer-provisioned infrastructure is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see Technology Preview Features Support Scope.

**20.5.1. Prerequisites**

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You configured an IBM Cloud® account to host the cluster.
- If you use a firewall, you configured it to allow the sites that your cluster requires access to.
- You configured the `ccoctl` utility before you installed the cluster. For more information, see Configuring the Cloud Credential Operator utility.

**20.5.2. About using a custom VPC**

In OpenShift Container Platform 4.14, you can deploy a cluster using an existing IBM® Virtual Private Cloud (VPC).

Because the installation program cannot know what other components are in your existing subnets, it cannot choose subnet CIDRs and so forth. You must configure networking for the subnets to which you will install the cluster.

**20.5.2.1. Requirements for using your VPC**

You must correctly configure the existing VPC and its subnets before you install the cluster. The installation program does not create a VPC or VPC subnet in this scenario.
The installation program cannot:

- Subdivide network ranges for the cluster to use
- Set route tables for the subnets
- Set VPC options like DHCP

**NOTE**
The installation program requires that you use the cloud-provided DNS server. Using a custom DNS server is not supported and causes the installation to fail.

### 20.5.2.2. VPC validation

The VPC and all of the subnets must be in an existing resource group. The cluster is deployed to this resource group.

As part of the installation, specify the following in the `install-config.yaml` file:

- The name of the resource group
- The name of VPC
- The name of the VPC subnet

To ensure that the subnets that you provide are suitable, the installation program confirms that all of the subnets you specify exists.

**NOTE**
Subnet IDs are not supported.

### 20.5.2.3. Isolation between clusters

If you deploy OpenShift Container Platform to an existing network, the isolation of cluster services is reduced in the following ways:

- ICMP Ingress is allowed to the entire network.
- TCP port 22 Ingress (SSH) is allowed to the entire network.
- Control plane TCP 6443 Ingress (Kubernetes API) is allowed to the entire network.
- Control plane TCP 22623 Ingress (MCS) is allowed to the entire network.

### 20.5.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager Hybrid Cloud Console](https://console.redhat.com) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 20.5.4. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the `core` user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user `core`. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `/openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N '' -f <path>/<file_name>
   ```

   Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in your `~/.ssh` directory.
NOTE

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   $ cat <path>/<file_name>.pub

   For example, run the following to view the ~/.ssh/id_ed25519.pub public key:

   $ cat ~/.ssh/id_ed25519.pub

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the ./openshift-install gather command.

   NOTE

   On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.

   a. If the ssh-agent process is not already running for your local user, start it as a background task:

      $ eval "$(ssh-agent -s)"

      Example output

      Agent pid 31874

      NOTE

      If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the ssh-agent:

   $ ssh-add <path>/<file_name> 

   Specify the path and file name for your SSH private key, such as ~/.ssh/id_ed25519

   Example output

   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

Next steps
20.5.5. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

   **IMPORTANT**

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   **IMPORTANT**

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ tar -xvf openshift-install-linux.tar.gz
   ```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

20.5.6. Exporting the API key

You must set the API key you created as a global variable; the installation program ingests the variable during startup to set the API key.

Prerequisites
You have created either a user API key or service ID API key for your IBM Cloud® account.

Procedure

- Export your API key for your account as a global variable:

  $ export IBMCLUSTER_API_KEY=<api_key>

**IMPORTANT**

You must set the variable name exactly as specified; the installation program expects the variable name to be present during startup.

### 20.5.7. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on

**Prerequisites**

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Create the `install-config.yaml` file.
   
   a. Change to the directory that contains the installation program and run the following command:

      ```
      $./openshift-install create install-config --dir <installation_directory>  
      ```

      **NOTE**

      For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

      When specifying the directory:

      - Verify that the directory has the `execute` permission. This permission is required to run Terraform binaries under the installation directory.

      - Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

      **NOTE**

      Always delete the `~/.powervs` directory to avoid reusing a stale configuration. Run the following command:

      ```
      $ rm -rf ~/.powervs
      ```
b. At the prompts, provide the configuration details for your cloud:

   i. Optional: Select an SSH key to use to access your cluster machines.

   **NOTE**
   For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

   ii. Enter a descriptive name for your cluster.

2. Modify the `install-config.yaml` file. You can find more information about the available parameters in the "Installation configuration parameters" section.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

   **IMPORTANT**
   The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

**Additional resources**

- Installation configuration parameters for IBM Power® Virtual Server

**20.5.7.1. Minimum resource requirements for cluster installation**

Each cluster machine must meet the following minimum requirements:

**Table 20.3. Minimum resource requirements**

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>

</tr>
</tbody>
</table>

1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or hyperthreading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: \((\text{threads per core} \times \text{cores}) \times \text{sockets} = \text{vCPUs}\).

2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.
3. As with all user-provisioned installations, if you choose to use RHEL compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and has been removed in OpenShift Container Platform 4.10 and later.

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

Additional resources

- Optimizing storage

20.5.7.2. Sample customized install-config.yaml file for IBM Power Virtual Server

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

**IMPORTANT**

This sample YAML file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program and modify it.

```yaml
apiVersion: v1
baseDomain: example.com
compute: 12
- architecture: ppc64le
  hyperthreading: Enabled 3
  name: worker
  platform: {}
  replicas: 3
controlPlane: 45
  architecture: ppc64le
  hyperthreading: Enabled 6
  name: master
  platform: {}
  replicas: 3
metadata:
  creationTimestamp: null
  name: example-cluster-existing-vpc
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14 7
      hostPrefix: 23
  machineNetwork:
    - cidr: 192.168.0.0/24
  networkType: OVNKubernetes 8
  serviceNetwork:
    - 172.30.0.0/16
platform:
  powervs:
    userID: ibm-user-id
  powervsResourceGroup: "ibmcloud-resource-group"
  region: powervs-region
```
If you do not provide these parameters and values, the installation program provides the default value.

The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, -, and the first line of the controlPlane section must not. Both sections currently define a single machine pool. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading, or hyperthreading. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to Disabled. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

The machine CIDR must contain the subnets for the compute machines and control plane machines.

The cluster network plugin to install. The supported values are OVNKubernetes and OpenShiftSDN. The default value is OVNKubernetes.

Specify the name of an existing VPC.

Specify the name of the existing VPC subnet. The subnets must belong to the VPC that you specified. Specify a subnet for each availability zone in the region.

How to publish the user-facing endpoints of your cluster.

Required. The installation program prompts you for this value.

Provide the sshKey value that you use to access the machines in your cluster.

IMPORTANT

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.

NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.
20.5.7.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the install-config.yaml file.

Prerequisites

- You have an existing install-config.yaml file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the Proxy object’s spec.noProxy field to bypass the proxy if necessary.

NOTE

The Proxy object status.noProxy field is populated with the values of the networking.machineNetwork[].cidr, networking.clusterNetwork[].cidr, and networking.serviceNetwork[] fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object status.noProxy field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your install-config.yaml file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port>
  httpsProxy: https://<username>:<pswd>@<ip>:<port>
  noProxy: example.com
  additionalTrustBundle:
    -----BEGIN CERTIFICATE-----
    <MY_TRUSTED_CA_CERT>
    -----END CERTIFICATE-----
    additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle>
```

1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.
2. A proxy URL to use for creating HTTPS connections outside the cluster.
3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example,.y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.
4. If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then
creates a `trusted-ca-bundle` config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the `trustedCA` field of the `Proxy` object. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

Optional: The policy to determine the configuration of the `Proxy` object to reference the `user-ca-bundle` config map in the `trustedCA` field. The allowed values are `Proxyonly` and `Always`. Use `Proxyonly` to reference the `user-ca-bundle` config map only when `http/https` proxy is configured. Use `Always` to always reference the `user-ca-bundle` config map. The default value is `Proxyonly`.

**NOTE**

The installation program does not support the proxy `readinessEndpoints` field.

**NOTE**

If the installer times out, restart and then complete the deployment by using the `wait-for` command of the installer. For example:

```
$ ./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

**NOTE**

Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

### 20.5.8. Manually creating IAM

Installing the cluster requires that the Cloud Credential Operator (CCO) operate in manual mode. While the installation program configures the CCO for manual mode, you must specify the identity and access management secrets for your cloud provider.

You can use the Cloud Credential Operator (CCO) utility (`ccocctl`) to create the required IBM Cloud® resources.

**Prerequisites**

- You have configured the `ccocctl` binary.
- You have an existing `install-config.yaml` file.

**Procedure**

1. Edit the `install-config.yaml` configuration file so that it contains the `credentialsMode` parameter set to `Manual`.

2852
Example install-config.yaml configuration file

```yaml
apiVersion: v1
baseDomain: cluster1.example.com
credentialsMode: Manual

compute:
- architecture: ppc64le
  hyperthreading: Enabled

1. This line is added to set the credentialsMode parameter to Manual.

2. To generate the manifests, run the following command from the directory that contains the installation program:

   ```
   $ openshift-install create manifests --dir <installation_directory>
   ```

3. From the directory that contains the installation program, set a $RELEASE_IMAGE variable with the release image from your installation file by running the following command:

   ```
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
   ```

4. Extract the list of CredentialsRequest custom resources (CRs) from the OpenShift Container Platform release image by running the following command:

   ```
   $ oc adm release extract \
   --from=$RELEASE_IMAGE \
   --credentials-requests \ 
   --included \ 
   --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \ 
   --to=<path_to_directory_for_credentials_requests>
   ```

1. The --included parameter includes only the manifests that your specific cluster configuration requires.

2. Specify the location of the install-config.yaml file.

3. Specify the path to the directory where you want to store the CredentialsRequest objects. If the specified directory does not exist, this command creates it.

   This command creates a YAML file for each CredentialsRequest object.

Sample CredentialsRequest object

```yaml
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
  labels:
    controller-tools.k8s.io: "1.0"
name: openshift-image-registry-ibmcos
namespace: openshift-cloud-credential-operator
spec:
  secretRef:
```
5. Create the service ID for each credential request, assign the policies defined, create an API key, and generate the secret:

```
$ ccoctl ibmcloud create-service-id
    --credentials-requests-dir=<path_to_credential_requests_directory> 1
    --name=<cluster_name> 2
    --output-dir=<installation_directory> 3
    --resource-group-name=<resource_group_name> 4
```

1. Specify the directory containing the files for the component `CredentialsRequest` objects.
2. Specify the name of the OpenShift Container Platform cluster.
3. Optional: Specify the directory in which you want the `ccoctl` utility to create objects. By default, the utility creates objects in the directory in which the commands are run.
4. Optional: Specify the name of the resource group used for scoping the access policies.

**NOTE**

If your cluster uses Technology Preview features that are enabled by the `TechPreviewNoUpgrade` feature set, you must include the `-enable-tech-preview` parameter.

If an incorrect resource group name is provided, the installation fails during the bootstrap phase. To find the correct resource group name, run the following command:

```
$ grep resourceGroup <installation_directory>/manifests/cluster.Infrastructure-02-config.yml
```

**Verification**
• Ensure that the appropriate secrets were generated in your cluster’s manifests directory.

20.5.9. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

IMPORTANT

You can run the create cluster command of the installation program only once, during initial installation.

Prerequisites

• You have configured an account with the cloud platform that hosts your cluster.

• You have the OpenShift Container Platform installation program and the pull secret for your cluster.

• You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.

Procedure

• Change to the directory that contains the installation program and initialize the cluster deployment:

```
$ ./openshift-install create cluster --dir <installation_directory> \  
  --log-level=info  2
```

  1 For `<installation_directory>`, specify the location of your customized `/install-config.yaml` file.

  2 To view different installation details, specify warn, debug, or error instead of info.

Verification

When the cluster deployment completes successfully:

• The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the kubeadmin user.

• Credential information also outputs to `<installation_directory>/openshift_install.log`.

IMPORTANT

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

Example output

```
...  
INFO Install complete!
```
20.5.10. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of oc.

**Installing the OpenShift CLI on Linux**

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

**Procedure**

2. Select the architecture from the Product Variant drop-down list.

3. Select the appropriate version from the Version drop-down list.

4. Click Download Now next to the OpenShift v4.14 Linux Client entry and save the file.

5. Unpack the archive:

   $ tar xvf <file>

6. Place the oc binary in a directory that is on your PATH.

   To check your PATH, execute the following command:
$ echo $PATH

Verification

- After you install the OpenShift CLI, it is available using the oc command:

  $ oc <command>

Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

Procedure

2. Select the appropriate version from the Version drop-down list.

3. Click Download Now next to the OpenShift v4.14 Windows Client entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the oc binary to a directory that is on your PATH.

   To check your PATH, open the command prompt and execute the following command:

     C:> path

Verification

- After you install the OpenShift CLI, it is available using the oc command:

  C:> oc <command>

Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.

Procedure

2. Select the appropriate version from the Version drop-down list.

3. Click Download Now next to the OpenShift v4.14 macOS Client entry and save the file.

4. Unpack and unzip the archive.

5. Move the oc binary to a directory on your PATH.

   To check your PATH, open a terminal and execute the following command:

     $ echo $PATH

NOTE

For macOS arm64, choose the OpenShift v4.14 macOS arm64 Client entry.
$ echo $PATH

Verification

- After you install the OpenShift CLI, it is available using the `oc` command:

  $ oc <command>

20.5.11. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

Procedure

1. Export the `kubeadm` credentials:

   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig

   1 For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   $ oc whoami

   Example output

   system:admin

Additional resources

- Accessing the web console

20.5.12. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager Hybrid Cloud Console.

After you confirm that your OpenShift Cluster Manager Hybrid Cloud Console inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use
subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- About remote health monitoring

20.5.13. Next steps

- Customize your cluster
- Optional: Opt out of remote health reporting

20.6. INSTALLING A PRIVATE CLUSTER ON IBM POWER VIRTUAL SERVER

In OpenShift Container Platform version 4.14, you can install a private cluster into an existing VPC and IBM Power® Virtual Server Workspace. The installation program provisions the rest of the required infrastructure, which you can further customize. To customize the installation, you modify parameters in the `install-config.yaml` file before you install the cluster.

**IMPORTANT**

IBM Power® Virtual Server using installer-provisioned infrastructure is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see [Technology Preview Features Support Scope](#).

20.6.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You configured an IBM Cloud® account to host the cluster.
- If you use a firewall, you configured it to allow the sites that your cluster requires access to.
- You configured the `ccoctl` utility before you installed the cluster. For more information, see [Configuring the Cloud Credential Operator utility](#).

20.6.2. Private clusters

You can deploy a private OpenShift Container Platform cluster that does not expose external endpoints. Private clusters are accessible from only an internal network and are not visible to the internet.
By default, OpenShift Container Platform is provisioned to use publicly-accessible DNS and endpoints. A private cluster sets the DNS, Ingress Controller, and API server to private when you deploy your cluster. This means that the cluster resources are only accessible from your internal network and are not visible to the internet.

**IMPORTANT**

If the cluster has any public subnets, load balancer services created by administrators might be publicly accessible. To ensure cluster security, verify that these services are explicitly annotated as private.

To deploy a private cluster, you must:

- Use existing networking that meets your requirements.
- Create a DNS zone using IBM Cloud® DNS Services and specify it as the base domain of the cluster. For more information, see "Using IBM Cloud® DNS Services to configure DNS resolution".
- Deploy from a machine that has access to:
  - The API services for the cloud to which you provision.
  - The hosts on the network that you provision.
  - The internet to obtain installation media.

You can use any machine that meets these access requirements and follows your company’s guidelines. For example, this machine can be a bastion host on your cloud network or a machine that has access to the network through a VPN.

### 20.6.3. Private clusters in IBM Power Virtual Server

To create a private cluster on IBM Power® Virtual Server, you must provide an existing private Virtual Private Cloud (VPC) and subnets to host the cluster. The installation program must also be able to resolve the DNS records that the cluster requires. The installation program configures the Ingress Operator and API server for only internal traffic.

The cluster still requires access to internet to access the IBM Cloud® APIs.

The following items are not required or created when you install a private cluster:

- Public subnets
- Public network load balancers, which support public Ingress
- A public DNS zone that matches the `baseDomain` for the cluster

You will also need to create an IBM® DNS service containing a DNS zone that matches your `baseDomain`. Unlike standard deployments on Power VS which use IBM® CIS for DNS, you must use IBM® DNS for your DNS service.

### 20.6.3.1. Limitations

Private clusters on IBM Power® Virtual Server are subject only to the limitations associated with the existing VPC that was used for cluster deployment.
20.6.4. Requirements for using your VPC

You must correctly configure the existing VPC and its subnets before you install the cluster. The installation program does not create a VPC or VPC subnet in this scenario.

The installation program cannot:

- Subdivide network ranges for the cluster to use
- Set route tables for the subnets
- Set VPC options like DHCP

**NOTE**

The installation program requires that you use the cloud-provided DNS server. Using a custom DNS server is not supported and causes the installation to fail.

20.6.4.1. VPC validation

The VPC and all of the subnets must be in an existing resource group. The cluster is deployed to this resource group.

As part of the installation, specify the following in the `install-config.yaml` file:

- The name of the resource group
- The name of VPC
- The name of the VPC subnet

To ensure that the subnets that you provide are suitable, the installation program confirms that all of the subnets you specify exists.

**NOTE**

Subnet IDs are not supported.

20.6.4.2. Isolation between clusters

If you deploy OpenShift Container Platform to an existing network, the isolation of cluster services is reduced in the following ways:

- ICMP Ingress is allowed to the entire network.
- TCP port 22 Ingress (SSH) is allowed to the entire network.
- Control plane TCP 6443 Ingress (Kubernetes API) is allowed to the entire network.
- Control plane TCP 22623 Ingress (MCS) is allowed to the entire network.

20.6.5. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:
- Access OpenShift Cluster Manager Hybrid Cloud Console to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- Access Quay.io to obtain the packages that are required to install your cluster.

- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 20.6.6. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the `core` user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user `core`. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> 1
   ```

   Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.
2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

```
$ cat ~/.ssh/id_ed25519.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `/openshift-install gather` command.

**NOTE**

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

a. If the `ssh-agent` process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

**Example output**

```
Agent pid 31874
```

4. Add your SSH private key to the `ssh-agent`:

```
$ ssh-add <path>/<file_name> 1
```

Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

**Example output**

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

**20.6.7. Obtaining the installation program**

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

**Prerequisites**

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.
Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

   **IMPORTANT**
   
   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   **IMPORTANT**
   
   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ tar -xvf openshift-install-linux.tar.gz
   ```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

20.6.8. Exporting the API key

You must set the API key you created as a global variable; the installation program ingests the variable during startup to set the API key.

**Prerequisites**

- You have created either a user API key or service ID API key for your IBM Cloud® account.

**Procedure**

- Export your API key for your account as a global variable:

  ```
  $ export IBMCL oud_API_KEY=<api_key>
  ```
**20.6.9. Manually creating the installation configuration file**

When installing a private OpenShift Container Platform cluster, you must manually generate the installation configuration file.

**Prerequisites**

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.
- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Create an installation directory to store your required installation assets in:

   ```bash
   $ mkdir <installation_directory>
   ```

   **IMPORTANT**

   You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample `install-config.yaml` file template that is provided and save it in the `<installation_directory>`.

   **NOTE**

   You must name this configuration file `install-config.yaml`.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

   **IMPORTANT**

   The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.

**Additional resources**

- Installation configuration parameters for IBM Power® Virtual Server
20.6.9.1. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

Table 20.4. Minimum resource requirements

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>

</tbody>
</table>

1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or hyperthreading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: \((\text{threads per core} \times \text{cores}) \times \text{sockets} = \text{vCPUs}\).

2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

Additional resources

- Optimizing storage

20.6.9.2. Sample customized install-config.yaml file for IBM Power Virtual Server

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

**IMPORTANT**

This sample YAML file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program and modify it.

```yaml
apiVersion: v1
baseDomain: example.com
compute: 1 2
- architecture: ppc64le
  hyperthreading: Enabled 3
name: worker
platform: {}
replicas: 3
controlPlane: 4 5
architecture: ppc64le
```
hyperthreading: Enabled
name: master
platform: {}
replicas: 3
metadata:
  creationTimestamp: null
name: example-private-cluster-name
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
  hostPrefix: 23
machineNetwork:
  - cidr: 192.168.0.0/24
networkType: OVNKubernetes
serviceNetwork:
  - 172.30.0.0/16
platform:
powervs:
  userID: ibm-user-id
  powervsResourceGroup: "ibmcloud-resource-group"
  region: powervs-region
  vpcName: name-of-existing-vpc
  cloudConnectionName: powervs-region-example-cloud-con-priv
  vpcSubnets:
    - powervs-region-example-subnet-1
  vpcRegion : vpc-region
  zone: powervs-zone
  serviceInstanceID: "powervs-region-service-instance-id"
publish: Internal
  pullSecret: '{"auths": ...}'
  sshKey: ssh-ed25519 AAAA...

1. If you do not provide these parameters and values, the installation program provides the default value.

2. The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, -, and the first line of the controlPlane section must not. Both sections currently define a single machine pool. Only one control plane pool is used.

3. Whether to enable or disable simultaneous multithreading, or hyperthreading. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to Disabled. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

4. The machine CIDR must contain the subnets for the compute machines and control plane machines.

5. The cluster network plugin to install. The supported values are OVNKubernetes and OpenShiftSDN. The default value is OVNKubernetes.

6. Specify the name of an existing VPC.

7. How to publish the user-facing endpoints of your cluster. Set publish to Internal to deploy a private cluster.
11. Required. The installation program prompts you for this value.

12. Provide the sshKey value that you use to access the machines in your cluster.

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

### 20.6.9.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**Prerequisites**

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

**Procedure**

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port> 1
  httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
  noProxy: example.com 3
  additionalTrustBundle: | 4
```
-----BEGIN CERTIFICATE-----
<MY_TRUSTED_CA_CERT>
-----END CERTIFICATE-----

A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.

A proxy URL to use for creating HTTPS connections outside the cluster.

A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.

If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the trustedCA field of the Proxy object. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

Optional: The policy to determine the configuration of the Proxy object to reference the user-ca-bundle config map in the trustedCA field. The allowed values are Proxyonly and Always. Use Proxyonly to reference the user-ca-bundle config map only when http/https proxy is configured. Use Always to always reference the user-ca-bundle config map. The default value is Proxyonly.

NOTE
The installation program does not support the proxy readinessEndpoints field.

NOTE
If the installer times out, restart and then complete the deployment by using the wait-for command of the installer. For example:

$ ./openshift-install wait-for install-complete --log-level debug

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

NOTE
Only the Proxy object named cluster is supported, and no additional proxies can be created.

20.6.10. Manually creating IAM
Installing the cluster requires that the Cloud Credential Operator (CCO) operate in manual mode. While the installation program configures the CCO for manual mode, you must specify the identity and access management secrets for your cloud provider.

You can use the Cloud Credential Operator (CCO) utility (ccoctl) to create the required IBM Cloud® resources.

Prerequisites

- You have configured the ccoctl binary.
- You have an existing install-config.yaml file.

Procedure

1. Edit the install-config.yaml configuration file so that it contains the credentialsMode parameter set to Manual.

   Example install-config.yaml configuration file

   ```yaml
   apiVersion: v1
   baseDomain: cluster1.example.com
   credentialsMode: Manual
   compute:
     - architecture: ppc64le
   hyperthreading: Enabled
   
   1 This line is added to set the credentialsMode parameter to Manual.
   
2. To generate the manifests, run the following command from the directory that contains the installation program:

   ```bash
   $ openshift-install create manifests --dir <installation_directory>
   
   3
   
3. From the directory that contains the installation program, set a $RELEASE_IMAGE variable with the release image from your installation file by running the following command:

   ```bash
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
   
   4
   
4. Extract the list of CredentialsRequest custom resources (CRs) from the OpenShift Container Platform release image by running the following command:

   ```bash
   $ oc adm release extract \
   --from=$RELEASE_IMAGE \
   --credentials-requests \
   --included \
       --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \n   --to=<path_to_directory_for_credentials_requests>
   
   1 The --included parameter includes only the manifests that your specific cluster configuration requires.
Specify the location of the `install-config.yaml` file.

Specify the path to the directory where you want to store the `CredentialsRequest` objects. If the specified directory does not exist, this command creates it.

This command creates a YAML file for each `CredentialsRequest` object.

### Sample CredentialsRequest object

```yaml
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
  labels:
    controller-tools.k8s.io: "1.0"
  name: openshift-image-registry-ibmcos
  namespace: openshift-cloud-credential-operator
spec:
  secretRef:
  name: installer-cloud-credentials
  namespace: openshift-image-registry
providerSpec:
  apiVersion: cloudcredential.openshift.io/v1
  kind: IBMCloudProviderSpec
  policies:
    - attributes:
      - name: serviceName
        value: cloud-object-storage
      roles:
        - crn: v1:bluemix:public:iam::::role:Viewer
        - crn: v1:bluemix:public:iam::::role:Operator
        - crn: v1:bluemix:public:iam::::role:Editor
        - crn: v1:bluemix:public:iam::::serviceRole:Reader
        - crn: v1:bluemix:public:iam::::serviceRole:Writer
    - attributes:
      - name: resourceType
        value: resource-group
      roles:
        - crn: v1:bluemix:public:iam::::role:Viewer
```

5. Create the service ID for each credential request, assign the policies defined, create an API key, and generate the secret:

```
$ ccoctl ibmcloud create-service-id \
  --credentials-requests-dir=<path_to_credential_requests_directory> \
  --name=<cluster_name> \
  --output-dir=<installation_directory> \
  --resource-group-name=<resource_group_name>
```

1. Specify the directory containing the files for the component `CredentialsRequest` objects.
2. Specify the name of the OpenShift Container Platform cluster.
3. Optional: Specify the directory in which you want the `ccoctl` utility to create objects. By default, the utility creates objects in the directory in which the commands are run.
Optional: Specify the name of the resource group used for scoping the access policies.

**NOTE**

If your cluster uses Technology Preview features that are enabled by the `TechPreviewNoUpgrade` feature set, you must include the `--enable-tech-preview` parameter.

If an incorrect resource group name is provided, the installation fails during the bootstrap phase. To find the correct resource group name, run the following command:

```
$ grep resourceGroup <installation_directory>/manifests/cluster-infrastructure-02-config.yml
```

**Verification**

- Ensure that the appropriate secrets were generated in your cluster’s manifests directory.

### 20.6.11. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

**Prerequisites**

- You have configured an account with the cloud platform that hosts your cluster.
- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.

**Procedure**

- Change to the directory that contains the installation program and initialize the cluster deployment:

  ```bash
  $ ./openshift-install create cluster --dir <installation_directory> \ 1
  --log-level=info 2
  ```

  1. For `<installation_directory>`, specify the location of your customized `./install-config.yaml` file.
  2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.  

2872
Verification

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the **kubeadmin** user.

- Credential information also outputs to `<installation_directory>/.openshift_install.log`.

**IMPORTANT**

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

Example output

```
... INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for **Recovering from expired control plane certificates** for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

20.6.12. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of **oc**.

Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.
Procedure

2. Select the architecture from the Product Variant drop-down list.

3. Select the appropriate version from the Version drop-down list.

4. Click Download Now next to the OpenShift v4.14 Linux Client entry and save the file.

5. Unpack the archive:

   ```
   $ tar xvf <file>
   ```

6. Place the oc binary in a directory that is on your PATH.
   To check your PATH, execute the following command:

   ```
   $ echo $PATH
   ```

Verification

- After you install the OpenShift CLI, it is available using the oc command:

  ```
  $ oc <command>
  ```

Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

Procedure

2. Select the appropriate version from the Version drop-down list.

3. Click Download Now next to the OpenShift v4.14 Windows Client entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the oc binary to a directory that is on your PATH.
   To check your PATH, open the command prompt and execute the following command:

   ```
   C:\> path
   ```

Verification

- After you install the OpenShift CLI, it is available using the oc command:

  ```
  C:\> oc <command>
  ```

Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.
Procedure

2. Select the appropriate version from the Version drop-down list.

3. Click Download Now next to the OpenShift v4.14 macOS Client entry and save the file.

   NOTE
   For macOS arm64, choose the OpenShift v4.14 macOS arm64 Client entry.

4. Unpack and unzip the archive.

5. Move the oc binary to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:

   ```
   $ echo $PATH
   ```

Verification

- After you install the OpenShift CLI, it is available using the oc command:

  ```
  $ oc <command>
  ```

20.6.13. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster kubeconfig file. The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.

- You installed the oc CLI.

Procedure

1. Export the kubeadmin credentials:

   ```
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For <installation_directory>, specify the path to the directory that you stored the installation files in.

2. Verify you can run oc commands successfully using the exported configuration:

   ```
   $ oc whoami
   ```
Example output

- system:admin

Additional resources

- Accessing the web console

20.6.14. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager Hybrid Cloud Console.

After you confirm that your OpenShift Cluster Manager Hybrid Cloud Console inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- About remote health monitoring

20.6.15. Next steps

- Customize your cluster
- Optional: Opt out of remote health reporting

20.7. INSTALLING A CLUSTER ON IBM POWER VIRTUAL SERVER IN A RESTRICTED NETWORK

In OpenShift Container Platform 4.14, you can install a cluster on IBM Cloud® in a restricted network by creating an internal mirror of the installation release content on an existing Virtual Private Cloud (VPC) on IBM Cloud®.

IMPORTANT

IBM Power® Virtual Server using installer-provisioned infrastructure is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see Technology Preview Features Support Scope.

20.7.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
You read the documentation on selecting a cluster installation method and preparing it for users.

You configured an IBM Cloud® account to host the cluster.

You mirrored the images for a disconnected installation to your registry and obtained the imageContentSources data for your version of OpenShift Container Platform.

**IMPORTANT**

Because the installation media is on the mirror host, you can use that computer to complete all installation steps.

You have an existing VPC in IBM Cloud®. When installing a cluster in a restricted network, you cannot use the installer-provisioned VPC. You must use a user-provisioned VPC that satisfies one of the following requirements:

- Contains the mirror registry
- Has firewall rules or a peering connection to access the mirror registry hosted elsewhere

If you use a firewall, you configured it to allow the sites that your cluster requires access to.

You configured the ccoctl utility before you installed the cluster. For more information, see Configuring the Cloud Credential Operator utility.

### 20.7.2. About installations in restricted networks

In OpenShift Container Platform 4.14, you can perform an installation that does not require an active connection to the internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service’s Route 53 DNS and IAM services, require internet access. Depending on your network, you might require less internet access for an installation on bare metal hardware, Nutanix, or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift image registry and contains the installation media. You can create this registry on a mirror host, which can access both the internet and your closed network, or by using other methods that meet your restrictions.

#### 20.7.2.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The ClusterVersion status includes an Unable to retrieve available updates error.

- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

### 20.7.3. About using a custom VPC
In OpenShift Container Platform 4.14, you can deploy a cluster into the subnets of an existing IBM® Virtual Private Cloud (VPC).

### 20.7.3.1. Requirements for using your VPC

You must correctly configure the existing VPC and its subnets before you install the cluster. The installation program does not create a VPC or VPC subnet in this scenario.

The installation program cannot:

- Subdivide network ranges for the cluster to use
- Set route tables for the subnets
- Set VPC options like DHCP

**NOTE**

The installation program requires that you use the cloud-provided DNS server. Using a custom DNS server is not supported and causes the installation to fail.

### 20.7.3.2. VPC validation

The VPC and all of the subnets must be in an existing resource group. The cluster is deployed to this resource group.

As part of the installation, specify the following in the `install-config.yaml` file:

- The name of the resource group
- The name of VPC
- The name of the VPC subnet

To ensure that the subnets that you provide are suitable, the installation program confirms that all of the subnets you specify exists.

**NOTE**

Subnet IDs are not supported.

### 20.7.3.3. Isolation between clusters

If you deploy OpenShift Container Platform to an existing network, the isolation of cluster services is reduced in the following ways:

- ICMP Ingress is allowed to the entire network.
- TCP port 22 Ingress (SSH) is allowed to the entire network.
- Control plane TCP 6443 Ingress (Kubernetes API) is allowed to the entire network.
- Control plane TCP 22623 Ingress (MCS) is allowed to the entire network.

### 20.7.4. Internet access for OpenShift Container Platform
In OpenShift Container Platform 4.14, you require access to the internet to obtain the images that are necessary to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager Hybrid Cloud Console to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

20.7.5. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The ./openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>  
   ```

   Specify the path and file name, such as ~/.ssh/id_ed25519, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

2. View the public SSH key:

   ```bash
   $ cat <path>/<file_name>.pub
   ```
For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

```
$ cat ~/.ssh/id_ed25519.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

**NOTE**

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

a. If the `ssh-agent` process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

**Example output**

Agent pid 31874

4. Add your SSH private key to the `ssh-agent`:

```
$ ssh-add <path>/<file_name>
```

Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

**Example output**

Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

**20.7.6. Exporting the API key**

You must set the API key you created as a global variable; the installation program ingests the variable during startup to set the API key.

**Prerequisites**

- You have created either a user API key or service ID API key for your IBM Cloud® account.

**Procedure**

- Export your API key for your account as a global variable:

  ```
  $ export IBMCLoud_API_KEY=<api_key>
  ```
IMPORTANT

You must set the variable name exactly as specified; the installation program expects the variable name to be present during startup.

20.7.7. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on

Prerequisites

- You have the OpenShift Container Platform installation program and the pull secret for your cluster. For a restricted network installation, these files are on your mirror host.
- You have the `imageContentSources` values that were generated during mirror registry creation.
- You have obtained the contents of the certificate for your mirror registry.
- You have retrieved a Red Hat Enterprise Linux CoreOS (RHCOS) image and uploaded it to an accessible location.

Procedure

1. Create the `install-config.yaml` file.
   a. Change to the directory that contains the installation program and run the following command:

```
$ ./openshift-install create install-config --dir <installation_directory> 1
```

   **NOTE**
   
   Always delete the `~/.powervs` directory to avoid reusing a stale configuration. Run the following command:

```
$ rm -rf ~/.powervs
```
b. At the prompts, provide the configuration details for your cloud:
   
i. Optional: Select an SSH key to use to access your cluster machines.

   **NOTE**

   For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

   ii. Select `powervs` as the platform to target.

   iii. Select the region to deploy the cluster to.

   iv. Select the zone to deploy the cluster to.

   v. Select the base domain to deploy the cluster to. The base domain corresponds to the public DNS zone that you created for your cluster.

   vi. Enter a descriptive name for your cluster.

2. Edit the `install-config.yaml` file to give the additional information that is required for an installation in a restricted network.

   a. Update the `pullSecret` value to contain the authentication information for your registry:

   ```yaml
   pullSecret: 
   "{"auths":{"<mirror_host_name>:5000": {"auth": ";<credentials>"","email": ";you@example.com"}}}
   
   For `<mirror_host_name>`, specify the registry domain name that you specified in the certificate for your mirror registry, and for `<credentials>`, specify the base64-encoded user name and password for your mirror registry.

   b. Add the `additionalTrustBundle` parameter and value.

   ```yaml
   additionalTrustBundle:
   -----BEGIN CERTIFICATE-----
   ZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZ
   -----END CERTIFICATE-----

   The value must be the contents of the certificate file that you used for your mirror registry. The certificate file can be an existing, trusted certificate authority, or the self-signed certificate that you generated for the mirror registry.

   c. Define the network and subnets for the VPC to install the cluster in under the parent `platform.ibmcloud` field:

   ```yaml
   vpcName: <existing_vpc>
   vpcSubnets: <vpcSubnet>
   
   For `platform.powervs.vpcName`, specify the name for the existing IBM Cloud®. For `platform.powervs.vpcSubnets`, specify the existing subnets.

   d. Add the image content resources, which resemble the following YAML excerpt:

   ```yaml
   ```
imageContentSources:
- mirrors:
  - <mirror_host_name>:5000/<repo_name>/release
    source: quay.io/openshift-release-dev/ocp-release
- mirrors:
  - <mirror_host_name>:5000/<repo_name>/release
    source: registry.redhat.io/ocp/release

For these values, use the imageContentSources that you recorded during mirror registry creation.

e. Optional: Set the publishing strategy to Internal:

   publish: Internal

By setting this option, you create an internal Ingress Controller and a private load balancer.

IMPORTANT

Azure Firewall does not work seamlessly with Azure Public Load balancers. Thus, when using Azure Firewall for restricting internet access, the publish field in install-config.yaml should be set to Internal.

3. Make any other modifications to the install-config.yaml file that you require. You can find more information about the available parameters in the Installation configuration parameters section.

4. Back up the install-config.yaml file so that you can use it to install multiple clusters.

IMPORTANT

The install-config.yaml file is consumed during the installation process. If you want to reuse the file, you must back it up now.

Additional resources

- Installation configuration parameters for IBM Power® Virtual Server

20.7.7.1. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

Table 20.5. Minimum resource requirements

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>

<td>100 GB</td>
<td>300</td>
</tr>
</tbody>
</table>

1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or hyperthreading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: (threads per core × cores) × sockets = vCPUs.

2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

Additional resources

- Optimizing storage

20.7.7.2. Sample customized install-config.yaml file for IBM Power Virtual Server

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

**IMPORTANT**

This sample YAML file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program and modify it.

```yaml
apiVersion: v1
baseDomain: example.com
controlPlane:
  - hyperthreading: Enabled
    name: master
    platform:
      replicas: 3
      compute:
        - hyperthreading: Enabled
          name: worker
          platform:
            ibmcloud: {}
            replicas: 3
            metadata:
              name: example-restricted-cluster-name
            networking:
              clusterNetwork:
                - cidr: 10.128.0.0/14
                hostPrefix: 23
```

      source: quay.io/openshift-release-dev/ocp-v4.0-art-dev

---

**Required.**

If you do not provide these parameters and values, the installation program provides the default value.

**The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, -, and the first line of the controlPlane section must not. Only one control plane pool is used.**

**Enables or disables simultaneous multithreading, also known as Hyper-Threading. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to Disabled. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.**

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger machine types, such as n1-standard-8, for your machines if you disable simultaneous multithreading.
The machine CIDR must contain the subnets for the compute machines and control plane machines.

The CIDR must contain the subnets defined in `platform.ibmcloud.controlPlaneSubnets` and `platform.ibmcloud.computeSubnets`.

The cluster network plugin to install. The supported values are `OVNKubernetes` and `OpenShiftSDN`. The default value is `OVNKubernetes`.

The name of an existing resource group. The existing VPC and subnets should be in this resource group. The cluster is deployed to this resource group.

Specify the name of an existing VPC.

Specify the name of the existing VPC subnet. The subnets must belong to the VPC that you specified. Specify a subnet for each availability zone in the region.

For `<local_registry>`, specify the registry domain name, and optionally the port, that your mirror registry uses to serve content. For example, registry.example.com or registry.example.com:5000. For `<credentials>`, specify the base64-encoded user name and password for your mirror registry.

You can optionally provide the `sshKey` value that you use to access the machines in your cluster.

Provide the contents of the certificate file that you used for your mirror registry.

Provide the `imageContentSources` section from the output of the command to mirror the repository.

NOTE
For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

20.7.7.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

Prerequisites

- You have an existing `install-config.yaml` file.

- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.
The Proxy object status.noProxy field is populated with the values of the networking.machineNetwork[].cidr, networking.clusterNetwork[].cidr, and networking.serviceNetwork[] fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object status.noProxy field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your install-config.yaml file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
     httpProxy: http://<username>:<pswd>@<ip>:<port>
     httpsProxy: https://<username>:<pswd>@<ip>:<port>
     noProxy: example.com
   additionalTrustBundle: |
     -----BEGIN CERTIFICATE-----
     <MY_TRUSTED_CA_CERT>
     -----END CERTIFICATE-----
   additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle>
   ```

   1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.
   2. A proxy URL to use for creating HTTPS connections outside the cluster.
   3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.
   4. If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the trustedCA field of the Proxy object. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.
   5. Optional: The policy to determine the configuration of the Proxy object to reference the user-ca-bundle config map in the trustedCA field. The allowed values are Proxyonly and Always. Use Proxyonly to reference the user-ca-bundle config map only when http/https proxy is configured. Use Always to always reference the user-ca-bundle config map. The default value is Proxyonly.

NOTE

The installation program does not support the proxy readinessEndpoints field.
If the installer times out, restart and then complete the deployment by using the `wait-for` command of the installer. For example:

```
$ ./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

**NOTE**

Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

### 20.7.8. Manually creating IAM

Installing the cluster requires that the Cloud Credential Operator (CCO) operate in manual mode. While the installation program configures the CCO for manual mode, you must specify the identity and access management secrets for your cloud provider.

You can use the Cloud Credential Operator (CCO) utility (`ccocctl`) to create the required IBM Cloud® resources.

**Prerequisites**

- You have configured the `ccocctl` binary.
- You have an existing `install-config.yaml` file.

**Procedure**

1. Edit the `install-config.yaml` configuration file so that it contains the `credentialsMode` parameter set to `Manual`.

   **Example `install-config.yaml` configuration file**

   ```yaml
   apiVersion: v1
   baseDomain: cluster1.example.com
   credentialsMode: Manual
   compute:
     - architecture: ppc64le
       hyperthreading: Enabled
   ```

   This line is added to set the `credentialsMode` parameter to `Manual`.

2. To generate the manifests, run the following command from the directory that contains the installation program:
3. From the directory that contains the installation program, set a `$RELEASE_IMAGE` variable with the release image from your installation file by running the following command:

```bash
$ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
```

4. Extract the list of `CredentialsRequest` custom resources (CRs) from the OpenShift Container Platform release image by running the following command:

```bash
$ oc adm release extract \
  --from=$RELEASE_IMAGE \n  --credentials-requests \n  --included \n  --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \n  --to=<path_to_directory_for_credentials_requests>
```

1. The `--included` parameter includes only the manifests that your specific cluster configuration requires.

2. Specify the location of the `install-config.yaml` file.

3. Specify the path to the directory where you want to store the `CredentialsRequest` objects. If the specified directory does not exist, this command creates it.

This command creates a YAML file for each `CredentialsRequest` object.

**Sample `CredentialsRequest` object**

```yaml
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
  labels:
    controller-tools.k8s.io: "1.0"
name: openshift-image-registry-ibmcos
namespace: openshift-image-registry-ibmcos
spec:
  secretRef:
    name: installer-cloud-credentials
    namespace: openshift-image-registry
  providerSpec:
    apiVersion: cloudcredential.openshift.io/v1
    kind: IBMCloudProviderSpec
    policies:
      - attributes:
          - name: serviceName
            value: cloud-object-storage
          - name: provider
            value: ibmcos
        roles:
          - crn: v1:bluemix:public:iam:::role:Viewer
          - crn: v1:bluemix:public:iam:::role:Operator
          - crn: v1:bluemix:public:iam:::role:Editor
          - crn: v1:bluemix:public:iam:::serviceRole:Reader
          - crn: v1:bluemix:public:iam:::serviceRole:Writer
```
5. Create the service ID for each credential request, assign the policies defined, create an API key, and generate the secret:

```
$ ccoctl ibmcloud create-service-id \
  --credentials-requests-dir=<path_to_credential_requests_directory> \
  --name=<cluster_name> \
  --output-dir=<installation_directory> \
  --resource-group-name=<resource_group_name>
```

1. Specify the directory containing the files for the component **CredentialsRequest** objects.
2. Specify the name of the OpenShift Container Platform cluster.
3. Optional: Specify the directory in which you want the **ccoctl** utility to create objects. By default, the utility creates objects in the directory in which the commands are run.
4. Optional: Specify the name of the resource group used for scoping the access policies.

**NOTE**

If your cluster uses Technology Preview features that are enabled by the **TechPreviewNoUpgrade** feature set, you must include the **--enable-tech-preview** parameter.

If an incorrect resource group name is provided, the installation fails during the bootstrap phase. To find the correct resource group name, run the following command:

```
$ grep resourceGroup <installation_directory>/manifests/cluster-infrastructure-02-config.yml
```

**Verification**

- Ensure that the appropriate secrets were generated in your cluster’s **manifests** directory.

**20.7.9. Deploying the cluster**

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the **create cluster** command of the installation program only once, during initial installation.

**Prerequisites**
You have configured an account with the cloud platform that hosts your cluster.

You have the OpenShift Container Platform installation program and the pull secret for your cluster.

You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.

**Procedure**

- Change to the directory that contains the installation program and initialize the cluster deployment:

  $ ./openshift-install create cluster --dir <installation_directory> \  
  --log-level=info  

  1 For `<installation_directory>`, specify the location of your customized `.install-config.yaml` file.

  2 To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

**Verification**

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the `kubeadmin` user.

- Credential information also outputs to `<installation_directory>/.openshift_install.log`.

**IMPORTANT**

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

**Example output**

```
...  
INFO Install complete!  
INFO To access the cluster as the system:admin user when using "oc", run "export  
KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig"  
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com  
INFO Login to the console with user: "kubeadmin", and password: "password"  
INFO Time elapsed: 36m22s
```
IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

20.7.10. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

IMPORTANT

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of oc.

Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure

2. Select the architecture from the Product Variant drop-down list.

3. Select the appropriate version from the Version drop-down list.

4. Click Download Now next to the OpenShift v4.14 Linux Client entry and save the file.

5. Unpack the archive:

   $ tar xvf <file>

6. Place the oc binary in a directory that is on your PATH.

   To check your PATH, execute the following command:

   $ echo $PATH

Verification

- After you install the OpenShift CLI, it is available using the oc command:

   $ oc <command>
Installing the OpenShift CLI on Windows
You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version from the **Version** drop-down list.

3. Click **Download Now** next to the **OpenShift v4.14 Windows Client** entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the oc binary to a directory that is on your **PATH**.
   To check your **PATH**, open the command prompt and execute the following command:

   ```
   C:\> path
   ```

**Verification**

- After you install the OpenShift CLI, it is available using the oc command:

  ```
  C:\> oc <command>
  ```

Installing the OpenShift CLI on macOS
You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version from the **Version** drop-down list.

3. Click **Download Now** next to the **OpenShift v4.14 macOS Client** entry and save the file.

   **NOTE**
   
   For macOS arm64, choose the **OpenShift v4.14 macOS arm64 Client** entry.

4. Unpack and unzip the archive.

5. Move the oc binary to a directory on your PATH.
   To check your **PATH**, open a terminal and execute the following command:

   ```
   $ echo $PATH
   ```

**Verification**

- After you install the OpenShift CLI, it is available using the oc command:
20.7.11. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   ```

   **Example output**

   ```
   system:admin
   ```

**Additional resources**

- Accessing the web console

---

20.7.12. Disabling the default OperatorHub catalog sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

**Procedure**

- Disable the sources for the default catalogs by adding `disableAllDefaultSources: true` to the `OperatorHub` object:

  ```bash
  $ oc patch OperatorHub cluster --type json -p '[["op": "add", "path": "/spec/disableAllDefaultSources", "value": true]]'
  ```
TIP

Alternatively, you can use the web console to manage catalog sources. From the Administration → Cluster Settings → Configuration → OperatorHub page, click the Sources tab, where you can create, update, delete, disable, and enable individual sources.

20.7.13. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager Hybrid Cloud Console.

After you confirm that your OpenShift Cluster Manager Hybrid Cloud Console inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources
- About remote health monitoring

20.7.14. Next steps
- Customize your cluster
- Optional: Opt out of remote health reporting
- Optional: Registering your disconnected cluster

20.8. UNINSTALLING A CLUSTER ON IBM POWER VIRTUAL SERVER

You can remove a cluster that you deployed to IBM Power® Virtual Server.

20.8.1. Removing a cluster that uses installer-provisioned infrastructure

You can remove a cluster that uses installer-provisioned infrastructure from your cloud.

NOTE

After uninstallation, check your cloud provider for any resources not removed properly, especially with User Provisioned Infrastructure (UPI) clusters. There might be resources that the installer did not create or that the installer is unable to access.

Prerequisites
- You have a copy of the installation program that you used to deploy the cluster.
- You have the files that the installation program generated when you created your cluster.
- You have configured the ccoctl binary.
- You have installed the IBM Cloud® CLI and installed or updated the VPC infrastructure service plugin. For more information see "Prerequisites" in the IBM Cloud® CLI documentation.
Procedure

1. If the following conditions are met, this step is required:
   
   - The installer created a resource group as part of the installation process.
   
   - You or one of your applications created persistent volume claims (PVCs) after the cluster was deployed.

   In which case, the PVCs are not removed when uninstalling the cluster, which might prevent the resource group from being successfully removed. To prevent a failure:

   a. Log in to the IBM Cloud® using the CLI.
   
   b. To list the PVCs, run the following command:

   ```
   $ ibmcloud is volumes --resource-group-name <infrastructure_id>
   
   For more information about listing volumes, see the IBM Cloud® CLI documentation.
   ```
   
   c. To delete the PVCs, run the following command:

   ```
   $ ibmcloud is volume-delete --force <volume_id>
   
   For more information about deleting volumes, see the IBM Cloud® CLI documentation.
   ```

2. Export the API key that was created as part of the installation process.

   ```
   $ export IBM_CLOUD_API_KEY=<api_key>
   ```

   **NOTE**

   You must set the variable name exactly as specified. The installation program expects the variable name to be present to remove the service IDs that were created when the cluster was installed.

3. From the directory that contains the installation program on the computer that you used to install the cluster, run the following command:

   ```
   $ ./openshift-install destroy cluster \ 
   --dir <installation_directory> --log-level info
   ```

   **1** For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   **2** To view different details, specify `warn`, `debug`, or `error` instead of `info`. 
NOTE

- You must specify the directory that contains the cluster definition files for your cluster. The installation program requires the metadata.json file in this directory to delete the cluster.

- You might have to run the openshift-install destroy command up to three times to ensure a proper cleanup.

4. Remove the manual CCO credentials that were created for the cluster:

```
$ ccoctl ibmcloud delete-service-id \
    --credentials-requests-dir <path_to_credential_requests_directory> \
    --name <cluster_name>
```

NOTE

If your cluster uses Technology Preview features that are enabled by the TechPreviewNoUpgrade feature set, you must include the --enable-tech-preview parameter.

5. Optional: Delete the <installation_directory> directory and the OpenShift Container Platform installation program.

### 20.9. INSTALLATION CONFIGURATION PARAMETERS FOR IBM POWER VIRTUAL SERVER

Before you deploy an OpenShift Container Platform on IBM Power® Virtual Server, you provide parameters to customize your cluster and the platform that hosts it. When you create the install-config.yaml file, you provide values for the required parameters through the command line. You can then modify the install-config.yaml file to customize your cluster further.

### 20.9.1. Available installation configuration parameters for IBM Power Virtual Server

The following tables specify the required, optional, and IBM Power Virtual Server-specific installation configuration parameters that you can set as part of the installation process.

#### NOTE

After installation, you cannot modify these parameters in the install-config.yaml file.

### 20.9.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
</table>

Table 20.6. Required parameters
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion:</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is v1. The installation program may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>baseDomain:</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the baseDomain and metadata.name parameter values that uses the <code>&lt;metadata.name&gt;.&lt;baseDomain&gt;</code> format.</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
</tr>
<tr>
<td>metadata:</td>
<td>Kubernetes resource <code>ObjectMeta</code>, from which only the name parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata: name:</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of <code>{.metadata.name}.{.baseDomain}</code>.</td>
<td>String of lowercase letters, hyphens (-), and periods (.), such as dev.</td>
</tr>
<tr>
<td>platform:</td>
<td>The configuration for the specific platform upon which to perform the installation: alibabacloud, aws, baremetal, azure, gcp, ibmcloud, nutanix, openstack, powervs, vsphere, or {}. For additional information about platform. &lt;platform&gt; parameters, consult the table for your specific platform that follows.</td>
<td>Object</td>
</tr>
</tbody>
</table>
### Parameter Description Values

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
</table>

    },
    "quay.io":{
      "auth":"b3Blb=",
      "email":"you@example.com"
    }
  }
} |
| platform: powervs:    | The UserID is the login for the user’s IBM Cloud® account.  
  userID: |
|                      | String. For example, `existing_user_id`. |
| platform: powervs:    | The PowerVSResourceGroup is the resource group in which IBM Power® Virtual Server resources are created. If using an existing VPC, the existing VPC and subnets should be in this resource group.  
  powervsResourseGroup: |
|                      | String. For example, `existing_resource_group`. |
| platform: powervs:    | Specifies the IBM Cloud® colo region where the cluster will be created.  
  region: |
|                      | String. For example, `existing_region`. |
| platform: powervs:    | Specifies the IBM Cloud® colo region where the cluster will be created.  
  zone: |
|                      | String. For example, `existing_zone`. |
| platform: powervs:    | The ServiceInstanceID is the ID of the Power IAAS instance created from the IBM Cloud® Catalog.  
  serviceInstanceId: |
|                      | String. For example, `existing_service_instance_ID`. |

### 20.9.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network.
You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

**NOTE**

Globalnet is not supported with Red Hat OpenShift Data Foundation disaster recovery solutions. For regional disaster recovery scenarios, ensure that you use a nonoverlapping range of private IP addresses for the cluster and service networks in each cluster.

Table 20.7. Network parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking:</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>You cannot modify parameters specified by the <code>networking</code> object after installation.</td>
<td></td>
</tr>
<tr>
<td>networking:</td>
<td>networkType:</td>
<td>The default value is <strong>OVNKubernetes</strong>.</td>
</tr>
<tr>
<td></td>
<td>The Red Hat OpenShift Networking network plugin to install.</td>
<td></td>
</tr>
<tr>
<td>networking:</td>
<td>clusterNetwork:</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td>The IP address blocks for pods.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>The default value is <strong>10.128.0.0/14</strong> with a host prefix of <strong>/23</strong>.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td></td>
</tr>
<tr>
<td>networking:</td>
<td>clusterNetwork: cidr:</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td></td>
<td>Required if you use <code>networking.clusterNetwork</code>. An IP address block.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>An IPv4 network.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>The subnet prefix length to assign to each individual node. For example, if <code>hostPrefix</code> is set to <strong>23</strong> then each node is assigned a <strong>/23</strong> subnet out of the given <code>cidr</code>. A <code>hostPrefix</code> value of <strong>23</strong> provides 510 (2^(32 - 23) - 2) pod IP addresses.</td>
<td>The default value is <strong>23</strong>.</td>
</tr>
</tbody>
</table>
### networking: serviceNetwork:

The IP address block for services. The default value is **172.30.0.0/16**.

The OpenShift SDN and OVN-Kubernetes network plugins support only a single IP address block for the service network.

An array with an IP address block in CIDR format. For example:

```
networking:
  serviceNetwork:
    - 172.30.0.0/16
```

### networking: machineNetwork:

The IP address blocks for machines.

An array of objects. For example:

```
networking:
  machineNetwork:
```

### networking: machineNetwork: cidr:

Required if you use `networking.machineNetwork`. An IP address block. The default value is **10.0.0.0/16** for all platforms other than libvirt and IBM Power® Virtual Server. For libvirt, the default value is **192.168.126.0/24**. For IBM Power® Virtual Server, the default value is **192.168.0.0/24**.

An IP network block in CIDR notation. For example, **192.168.0.0/24**.

**NOTE**

Set the `networking.machineNetwork` to match the CIDR that the preferred NIC resides in.

### 20.9.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

**Table 20.8. Optional parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle:</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>capabilities:</td>
<td>Controls the installation of optional core cluster components. You can reduce the footprint of your OpenShift Container Platform cluster by disabling optional components. For more information, see the &quot;Cluster capabilities&quot; page in Installing.</td>
<td>String array</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>---------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-----------------</td>
</tr>
<tr>
<td>capabilities:</td>
<td>Selects an initial set of optional capabilities to enable. Valid values are</td>
<td>String</td>
</tr>
<tr>
<td>baselineCapabilitySet:</td>
<td>None, v4.11, v4.12 and vCurrent. The default value is vCurrent.</td>
<td></td>
</tr>
<tr>
<td>capabilities:</td>
<td>Extends the set of optional capabilities beyond what you specify in</td>
<td>String array</td>
</tr>
<tr>
<td>additionalEnabledCapabilities:</td>
<td>baselineCapabilitySet. You may specify multiple capabilities in this</td>
<td></td>
</tr>
<tr>
<td>cpuPartitioningMode:</td>
<td>Enables workload partitioning, which isolates OpenShift Container Platform</td>
<td>None or AllNodes. None is the default value.</td>
</tr>
<tr>
<td></td>
<td>services, cluster management workloads, and infrastructure pods to run on</td>
<td></td>
</tr>
<tr>
<td></td>
<td>a reserved set of CPUs. Workload partitioning can only be enabled during</td>
<td></td>
</tr>
<tr>
<td></td>
<td>installation and cannot be disabled after installation. While this field</td>
<td></td>
</tr>
<tr>
<td></td>
<td>enables workload partitioning, it does not configure workloads to use</td>
<td></td>
</tr>
<tr>
<td></td>
<td>specific CPUs. For more information, see the Workload partitioning page in</td>
<td></td>
</tr>
<tr>
<td></td>
<td>the Scalability and Performance section.</td>
<td></td>
</tr>
<tr>
<td>compute:</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of MachinePool objects.</td>
</tr>
<tr>
<td>compute: architecture:</td>
<td>Determines the instruction set architecture of the machines in the pool.</td>
<td>String</td>
</tr>
<tr>
<td></td>
<td>Currently, heterogeneous clusters are not supported, so all pools must</td>
<td></td>
</tr>
<tr>
<td></td>
<td>specify the same architecture. Valid values are ppc64le (the default).</td>
<td></td>
</tr>
</tbody>
</table>
### Parameter Description

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>compute: hyperthreading:</td>
<td>Whether to enable or disable simultaneous multithreading, or <strong>hyperthreading</strong>, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td><strong>Enabled</strong> or <strong>Disabled</strong></td>
</tr>
<tr>
<td><strong>IMPORTANT</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td></td>
</tr>
<tr>
<td>compute: name:</td>
<td>Required if you use <code>compute</code>. The name of the machine pool.</td>
<td><strong>worker</strong></td>
</tr>
<tr>
<td>compute: platform:</td>
<td>Required if you use <code>compute</code>. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <code>controlPlane.platform</code> parameter value. Example usage, <code>compute.platform.powervs.sysType</code>.</td>
<td><code>alibabacloud, aws, azure, gcp, ibmcloud, nutanix, openstack, powervs, vsphere, or {}</code></td>
</tr>
<tr>
<td>compute: replicas:</td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>---------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------</td>
</tr>
<tr>
<td>featureSet:</td>
<td>Enables the cluster for a feature set. A feature set is a collection of OpenShift Container Platform features that are not enabled by default. For more information about enabling a feature set during installation, see &quot;Enabling features using feature gates&quot;.</td>
<td>String. The name of the feature set to enable, such as TechPreviewNoUpgrade.</td>
</tr>
<tr>
<td>controlPlane:</td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of MachinePool objects.</td>
</tr>
<tr>
<td>controlPlane:</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are ppc64le (the default).</td>
<td>String</td>
</tr>
<tr>
<td>controlPlane:</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>controlPlane:</td>
<td>Required if you use controlPlane. The name of the machine pool.</td>
<td>master</td>
</tr>
</tbody>
</table>

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlPlane</td>
<td>Required if you use <code>controlPlane</code>. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the <code>compute.platform</code> parameter value. Example usage, <code>controlPlane.platform.powervs.processors</code>.</td>
<td><code>alibabacloud, aws, azure, gcp, ibmcloud, nutanix, openstack, powervs, vsphere, or {}</code></td>
</tr>
<tr>
<td>controlPlane:</td>
<td></td>
<td>The number of control plane machines to provision.</td>
</tr>
<tr>
<td>replicas:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>credentialsMode:</td>
<td></td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
</tr>
<tr>
<td>imageContentSour</td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects. Includes a <code>source</code> and, optionally, <code>mirrors</code>, as described in the following rows of this table.</td>
</tr>
<tr>
<td>imageContentSour:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>sources:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>source:</td>
<td>Required if you use <code>imageContentSources</code>. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td>mirrors:</td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
<tr>
<td>publish:</td>
<td>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</td>
<td><code>Internal</code> or <code>External</code>. The default value is <code>External</code>. Setting this field to <code>Internal</code> is not supported on non-cloud platforms.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------</td>
</tr>
<tr>
<td>sshKey:</td>
<td>The SSH key to authenticate access to your cluster machines.</td>
<td>For example, <code>sshKey: ssh-ed25519 AAAA...</code></td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>For production OpenShift Container Platform clusters on which you want to</td>
<td></td>
</tr>
<tr>
<td></td>
<td>perform installation debugging or disaster recovery, specify an SSH key</td>
<td></td>
</tr>
<tr>
<td></td>
<td>that your <code>ssh-agent</code> process uses.</td>
<td></td>
</tr>
<tr>
<td>platform: powervs: vpcRegion:</td>
<td>Specifies the IBM Cloud® region in which to create VPC resources.</td>
<td><code>existing_vpc_region</code></td>
</tr>
<tr>
<td>platform: powervs: vpcSubnets:</td>
<td>Specifies existing subnets (by name) where cluster resources will be</td>
<td><code>powervs_region_example_subnet</code></td>
</tr>
<tr>
<td>platform: powervs: vpcName:</td>
<td>Specifies the IBM Cloud® name.</td>
<td><code>existing_vpcName</code></td>
</tr>
<tr>
<td>platform: powervs: cloudConnectionName:</td>
<td>The CloudConnectionName is the name of an existing PowerVS Cloud</td>
<td><code>existing_cloudConnectionName</code></td>
</tr>
<tr>
<td>platform: powervs: clusterOSImage:</td>
<td>The ClusterOSImage is a pre-created IBM Power® Virtual Server boot image</td>
<td><code>existing_cluster_os_image</code></td>
</tr>
<tr>
<td></td>
<td>that overrides the default image for cluster nodes.</td>
<td></td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td>platform: powervs: defaultMachinePlatform:</td>
<td>The DefaultMachinePlatform is the default configuration used when installing on IBM Power® Virtual Server for machine pools that do not define their own platform configuration.</td>
<td>String. For example, <em>existing_machine_platform</em>.</td>
</tr>
<tr>
<td>platform: powervs: memoryGiB:</td>
<td>The size of a virtual machine’s memory, in GB.</td>
<td>The valid integer must be an integer number of GB that is at least 2 and no more than 64, depending on the machine type.</td>
</tr>
<tr>
<td>platform: powervs: procType:</td>
<td>The ProcType defines the processor sharing model for the instance.</td>
<td>The valid values are Capped, Dedicated, and Shared.</td>
</tr>
<tr>
<td>platform: powervs: processors:</td>
<td>The Processors defines the processing units for the instance.</td>
<td>The number of processors must be from .5 to 32 cores. The processors must be in increments of .25.</td>
</tr>
<tr>
<td>platform: powervs: sysType:</td>
<td>The SysType defines the system type for the instance.</td>
<td>The system type must be either <em>e980</em> or <em>s922</em>.</td>
</tr>
</tbody>
</table>

1. Not all CCO modes are supported for all cloud providers. For more information about CCO modes, see the “Managing cloud provider credentials” entry in the *Authentication and authorization* content.

**NOTE**

Cloud connections are no longer supported in the *install-config.yaml* while deploying in the *dal10* region, as they have been replaced by the Power Edge Router (PER).
CHAPTER 21. INSTALLING ON OPENSTACK

21.1. PREPARING TO INSTALL ON OPENSTACK

You can install OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP).

21.1.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.

21.1.2. Choosing a method to install OpenShift Container Platform on OpenStack

You can install OpenShift Container Platform on installer-provisioned or user-provisioned infrastructure. The default installation type uses installer-provisioned infrastructure, where the installation program provisions the underlying infrastructure for the cluster. You can also install OpenShift Container Platform on infrastructure that you provision. If you do not use infrastructure that the installation program provisions, you must manage and maintain the cluster resources yourself.

See Installation process for more information about installer-provisioned and user-provisioned installation processes.

21.1.2.1. Installing a cluster on installer-provisioned infrastructure

You can install a cluster on RHOSP infrastructure that is provisioned by the OpenShift Container Platform installation program, by using one of the following methods:

- **Installing a cluster on OpenStack with customizations** You can install a customized cluster on RHOSP. The installation program allows for some customization to be applied at the installation stage. Many other customization options are available post-installation.

- **Installing a cluster on OpenStack with Kuryr** You can install a customized OpenShift Container Platform cluster on RHOSP that uses Kuryr SDN. Kuryr and OpenShift Container Platform integration is primarily designed for OpenShift Container Platform clusters running on RHOSP VMs. Kuryr improves the network performance by plugging OpenShift Container Platform pods into RHOSP SDN. In addition, it provides interconnectivity between pods and RHOSP virtual instances.

- **Installing a cluster on OpenStack in a restricted network** You can install OpenShift Container Platform on RHOSP in a restricted or disconnected network by creating an internal mirror of the installation release content. You can use this method to install a cluster that does not require an active internet connection to obtain the software components. You can also use this installation method to ensure that your clusters only use container images that satisfy your organizational controls on external content.

21.1.2.2. Installing a cluster on user-provisioned infrastructure

You can install a cluster on RHOSP infrastructure that you provision, by using one of the following methods:

- **Installing a cluster on OpenStack on your own infrastructure** You can install OpenShift
Container Platform on user-provisioned RHOSP infrastructure. By using this installation method, you can integrate your cluster with existing infrastructure and modifications. For installations on user-provisioned infrastructure, you must create all RHOSP resources, like Nova servers, Neutron ports, and security groups. You can use the provided Ansible playbooks to assist with the deployment process.

- **Installing a cluster on OpenStack with Kuryr on your own infrastructure** You can install OpenShift Container Platform on user-provisioned RHOSP infrastructure that uses Kuryr SDN.

### 21.1.3. Scanning RHOSP endpoints for legacy HTTPS certificates

Beginning with OpenShift Container Platform 4.10, HTTPS certificates must contain subject alternative name (SAN) fields. Run the following script to scan each HTTPS endpoint in a Red Hat OpenStack Platform (RHOSP) catalog for legacy certificates that only contain the **CommonName** field.

**IMPORTANT**

OpenShift Container Platform does not check the underlying RHOSP infrastructure for legacy certificates prior to installation or updates. Use the provided script to check for these certificates yourself. Failing to update legacy certificates prior to installing or updating a cluster will result in cluster dysfunction.

**Prerequisites**

- On the machine where you run the script, have the following software:
  - Bash version 4.0 or greater
  - `grep`
  - OpenStack client
  - `jq`
  - OpenSSL version 1.1.1l or greater
- Populate the machine with RHOSP credentials for the target cloud.

**Procedure**

1. Save the following script to your machine:

```bash
#!/usr/bin/env bash
set -Eeuo pipefail
declare catalog san
catalog="$(mktemp)"
san="$(mktemp)"
readonly catalog san
declare invalid=0
openstack catalog list --format json --column Name --column Endpoints \
  | jq -r ".Name as $name | .Endpoints[] | select(.interface=="public") | [$name, .interface,
```
while read -r name interface url; do
# Ignore HTTP
if [[ ${url#"http://"} != "$url" ]]; then
continue
fi

# Remove the schema from the URL
noschema=${url#"https://"}

# If the schema was not HTTPS, error
if [[ "$noschema" == "$url" ]]; then
echo "ERROR (unknown schema): $name $interface $url"
exit 2
fi

# Remove the path and only keep host and port
noschema="${noschema%%/*}"
host="${noschema%%:*}"
port="${noschema##*:}"

# Add the port if was implicit
if [[ "$port" == "$host" ]]; then
port=443
fi

# Get the SAN fields
openssl s_client -showcerts -servername "$host" -connect "$host:$port" <dev/null 2>/dev/null
| openssl x509 -noout -ext subjectAltName < $san

# openssl returns the empty string if no SAN is found.
# If a SAN is found, openssl is expected to return something like:
#
# X509v3 Subject Alternative Name:
# DNS:standalone, DNS:osp1, IP Address:192.168.2.1, IP Address:10.254.1.2
if [[ $(grep -c "Subject Alternative Name" "$san" || true) -gt 0 ]]; then
  echo "PASS: $name $interface $url"
else
  invalid=$((invalid+1))
  echo "INVALID: $name $interface $url"
fi
done < "$catalog"

# clean up temporary files
rm "$catalog" "$san"

if [[ $invalid -gt 0 ]]; then
  echo "$invalid legacy certificates were detected. Update your certificates to include a SAN field."
  exit 1
2. Run the script.

3. Replace any certificates that the script reports as **INVALID** with certificates that contain SAN fields.

**IMPORTANT**

You must replace all legacy HTTPS certificates before you install OpenShift Container Platform 4.10 or update a cluster to that version. Legacy certificates will be rejected with the following message:

```
x509: certificate relies on legacy Common Name field, use SANs instead
```

### 21.1.3.1. Scanning RHOSP endpoints for legacy HTTPS certificates manually

Beginning with OpenShift Container Platform 4.10, HTTPS certificates must contain subject alternative name (SAN) fields. If you do not have access to the prerequisite tools that are listed in "Scanning RHOSP endpoints for legacy HTTPS certificates", perform the following steps to scan each HTTPS endpoint in a Red Hat OpenStack Platform (RHOSP) catalog for legacy certificates that only contain the **CommonName** field.

**IMPORTANT**

OpenShift Container Platform does not check the underlying RHOSP infrastructure for legacy certificates prior to installation or updates. Use the following steps to check for these certificates yourself. Failing to update legacy certificates prior to installing or updating a cluster will result in cluster dysfunction.

**Procedure**

1. On a command line, run the following command to view the URL of RHOSP public endpoints:

```bash
$ openstack catalog list
```

Record the URL for each HTTPS endpoint that the command returns.

2. For each public endpoint, note the host and the port.

**TIP**

Determine the host of an endpoint by removing the scheme, the port, and the path.

3. For each endpoint, run the following commands to extract the SAN field of the certificate:
   a. Set a **host** variable:

```bash
$ host=<host_name>
```

   b. Set a **port** variable:
$ port=<port_number>

If the URL of the endpoint does not have a port, use the value 443.

c. Retrieve the SAN field of the certificate:

```bash
$ openssl s_client -showcerts -servername "$host" -connect "$host:$port" <dev/null 2>/dev/null \\ | openssl x509 -noout -ext subjectAltName
```

**Example output**

```
X509v3 Subject Alternative Name:
 DNS:your.host.example.net
```

For each endpoint, look for output that resembles the previous example. If there is no output for an endpoint, the certificate of that endpoint is invalid and must be re-issued.

**IMPORTANT**

You must replace all legacy HTTPS certificates before you install OpenShift Container Platform 4.10 or update a cluster to that version. Legacy certificates are rejected with the following message:

```
x509: certificate relies on legacy Common Name field, use SANs instead
```

## 21.2. PREPARING TO INSTALL A CLUSTER THAT USES SR-IOV OR OVS-DPDK ON OPENSTACK

Before you install a OpenShift Container Platform cluster that uses single-root I/O virtualization (SR-IOV) or Open vSwitch with the Data Plane Development Kit (OVS-DPDK) on Red Hat OpenStack Platform (RHOSP), you must understand the requirements for each technology and then perform preparatory tasks.

### 21.2.1. Requirements for clusters on RHOSP that use either SR-IOV or OVS-DPDK

If you use SR-IOV or OVS-DPDK with your deployment, you must meet the following requirements:

- RHOSP compute nodes must use a flavor that supports huge pages.

### 21.2.1.1. Requirements for clusters on RHOSP that use SR-IOV

To use single-root I/O virtualization (SR-IOV) with your deployment, you must meet the following requirements:

- **Plan your Red Hat OpenStack Platform (RHOSP) SR-IOV deployment**.

- OpenShift Container Platform must support the NICs that you use. For a list of supported NICs, see "About Single Root I/O Virtualization (SR-IOV) hardware networks" in the "Hardware networks" subsection of the "Networking" documentation.

- For each node that will have an attached SR-IOV NIC, your RHOSP cluster must have:
• One instance from the RHOSP quota
• One port attached to the machines subnet
• One port for each SR-IOV Virtual Function
• A flavor with at least 16 GB memory, 4 vCPUs, and 25 GB storage space

• SR-IOV deployments often employ performance optimizations, such as dedicated or isolated CPUs. For maximum performance, configure your underlying RHOSP deployment to use these optimizations, and then run OpenShift Container Platform compute machines on the optimized infrastructure.

• For more information about configuring performant RHOSP compute nodes, see Configuring Compute nodes for performance.

21.2.1.2. Requirements for clusters on RHOSP that use OVS-DPDK

To use Open vSwitch with the Data Plane Development Kit (OVS-DPDK) with your deployment, you must meet the following requirements:

• Plan your Red Hat OpenStack Platform (RHOSP) OVS-DPDK deployment by referring to Planning your OVS-DPDK deployment in the Network Functions Virtualization Planning and Configuration Guide.

• Configure your RHOSP OVS-DPDK deployment according to Configuring an OVS-DPDK deployment in the Network Functions Virtualization Planning and Configuration Guide.

21.2.2. Preparing to install a cluster that uses SR-IOV

You must configure RHOSP before you install a cluster that uses SR-IOV on it.

When installing a cluster using SR-IOV, you must deploy clusters using cgroup v1. For more information, Enabling Linux control group version 1 (cgroup v1).

21.2.2.1. Creating SR-IOV networks for compute machines

If your Red Hat OpenStack Platform (RHOSP) deployment supports single root I/O virtualization (SR-IOV), you can provision SR-IOV networks that compute machines run on.

**NOTE**

The following instructions entail creating an external flat network and an external, VLAN-based network that can be attached to a compute machine. Depending on your RHOSP deployment, other network types might be required.

**Prerequisites**

• Your cluster supports SR-IOV.

**NOTE**

If you are unsure about what your cluster supports, review the OpenShift Container Platform SR-IOV hardware networks documentation.
You created radio and uplink provider networks as part of your RHOSP deployment. The names **radio** and **uplink** are used in all example commands to represent these networks.

### Procedure

1. On a command line, create a radio RHOSP network:

   ```
   $ openstack network create radio --provider-physical-network radio --provider-network-type flat --external
   ```

2. Create an uplink RHOSP network:

   ```
   $ openstack network create uplink --provider-physical-network uplink --provider-network-type vlan --external
   ```

3. Create a subnet for the radio network:

   ```
   $ openstack subnet create --network radio --subnet-range <radio_network_subnet_range> radio
   ```

4. Create a subnet for the uplink network:

   ```
   $ openstack subnet create --network uplink --subnet-range <uplink_network_subnet_range> uplink
   ```

### 21.2.3. Preparing to install a cluster that uses OVS-DPDK

You must configure RHOSP before you install a cluster that uses SR-IOV on it.

- Complete [Creating a flavor and deploying an instance for OVS-DPDK](#) before you install a cluster on RHOSP.

After you perform preinstallation tasks, install your cluster by following the most relevant OpenShift Container Platform on RHOSP installation instructions. Then, perform the tasks under "Next steps" on this page.

### 21.2.4. Next steps

- For either type of deployment:
  - Configure the Node Tuning Operator with huge pages support.

- To complete SR-IOV configuration after you deploy your cluster:
  - Install the SR-IOV Operator.
  - Configure your SR-IOV network device.
  - Create SR-IOV compute machines.

- Consult the following references after you deploy your cluster to improve its performance:
  - A test pod template for clusters that use OVS-DPDK on OpenStack.
  - A test pod template for clusters that use SR-IOV on OpenStack.
21.3. INSTALLING A CLUSTER ON OPENSTACK WITH CUSTOMIZATIONS

In OpenShift Container Platform version 4.14, you can install a customized cluster on Red Hat OpenStack Platform (RHOSP). To customize the installation, modify parameters in the `install-config.yaml` before you install the cluster.

21.3.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You verified that OpenShift Container Platform 4.14 is compatible with your RHOSP version by using the Supported platforms for OpenShift clusters section. You can also compare platform support across different versions by viewing the OpenShift Container Platform on RHOSP support matrix.
- You have a storage service installed in RHOSP, such as block storage (Cinder) or object storage (Swift). Object storage is the recommended storage technology for OpenShift Container Platform registry cluster deployment. For more information, see Optimizing storage.
- You understand performance and scalability practices for cluster scaling, control plane sizing, and etcd. For more information, see Recommended practices for scaling the cluster.
- You have the metadata service enabled in RHOSP.

21.3.2. Resource guidelines for installing OpenShift Container Platform on RHOSP

To support an OpenShift Container Platform installation, your Red Hat OpenStack Platform (RHOSP) quota must meet the following requirements:

Table 21.1. Recommended resources for a default OpenShift Container Platform cluster on RHOSP

<table>
<thead>
<tr>
<th>Resource</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Floating IP addresses</td>
<td>3</td>
</tr>
<tr>
<td>Ports</td>
<td>15</td>
</tr>
<tr>
<td>Routers</td>
<td>1</td>
</tr>
<tr>
<td>Subnets</td>
<td>1</td>
</tr>
<tr>
<td>RAM</td>
<td>88 GB</td>
</tr>
<tr>
<td>vCPUs</td>
<td>22</td>
</tr>
</tbody>
</table>
## Resource and Value Table

<table>
<thead>
<tr>
<th>Resource</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Volume storage</td>
<td>275 GB</td>
</tr>
<tr>
<td>Instances</td>
<td>7</td>
</tr>
<tr>
<td>Security groups</td>
<td>3</td>
</tr>
<tr>
<td>Security group rules</td>
<td>60</td>
</tr>
<tr>
<td>Server groups</td>
<td>2 - plus 1 for each additional availability zone in each machine pool</td>
</tr>
</tbody>
</table>

A cluster might function with fewer than recommended resources, but its performance is not guaranteed.

**IMPORTANT**

If RHOSP object storage (Swift) is available and operated by a user account with the `swiftoperator` role, it is used as the default backend for the OpenShift Container Platform image registry. In this case, the volume storage requirement is 175 GB. Swift space requirements vary depending on the size of the image registry.

**NOTE**

By default, your security group and security group rule quotas might be low. If you encounter problems, run `openstack quota set --secgroups 3 --secgroup-rules 60 <project>` as an administrator to increase them.

An OpenShift Container Platform deployment comprises control plane machines, compute machines, and a bootstrap machine.

### 21.3.2.1. Control plane machines

By default, the OpenShift Container Platform installation process creates three control plane machines.

Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory and 4 vCPUs
- At least 100 GB storage space from the RHOSP quota

### 21.3.2.2. Compute machines

By default, the OpenShift Container Platform installation process creates three compute machines.

Each machine requires:
• An instance from the RHOSP quota
• A port from the RHOSP quota
• A flavor with at least 8 GB memory and 2 vCPUs
• At least 100 GB storage space from the RHOSP quota

TIP

Compute machines host the applications that you run on OpenShift Container Platform; aim to run as many as you can.

21.3.2.3. Bootstrap machine

During installation, a bootstrap machine is temporarily provisioned to stand up the control plane. After the production control plane is ready, the bootstrap machine is deprovisioned.

The bootstrap machine requires:
• An instance from the RHOSP quota
• A port from the RHOSP quota
• A flavor with at least 16 GB memory and 4 vCPUs
• At least 100 GB storage space from the RHOSP quota

21.3.2.4. Load balancing requirements for user-provisioned infrastructure

Before you install OpenShift Container Platform, you can provision your own API and application ingress load balancing infrastructure to use in place of the default, internal load balancing solution. In production scenarios, you can deploy the API and application Ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

NOTE

If you want to deploy the API and application Ingress load balancers with a Red Hat Enterprise Linux (RHEL) instance, you must purchase the RHEL subscription separately.

The load balancing infrastructure must meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
   • Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.
   • A stateless load balancing algorithm. The options vary based on the load balancer implementation.
Do not configure session persistence for an API load balancer. Configuring session persistence for a Kubernetes API server might cause performance issues from excess application traffic for your OpenShift Container Platform cluster and the Kubernetes API that runs inside the cluster.

Configure the following ports on both the front and back of the load balancers:

Table 21.2. API load balancer

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the /readyz endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the /readyz endpoint to the removal of the API server instance from the pool. Within the time frame after /readyz returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. Application Ingress load balancer: Provides an ingress point for application traffic flowing in from outside the cluster. A working configuration for the Ingress router is required for an OpenShift Container Platform cluster.

Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

TIP

If the true IP address of the client can be seen by the application Ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.
Configure the following ports on both the front and back of the load balancers:

### Table 21.3. Application Ingress load balancer

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>

**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application Ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

### 21.3.2.4.1. Example load balancer configuration for clusters that are deployed with user-managed load balancers

This section provides an example API and application Ingress load balancer configuration that meets the load balancing requirements for clusters that are deployed with user-managed load balancers. The sample is an `/etc/haproxy/haproxy.cfg` configuration for an HAProxy load balancer. The example is not meant to provide advice for choosing one load balancing solution over another.

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

**NOTE**

If you are using HAProxy as a load balancer and SELinux is set to enforcing, you must ensure that the HAProxy service can bind to the configured TCP port by running `setsebool -P haproxy_connect_any=1`.

### Example 21.1. Sample API and application Ingress load balancer configuration

```conf
global
log    127.0.0.1 local2
pidfile /var/run/haproxy.pid
maxconn 4000
daemon
defaults
  mode http
  log global
  option dontlognull
  option http-server-close
  option redispatch
  retries 3
```
Port 6443 handles the Kubernetes API traffic and points to the control plane machines.

The bootstrap entries must be in place before the OpenShift Container Platform cluster installation and they must be removed after the bootstrap process is complete.

Port 22623 handles the machine config server traffic and points to the control plane machines.

Port 443 handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

Port 80 handles the HTTP traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application Ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.
TIP

If you are using HAProxy as a load balancer, you can check that the **haproxy** process is listening on ports 6443, 22623, 443, and 80 by running `netstat -nltupe` on the HAPerxy node.

21.3.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager Hybrid Cloud Console to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- Access Quay.io to obtain the packages that are required to install your cluster.

- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

21.3.4. Enabling Swift on RHOSP

Swift is operated by a user account with the **switoperator** role. Add the role to an account before you run the installation program.

**IMPORTANT**

If the Red Hat OpenStack Platform (RHOSP) object storage service, commonly known as Swift, is available, OpenShift Container Platform uses it as the image registry storage. If it is unavailable, the installation program relies on the RHOSP block storage service, commonly known as Cinder.

If Swift is present and you want to use it, you must enable access to it. If it is not present, or if you do not want to use it, skip this section.

**IMPORTANT**

RHOSP 17 sets the `rgw_max_attr_size` parameter of Ceph RGW to 256 characters. This setting causes issues with uploading container images to the OpenShift Container Platform registry. You must set the value of `rgw_max_attr_size` to at least 1024 characters.

Before installation, check if your RHOSP deployment is affected by this problem. If it is, reconfigure Ceph RGW.
Prerequisites

- You have a RHOSP administrator account on the target environment.
- The Swift service is installed.
- On Ceph RGW, the account in url option is enabled.

Procedure

To enable Swift on RHOSP:

1. As an administrator in the RHOSP CLI, add the `swiftoperator` role to the account that will access Swift:

   ```
   $ openstack role add --user <user> --project <project> swiftoperator
   ```

   Your RHOSP deployment can now use Swift for the image registry.

21.3.5. Configuring an image registry with custom storage on clusters that run on RHOSP

After you install a cluster on Red Hat OpenStack Platform (RHOSP), you can use a Cinder volume that is in a specific availability zone for registry storage.

Procedure

1. Create a YAML file that specifies the storage class and availability zone to use. For example:

   ```yaml
   apiVersion: storage.k8s.io/v1
   kind: StorageClass
   metadata:
     name: custom-csi-storageclass
   provisioner: cinder.csi.openstack.org
   volumeBindingMode: WaitForFirstConsumer
   allowVolumeExpansion: true
   parameters:
     availability: <availability_zone_name>
   ```

   **NOTE**

   OpenShift Container Platform does not verify the existence of the availability zone you choose. Verify the name of the availability zone before you apply the configuration.

2. From a command line, apply the configuration:

   ```
   $ oc apply -f <storage_class_file_name>
   ```

Example output

```
storageclass.storage.k8s.io/custom-csi-storageclass created
```
3. Create a YAML file that specifies a persistent volume claim (PVC) that uses your storage class and the `openshift-image-registry` namespace. For example:

```yaml
apiVersion: v1
kind: PersistentVolumeClaim
metadata:
  name: csi-pvc-imageregistry
  namespace: openshift-image-registry
  annotations:
    imageregistry.openshift.io: "true"
spec:
  accessModes:
  - ReadWriteOnce
  volumeMode: Filesystem
  resources:
    requests:
      storage: 100Gi
  storageClassName: <your_custom_storage_class>
```

1. Enter the namespace `openshift-image-registry`. This namespace allows the Cluster Image Registry Operator to consume the PVC.

2. Optional: Adjust the volume size.

3. Enter the name of the storage class that you created.

4. From a command line, apply the configuration:

   `$ oc apply -f <pvc_file_name>`

   **Example output**

   `persistentvolumeclaim/csi-pvc-imageregistry created`

5. Replace the original persistent volume claim in the image registry configuration with the new claim:

   `$ oc patch configs.imageregistry.operator.openshift.io/cluster --type 'json' -p='["op": "replace", "path": "/spec/storage/pvc/claim", "value": "csi-pvc-imageregistry" ]']`

   **Example output**

   `config.imageregistry.operator.openshift.io/cluster patched`

   Over the next several minutes, the configuration is updated.

**Verification**

To confirm that the registry is using the resources that you defined:

1. Verify that the PVC claim value is identical to the name that you provided in your PVC definition:

   `$ oc get configs.imageregistry.operator.openshift.io/cluster -o yaml`
Verify that the status of the PVC is **Bound**:

```bash
$ oc get pvc -n openshift-image-registry csi-pvc-imageregistry
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>VOLUME</th>
<th>CAPACITY</th>
<th>ACCESS MODES</th>
</tr>
</thead>
<tbody>
<tr>
<td>csi-pvc-imageregistry</td>
<td>Bound</td>
<td>pvc-72a8f9c9-f462-11e8-b6b6-fa163e18b7b5</td>
<td>100Gi</td>
<td>RWO</td>
</tr>
<tr>
<td></td>
<td></td>
<td>custom-csi-storageclass</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**21.3.6. Verifying external network access**

The OpenShift Container Platform installation process requires external network access. You must provide an external network value to it, or deployment fails. Before you begin the process, verify that a network with the external router type exists in Red Hat OpenStack Platform (RHOSP).

**Prerequisites**

- Configure OpenStack’s networking service to have DHCP agents forward instances’ DNS queries

**Procedure**

1. Using the RHOSP CLI, verify the name and ID of the 'External' network:

```bash
$ openstack network list --long -c ID -c Name -c "Router Type"
```

**Example output**

```
+--------------------------------------+----------------+-------------+
| ID                                   | Name           | Router Type |
+--------------------------------------+----------------+-------------+
| 148a8023-62a7-4672-b018-003462f8d7dc | public_network | External    |
```

A network with an external router type appears in the network list. If at least one does not, see Creating a default floating IP network and Creating a default provider network.
If the external network’s CIDR range overlaps one of the default network ranges, you must change the matching network ranges in the `install-config.yaml` file before you start the installation process.

The default network ranges are:

<table>
<thead>
<tr>
<th>Network</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>machineNetwork</td>
<td>10.0.0.0/16</td>
</tr>
<tr>
<td>serviceNetwork</td>
<td>172.30.0.0/16</td>
</tr>
<tr>
<td>clusterNetwork</td>
<td>10.128.0.0/14</td>
</tr>
</tbody>
</table>

**WARNING**

If the installation program finds multiple networks with the same name, it sets one of them at random. To avoid this behavior, create unique names for resources in RHOSP.

**NOTE**

If the Neutron trunk service plugin is enabled, a trunk port is created by default. For more information, see Neutron trunk port.

### 21.3.7. Defining parameters for the installation program

The OpenShift Container Platform installation program relies on a file that is called `clouds.yaml`. The file describes Red Hat OpenStack Platform (RHOSP) configuration parameters, including the project name, log in information, and authorization service URLs.

**Procedure**

1. Create the `clouds.yaml` file:
   - If your RHOSP distribution includes the Horizon web UI, generate a `clouds.yaml` file in it.
     
     **IMPORTANT**
     
     Remember to add a password to the `auth` field. You can also keep secrets in a separate file from `clouds.yaml`.
   - If your RHOSP distribution does not include the Horizon web UI, or you do not want to use Horizon, create the file yourself. For detailed information about `clouds.yaml`, see Config files in the RHOSP documentation.
If your RHOSP installation uses self-signed certificate authority (CA) certificates for endpoint authentication:

a. Copy the certificate authority file to your machine.

b. Add the `cacerts` key to the `clouds.yaml` file. The value must be an absolute, non-root-accessible path to the CA certificate:

   ```yaml
   clouds:
     shiftstack:
       ... 
       cacert: "/etc/pki/ca-trust/source/anchors/ca.crt.pem"
   
   TIP
   
   After you run the installer with a custom CA certificate, you can update the certificate by editing the value of the `ca-cert.pem` key in the `cloud-provider-config` keymap. On a command line, run:

   ```bash
   $ oc edit configmap -n openshift-config cloud-provider-config
   
   3. Place the `clouds.yaml` file in one of the following locations:

   a. The value of the `OS_CLIENT_CONFIG_FILE` environment variable

   b. The current directory

   c. A Unix-specific user configuration directory, for example `~/.config/openstack/clouds.yaml`

   d. A Unix-specific site configuration directory, for example `/etc/openstack/clouds.yaml`

The installation program searches for `clouds.yaml` in that order.

### 21.3.8. Setting OpenStack Cloud Controller Manager options

Optionally, you can edit the OpenStack Cloud Controller Manager (CCM) configuration for your cluster. This configuration controls how OpenShift Container Platform interacts with Red Hat OpenStack Platform (RHOSP).
For a complete list of configuration parameters, see the "OpenStack Cloud Controller Manager reference guide" page in the "Installing on OpenStack" documentation.

**Procedure**

1. If you have not already generated manifest files for your cluster, generate them by running the following command:

\[
$\text{openshift-install --dir <destination_directory> create manifests}
\]

2. In a text editor, open the cloud-provider configuration manifest file. For example:

\[
$\text{vi openshift/manifests/cloud-provider-config.yaml}
\]

3. Modify the options according to the CCM reference guide.

Configuring Octavia for load balancing is a common case for clusters that do not use Kuryr. For example:

```
[LoadBalancer]
lb-provider = "amphora"
floating-network-id="d3deb660-4190-40a3-91f1-37326fe6ec4a"
create-monitor = True
monitor-delay = 10s
monitor-timeout = 10s
monitor-max-retries = 1
```

1. This property sets the Octavia provider that your load balancer uses. It accepts "ovn" or "amphora" as values. If you choose to use OVN, you must also set `lb-method` to `SOURCE_IP_PORT`.

2. This property is required if you want to use multiple external networks with your cluster. The cloud provider creates floating IP addresses on the network that is specified here.

3. This property controls whether the cloud provider creates health monitors for Octavia load balancers. Set the value to `True` to create health monitors. As of RHOSP 16.2, this feature is only available for the Amphora provider.

4. This property sets the frequency with which endpoints are monitored. The value must be in the `time.ParseDuration()` format. This property is required if the value of the `create-monitor` property is `True`.

5. This property sets the time that monitoring requests are open before timing out. The value must be in the `time.ParseDuration()` format. This property is required if the value of the `create-monitor` property is `True`.

6. This property defines how many successful monitoring requests are required before a load balancer is marked as online. The value must be an integer. This property is required if the value of the `create-monitor` property is `True`. 
IMPORTANT
Prior to saving your changes, verify that the file is structured correctly. Clusters might fail if properties are not placed in the appropriate section.

IMPORTANT
You must set the value of the create-monitor property to True if you use services that have the value of the .spec.externalTrafficPolicy property set to Local. The OVN Octavia provider in RHOSP 16.2 does not support health monitors. Therefore, services that have ETP parameter values set to Local might not respond when the lb-provider value is set to “ovn”.

IMPORTANT
For installations that use Kuryr, Kuryr handles relevant services. There is no need to configure Octavia load balancing in the cloud provider.

4. Save the changes to the file and proceed with installation.

TIP
You can update your cloud provider configuration after you run the installer. On a command line, run:

```
$ oc edit configmap -n openshift-config cloud-provider-config
```

After you save your changes, your cluster will take some time to reconfigure itself. The process is complete if none of your nodes have a SchedulingDisabled status.

21.3.9. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.
IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

21.3.10. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Red Hat OpenStack Platform (RHOSP).

Prerequisites

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Create the `install-config.yaml` file.

   a. Change to the directory that contains the installation program and run the following command:

   ```
   $ ./openshift-install create install-config --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

   When specifying the directory:

   - Verify that the directory has the `execute` permission. This permission is required to run Terraform binaries under the installation directory.

   - Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If
you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

**NOTE**

Always delete the `~/.powervs` directory to avoid reusing a stale configuration. Run the following command:

```
$ rm -rf ~/.powervs
```

b. At the prompts, provide the configuration details for your cloud:

i. Optional: Select an SSH key to use to access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

ii. Select `openstack` as the platform to target.

iii. Specify the Red Hat OpenStack Platform (RHOSP) external network name to use for installing the cluster.

iv. Specify the floating IP address to use for external access to the OpenShift API.

v. Specify a RHOSP flavor with at least 16 GB RAM to use for control plane nodes and 8 GB RAM for compute nodes.

vi. Select the base domain to deploy the cluster to. All DNS records will be sub-domains of this base and will also include the cluster name.

vii. Enter a name for your cluster. The name must be 14 or fewer characters long.

2. Modify the `install-config.yaml` file. You can find more information about the available parameters in the "Installation configuration parameters" section.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

**IMPORTANT**

The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

**Additional resources**

- Installation configuration parameters for OpenStack

**21.3.10.1. Configuring the cluster-wide proxy during installation**

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy.
Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**Prerequisites**

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (`169.254.169.254`).

**Procedure**

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:@<ip>:<port> ①
  httpsProxy: https://<username>:@<ip>:<port> ②
  noProxy: example.com ③
additionalTrustBundle:
  -----BEGIN CERTIFICATE-----
  <MY_TRUSTED_CA_CERT>
  -----END CERTIFICATE-----
additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> ⑤
```

① A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.

② A proxy URL to use for creating HTTPS connections outside the cluster.

③ A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, `.y.com` matches `x.y.com`, but not `y.com`. Use * to bypass the proxy for all destinations.

④ If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the
trustedCA field of the Proxy object. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

Optional: The policy to determine the configuration of the Proxy object to reference the user-ca-bundle config map in the trustedCA field. The allowed values are Proxyonly and Always. Use Proxyonly to reference the user-ca-bundle config map only when http/https proxy is configured. Use Always to always reference the user-ca-bundle config map. The default value is Proxyonly.

**NOTE**
The installation program does not support the proxy readinessEndpoints field.

**NOTE**
If the installer times out, restart and then complete the deployment by using the wait-for command of the installer. For example:

```shell
$ ./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

**NOTE**
Only the Proxy object named cluster is supported, and no additional proxies can be created.

### 21.3.10.2. Custom subnets in RHOSP deployments

Optionally, you can deploy a cluster on a Red Hat OpenStack Platform (RHOSP) subnet of your choice. The subnet’s GUID is passed as the value of platform.openstack.machinesSubnet in the install-config.yaml file.

This subnet is used as the cluster’s primary subnet. By default, nodes and ports are created on it. You can create nodes and ports on a different RHOSP subnet by setting the value of the platform.openstack.machinesSubnet property to the subnet’s UUID.

Before you run the OpenShift Container Platform installer with a custom subnet, verify that your configuration meets the following requirements:

- The subnet that is used by platform.openstack.machinesSubnet has DHCP enabled.
- The CIDR of platform.openstack.machinesSubnet matches the CIDR of networking.machineNetwork.
- The installation program user has permission to create ports on this network, including ports with fixed IP addresses.

Clusters that use custom subnets have the following limitations:
If you plan to install a cluster that uses floating IP addresses, the `platform.openstack.machinesSubnet` subnet must be attached to a router that is connected to the `externalNetwork` network.

If the `platform.openstack.machinesSubnet` value is set in the `install-config.yaml` file, the installation program does not create a private network or subnet for your RHOSP machines.

You cannot use the `platform.openstack.externalDNS` property at the same time as a custom subnet. To add DNS to a cluster that uses a custom subnet, configure DNS on the RHOSP network.

**NOTE**

By default, the API VIP takes x.x.x.5 and the Ingress VIP takes x.x.x.7 from your network’s CIDR block. To override these default values, set values for `platform.openstack.apiVIPs` and `platform.openstack.ingressVIPs` that are outside of the DHCP allocation pool.

**IMPORTANT**

The CIDR ranges for networks are not adjustable after cluster installation. Red Hat does not provide direct guidance on determining the range during cluster installation because it requires careful consideration of the number of created pods per namespace.

### 21.3.10.3. Deploying a cluster with bare metal machines

If you want your cluster to use bare metal machines, modify the `install-config.yaml` file. Your cluster can have both control plane and compute machines running on bare metal, or just compute machines.

Bare-metal compute machines are not supported on clusters that use Kuryr.

**NOTE**

Be sure that your `install-config.yaml` file reflects whether the RHOSP network that you use for bare metal workers supports floating IP addresses or not.

**Prerequisites**

- The RHOSP Bare Metal service (Ironic) is enabled and accessible via the RHOSP Compute API.
- Bare metal is available as a RHOSP flavor.
- If your cluster runs on an RHOSP version that is more than 16.1.6 and less than 16.2.4, bare metal workers do not function due to a known issue that causes the metadata service to be unavailable for services on OpenShift Container Platform nodes.
- The RHOSP network supports both VM and bare metal server attachment.
- Your network configuration does not rely on a provider network. Provider networks are not supported.
- If you want to deploy the machines on a pre-existing network, a RHOSP subnet is provisioned.
- If you want to deploy the machines on an installer-provisioned network, the RHOSP Bare Metal service (Ironic) is able to listen for and interact with Preboot eXecution Environment (PXE) boot machines that run on tenant networks.
You created an `install-config.yaml` file as part of the OpenShift Container Platform installation process.

**Procedure**

1. In the `install-config.yaml` file, edit the flavors for machines:
   
   a. If you want to use bare-metal control plane machines, change the value of `controlPlane.platform.openstack.type` to a bare metal flavor.

   b. Change the value of `compute.platform.openstack.type` to a bare metal flavor.

   c. If you want to deploy your machines on a pre-existing network, change the value of `platform.openstack.machinesSubnet` to the RHOSP subnet UUID of the network. Control plane and compute machines must use the same subnet.

**An example bare metal install-config.yaml file**

```yaml
controlPlane:
  platform:
    openstack:
      type: <bare_metal_control_plane_flavor> ¹

compute:
  - architecture: amd64
    hyperthreading: Enabled
    name: worker
    platform:
      openstack:
        type: <bare_metal_compute_flavor> ²
    replicas: 3

platform:
  openstack:
    machinesSubnet: <subnet_UUID> ³
```

1. If you want to have bare-metal control plane machines, change this value to a bare metal flavor.

2. Change this value to a bare metal flavor to use for compute machines.

3. If you want to use a pre-existing network, change this value to the UUID of the RHOSP subnet.

Use the updated `install-config.yaml` file to complete the installation process. The compute machines that are created during deployment use the flavor that you added to the file.
The installer may time out while waiting for bare metal machines to boot. If the installer times out, restart and then complete the deployment by using the `wait-for` command of the installer. For example:

```
$ ./openshift-install wait-for install-complete --log-level debug
```

### 21.3.10.4. Cluster deployment on RHOSP provider networks

You can deploy your OpenShift Container Platform clusters on Red Hat OpenStack Platform (RHOSP) with a primary network interface on a provider network. Provider networks are commonly used to give projects direct access to a public network that can be used to reach the internet. You can also share provider networks among projects as part of the network creation process.

RHOSP provider networks map directly to an existing physical network in the data center. A RHOSP administrator must create them.

In the following example, OpenShift Container Platform workloads are connected to a data center by using a provider network:
OpenShift Container Platform clusters that are installed on provider networks do not require tenant networks or floating IP addresses. The installer does not create these resources during installation.

Example provider network types include flat (untagged) and VLAN (802.1Q tagged).

**NOTE**

A cluster can support as many provider network connections as the network type allows. For example, VLAN networks typically support up to 4096 connections.

You can learn more about provider and tenant networks in the [RHOSP documentation](https://example.com).

---

### 21.3.10.4.1. RHOSP provider network requirements for cluster installation

Before you install an OpenShift Container Platform cluster, your Red Hat OpenStack Platform (RHOSP) deployment and provider network must meet a number of conditions:

- The [RHOSP networking service (Neutron)](https://example.com) is enabled and accessible through the RHOSP networking API.

- The RHOSP networking service has the port security and allowed address pairs extensions enabled.

- The provider network can be shared with other tenants.

**TIP**

Use the `openstack network create` command with the `--share` flag to create a network that can be shared.

- The RHOSP project that you use to install the cluster must own the provider network, as well as an appropriate subnet.

**TIP**

To create a network for a project that is named "openshift," enter the following command:

```bash
$ openstack network create --project openshift
```

To create a subnet for a project that is named "openshift," enter the following command:

```bash
$ openstack subnet create --project openshift
```

To learn more about creating networks on RHOSP, read the [provider networks documentation](https://example.com).

If the cluster is owned by the `admin` user, you must run the installer as that user to create ports on the network.
IMPORTANT

Provider networks must be owned by the RHOSP project that is used to create the cluster. If they are not, the RHOSP Compute service (Nova) cannot request a port from that network.

- Verify that the provider network can reach the RHOSP metadata service IP address, which is 169.254.169.254 by default. Depending on your RHOSP SDN and networking service configuration, you might need to provide the route when you create the subnet. For example:

  ```
  $ openstack subnet create --dhcp --host-route destination=169.254.169.254/32,gateway=192.0.2.2 ...
  ```

- Optional: To secure the network, create role-based access control (RBAC) rules that limit network access to a single project.

21.3.10.4.2. Deploying a cluster that has a primary interface on a provider network

You can deploy an OpenShift Container Platform cluster that has its primary network interface on an Red Hat OpenStack Platform (RHOSP) provider network.

**Prerequisites**

- Your Red Hat OpenStack Platform (RHOSP) deployment is configured as described by “RHOSP provider network requirements for cluster installation”.

**Procedure**

1. In a text editor, open the `install-config.yaml` file.

2. Set the value of the `platform.openstack.apiVIPs` property to the IP address for the API VIP.

3. Set the value of the `platform.openstack.ingressVIPs` property to the IP address for the Ingress VIP.

4. Set the value of the `platform.openstack.machinesSubnet` property to the UUID of the provider network subnet.

5. Set the value of the `networking.machineNetwork.cidr` property to the CIDR block of the provider network subnet.

**IMPORTANT**

The `platform.openstack.apiVIPs` and `platform.openstack.ingressVIPs` properties must both be unassigned IP addresses from the `networking.machineNetwork.cidr` block.

Section of an installation configuration file for a cluster that relies on a RHOSP provider network

```
...
platform:
  openstack:
    apiVIPs: 1
```
In OpenShift Container Platform 4.12 and later, the `apiVIP` and `ingressVIP` configuration settings are deprecated. Instead, use a list format to enter values in the `apiVIPs` and `ingressVIPs` configuration settings.

**WARNING**

You cannot set the `platform.openstack.externalNetwork` or `platform.openstack.externalDNS` parameters while using a provider network for the primary network interface.

When you deploy the cluster, the installer uses the `install-config.yaml` file to deploy the cluster on the provider network.

**TIP**

You can add additional networks, including provider networks, to the `platform.openstack.additionalNetworkIDs` list.

After you deploy your cluster, you can attach pods to additional networks. For more information, see [Understanding multiple networks](#).

### 21.3.10.5. Sample customized install-config.yaml file for RHOSP

This sample `install-config.yaml` demonstrates all of the possible Red Hat OpenStack Platform (RHOSP) customization options.

**IMPORTANT**

This sample file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program.

```yaml
- 192.0.2.13
ingressVIPs:
- 192.0.2.23
machinesSubnet: fa806b2f-ac49-4bce-b9db-124bc64209bf
# ...
networking:
machineNetwork:
- cidr: 192.0.2.0/24
```

```yaml
apiVersion: v1
baseDomain: example.com
controlPlane:
  name: master
platform: {}
  replicas: 3
compute:
  - name: worker
```
21.3.10.6. Optional: Configuring a cluster with dual-stack networking

IMPORTANT

Dual-stack configuration for OpenStack is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see Technology Preview Features Support Scope.

You can create a dual-stack cluster on RHOSP. However, the dual-stack configuration is enabled only if you are using an RHOSP network with IPv4 and IPv6 subnets.

NOTE

RHOSP does not support the following configurations:

- Conversion of an IPv4 single-stack cluster to a dual-stack cluster network.
- IPv6 as the primary address family for dual-stack cluster network.

21.3.10.6.1. Deploying the dual-stack cluster

Procedure
1. Create a network with IPv4 and IPv6 subnets. The available address modes for `ipv6-ra-mode` and `ipv6-address-mode` fields are: stateful, stateless and slaac.

   **NOTE**

   The dualstack network MTU must accommodate both the minimum MTU for IPv6, which is 1280, and the OVN-Kubernetes encapsulation overhead, which is 100.

   **NOTE**

   DHCP must be enabled on the subnets.

2. Create the API and Ingress VIPs ports.

3. Add the IPv6 subnet to the router to enable router advertisements. If you are using a provider network, you can enable router advertisements by adding the network as an external gateway, which also enables external connectivity.

4. To configure IPv4 and IPv6 address endpoints for cluster nodes, edit the `install-config.yaml` file. The following is an example of an `install-config.yaml` file.

   **Example install-config.yaml**

   ```yaml
   apiVersion: v1
   baseDomain: mydomain.test
   featureSet: TechPreviewNoUpgrade

   compute:
   - name: worker
     platform:
       openstack:
         type: m1.xlarge
         replicas: 3
   controlPlane:
   name: master
   platform:
     openstack:
       type: m1.xlarge
       replicas: 3

   metadata:
   name: mycluster
   networking:
   machineNetwork:  
   - cidr: "192.168.25.0/24"
   - cidr: "fd2e:6f44:5dd8:c956::/64"

   clusterNetwork:  
   - cidr: 10.128.0.0/14
     hostPrefix: 23
   - cidr: fd01::/48
     hostPrefix: 64

   serviceNetwork:  
   - 172.30.0.0/16
   - fd02::/112
   platform:
   ```
Dual-stack clusters are supported only with the `TechPreviewNoUpgrade` value.

You must specify an IP address range in the `cidr` field for both IPv4 and IPv6 address families.

Specify the virtual IP (VIP) address endpoints for the Ingress VIP services to provide an interface to the cluster.

Specify the virtual IP (VIP) address endpoints for the API VIP services to provide an interface to the cluster.

Specify the dual-stack network details that are used by all the nodes across the cluster.

The CIDR of any subnet specified in this field must match the CIDRs listed on `networks.machineNetwork`.

You can specify a value for either `name` or `id`, or both.

**21.3.10.7. Installation configuration for a cluster on OpenStack with a user-managed load balancer**

The following example `install-config.yaml` file demonstrates how to configure a cluster that uses an external, user-managed load balancer rather than the default internal load balancer.

```yaml
apiVersion: v1
baseDomain: mydomain.test
compute:
- name: worker
  platform:
    openstack:
      type: m1.xlarge
      replicas: 3
controlPlane:
- name: master
  platform:
    openstack:
      type: m1.xlarge
      replicas: 3
metadata:
  name: mycluster
```
Regardless of which load balancer you use, the load balancer is deployed to this subnet.

The UserManaged value indicates that you are using an user-managed load balancer.

21.3.11. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH into the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH into your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>
   ```

   Specify the path and file name, such as ~/.ssh/id_ed25519, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.
NOTE
If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   $ cat <path>/<file_name>.pub

For example, run the following to view the ~/.ssh/id_ed25519.pub public key:

   $ cat ~/.ssh/id_ed25519.pub

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the ./openshift-install gather command.

   NOTE
   On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.

   a. If the ssh-agent process is not already running for your local user, start it as a background task:

      $ eval "$(ssh-agent -s)"

      Example output

      Agent pid 31874

   NOTE
   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the ssh-agent:

   $ ssh-add <path>/<file_name> ①

   ① Specify the path and file name for your SSH private key, such as ~/.ssh/id_ed25519

   Example output

   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

Next steps
When you install OpenShift Container Platform, provide the SSH public key to the installation program.

21.3.12. Enabling access to the environment

At deployment, all OpenShift Container Platform machines are created in a Red Hat OpenStack Platform (RHOSP)-tenant network. Therefore, they are not accessible directly in most RHOSP deployments.

You can configure OpenShift Container Platform API and application access by using floating IP addresses (FIPs) during installation. You can also complete an installation without configuring FIPs, but the installer will not configure a way to reach the API or applications externally.

21.3.12.1. Enabling access with floating IP addresses

Create floating IP (FIP) addresses for external access to the OpenShift Container Platform API and cluster applications.

Procedure

1. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the API FIP:

   ```bash
   $ openstack floating ip create --description "API <cluster_name>.<base_domain>" <external_network>
   ```

2. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the apps, or Ingress, FIP:

   ```bash
   $ openstack floating ip create --description "Ingress <cluster_name>.<base_domain>" <external_network>
   ```

3. Add records that follow these patterns to your DNS server for the API and Ingress FIPs:

   ```
   api.<cluster_name>.<base_domain>. IN A <API_FIP>
   *.apps.<cluster_name>.<base_domain>. IN A <apps_FIP>
   ```
NOTE

If you do not control the DNS server, you can access the cluster by adding the cluster domain names such as the following to your `/etc/hosts` file:

- `<api_floating_ip> api.<cluster_name>.<base_domain>`
- `<application_floating_ip> grafana-openshift-monitoring.apps.<cluster_name>.<base_domain>`
- `<application_floating_ip> prometheus-k8s-openshift-monitoring.apps.<cluster_name>.<base_domain>`
- `<application_floating_ip> oauth-openshift.apps.<cluster_name>.<base_domain>`
- `<application_floating_ip> console-openshift-console.apps.<cluster_name>.<base_domain>`
- `<application_floating_ip> integrated-oauth-server-openshift-authentication.apps.<cluster_name>.<base_domain>`

The cluster domain names in the `/etc/hosts` file grant access to the web console and the monitoring interface of your cluster locally. You can also use the `kubectl` or `oc`. You can access the user applications by using the additional entries pointing to the `<application_floating_ip>`. This action makes the API and applications accessible to only you, which is not suitable for production deployment, but does allow installation for development and testing.

4. Add the FIPs to the `install-config.yaml` file as the values of the following parameters:
   - `platform.openstack.ingressFloatingIP`
   - `platform.openstack.apiFloatingIP`

If you use these values, you must also enter an external network as the value of the `platform.openstack.externalNetwork` parameter in the `install-config.yaml` file.

TIP

You can make OpenShift Container Platform resources available outside of the cluster by assigning a floating IP address and updating your firewall configuration.

21.3.12.2. Completing installation without floating IP addresses

You can install OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) without providing floating IP addresses.

In the `install-config.yaml` file, do not define the following parameters:

- `platform.openstack.ingressFloatingIP`
- `platform.openstack.apiFloatingIP`

If you cannot provide an external network, you can also leave `platform.openstack.externalNetwork` blank. If you do not provide a value for `platform.openstack.externalNetwork`, a router is not created for
you, and, without additional action, the installer will fail to retrieve an image from Glance. You must configure external connectivity on your own.

If you run the installer from a system that cannot reach the cluster API due to a lack of floating IP addresses or name resolution, installation fails. To prevent installation failure in these cases, you can use a proxy network or run the installer from a system that is on the same network as your machines.

**NOTE**

You can enable name resolution by creating DNS records for the API and Ingress ports. For example:

```
api.<cluster_name>.<base_domain>. IN A <api_port_IP>
*apps.<cluster_name>.<base_domain>. IN A <ingress_port_IP>
```

If you do not control the DNS server, you can add the record to your `/etc/hosts` file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

### 21.3.13. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

**Prerequisites**

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.

**Procedure**

- Change to the directory that contains the installation program and initialize the cluster deployment:

  ```bash
  $ ./openshift-install create cluster --dir <installation_directory> \ 
  --log-level=info
  ```

  **1** For `<installation_directory>`, specify the location of your customized `.install-config.yaml` file.

  **2** To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

**Verification**

When the cluster deployment completes successfully:
The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the **kubeadmin** user.

Credential information also outputs to `<installation_directory>/.openshift_install.log`.

**IMPORTANT**

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

**Example output**

```
...  
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for **Recovering from expired control plane certificates** for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

### 21.3.14. Verifying cluster status

You can verify your OpenShift Container Platform cluster’s status during or after installation.

**Procedure**

1. In the cluster environment, export the administrator’s kubeconfig file:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   **1** For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server.
2. View the control plane and compute machines created after a deployment:

$ oc get nodes

3. View your cluster’s version:

$ oc get clusterversion

4. View your Operators’ status:

$ oc get clusteroperator

5. View all running pods in the cluster:

$ oc get pods -A

21.3.15. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster kubeconfig file. The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the oc CLI.

Procedure

1. Export the kubeadmin credentials:

   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig 1

   1 For <installation_directory>, specify the path to the directory that you stored the installation files in.

2. Verify you can run oc commands successfully using the exported configuration:

   $ oc whoami

   Example output

   system:admin

Additional resources

- See Accessing the web console for more details about accessing and understanding the OpenShift Container Platform web console.
21.3.16. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager Hybrid Cloud Console.

After you confirm that your OpenShift Cluster Manager Hybrid Cloud Console inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service

21.3.17. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- If you need to enable external access to node ports, configure ingress cluster traffic by using a node port.
- If you did not configure RHOSP to accept application traffic over floating IP addresses, configure RHOSP access with floating IP addresses.

21.4. INSTALLING A CLUSTER ON OPENSTACK WITH KURYR

IMPORTANT

Kuryr is a deprecated feature. Deprecated functionality is still included in OpenShift Container Platform and continues to be supported; however, it will be removed in a future release of this product and is not recommended for new deployments.

For the most recent list of major functionality that has been deprecated or removed within OpenShift Container Platform, refer to the Deprecated and removed features section of the OpenShift Container Platform release notes.

In OpenShift Container Platform version 4.14, you can install a customized cluster on Red Hat OpenStack Platform (RHOSP) that uses Kuryr SDN. To customize the installation, modify parameters in the install-config.yaml before you install the cluster.

21.4.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You verified that OpenShift Container Platform 4.14 is compatible with your RHOSP version by using the Supported platforms for OpenShift clusters section. You can also compare platform
support across different versions by viewing the OpenShift Container Platform on RHOSP support matrix.

- You have a storage service installed in RHOSP, such as block storage (Cinder) or object storage (Swift). Object storage is the recommended storage technology for OpenShift Container Platform registry cluster deployment. For more information, see Optimizing storage.

- You understand performance and scalability practices for cluster scaling, control plane sizing, and etcd. For more information, see Recommended practices for scaling the cluster.

21.4.2. About Kuryr SDN

IMPORTANT

Kuryr is a deprecated feature. Deprecated functionality is still included in OpenShift Container Platform and continues to be supported; however, it will be removed in a future release of this product and is not recommended for new deployments.

For the most recent list of major functionality that has been deprecated or removed within OpenShift Container Platform, refer to the Deprecated and removed features section of the OpenShift Container Platform release notes.

Kuryr is a container network interface (CNI) plugin solution that uses the Neutron and Octavia Red Hat OpenStack Platform (RHOSP) services to provide networking for pods and Services.

Kuryr and OpenShift Container Platform integration is primarily designed for OpenShift Container Platform clusters running on RHOSP VMs. Kuryr improves the network performance by plugging OpenShift Container Platform pods into RHOSP SDN. In addition, it provides interconnectivity between pods and RHOSP virtual instances.

Kuryr components are installed as pods in OpenShift Container Platform using the openshift-kuryr namespace:

- **kuryr-controller** - a single service instance installed on a master node. This is modeled in OpenShift Container Platform as a Deployment object.

- **kuryr-cni** - a container installing and configuring Kuryr as a CNI driver on each OpenShift Container Platform node. This is modeled in OpenShift Container Platform as a DaemonSet object.

The Kuryr controller watches the OpenShift Container Platform API server for pod, service, and namespace create, update, and delete events. It maps the OpenShift Container Platform API calls to corresponding objects in Neutron and Octavia. This means that every network solution that implements the Neutron trunk port functionality can be used to back OpenShift Container Platform via Kuryr. This includes open source solutions such as Open vSwitch (OVS) and Open Virtual Network (OVN) as well as Neutron-compatible commercial SDNs.

Kuryr is recommended for OpenShift Container Platform deployments on encapsulated RHOSP tenant networks to avoid double encapsulation, such as running an encapsulated OpenShift Container Platform SDN over an RHOSP network.

If you use provider networks or tenant VLANs, you do not need to use Kuryr to avoid double encapsulation. The performance benefit is negligible. Depending on your configuration, though, using Kuryr to avoid having two overlays might still be beneficial.

Kuryr is not recommended in deployments where all of the following criteria are true:
- The RHOSP version is less than 16.
- The deployment uses UDP services, or a large number of TCP services on few hypervisors.

or

- The `ovn-octavia` Octavia driver is disabled.
- The deployment uses a large number of TCP services on few hypervisors.

### 21.4.3. Resource guidelines for installing OpenShift Container Platform on RHOSP with Kuryr

When using Kuryr SDN, the pods, services, namespaces, and network policies are using resources from the RHOSP quota; this increases the minimum requirements. Kuryr also has some additional requirements on top of what a default install requires.

Use the following quota to satisfy a default cluster’s minimum requirements:

**Table 21.4. Recommended resources for a default OpenShift Container Platform cluster on RHOSP with Kuryr**

<table>
<thead>
<tr>
<th>Resource</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Floating IP addresses</td>
<td>3 - plus the expected number of Services of LoadBalancer type</td>
</tr>
<tr>
<td>Ports</td>
<td>1500 - 1 needed per Pod</td>
</tr>
<tr>
<td>Routers</td>
<td>1</td>
</tr>
<tr>
<td>Subnets</td>
<td>250 - 1 needed per Namespace/Project</td>
</tr>
<tr>
<td>Networks</td>
<td>250 - 1 needed per Namespace/Project</td>
</tr>
<tr>
<td>RAM</td>
<td>112 GB</td>
</tr>
<tr>
<td>vCPUs</td>
<td>28</td>
</tr>
<tr>
<td>Volume storage</td>
<td>275 GB</td>
</tr>
<tr>
<td>Instances</td>
<td>7</td>
</tr>
<tr>
<td>Security groups</td>
<td>250 - 1 needed per Service and per NetworkPolicy</td>
</tr>
<tr>
<td>Security group rules</td>
<td>1000</td>
</tr>
<tr>
<td>Server groups</td>
<td>2 - plus 1 for each additional availability zone in each machine pool</td>
</tr>
<tr>
<td>Load balancers</td>
<td>100 - 1 needed per Service</td>
</tr>
</tbody>
</table>
A cluster might function with fewer than recommended resources, but its performance is not guaranteed.

**IMPORTANT**

If RHOSP object storage (Swift) is available and operated by a user account with the `swiftoperator` role, it is used as the default backend for the OpenShift Container Platform image registry. In this case, the volume storage requirement is 175 GB. Swift space requirements vary depending on the size of the image registry.

**IMPORTANT**

If you are using Red Hat OpenStack Platform (RHOSP) version 16 with the Amphora driver rather than the OVN Octavia driver, security groups are associated with service accounts instead of user projects.

Take the following notes into consideration when setting resources:

- The number of ports that are required is larger than the number of pods. Kuryr uses ports pools to have pre-created ports ready to be used by pods and speed up the pods' booting time.

- Each network policy is mapped into an RHOSP security group, and depending on the `NetworkPolicy` spec, one or more rules are added to the security group.

- Each service is mapped to an RHOSP load balancer. Consider this requirement when estimating the number of security groups required for the quota.
  - If you are using RHOSP version 15 or earlier, or the `ovn-octavia driver`, each load balancer has a security group with the user project.
  - If you are using RHOSP version 16 with the OVN Octavia driver enabled, only one load balancer VM is generated; services are load balanced through OVN flows.

An OpenShift Container Platform deployment comprises control plane machines, compute machines, and a bootstrap machine.

To enable Kuryr SDN, your environment must meet the following requirements:

- Run RHOSP 13+.
- Have Overcloud with Octavia.
- Use Neutron Trunk ports extension.
• Use **openvswitch** firewall driver if ML2/OVS Neutron driver is used instead of **ovs-hybrid**.

### 21.4.3.1. Increasing quota

When using Kuryr SDN, you must increase quotas to satisfy the Red Hat OpenStack Platform (RHOSP) resources used by pods, services, namespaces, and network policies.

**Procedure**

- Increase the quotas for a project by running the following command:

  ```
  $ sudo openstack quota set --secgroups 250 --secgroup-rules 1000 --ports 1500 --subnets 250 --networks 250 <project>
  ```

### 21.4.3.2. Configuring Neutron

Kuryr CNI leverages the Neutron Trunks extension to plug containers into the Red Hat OpenStack Platform (RHOSP) SDN, so you must use the **trunks** extension for Kuryr to properly work.

In addition, if you leverage the default ML2/OVS Neutron driver, the firewall must be set to **openvswitch** instead of **ovs_hybrid** so that security groups are enforced on trunk subports and Kuryr can properly handle network policies.

### 21.4.3.3. Configuring Octavia

Kuryr SDN uses Red Hat OpenStack Platform (RHOSP)’s Octavia LBaaS to implement OpenShift Container Platform services. Thus, you must install and configure Octavia components in RHOSP to use Kuryr SDN.

To enable Octavia, you must include the Octavia service during the installation of the RHOSP Overcloud, or upgrade the Octavia service if the Overcloud already exists. The following steps for enabling Octavia apply to both a clean install of the Overcloud or an Overcloud update.

**NOTE**

The following steps only capture the key pieces required during the deployment of RHOSP when dealing with Octavia. It is also important to note that registry methods vary.

This example uses the local registry method.

**Procedure**

1. If you are using the local registry, create a template to upload the images to the registry. For example:

   ```
   (undercloud) $ openstack overcloud container image prepare \
   -e /usr/share/openstack-tripleo-heat-templates/environments/services-docker/octavia.yaml \
   --namespace=registry.access.redhat.com/rhosp13 \
   --push-destination=<local-ip-from-undercloud.conf>:8787 \
   --prefix=openstack- \
   --tag-from-label {version}-{product-version} \
   --output-env-file=/home/stack/templates/overcloud_images.yaml \
   --output-images-file /home/stack/local_registry_images.yaml
   ```
2. Verify that the `local_registry_images.yaml` file contains the Octavia images. For example:

   ```yaml
   ...
   - imagename: registry.access.redhat.com/rhosp13/openstack-octavia-api:13.0-43
     push_destination: <local-ip-from-undercloud.conf>:8787
   - imagename: registry.access.redhat.com/rhosp13/openstack-octavia-health-manager:13.0-45
     push_destination: <local-ip-from-undercloud.conf>:8787
   - imagename: registry.access.redhat.com/rhosp13/openstack-octavia-housekeeping:13.0-45
     push_destination: <local-ip-from-undercloud.conf>:8787
   - imagename: registry.access.redhat.com/rhosp13/openstack-octavia-worker:13.0-44
     push_destination: <local-ip-from-undercloud.conf>:8787
   ```

   **NOTE**
   The Octavia container versions vary depending upon the specific RHOSP release installed.

3. Pull the container images from `registry.redhat.io` to the Undercloud node:

   ```sh
   (undercloud) $ sudo openstack overcloud container image upload \
     --config-file /home/stack/local_registry_images.yaml \
     --verbose
   ```
   
   This may take some time depending on the speed of your network and Undercloud disk.

4. Install or update your Overcloud environment with Octavia:

   ```sh
   $ openstack overcloud deploy --templates \
     -e /usr/share/openstack-tripleo-heat-templates/environments/services-docker/octavia.yaml \
     -e octavia_timeouts.yaml
   ```

   **NOTE**
   This command only includes the files associated with Octavia; it varies based on your specific installation of RHOSP. See the RHOSP documentation for further information. For more information on customizing your Octavia installation, see installation of Octavia using Director.

   **NOTE**
   When leveraging Kuryr SDN, the Overcloud installation requires the Neutron trunk extension. This is available by default on director deployments. Use the openvswitch firewall instead of the default ovs-hybrid when the Neutron backend is ML2/OVS. There is no need for modifications if the backend is ML2/OVN.

### 21.4.3.3.1. The Octavia OVN Driver

Octavia supports multiple provider drivers through the Octavia API.

To see all available Octavia provider drivers, on a command line, enter:
Beginning with RHOSP version 16, the Octavia OVN provider driver (ovn) is supported on OpenShift Container Platform on RHOSP deployments.

ovn is an integration driver for the load balancing that Octavia and OVN provide. It supports basic load balancing capabilities, and is based on OpenFlow rules. The driver is automatically enabled in Octavia by Director on deployments that use OVN Neutron ML2.

The Amphora provider driver is the default driver. If ovn is enabled, however, Kuryr uses it.

If Kuryr uses ovn instead of Amphora, it offers the following benefits:

- Decreased resource requirements. Kuryr does not require a load balancer VM for each service.
- Reduced network latency.
- Increased service creation speed by using OpenFlow rules instead of a VM for each service.
- Distributed load balancing actions across all nodes instead of centralized on Amphora VMs.

You can configure your cluster to use the Octavia OVN driver after your RHOSP cloud is upgraded from version 13 to version 16.

### 21.4.3.4. Known limitations of installing with Kuryr

Using OpenShift Container Platform with Kuryr SDN has several known limitations.

#### RHOSP general limitations

Using OpenShift Container Platform with Kuryr SDN has several limitations that apply to all versions and environments:

- **Service** objects with the **NodePort** type are not supported.

- Clusters that use the OVN Octavia provider driver support **Service** objects for which the **.spec.selector** property is unspecified only if the **.subsets.addresses** property of the **Endpoints** object includes the subnet of the nodes or pods.

- If the subnet on which machines are created is not connected to a router, or if the subnet is connected, but the router has no external gateway set, Kuryr cannot create floating IPs for **Service** objects with type **LoadBalancer**.

- Configuring the **sessionAffinity=ClientIP** property on **Service** objects does not have an effect. Kuryr does not support this setting.

#### RHOSP version limitations

```bash
$ openstack loadbalancer provider list
+---------+-------------------------------------------------+
| name    | description                                     |
+---------+-------------------------------------------------+
| amphora | The Octavia Amphora driver.                     |
| octavia | Deprecated alias of the Octavia Amphora driver. |
| ovn     | Octavia OVN driver.                             |
+---------+-------------------------------------------------+
```
Using OpenShift Container Platform with Kuryr SDN has several limitations that depend on the RHOSP version:

- RHOSP versions before 16 use the default Octavia load balancer driver (Amphora). This driver requires that one Amphora load balancer VM is deployed per OpenShift Container Platform service. Creating too many services can cause you to run out of resources. Deployments of later versions of RHOSP that have the OVN Octavia driver disabled also use the Amphora driver. They are subject to the same resource concerns as earlier versions of RHOSP.

- Kuryr SDN does not support automatic unidling by a service.

**RHOSP upgrade limitations**

As a result of the RHOSP upgrade process, the Octavia API might be changed, and upgrades to the Amphora images that are used for load balancers might be required.

You can address API changes on an individual basis.

If the Amphora image is upgraded, the RHOSP operator can handle existing load balancer VMs in two ways:

- Upgrade each VM by triggering a load balancer failover.
- Leave responsibility for upgrading the VMs to users.

If the operator takes the first option, there might be short downtimes during failovers.

If the operator takes the second option, the existing load balancers will not support upgraded Octavia API features, like UDP listeners. In this case, users must recreate their Services to use these features.

### 21.4.3.5. Control plane machines

By default, the OpenShift Container Platform installation process creates three control plane machines.

Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory and 4 vCPUs
- At least 100 GB storage space from the RHOSP quota

### 21.4.3.6. Compute machines

By default, the OpenShift Container Platform installation process creates three compute machines.

Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 8 GB memory and 2 vCPUs
- At least 100 GB storage space from the RHOSP quota
TIP

Compute machines host the applications that you run on OpenShift Container Platform; aim to run as many as you can.

21.4.3.7. Bootstrap machine

During installation, a bootstrap machine is temporarily provisioned to stand up the control plane. After the production control plane is ready, the bootstrap machine is deprovisioned.

The bootstrap machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory and 4 vCPUs
- At least 100 GB storage space from the RHOSP quota

21.4.3.8. Load balancing requirements for user-provisioned infrastructure

Before you install OpenShift Container Platform, you can provision your own API and application ingress load balancing infrastructure to use in place of the default, internal load balancing solution. In production scenarios, you can deploy the API and application Ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

**NOTE**

If you want to deploy the API and application Ingress load balancers with a Red Hat Enterprise Linux (RHEL) instance, you must purchase the RHEL subscription separately.

The load balancing infrastructure must meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:

   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.

   - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

   **IMPORTANT**

   Do not configure session persistence for an API load balancer. Configuring session persistence for a Kubernetes API server might cause performance issues from excess application traffic for your OpenShift Container Platform cluster and the Kubernetes API that runs inside the cluster.

   Configure the following ports on both the front and back of the load balancers:

   **Table 21.5. API load balancer**
<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the /readyz endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>

**NOTE**

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the /readyz endpoint to the removal of the API server instance from the pool. Within the time frame after /readyz returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application Ingress load balancer**: Provides an ingress point for application traffic flowing in from outside the cluster. A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

**TIP**

If the true IP address of the client can be seen by the application Ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

Configure the following ports on both the front and back of the load balancers:

**Table 21.6. Application Ingress load balancer**
The machines that run the Ingress Controller pods, compute, or worker, by default.

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>

**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application Ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

21.4.3.8.1. Example load balancer configuration for clusters that are deployed with user-managed load balancers

This section provides an example API and application Ingress load balancer configuration that meets the load balancing requirements for clusters that are deployed with user-managed load balancers. The sample is an `/etc/haproxy/haproxy.cfg` configuration for an HAProxy load balancer. The example is not meant to provide advice for choosing one load balancing solution over another.

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

**NOTE**

If you are using HAProxy as a load balancer and SELinux is set to enforcing, you must ensure that the HAProxy service can bind to the configured TCP port by running `setsebool -P haproxy_connect_any=1`.

**Example 21.2. Sample API and application Ingress load balancer configuration**

```
global
log 127.0.0.1 local2
pidfile /var/run/haproxy.pid
maxconn 4000
daemon
defaults
mode http
log global
do
option dontlognull
option http-server-close
option redolog
retries 3
timeout http-request 10s
timeout queue 1m
timeout connect 10s
```
Port 6443 handles the Kubernetes API traffic and points to the control plane machines.

The bootstrap entries must be in place before the OpenShift Container Platform cluster installation and they must be removed after the bootstrap process is complete.

Port 22623 handles the machine config server traffic and points to the control plane machines.

Port 443 handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

Port 80 handles the HTTP traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application Ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.
TIP

If you are using HAProxy as a load balancer, you can check that the haproxy process is listening on ports 6443, 22623, 443, and 80 by running netstat -ntupe on the HAProxy node.

21.4.4. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager Hybrid Cloud Console to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

21.4.5. Enabling Swift on RHOSP

Swift is operated by a user account with the swiftoperator role. Add the role to an account before you run the installation program.

IMPORTANT

If the Red Hat OpenStack Platform (RHOSP) object storage service, commonly known as Swift, is available, OpenShift Container Platform uses it as the image registry storage. If it is unavailable, the installation program relies on the RHOSP block storage service, commonly known as Cinder.

If Swift is present and you want to use it, you must enable access to it. If it is not present, or if you do not want to use it, skip this section.

IMPORTANT

RHOSP 17 sets the rgw_max_attr_size parameter of Ceph RGW to 256 characters. This setting causes issues with uploading container images to the OpenShift Container Platform registry. You must set the value of rgw_max_attr_size to at least 1024 characters.

Before installation, check if your RHOSP deployment is affected by this problem. If it is, reconfigure Ceph RGW.

Prerequisites
You have a RHOSP administrator account on the target environment.

- The Swift service is installed.
- On Ceph RGW, the account in url option is enabled.

**Procedure**

To enable Swift on RHOSP:

1. As an administrator in the RHOSP CLI, add the **swiftoperator** role to the account that will access Swift:

   ```
   $ openstack role add --user <user> --project <project> swiftoperator
   ``

Your RHOSP deployment can now use Swift for the image registry.

**21.4.6. Verifying external network access**

The OpenShift Container Platform installation process requires external network access. You must provide an external network value to it, or deployment fails. Before you begin the process, verify that a network with the external router type exists in Red Hat OpenStack Platform (RHOSP).

**Prerequisites**

- Configure OpenStack’s networking service to have DHCP agents forward instances’ DNS queries

**Procedure**

1. Using the RHOSP CLI, verify the name and ID of the ‘External’ network:

   ```
   $ openstack network list --long --c ID --c Name --c "Router Type"
   ``

   **Example output**

   ```
   +--------------------------------------+----------------+-------------+
   | ID                                   | Name           | Router Type |
   +--------------------------------------+----------------+-------------+
   | 148a8023-62a7-4672-b018-003462f8d7dc | public_network | External    |
   +--------------------------------------+----------------+-------------+
   ```

   A network with an external router type appears in the network list. If at least one does not, see **Creating a default floating IP network** and **Creating a default provider network**.
**IMPORTANT**

If the external network’s CIDR range overlaps one of the default network ranges, you must change the matching network ranges in the `install-config.yaml` file before you start the installation process.

The default network ranges are:

<table>
<thead>
<tr>
<th>Network</th>
<th>Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>machineNetwork</td>
<td>10.0.0.0/16</td>
</tr>
<tr>
<td>serviceNetwork</td>
<td>172.30.0.0/16</td>
</tr>
<tr>
<td>clusterNetwork</td>
<td>10.128.0.0/14</td>
</tr>
</tbody>
</table>

**WARNING**

If the installation program finds multiple networks with the same name, it sets one of them at random. To avoid this behavior, create unique names for resources in RHOSP.

**NOTE**

If the Neutron trunk service plugin is enabled, a trunk port is created by default. For more information, see [Neutron trunk port](#).

### 21.4.7. Defining parameters for the installation program

The OpenShift Container Platform installation program relies on a file that is called `clouds.yaml`. The file describes Red Hat OpenStack Platform (RHOSP) configuration parameters, including the project name, log in information, and authorization service URLs.

**Procedure**

1. Create the `clouds.yaml` file:
   
   - If your RHOSP distribution includes the Horizon web UI, generate a `clouds.yaml` file in it.

   **IMPORTANT**

   Remember to add a password to the `auth` field. You can also keep secrets in a separate file from `clouds.yaml`.

   - If your RHOSP distribution does not include the Horizon web UI, or you do not want to use Horizon, create the file yourself. For detailed information about `clouds.yaml`, see [Config files](#) in the RHOSP documentation.
2. If your RHOSP installation uses self-signed certificate authority (CA) certificates for endpoint authentication:

   a. Copy the certificate authority file to your machine.

   b. Add the `cacerts` key to the `clouds.yaml` file. The value must be an absolute, non-root-accessible path to the CA certificate:

   ```yaml
   clouds:
   shiftstack:
   ...  
   cacert: "/etc/pki/ca-trust/source/anchors/ca.crt.pem"
   ```

   **TIP**

   After you run the installer with a custom CA certificate, you can update the certificate by editing the value of the `ca-cert.pem` key in the `cloud-provider-config` keymap. On a command line, run:

   ```bash
   $ oc edit configmap -n openshift-config cloud-provider-config
   ```

3. Place the `clouds.yaml` file in one of the following locations:

   a. The value of the `OS_CLIENT_CONFIG_FILE` environment variable

   b. The current directory

   c. A Unix-specific user configuration directory, for example `~/.config/openstack/clouds.yaml`

   d. A Unix-specific site configuration directory, for example `/etc/openstack/clouds.yaml`

   The installation program searches for `clouds.yaml` in that order.

### 21.4.8. Setting OpenStack Cloud Controller Manager options

Optionally, you can edit the OpenStack Cloud Controller Manager (CCM) configuration for your cluster. This configuration controls how OpenShift Container Platform interacts with Red Hat OpenStack Platform (RHOSP).
For a complete list of configuration parameters, see the "OpenStack Cloud Controller Manager reference guide" page in the "Installing on OpenStack" documentation.

Procedure

1. If you have not already generated manifest files for your cluster, generate them by running the following command:

   ```
   $ openshift-install --dir <destination_directory> create manifests
   ```

2. In a text editor, open the cloud-provider configuration manifest file. For example:

   ```
   $ vi openshift/manifests/cloud-provider-config.yaml
   ```

3. Modify the options according to the CCM reference guide.

   Configuring Octavia for load balancing is a common case for clusters that do not use Kuryr. For example:

   ```yaml
   [LoadBalancer]
   lb-provider = "amphora"
   floating-network-id="d3deb660-4190-40a3-91f1-37326fe6ec4a"
   create-monitor = True
   monitor-delay = 10s
   monitor-timeout = 10s
   monitor-max-retries = 1
   ```

   - **1** This property sets the Octavia provider that your load balancer uses. It accepts "ovn" or "amphora" as values. If you choose to use OVN, you must also set the `lb-method` to `SOURCE_IP_PORT`.
   - **2** This property is required if you want to use multiple external networks with your cluster. The cloud provider creates floating IP addresses on the network that is specified here.
   - **3** This property controls whether the cloud provider creates health monitors for Octavia load balancers. Set the value to `True` to create health monitors. As of RHOSP 16.2, this feature is only available for the Amphora provider.
   - **4** This property sets the frequency with which endpoints are monitored. The value must be in the `time.ParseDuration()` format. This property is required if the value of the `create-monitor` property is `True`.
   - **5** This property sets the time that monitoring requests are open before timing out. The value must be in the `time.ParseDuration()` format. This property is required if the value of the `create-monitor` property is `True`.
   - **6** This property defines how many successful monitoring requests are required before a load balancer is marked as online. The value must be an integer. This property is required if the value of the `create-monitor` property is `True`. 
IMPORTANT
Prior to saving your changes, verify that the file is structured correctly. Clusters might fail if properties are not placed in the appropriate section.

IMPORTANT
You must set the value of the `create-monitor` property to `True` if you use services that have the value of the `.spec.externalTrafficPolicy` property set to `Local`. The OVN Octavia provider in RHOSP 16.2 does not support health monitors. Therefore, services that have ETP parameter values set to `Local` might not respond when the `lb-provider` value is set to “ovn”.

IMPORTANT
For installations that use Kuryr, Kuryr handles relevant services. There is no need to configure Octavia load balancing in the cloud provider.

4. Save the changes to the file and proceed with installation.

TIP
You can update your cloud provider configuration after you run the installer. On a command line, run:

```bash
$ oc edit configmap -n openshift-config cloud-provider-config
```

After you save your changes, your cluster will take some time to reconfigure itself. The process is complete if none of your nodes have a `SchedulingDisabled` status.

21.4.9. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

Prerequisites
- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

Procedure
1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.
IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   $ tar -xvf openshift-install-linux.tar.gz

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

21.4.10. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Red Hat OpenStack Platform (RHOSP).

Prerequisites

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Create the install-config.yaml file.

   a. Change to the directory that contains the installation program and run the following command:

      $ ./openshift-install create install-config --dir <installation_directory>

   1 For <installation_directory>, specify the directory name to store the files that the installation program creates.

When specifying the directory:

- Verify that the directory has the execute permission. This permission is required to run Terraform binaries under the installation directory.

- Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory.
you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

NOTE

Always delete the ~/.powervs directory to avoid reusing a stale configuration. Run the following command:

```
$ rm -rf ~/.powervs
```

b. At the prompts, provide the configuration details for your cloud:

i. Optional: Select an SSH key to use to access your cluster machines.

NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

ii. Select openstack as the platform to target.

iii. Specify the Red Hat OpenStack Platform (RHOSP) external network name to use for installing the cluster.

iv. Specify the floating IP address to use for external access to the OpenShift API.

v. Specify a RHOSP flavor with at least 16 GB RAM to use for control plane nodes and 8 GB RAM for compute nodes.

vi. Select the base domain to deploy the cluster to. All DNS records will be sub-domains of this base and will also include the cluster name.

vii. Enter a name for your cluster. The name must be 14 or fewer characters long.

2. Modify the install-config.yaml file. You can find more information about the available parameters in the "Installation configuration parameters" section.

3. Back up the install-config.yaml file so that you can use it to install multiple clusters.

IMPORTANT

The install-config.yaml file is consumed during the installation process. If you want to reuse the file, you must back it up now.

Additional resources

- Installation configuration parameters for OpenStack

21.4.10.1. Configuring the cluster-wide proxy during installation

2968
Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**NOTE**

Kuryr installations default to HTTP proxies.

**Prerequisites**

- For Kuryr installations on restricted networks that use the **Proxy** object, the proxy must be able to reply to the router that the cluster uses. To add a static route for the proxy configuration, from a command line as the root user, enter:

  ```
  $ ip route add <cluster_network_cidr> via <installer_subnet_gateway>
  ```

- The restricted subnet must have a gateway that is defined and available to be linked to the **Router** resource that Kuryr creates.

- You have an existing `install-config.yaml` file.

- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object’s **spec.noProxy** field to bypass the proxy if necessary.

  **NOTE**

  The **Proxy** object **status.noProxy** field is populated with the values of the `networking.machineNetwork[]`.cidr`, `networking.clusterNetwork[]`.cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

  For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (169.254.169.254).

**Procedure**

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
     httpProxy: http://<username>:<pswd>@<ip>:<port>
     httpsProxy: https://<username>:<pswd>@<ip>:<port>
     noProxy: example.com
   additionalTrustBundle: |
     -----BEGIN CERTIFICATE-----
     <MY_TRUSTED_CA_CERT>
     -----END CERTIFICATE-----
   additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle>
   ```
1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.

2. A proxy URL to use for creating HTTPS connections outside the cluster.

3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.

4. If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the trustedCA field of the Proxy object. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

5. Optional: The policy to determine the configuration of the Proxy object to reference the user-ca-bundle config map in the trustedCA field. The allowed values are Proxyonly and Always. Use Proxyonly to reference the user-ca-bundle config map only when http/https proxy is configured. Use Always to always reference the user-ca-bundle config map. The default value is Proxyonly.

**NOTE**

The installation program does not support the proxy readinessEndpoints field.

**NOTE**

If the installer times out, restart and then complete the deployment by using the wait-for command of the installer. For example:

```
$ ./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

**NOTE**

Only the Proxy object named cluster is supported, and no additional proxies can be created.

21.4.10.2. Custom subnets in RHOSP deployments

Optionally, you can deploy a cluster on a Red Hat OpenStack Platform (RHOSP) subnet of your choice. The subnet’s GUID is passed as the value of platform.openstack.machinesSubnet in the install-config.yaml file.
This subnet is used as the cluster’s primary subnet. By default, nodes and ports are created on it. You can create nodes and ports on a different RHOSP subnet by setting the value of the `platform.openstack.machinesSubnet` property to the subnet's UUID.

Before you run the OpenShift Container Platform installer with a custom subnet, verify that your configuration meets the following requirements:

- The subnet that is used by `platform.openstack.machinesSubnet` has DHCP enabled.
- The CIDR of `platform.openstack.machinesSubnet` matches the CIDR of `networking.machineNetwork`.
- The installation program user has permission to create ports on this network, including ports with fixed IP addresses.

Clusters that use custom subnets have the following limitations:

- If you plan to install a cluster that uses floating IP addresses, the `platform.openstack.machinesSubnet` subnet must be attached to a router that is connected to the `externalNetwork` network.

- If the `platform.openstack.machinesSubnet` value is set in the `install-config.yaml` file, the installation program does not create a private network or subnet for your RHOSP machines.

- You cannot use the `platform.openstack.externalDNS` property at the same time as a custom subnet. To add DNS to a cluster that uses a custom subnet, configure DNS on the RHOSP network.

**NOTE**

By default, the API VIP takes x.x.x.5 and the Ingress VIP takes x.x.x.7 from your network’s CIDR block. To override these default values, set values for `platform.openstack.apiVIPs` and `platform.openstack.ingressVIPs` that are outside of the DHCP allocation pool.

**IMPORTANT**

The CIDR ranges for networks are not adjustable after cluster installation. Red Hat does not provide direct guidance on determining the range during cluster installation because it requires careful consideration of the number of created pods per namespace.

### 21.4.10.3. Sample customized install-config.yaml file for RHOSP with Kuryr

To deploy with Kuryr SDN instead of the default OVN-Kubernetes network plugin, you must modify the `install-config.yaml` file to include `Kuryr` as the desired `networking.networkType`. This sample `install-config.yaml` demonstrates all of the possible Red Hat OpenStack Platform (RHOSP) customization options.

**IMPORTANT**

This sample file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program.

```yaml
apiVersion: v1
baseDomain: example.com
controlPlane:
```
The Amphora Octavia driver creates two ports per load balancer. As a result, the service subnet that the installer creates is twice the size of the CIDR that is specified as the value of the `serviceNetwork` property. The larger range is required to prevent IP address conflicts.

The cluster network plugin to install. The supported values are Kuryr, OVNKubernetes, and OpenShiftSDN. The default value is OVNKubernetes.

Both trunkSupport and octaviaSupport are automatically discovered by the installer, so there is no need to set them. But if your environment does not meet both requirements, Kuryr SDN will not properly work. Trunks are needed to connect the pods to the RHOSP network and Octavia is required to create the OpenShift Container Platform services.

21.4.10.4. Installation configuration for a cluster on OpenStack with a user-managed load balancer

The following example `install-config.yaml` file demonstrates how to configure a cluster that uses an external, user-managed load balancer rather than the default internal load balancer.
Regardless of which load balancer you use, the load balancer is deployed to this subnet.

The **UserManaged** value indicates that you are using an user-managed load balancer.

### 21.4.10.5. Cluster deployment on RHOSP provider networks

You can deploy your OpenShift Container Platform clusters on Red Hat OpenStack Platform (RHOSP) with a primary network interface on a provider network. Provider networks are commonly used to give projects direct access to a public network that can be used to reach the internet. You can also share provider networks among projects as part of the network creation process.

RHOSP provider networks map directly to an existing physical network in the data center. A RHOSP administrator must create them.

In the following example, OpenShift Container Platform workloads are connected to a data center by using a provider network:
OpenShift Container Platform clusters that are installed on provider networks do not require tenant networks or floating IP addresses. The installer does not create these resources during installation.

Example provider network types include flat (untagged) and VLAN (802.1Q tagged).

NOTE

A cluster can support as many provider network connections as the network type allows. For example, VLAN networks typically support up to 4096 connections.

You can learn more about provider and tenant networks in the RHOSP documentation.

21.4.10.5.1. RHOSP provider network requirements for cluster installation

Before you install an OpenShift Container Platform cluster, your Red Hat OpenStack Platform (RHOSP) deployment and provider network must meet a number of conditions:

- The RHOSP networking service (Neutron) is enabled and accessible through the RHOSP networking API.
- The RHOSP networking service has the port security and allowed address pairs extensions enabled.
The provider network can be shared with other tenants.

**TIP**

Use the `openstack network create` command with the `--share` flag to create a network that can be shared.

The RHOSP project that you use to install the cluster must own the provider network, as well as an appropriate subnet.

**TIP**

To create a network for a project that is named "openshift," enter the following command:

```bash
$ openstack network create --project openshift
```

To create a subnet for a project that is named "openshift," enter the following command:

```bash
$ openstack subnet create --project openshift
```

To learn more about creating networks on RHOSP, read the provider networks documentation.

If the cluster is owned by the `admin` user, you must run the installer as that user to create ports on the network.

**IMPORTANT**

Provider networks must be owned by the RHOSP project that is used to create the cluster. If they are not, the RHOSP Compute service (Nova) cannot request a port from that network.

- Verify that the provider network can reach the RHOSP metadata service IP address, which is `169.254.169.254` by default.
  Depending on your RHOSP SDN and networking service configuration, you might need to provide the route when you create the subnet. For example:

```bash
$ openstack subnet create --dhcp --host-route
destination=169.254.169.254/32,gateway=192.0.2.2 ...
```

- Optional: To secure the network, create role-based access control (RBAC) rules that limit network access to a single project.

### 21.4.10.5.2. Deploying a cluster that has a primary interface on a provider network

You can deploy an OpenShift Container Platform cluster that has its primary network interface on an Red Hat OpenStack Platform (RHOSP) provider network.

**Prerequisites**

- Your Red Hat OpenStack Platform (RHOSP) deployment is configured as described by “RHOSP provider network requirements for cluster installation”.

---

**CHAPTER 21. INSTALLING ON OPENSTACK**

2975
Procedure

1. In a text editor, open the `install-config.yaml` file.

2. Set the value of the `platform.openstack.apiVIPs` property to the IP address for the API VIP.

3. Set the value of the `platform.openstack.ingressVIPs` property to the IP address for the Ingress VIP.

4. Set the value of the `platform.openstack.machinesSubnet` property to the UUID of the provider network subnet.

5. Set the value of the `networking.machineNetwork.cidr` property to the CIDR block of the provider network subnet.

**IMPORTANT**

The `platform.openstack.apiVIPs` and `platform.openstack.ingressVIPs` properties must both be unassigned IP addresses from the `networking.machineNetwork.cidr` block.

Section of an installation configuration file for a cluster that relies on a RHOSP provider network

```yaml
platform:
  openstack:
    apiVIPs: [1]
    - 192.0.2.13
    ingressVIPs: [2]
    - 192.0.2.23
    machinesSubnet: fa806b2f-ac49-4bce-b9db-124bc64209bf

# ...

networking:
  machineNetwork:
    cidr: 192.0.2.0/24
```

1 2 In OpenShift Container Platform 4.12 and later, the `apiVIP` and `ingressVIP` configuration settings are deprecated. Instead, use a list format to enter values in the `apiVIPs` and `ingressVIPs` configuration settings.

**WARNING**

You cannot set the `platform.openstack.externalNetwork` or `platform.openstack.externalDNS` parameters while using a provider network for the primary network interface.

When you deploy the cluster, the installer uses the `install-config.yaml` file to deploy the cluster on the provider network.
TIP

You can add additional networks, including provider networks, to the `platform.openstack.additionalNetworkIDs` list.

After you deploy your cluster, you can attach pods to additional networks. For more information, see [Understanding multiple networks](#).

21.4.10.6. Kuryr ports pools

A Kuryr ports pool maintains a number of ports on standby for pod creation.

Keeping ports on standby minimizes pod creation time. Without ports pools, Kuryr must explicitly request port creation or deletion whenever a pod is created or deleted.

The Neutron ports that Kuryr uses are created in subnets that are tied to namespaces. These pod ports are also added as subports to the primary port of OpenShift Container Platform cluster nodes.

Because Kuryr keeps each namespace in a separate subnet, a separate ports pool is maintained for each namespace-worker pair.

Prior to installing a cluster, you can set the following parameters in the `cluster-network-03-config.yml` manifest file to configure ports pool behavior:

- The `enablePortPoolsPrepopulation` parameter controls pool prepopulation, which forces Kuryr to add Neutron ports to the pools when the first pod that is configured to use the dedicated network for pods is created in a namespace. The default value is `false`.

- The `poolMinPorts` parameter is the minimum number of free ports that are kept in the pool. The default value is `1`.

- The `poolMaxPorts` parameter is the maximum number of free ports that are kept in the pool. A value of `0` disables that upper bound. This is the default setting. If your OpenStack port quota is low, or you have a limited number of IP addresses on the pod network, consider setting this option to ensure that unneeded ports are deleted.

- The `poolBatchPorts` parameter defines the maximum number of Neutron ports that can be created at once. The default value is `3`.

21.4.10.7. Adjusting Kuryr ports pools during installation

During installation, you can configure how Kuryr manages Red Hat OpenStack Platform (RHOSP) Neutron ports to control the speed and efficiency of pod creation.

Prerequisites

- Create and modify the `install-config.yaml` file.

Procedure

1. From a command line, create the manifest files:

```bash
$ ./openshift-install create manifests --dir <installation_directory>
```

---

2977
1. For `<installation_directory>`, specify the name of the directory that contains the `install-config.yaml` file for your cluster.

2. Create a file that is named `cluster-network-03-config.yml` in the `<installation_directory>/manifests/` directory:

   ```bash
   $ touch <installation_directory>/manifests/cluster-network-03-config.yml
   ```

3. After creating the file, several network configuration files are in the `manifests/` directory, as shown:

   ```bash
   $ ls <installation_directory>/manifests/cluster-network-*
   ```

   Example output

   ```
   cluster-network-01-crd.yml
   cluster-network-02-config.yml
   cluster-network-03-config.yml
   ```

4. Open the `cluster-network-03-config.yml` file in an editor, and enter a custom resource (CR) that describes the Cluster Network Operator configuration that you want:

   ```bash
   $ oc edit networks.operator.openshift.io cluster
   ```

   ```yaml
   apiVersion: operator.openshift.io/v1
   kind: Network
   metadata:
     name: cluster
   spec:
     clusterNetwork:
       - cidr: 10.128.0.0/14
         hostPrefix: 23
     serviceNetwork:
       - 172.30.0.0/16
     defaultNetwork:
       type: Kuryr
       kuryrConfig:
         enablePortPoolsPrepopulation: false
         poolMinPorts: 1
         poolBatchPorts: 3
         poolMaxPorts: 5
         openstackServiceNetwork: 172.30.0.0/15
   ```

   Set `enablePortPoolsPrepopulation` to `true` to make Kuryr create new Neutron ports when the first pod on the network for pods is created in a namespace. This setting raises the Neutron ports quota but can reduce the time that is required to spawn pods. The default value is `false`. 
Kuryr creates new ports for a pool if the number of free ports in that pool is lower than the value of `poolMinPorts`. The default value is 1.

`poolBatchPorts` controls the number of new ports that are created if the number of free ports is lower than the value of `poolMinPorts`. The default value is 3.

If the number of free ports in a pool is higher than the value of `poolMaxPorts`, Kuryr deletes them until the number matches that value. Setting this value to 0 disables this upper bound, preventing pools from shrinking. The default value is 0.

The `openStackServiceNetwork` parameter defines the CIDR range of the network from which IP addresses are allocated to RHOSP Octavia’s LoadBalancers.

If this parameter is used with the Amphora driver, Octavia takes two IP addresses from this network for each load balancer: one for OpenShift and the other for VRRP connections. Because these IP addresses are managed by OpenShift Container Platform and Neutron respectively, they must come from different pools. Therefore, the value of `openStackServiceNetwork` must be at least twice the size of the value of `serviceNetwork`, and the value of `serviceNetwork` must overlap entirely with the range that is defined by `openStackServiceNetwork`.

The CNO verifies that VRRP IP addresses that are taken from the range that is defined by this parameter do not overlap with the range that is defined by the `serviceNetwork` parameter.

If this parameter is not set, the CNO uses an expanded value of `serviceNetwork` that is determined by decrementing the prefix size by 1.

5. Save the `cluster-network-03-config.yml` file, and exit the text editor.

6. Optional: Back up the `manifests/cluster-network-03-config.yml` file. The installation program deletes the `manifests/` directory while creating the cluster.

### 21.4.11. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the `core` user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user `core`. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**Procedure**
1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   
   ```
   $ ssh-keygen -t ed25519 -N " " -f <path>/<file_name>
   ```

   Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the `x86_64`, `ppc64le`, and `s390x` architectures, do not create a key that uses the `ed25519` algorithm. Instead, create a key that uses the `rsa` or `ecdsa` algorithm.

2. View the public SSH key:

   ```
   $ cat <path>/<file_name>.pub
   ```

   For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

   ```
   $ cat ~/.ssh/id_ed25519.pub
   ```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `.openshift-install gather` command.

   **NOTE**

   On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

   a. If the `ssh-agent` process is not already running for your local user, start it as a background task:

   ```
   $ eval "$(ssh-agent -s)"
   ```

   **Example output**

   ```
   Agent pid 31874
   ```

   **NOTE**

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the `ssh-agent`:
Specify the path and file name for your SSH private key, such as ~/.ssh/id_ed25519

Example output

Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

21.4.12. Enabling access to the environment

At deployment, all OpenShift Container Platform machines are created in a Red Hat OpenStack Platform (RHOSP)-tenant network. Therefore, they are not accessible directly in most RHOSP deployments.

You can configure OpenShift Container Platform API and application access by using floating IP addresses (FIPs) during installation. You can also complete an installation without configuring FIPs, but the installer will not configure a way to reach the API or applications externally.

21.4.12.1. Enabling access with floating IP addresses

Create floating IP (FIP) addresses for external access to the OpenShift Container Platform API and cluster applications.

Procedure

1. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the API FIP:

   $ openstack floating ip create --description "API <cluster_name>.<base_domain>" <external_network>

2. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the apps, or Ingress, FIP:

   $ openstack floating ip create --description "Ingress <cluster_name>.<base_domain>" <external_network>

3. Add records that follow these patterns to your DNS server for the API and Ingress FIPs:

   api.<cluster_name>.<base_domain>. IN A <API_FIP>

   *.apps.<cluster_name>.<base_domain>. IN A <apps_FIP>
NOTE

If you do not control the DNS server, you can access the cluster by adding the cluster domain names such as the following to your `/etc/hosts` file:

- `<api_floating_ip> api.<cluster_name>.<base_domain>`
- `<application_floating_ip> grafana-openshift-monitoring.apps.<cluster_name>.<base_domain>`
- `<application_floating_ip> prometheus-k8s-openshift-monitoring.apps.<cluster_name>.<base_domain>`
- `<application_floating_ip> oauth-openshift.apps.<cluster_name>.<base_domain>`
- `<application_floating_ip> console-openshift-console.apps.<cluster_name>.<base_domain>`
- `<application_floating_ip> integrated-oauth-server-openshift-authentication.apps.<cluster_name>.<base_domain>`

The cluster domain names in the `/etc/hosts` file grant access to the web console and the monitoring interface of your cluster locally. You can also use the `kubectl` or `oc`. You can access the user applications by using the additional entries pointing to the `<application_floating_ip>`. This action makes the API and applications accessible to only you, which is not suitable for production deployment, but does allow installation for development and testing.

4. Add the FIPs to the `install-config.yaml` file as the values of the following parameters:
   - `platform.openstack.ingressFloatingIP`
   - `platform.openstack.apiFloatingIP`

   If you use these values, you must also enter an external network as the value of the `platform.openstack.externalNetwork` parameter in the `install-config.yaml` file.

TIP

You can make OpenShift Container Platform resources available outside of the cluster by assigning a floating IP address and updating your firewall configuration.

21.4.12.2. Completing installation without floating IP addresses

You can install OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) without providing floating IP addresses.

In the `install-config.yaml` file, do not define the following parameters:

- `platform.openstack.ingressFloatingIP`
- `platform.openstack.apiFloatingIP`

If you cannot provide an external network, you can also leave `platform.openstack.externalNetwork` blank. If you do not provide a value for `platform.openstack.externalNetwork`, a router is not created for
you, and, without additional action, the installer will fail to retrieve an image from Glance. You must configure external connectivity on your own.

If you run the installer from a system that cannot reach the cluster API due to a lack of floating IP addresses or name resolution, installation fails. To prevent installation failure in these cases, you can use a proxy network or run the installer from a system that is on the same network as your machines.

**NOTE**

You can enable name resolution by creating DNS records for the API and Ingress ports. For example:

```
api.<cluster_name>.<base_domain>. IN A <api_port_IP>
*apps.<cluster_name>.<base_domain>. IN A <ingress_port_IP>
```

If you do not control the DNS server, you can add the record to your `/etc/hosts` file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

### 21.4.13. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

**Prerequisites**

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.

- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.

**Procedure**

- Change to the directory that contains the installation program and initialize the cluster deployment:

  ```
  $ ./openshift-install create cluster --dir <installation_directory> \
  --log-level=info
  ```

  1. For `<installation_directory>`, specify the location of your customized `/install-config.yaml` file.

  2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

**Verification**

When the cluster deployment completes successfully:
• The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the kubeadmin user.

• Credential information also outputs to `<installation_directory>/openshift_install.log`.

**IMPORTANT**

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

Example output

```plaintext
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```

**IMPORTANT**

• The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

• It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

# 21.4.14. Verifying cluster status

You can verify your OpenShift Container Platform cluster’s status during or after installation.

**Procedure**

1. In the cluster environment, export the administrator’s kubeconfig file:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server.
2. View the control plane and compute machines created after a deployment:

   $ oc get nodes

3. View your cluster’s version:

   $ oc get clusterversion

4. View your Operators’ status:

   $ oc get clusteroperator

5. View all running pods in the cluster:

   $ oc get pods -A

21.4.15. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster kubeconfig file. The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the oc CLI.

Procedure

1. Export the kubeadmin credentials:

   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig

   For <installation_directory>, specify the path to the directory that you stored the installation files in.

2. Verify you can run oc commands successfully using the exported configuration:

   $ oc whoami

   Example output

   system:admin

Additional resources

- See Accessing the web console for more details about accessing and understanding the OpenShift Container Platform web console.
21.4.16. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager Hybrid Cloud Console.

After you confirm that your OpenShift Cluster Manager Hybrid Cloud Console inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service

21.4.17. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- If you need to enable external access to node ports, configure ingress cluster traffic by using a node port.
- If you did not configure RHOSP to accept application traffic over floating IP addresses, configure RHOSP access with floating IP addresses.

21.5. INSTALLING A CLUSTER ON OPENSTACK ON YOUR OWN INFRASTRUCTURE

In OpenShift Container Platform version 4.14, you can install a cluster on Red Hat OpenStack Platform (RHOSP) that runs on user-provisioned infrastructure.

Using your own infrastructure allows you to integrate your cluster with existing infrastructure and modifications. The process requires more labor on your part than installer-provisioned installations, because you must create all RHOSP resources, like Nova servers, Neutron ports, and security groups. However, Red Hat provides Ansible playbooks to help you in the deployment process.

21.5.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You verified that OpenShift Container Platform 4.14 is compatible with your RHOSP version by using the Supported platforms for OpenShift clusters section. You can also compare platform support across different versions by viewing the OpenShift Container Platform on RHOSP support matrix.
- You have an RHOSP account where you want to install OpenShift Container Platform.
You understand performance and scalability practices for cluster scaling, control plane sizing, and etcd. For more information, see Recommended practices for scaling the cluster.

On the machine from which you run the installation program, you have:
- A single directory in which you can keep the files you create during the installation process
- Python 3

### 21.5.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager Hybrid Cloud Console to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 21.5.3. Resource guidelines for installing OpenShift Container Platform on RHOSP

To support an OpenShift Container Platform installation, your Red Hat OpenStack Platform (RHOSP) quota must meet the following requirements:

**Table 21.7. Recommended resources for a default OpenShift Container Platform cluster on RHOSP**

<table>
<thead>
<tr>
<th>Resource</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Floating IP addresses</td>
<td>3</td>
</tr>
<tr>
<td>Ports</td>
<td>15</td>
</tr>
<tr>
<td>Routers</td>
<td>1</td>
</tr>
<tr>
<td>Subnets</td>
<td>1</td>
</tr>
<tr>
<td>RAM</td>
<td>88 GB</td>
</tr>
<tr>
<td>vCPUs</td>
<td>22</td>
</tr>
</tbody>
</table>
A cluster might function with fewer than recommended resources, but its performance is not guaranteed.

**IMPORTANT**

If RHOSP object storage (Swift) is available and operated by a user account with the `swiftoperator` role, it is used as the default backend for the OpenShift Container Platform image registry. In this case, the volume storage requirement is 175 GB. Swift space requirements vary depending on the size of the image registry.

**NOTE**

By default, your security group and security group rule quotas might be low. If you encounter problems, run `openstack quota set --secgroups 3 --secgroup-rules 60 <project>` as an administrator to increase them.

An OpenShift Container Platform deployment comprises control plane machines, compute machines, and a bootstrap machine.

**21.5.3.1. Control plane machines**

By default, the OpenShift Container Platform installation process creates three control plane machines.

Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory and 4 vCPUs
- At least 100 GB storage space from the RHOSP quota

**21.5.3.2. Compute machines**

By default, the OpenShift Container Platform installation process creates three compute machines.

Each machine requires:

<table>
<thead>
<tr>
<th>Resource</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Volume storage</td>
<td>275 GB</td>
</tr>
<tr>
<td>Instances</td>
<td>7</td>
</tr>
<tr>
<td>Security groups</td>
<td>3</td>
</tr>
<tr>
<td>Security group rules</td>
<td>60</td>
</tr>
<tr>
<td>Server groups</td>
<td>2 - plus 1 for each additional availability zone in each machine pool</td>
</tr>
</tbody>
</table>
An instance from the RHOSP quota

A port from the RHOSP quota

A flavor with at least 8 GB memory and 2 vCPUs

At least 100 GB storage space from the RHOSP quota

**TIP**

Compute machines host the applications that you run on OpenShift Container Platform; aim to run as many as you can.

### 21.5.3.3. Bootstrap machine

During installation, a bootstrap machine is temporarily provisioned to stand up the control plane. After the production control plane is ready, the bootstrap machine is deprovisioned.

The bootstrap machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory and 4 vCPUs
- At least 100 GB storage space from the RHOSP quota

### 21.5.4. Downloading playbook dependencies

The Ansible playbooks that simplify the installation process on user-provisioned infrastructure require several Python modules. On the machine where you will run the installer, add the modules' repositories and then download them.

**NOTE**

These instructions assume that you are using Red Hat Enterprise Linux (RHEL) 8.

**Prerequisites**

- Python 3 is installed on your machine.

**Procedure**

1. On a command line, add the repositories:
   a. Register with Red Hat Subscription Manager:

   ```
   $ sudo subscription-manager register # If not done already
   ```

   b. Pull the latest subscription data:

   ```
   $ sudo subscription-manager attach --pool=$YOUR_POOLID # If not done already
   ```
c. Disable the current repositories:

```
$ sudo subscription-manager repos --disable=* # If not done already
```

d. Add the required repositories:

```
$ sudo subscription-manager repos \
  --enable=rhel-8-for-x86_64-baseos-rpms \ 
  --enable=openstack-16-tools-for-rhel-8-x86_64-rpms \ 
  --enable=ansible-2.9-for-rhel-8-x86_64-rpms \ 
  --enable=rhel-8-for-x86_64-appstream-rpms
```

2. Install the modules:

```
$ sudo yum install python3-openstackclient ansible python3-openstacksdk python3-netaddr ansible-collections-openstack
```

3. Ensure that the python command points to python3:

```
$ sudo alternatives --set python /usr/bin/python3
```

### 21.5.5. Downloading the installation playbooks

Download Ansible playbooks that you can use to install OpenShift Container Platform on your own Red Hat OpenStack Platform (RHOSP) infrastructure.

**Prerequisites**

- The curl command-line tool is available on your machine.

**Procedure**

- To download the playbooks to your working directory, run the following script from a command line:

```
$ xargs -n 1 curl -O <<<<'

https://raw.githubusercontent.com/openshift/installer/release-4.14/upi/openstack/bootstrap.yaml
https://raw.githubusercontent.com/openshift/installer/release-4.14/upi/openstack/common.yaml
https://raw.githubusercontent.com/openshift/installer/release-4.14/upi/openstack/control-plane.yaml
https://raw.githubusercontent.com/openshift/installer/release-4.14/upi/openstack/inventory.yaml
https://raw.githubusercontent.com/openshift/installer/release-4.14/upi/openstack/security-groups.yaml

```
The playbooks are downloaded to your machine.

**IMPORTANT**

During the installation process, you can modify the playbooks to configure your deployment.

Retain all playbooks for the life of your cluster. You must have the playbooks to remove your OpenShift Container Platform cluster from RHOSP.

**IMPORTANT**

You must match any edits you make in the `bootstrap.yaml`, `compute-nodes.yaml`, `control-plane.yaml`, `network.yaml`, and `security-groups.yaml` files to the corresponding playbooks that are prefixed with `down-`. For example, edits to the `bootstrap.yaml` file must be reflected in the `down-bootstrap.yaml` file, too. If you do not edit both files, the supported cluster removal process will fail.

### 21.5.6. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

**Prerequisites**

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

**Procedure**

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.
The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   $ tar -xvf openshift-install-linux.tar.gz

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 21.5.7. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the `core` user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user `core`. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**
Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**
You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

### Procedure
1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N " -f <path>/<file_name>
```

Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

**NOTE**

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the `x86_64`, `ppc64le`, and `s390x` architectures, do not create a key that uses the `ed25519` algorithm. Instead, create a key that uses the `rsa` or `ecdsa` algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

```
$ cat ~/.ssh/id_ed25519.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `/openshift-install gather` command.

**NOTE**

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

a. If the `ssh-agent` process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

**Example output**

```
Agent pid 31874
```

**NOTE**

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the `ssh-agent`.
OpenShift Container Platform 4.14 Installing

$ ssh-add <path>/<file_name> 1

1 Specify the path and file name for your SSH private key, such as ~/.ssh/id_ed25519

Example output

Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

21.5.8. Creating the Red Hat Enterprise Linux CoreOS (RHCOS) image

The OpenShift Container Platform installation program requires that a Red Hat Enterprise Linux CoreOS (RHCOS) image be present in the Red Hat OpenStack Platform (RHOSP) cluster. Retrieve the latest RHCOS image, then upload it using the RHOSP CLI.

Prerequisites

- The RHOSP CLI is installed.

Procedure

   **IMPORTANT**
   
   The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available.

3. Download the Red Hat Enterprise Linux CoreOS (RHCOS) - OpenStack Image (QCOW).

4. Decompress the image.

   **NOTE**
   
   You must decompress the RHOSP image before the cluster can use it. The name of the downloaded file might not contain a compression extension, like .gz or .tgz. To find out if or how the file is compressed, in a command line, enter:

   $ file <name_of_downloaded_file>
5. From the image that you downloaded, create an image that is named `rhcos` in your cluster by using the RHOSP CLI:

```bash
$ openstack image create --container-format=bare --disk-format=qcow2 --file rhcos-$(RHCOS_VERSION)-openstack.qcow2 rhcos
```

**IMPORTANT**

Depending on your RHOSP environment, you might be able to upload the image in either `.raw` or `.qcow2` formats. If you use Ceph, you must use the `.raw` format.

**WARNING**

If the installation program finds multiple images with the same name, it chooses one of them at random. To avoid this behavior, create unique names for resources in RHOSP.

After you upload the image to RHOSP, it is usable in the installation process.

### 21.5.9. Verifying external network access

The OpenShift Container Platform installation process requires external network access. You must provide an external network value to it, or deployment fails. Before you begin the process, verify that a network with the external router type exists in Red Hat OpenStack Platform (RHOSP).

**Prerequisites**

- Configure OpenStack’s networking service to have DHCP agents forward instances’ DNS queries

**Procedure**

1. Using the RHOSP CLI, verify the name and ID of the 'External' network:

```bash
$ openstack network list --long -c ID -c Name -c "Router Type"
```

**Example output**

```
+--------------------------------------+----------------+-------------+
| ID                                   | Name           | Router Type |
+--------------------------------------+----------------+-------------+
| 148a8023-62a7-4672-b018-003462f8d7dc | public_network | External    |
+--------------------------------------+----------------+-------------+
```

A network with an external router type appears in the network list. If at least one does not, see Creating a default floating IP network and Creating a default provider network.
If the Neutron trunk service plugin is enabled, a trunk port is created by default. For more information, see Neutron trunk port.

21.5.10. Enabling access to the environment

At deployment, all OpenShift Container Platform machines are created in a Red Hat OpenStack Platform (RHOSP)-tenant network. Therefore, they are not accessible directly in most RHOSP deployments.

You can configure OpenShift Container Platform API and application access by using floating IP addresses (FIPs) during installation. You can also complete an installation without configuring FIPs, but the installer will not configure a way to reach the API or applications externally.

21.5.10.1. Enabling access with floating IP addresses

Create floating IP (FIP) addresses for external access to the OpenShift Container Platform API, cluster applications, and the bootstrap process.

Procedure

1. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the API FIP:

   $ openstack floating ip create --description "API <cluster_name>.<base_domain>" <external_network>

2. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the apps, or Ingress, FIP:

   $ openstack floating ip create --description "Ingress <cluster_name>.<base_domain>" <external_network>

3. By using the Red Hat OpenStack Platform (RHOSP) CLI, create the bootstrap FIP:

   $ openstack floating ip create --description "bootstrap machine" <external_network>

4. Add records that follow these patterns to your DNS server for the API and Ingress FIPs:

   api.<cluster_name>.<base_domain>. IN A <API_FIP>
   *.apps.<cluster_name>.<base_domain>. IN A <apps_FIP>
NOTE

If you do not control the DNS server, you can access the cluster by adding the cluster domain names such as the following to your `/etc/hosts` file:

- `<api_floating_ip> api.<cluster_name>.<base_domain>`
- `<application_floating_ip> grafana-openshift-monitoring.apps.<cluster_name>.<base_domain>`
- `<application_floating_ip> prometheus-k8s-openshift-monitoring.apps.<cluster_name>.<base_domain>`
- `<application_floating_ip> oauth-openshift.apps.<cluster_name>.<base_domain>`
- `<application_floating_ip> console-openshift-console.apps.<cluster_name>.<base_domain>`
- `<application_floating_ip> integrated-oauth-server-openshift-authentication.apps.<cluster_name>.<base_domain>`

The cluster domain names in the `/etc/hosts` file grant access to the web console and the monitoring interface of your cluster locally. You can also use the `kubectl` or `oc`. You can access the user applications by using the additional entries pointing to the `<application_floating_ip>`. This action makes the API and applications accessible to only you, which is not suitable for production deployment, but does allow installation for development and testing.

5. Add the FIPs to the `inventory.yaml` file as the values of the following variables:

- `os_api_fip`
- `os_bootstrap_fip`
- `os_ingress_fip`

If you use these values, you must also enter an external network as the value of the `os_external_network` variable in the `inventory.yaml` file.

TIP

You can make OpenShift Container Platform resources available outside of the cluster by assigning a floating IP address and updating your firewall configuration.

21.5.10.2. Completing installation without floating IP addresses

You can install OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) without providing floating IP addresses.

In the `inventory.yaml` file, do not define the following variables:

- `os_api_fip`
- `os_bootstrap_fip`
If you cannot provide an external network, you can also leave `os_external_network` blank. If you do not provide a value for `os_external_network`, a router is not created for you, and, without additional action, the installer will fail to retrieve an image from Glance. Later in the installation process, when you create network resources, you must configure external connectivity on your own.

If you run the installer with the `wait-for` command from a system that cannot reach the cluster API due to a lack of floating IP addresses or name resolution, installation fails. To prevent installation failure in these cases, you can use a proxy network or run the installer from a system that is on the same network as your machines.

**NOTE**

You can enable name resolution by creating DNS records for the API and Ingress ports. For example:

```
api.<cluster_name>.<base_domain>. IN A <api_port_IP>
*.apps.<cluster_name>.<base_domain>. IN A <ingress_port_IP>
```

If you do not control the DNS server, you can add the record to your `/etc/hosts` file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

### 21.5.11. Defining parameters for the installation program

The OpenShift Container Platform installation program relies on a file that is called `clouds.yaml`. The file describes Red Hat OpenStack Platform (RHOSP) configuration parameters, including the project name, log in information, and authorization service URLs.

**Procedure**

1. Create the `clouds.yaml` file:
   - If your RHOSP distribution includes the Horizon web UI, generate a `clouds.yaml` file in it.
     
     **IMPORTANT**

     Remember to add a password to the `auth` field. You can also keep secrets in a separate file from `clouds.yaml`.

   - If your RHOSP distribution does not include the Horizon web UI, or you do not want to use Horizon, create the file yourself. For detailed information about `clouds.yaml`, see Config files in the RHOSP documentation.

```yaml
clouds:
  shiftstack:
    auth:
      project_name: shiftstack
      username: <username>
      password: <password>
      user_domain_name: Default
      project_domain_name: Default
```
2. If your RHOSP installation uses self-signed certificate authority (CA) certificates for endpoint authentication:
   a. Copy the certificate authority file to your machine.
   b. Add the `cacerts` key to the `clouds.yaml` file. The value must be an absolute, non-root-accessible path to the CA certificate:

   ```yaml
   clouds:
     shiftstack:
       ...  
       cacert: "/etc/pki/ca-trust/source/anchors/ca.crt.pem"
   ```

   **TIP**

   After you run the installer with a custom CA certificate, you can update the certificate by editing the value of the `ca-cert.pem` key in the `cloud-provider-config` keymap. On a command line, run:

   ```bash
   $ oc edit configmap -n openshift-config cloud-provider-config
   ```

3. Place the `clouds.yaml` file in one of the following locations:
   a. The value of the `OS_CLIENT_CONFIG_FILE` environment variable
   b. The current directory
   c. A Unix-specific user configuration directory, for example `~/.config/openstack/clouds.yaml`
   d. A Unix-specific site configuration directory, for example `/etc/openstack/clouds.yaml`
   The installation program searches for `clouds.yaml` in that order.

### 21.5.12. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Red Hat OpenStack Platform (RHOSP).

**Prerequisites**

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Create the `install-config.yaml` file.
   a. Change to the directory that contains the installation program and run the following command:

   ```bash
   dev-env:
   region_name: RegionOne
   auth:
     ...  
   ```
a. Change to the directory that contains the installation program and run the following command:

   ```
   $ ./openshift-install create install-config --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

   When specifying the directory:
   
   - Verify that the directory has the execute permission. This permission is required to run Terraform binaries under the installation directory.
   - Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

   **NOTE**
   
   Always delete the `~/.powervs` directory to avoid reusing a stale configuration. Run the following command:

   ```
   $ rm -rf ~/.powervs
   ```

b. At the prompts, provide the configuration details for your cloud:

   i. Optional: Select an SSH key to use to access your cluster machines.

   **NOTE**
   
   For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

   ii. Select `openstack` as the platform to target.

   iii. Specify the Red Hat OpenStack Platform (RHOSP) external network name to use for installing the cluster.

   iv. Specify the floating IP address to use for external access to the OpenShift API.

   v. Specify a RHOSP flavor with at least 16 GB RAM to use for control plane nodes and 8 GB RAM for compute nodes.

   vi. Select the base domain to deploy the cluster to. All DNS records will be sub-domains of this base and will also include the cluster name.

   vii. Enter a name for your cluster. The name must be 14 or fewer characters long.

2. Modify the `install-config.yaml` file. You can find more information about the available parameters in the "Installation configuration parameters" section.
3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

**IMPORTANT**

The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

You now have the file `install-config.yaml` in the directory that you specified.

**Additional resources**

- Installation configuration parameters for OpenStack

**21.5.12.1. Custom subnets in RHOSP deployments**

Optionally, you can deploy a cluster on a Red Hat OpenStack Platform (RHOSP) subnet of your choice. The subnet’s GUID is passed as the value of `platform.openstack.machinesSubnet` in the `install-config.yaml` file.

This subnet is used as the cluster’s primary subnet. By default, nodes and ports are created on it. You can create nodes and ports on a different RHOSP subnet by setting the value of the `platform.openstack.machinesSubnet` property to the subnet’s UUID.

Before you run the OpenShift Container Platform installer with a custom subnet, verify that your configuration meets the following requirements:

- The subnet that is used by `platform.openstack.machinesSubnet` has DHCP enabled.
- The CIDR of `platform.openstack.machinesSubnet` matches the CIDR of `networking.machineNetwork`.
- The installation program user has permission to create ports on this network, including ports with fixed IP addresses.

Clusters that use custom subnets have the following limitations:

- If you plan to install a cluster that uses floating IP addresses, the `platform.openstack.machinesSubnet` subnet must be attached to a router that is connected to the `externalNetwork` network.
- If the `platform.openstack.machinesSubnet` value is set in the `install-config.yaml` file, the installation program does not create a private network or subnet for your RHOSP machines.
- You cannot use the `platform.openstack.externalDNS` property at the same time as a custom subnet. To add DNS to a cluster that uses a custom subnet, configure DNS on the RHOSP network.

**NOTE**

By default, the API VIP takes x.x.x.5 and the Ingress VIP takes x.x.x.7 from your network’s CIDR block. To override these default values, set values for `platform.openstack.apiVIPs` and `platform.openstack.ingressVIPs` that are outside of the DHCP allocation pool.
IMPORTANT

The CIDR ranges for networks are not adjustable after cluster installation. Red Hat does not provide direct guidance on determining the range during cluster installation because it requires careful consideration of the number of created pods per namespace.

21.5.12.2. Sample customized install-config.yaml file for RHOSP

This sample `install-config.yaml` demonstrates all of the possible Red Hat OpenStack Platform (RHOSP) customization options.

IMPORTANT

This sample file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program.

```yaml
apiVersion: v1
baseDomain: example.com
controlPlane:
  name: master
  platform: {}
  replicas: 3
compute:
  - name: worker
    platform:
      openstack:
        type: ml.large
        replicas: 3
metadata:
  name: example
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
      hostPrefix: 23
  machineNetwork:
    - cidr: 10.0.0.0/16
  serviceNetwork:
    - 172.30.0.0/16
networkType: OVNKubernetes
platform:
  openstack:
    cloud: mycloud
    externalNetwork: external
    computeFlavor: m1.xlarge
    apiFloatingIP: 128.0.0.1
fips: false
pullSecret: '{"auths": ...}'
sshKey: ssh-ed25519 AAAA...
```

21.5.12.3. Setting a custom subnet for machines

The IP range that the installation program uses by default might not match the Neutron subnet that you create when you install OpenShift Container Platform. If necessary, update the CIDR value for new machines by editing the installation configuration file.
Prerequisites

- You have the *install-config.yaml* file that was generated by the OpenShift Container Platform installation program.

Procedure

1. On a command line, browse to the directory that contains *install-config.yaml*.

2. From that directory, either run a script to edit the *install-config.yaml* file or update the file manually:

   - To set the value by using a script, run:
     ```python
     $ python -c '
     import yaml;
     path = "install-config.yaml";
     data = yaml.safe_load(open(path));
     data["networking"]["machineNetwork"] = [{"cidr": "192.168.0.0/18"}];
     open(path, "w").write(yaml.dump(data, default_flow_style=False))'
     
     Insert a value that matches your intended Neutron subnet, e.g. 192.0.2.0/24.

   - To set the value manually, open the file and set the value of *networking.machineCIDR* to something that matches your intended Neutron subnet.

21.5.12.4. Emptying compute machine pools

To proceed with an installation that uses your own infrastructure, set the number of compute machines in the installation configuration file to zero. Later, you create these machines manually.

Prerequisites

- You have the *install-config.yaml* file that was generated by the OpenShift Container Platform installation program.

Procedure

1. On a command line, browse to the directory that contains *install-config.yaml*.

2. From that directory, either run a script to edit the *install-config.yaml* file or update the file manually:

   - To set the value by using a script, run:
     ```python
     $ python -c '
     import yaml;
     path = "install-config.yaml";
     data = yaml.safe_load(open(path));
     data["compute"][0]["replicas"] = 0;
     open(path, "w").write(yaml.dump(data, default_flow_style=False))'
     
   - To set the value manually, open the file and set the value of *compute.<first entry>.replicas* to 0.
21.5.12.5. Cluster deployment on RHOSP provider networks

You can deploy your OpenShift Container Platform clusters on Red Hat OpenStack Platform (RHOSP) with a primary network interface on a provider network. Provider networks are commonly used to give projects direct access to a public network that can be used to reach the internet. You can also share provider networks among projects as part of the network creation process.

RHOSP provider networks map directly to an existing physical network in the data center. A RHOSP administrator must create them.

In the following example, OpenShift Container Platform workloads are connected to a data center by using a provider network:

![Diagram showing OpenStack and Datacenter with OpenShift workloads and a provider network](image)

OpenShift Container Platform clusters that are installed on provider networks do not require tenant networks or floating IP addresses. The installer does not create these resources during installation.

Example provider network types include flat (untagged) and VLAN (802.1Q tagged).

**NOTE**

A cluster can support as many provider network connections as the network type allows. For example, VLAN networks typically support up to 4096 connections.
You can learn more about provider and tenant networks in the RHOSP documentation.

21.5.2.5.1. RHOSP provider network requirements for cluster installation

Before you install an OpenShift Container Platform cluster, your Red Hat OpenStack Platform (RHOSP) deployment and provider network must meet a number of conditions:

- The RHOSP networking service (Neutron) is enabled and accessible through the RHOSP networking API.
- The RHOSP networking service has the port security and allowed address pairs extensions enabled.
- The provider network can be shared with other tenants.

TIP

Use the openstack network create command with the --share flag to create a network that can be shared.

- The RHOSP project that you use to install the cluster must own the provider network, as well as an appropriate subnet.

TIP

To create a network for a project that is named "openshift," enter the following command:

```
$ openstack network create --project openshift
```

To create a subnet for a project that is named "openshift," enter the following command:

```
$ openstack subnet create --project openshift
```

To learn more about creating networks on RHOSP, read the provider networks documentation.

If the cluster is owned by the admin user, you must run the installer as that user to create ports on the network.

IMPORTANT

Provider networks must be owned by the RHOSP project that is used to create the cluster. If they are not, the RHOSP Compute service (Nova) cannot request a port from that network.

- Verify that the provider network can reach the RHOSP metadata service IP address, which is 169.254.169.254 by default.
  Depending on your RHOSP SDN and networking service configuration, you might need to provide the route when you create the subnet. For example:

```
$ openstack subnet create --dhcp --host-route
destination=169.254.169.254/32,gateway=192.0.2.2 ...
```
Optional: To secure the network, create role-based access control (RBAC) rules that limit network access to a single project.

21.5.12.5.2. Deploying a cluster that has a primary interface on a provider network

You can deploy an OpenShift Container Platform cluster that has its primary network interface on an Red Hat OpenStack Platform (RHOSP) provider network.

Prerequisites

- Your Red Hat OpenStack Platform (RHOSP) deployment is configured as described by "RHOSP provider network requirements for cluster installation".

Procedure

1. In a text editor, open the install-config.yaml file.

2. Set the value of the platform.openstack.apiVIPs property to the IP address for the API VIP.

3. Set the value of the platform.openstack.ingressVIPs property to the IP address for the Ingress VIP.

4. Set the value of the platform.openstack.machinesSubnet property to the UUID of the provider network subnet.

5. Set the value of the networking.machineNetwork.cidr property to the CIDR block of the provider network subnet.

IMPORTANT

The platform.openstack.apiVIPs and platform.openstack.ingressVIPs properties must both be unassigned IP addresses from the networking.machineNetwork.cidr block.

Section of an installation configuration file for a cluster that relies on a RHOSP provider network

```yaml
...
platform:
  openstack:
    apiVIPs:
      - 192.0.2.13
    ingressVIPs:
      - 192.0.2.23
    machinesSubnet: fa806b2f-ac49-4bce-b9db-124bc64209bf
# ...
networking:
  machineNetwork:
    cidr: 192.0.2.0/24
```

In OpenShift Container Platform 4.12 and later, the apiVIP and ingressVIP configuration settings are deprecated. Instead, use a list format to enter values in the apiVIPs and ingressVIPs configuration settings.
WARNING
You cannot set the platform.openstack.externalNetwork or platform.openstack.externalDNS parameters while using a provider network for the primary network interface.

When you deploy the cluster, the installer uses the install-config.yaml file to deploy the cluster on the provider network.

TIP
You can add additional networks, including provider networks, to the platform.openstack.additionalNetworkIDs list.

After you deploy your cluster, you can attach pods to additional networks. For more information, see Understanding multiple networks.

21.5.13. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

IMPORTANT

- The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

Prerequisites

- You obtained the OpenShift Container Platform installation program.
- You created the install-config.yaml installation configuration file.

Procedure
1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

```
$ ./openshift-install create manifests --dir <installation_directory> 1
```

   `- For `<installation_directory>` specify the installation directory that contains the `install-config.yaml` file you created.

2. Remove the Kubernetes manifest files that define the control plane machines, compute machine sets, and control plane machine sets:

```
```

   `- Because you create and manage these resources yourself, you do not have to initialize them.

   `- You can preserve the compute machine set files to create compute machines by using the machine API, but you must update references to them to match your environment.

3. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:

   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.

   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.

   c. Save and exit the file.

4. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

```
$ ./openshift-install create ignition-configs --dir <installation_directory> 1
```

   `- For `<installation_directory>` specify the same installation directory.

   `- Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The `kubeadmin-password` and `kubeconfig` files are created in the `./<installation_directory>/auth` directory:

   ```
   ├── auth
   │   └── kubeadmin-password
   │       └── kubeconfig
   │           └── bootstrap.ign
   │                   └── master.ign
   │                           └── metadata.json
   │                                   └── worker.ign
   ```

5. Export the metadata file’s `infraID` key as an environment variable:
TIP

Extract the `infraID` key from `metadata.json` and use it as a prefix for all of the RHOSP resources that you create. By doing so, you avoid name conflicts when making multiple deployments in the same project.

### 21.5.14. Preparing the bootstrap Ignition files

The OpenShift Container Platform installation process relies on bootstrap machines that are created from a bootstrap Ignition configuration file.

Edit the file and upload it. Then, create a secondary bootstrap Ignition configuration file that Red Hat OpenStack Platform (RHOSP) uses to download the primary file.

#### Prerequisites

- You have the bootstrap Ignition file that the installer program generates, `bootstrap.ign`.
- The infrastructure ID from the installer’s metadata file is set as an environment variable (`$INFRA_ID`).
  - If the variable is not set, see Creating the Kubernetes manifest and Ignition config files
- You have an HTTP(S)-accessible way to store the bootstrap Ignition file.
  - The documented procedure uses the RHOSP image service (Glance), but you can also use the RHOSP storage service (Swift), Amazon S3, an internal HTTP server, or an ad hoc Nova server.

#### Procedure

1. Run the following Python script. The script modifies the bootstrap Ignition file to set the hostname and, if available, CA certificate file when it runs:

```python
import base64
import json
import os

with open('bootstrap.ign', 'r') as f:
    ignition = json.load(f)

files = ignition['storage'].get('files', [])
infra_id = os.environ.get('INFRA_ID', 'openshift').encode()
hostname_b64 = base64.standard_b64encode(infra_id + b'-bootstrap
').decode().strip()
files.append(
    {'path': '/etc/hostname',
     'mode': 420,
     'contents': {
         'source': 'data:text/plain;charset=utf-8;base64,' + hostname_b64
     }
})
```
Using the RHOSP CLI, create an image that uses the bootstrap Ignition file:

```
ignition['storage'] = files;
```

Retrieve the image service’s public address:

```
$ openstack catalog show image
```

Combine the public address with the image file value and save the result as the storage location. The location follows the pattern `<image_service_public_URL>/v2/images/<image_ID>/file`.

Generate an auth token and save the token ID:

```
$ openstack token issue -c id -f value
```

Insert the following content into a file called `$INFRA_ID-bootstrap-ignition.json` and edit the placeholders to match your own values:

```

7. Insert the following content into a file called `$INFRA_ID-bootstrap-ignition.json` and edit the placeholders to match your own values:

```python
ca_cert_path = os.environ.get("OS_CACERT", ")
if ca_cert_path:
    with open(ca_cert_path, 'r') as f:
        ca_cert = f.read(), encode()
        ca_cert_b64 = base64.standard_b64encode(ca_cert).decode().strip()

files.append(
    {
        'path': '/opt/openshift/tls/cloud-ca-cert.pem',
        'mode': 420,
        'contents': {
            'source': 'data:text/plain;charset=utf-8;base64,' + ca_cert_b64
        }
    }
)

ignition['storage']['files'] = files;

with open('bootstrap.ign', 'w') as f:
    json.dump(ignition, f)
```

NOTE

Verify that the image you created is active.
"config": {
  "merge": [{
    "source": "<storage_url>"  \1
    "httpHeaders": [{
      "name": "X-Auth-Token",  \2
      "value": "<token_ID>"  \3
    }]
  },
  "security": {
    "tls": {
      "certificateAuthorities": [{
        "source": "data:text/plain;charset=utf-8;base64,<base64_encoded_certificate>" \4
      }
    }
  },
  "version": "3.2.0"
}

1. Replace the value of `ignition.config.merge.source` with the bootstrap Ignition file storage URL.

2. Set `name` in `httpHeaders` to "X-Auth-Token".

3. Set `value` in `httpHeaders` to your token’s ID.

4. If the bootstrap Ignition file server uses a self-signed certificate, include the base64-encoded certificate.

8. Save the secondary Ignition config file.

The bootstrap Ignition data will be passed to RHOSP during installation.

**WARNING**

The bootstrap Ignition file contains sensitive information, like `clouds.yaml` credentials. Ensure that you store it in a secure place, and delete it after you complete the installation process.

### 21.5.15. Creating control plane Ignition config files on RHOSP

Installing OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) on your own infrastructure requires control plane Ignition config files. You must create multiple config files.

**NOTE**

As with the bootstrap Ignition configuration, you must explicitly define a hostname for each control plane machine.
Prerequisites

- The infrastructure ID from the installation program’s metadata file is set as an environment variable (`$INFRA_ID`).
  - If the variable is not set, see “Creating the Kubernetes manifest and Ignition config files”.

Procedure

- On a command line, run the following Python script:

```bash
$ for index in $(seq 0 2); do
    MASTER_HOSTNAME="$INFRA_ID-master-$index"
    python -c "import base64, json, sys;
    ignition = json.load(sys.stdin);
    storage = ignition.get('storage', {});
    files = storage.get('files', []);
    files.append({'path': '/etc/hostname', 'mode': 420, 'contents': {'source':
      'data:text/plain;charset=utf-8;base64,' +
      base64.standard_b64encode(b'$MASTER_HOSTNAME').decode().strip(), 'verification': {}},
      'filesystem': 'root'});
    storage['files'] = files;
    ignition['storage'] = storage
    json.dump(ignition, sys.stdout)"
    <master.ign >"$INFRA_ID-master-$index-ignition.json"
done
```

You now have three control plane Ignition files: `<INFRA_ID>-master-0-ignition.json`, `<INFRA_ID>-master-1-ignition.json`, and `<INFRA_ID>-master-2-ignition.json`.

21.5.16. Creating network resources on RHOSP

Create the network resources that an OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) installation on your own infrastructure requires. To save time, run supplied Ansible playbooks that generate security groups, networks, subnets, routers, and ports.

Prerequisites

- Python 3 is installed on your machine.
- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".

Procedure

1. Optional: Add an external network value to the `inventory.yaml` playbook:

```
Example external network value in the inventory.yaml Ansible playbook

...
    # The public network providing connectivity to the cluster. If not
    # provided, the cluster external connectivity must be provided in another
    # way.
```
IMPORTANT

If you did not provide a value for `os_external_network` in the `inventory.yaml` file, you must ensure that VMs can access Glance and an external connection yourself.

2. Optional: Add external network and floating IP (FIP) address values to the `inventory.yaml` playbook:

Example FIP values in the `inventory.yaml` Ansible playbook

```yaml
# Required for os_api_fip, os_ingress_fip, os_bootstrap_fip.
...
# OpenShift API floating IP address. If this value is non-empty, the
# corresponding floating IP will be attached to the Control Plane to
# serve the OpenShift API.
os_api_fip: '203.0.113.23'

# OpenShift Ingress floating IP address. If this value is non-empty, the
# corresponding floating IP will be attached to the worker nodes to serve
# the applications.
os_ingress_fip: '203.0.113.19'

# If this value is non-empty, the corresponding floating IP will be
# attached to the bootstrap machine. This is needed for collecting logs
# in case of install failure.
os_bootstrap_fip: '203.0.113.20'
```

IMPORTANT

If you do not define values for `os_api_fip` and `os_ingress_fip`, you must perform postinstallation network configuration.

If you do not define a value for `os_bootstrap_fip`, the installer cannot download debugging information from failed installations.

See “Enabling access to the environment” for more information.

3. On a command line, create security groups by running the `security-groups.yaml` playbook:

```bash
$ ansible-playbook -i inventory.yaml security-groups.yaml
```

4. On a command line, create a network, subnet, and router by running the `network.yaml` playbook:

```bash
$ ansible-playbook -i inventory.yaml network.yaml
```

5. Optional: If you want to control the default resolvers that Nova servers use, run the RHOSP CLI command:
Optionally, you can use the `inventory.yaml` file that you created to customize your installation. For example, you can deploy a cluster that uses bare metal machines.

21.5.16.1. Deploying a cluster with bare metal machines

If you want your cluster to use bare metal machines, modify the `inventory.yaml` file. Your cluster can have both control plane and compute machines running on bare metal, or just compute machines.

Bare-metal compute machines are not supported on clusters that use Kuryr.

**NOTE**

Be sure that your `install-config.yaml` file reflects whether the RHOSP network that you use for bare metal workers supports floating IP addresses or not.

**Prerequisites**

- The RHOSP Bare Metal service (Ironic) is enabled and accessible via the RHOSP Compute API.
- Bare metal is available as a RHOSP flavor.
- If your cluster runs on an RHOSP version that is more than 16.1.6 and less than 16.2.4, bare metal workers do not function due to a known issue that causes the metadata service to be unavailable for services on OpenShift Container Platform nodes.
- The RHOSP network supports both VM and bare metal server attachment.
- Your network configuration does not rely on a provider network. Provider networks are not supported.
- If you want to deploy the machines on a pre-existing network, a RHOSP subnet is provisioned.
- If you want to deploy the machines on an installer-provisioned network, the RHOSP Bare Metal service (Ironic) is able to listen for and interact with Preboot eXecution Environment (PXE) boot machines that run on tenant networks.
- You created an `inventory.yaml` file as part of the OpenShift Container Platform installation process.

**Procedure**

1. In the `inventory.yaml` file, edit the flavors for machines:
   a. If you want to use bare-metal control plane machines, change the value of `os_flavor_master` to a bare metal flavor.
   b. Change the value of `os_flavor_worker` to a bare metal flavor.

   **An example bare metal inventory.yaml file**

   ```yaml
   all:
     hosts:
   ```
If you want to have bare-metal control plane machines, change this value to a bare metal flavor.

Change this value to a bare metal flavor to use for compute machines.

Use the updated inventory.yaml file to complete the installation process. Machines that are created during deployment use the flavor that you added to the file.

NOTE

The installer may time out while waiting for bare metal machines to boot.

If the installer times out, restart and then complete the deployment by using the wait-for command of the installer. For example:

```bash
$ ./openshift-install wait-for install-complete --log-level debug
```

21.5.17. Creating the bootstrap machine on RHOSP

Create a bootstrap machine and give it the network access it needs to run on Red Hat OpenStack Platform (RHOSP). Red Hat provides an Ansible playbook that you run to simplify this process.

Prerequisites

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The inventory.yaml, common.yaml, and bootstrap.yaml Ansible playbooks are in a common directory.
- The metadata.json file that the installation program created is in the same directory as the Ansible playbooks.

Procedure

1. On a command line, change the working directory to the location of the playbooks.

2. On a command line, run the bootstrap.yaml playbook:

```bash
$ ansible-playbook -i inventory.yaml bootstrap.yaml
```
3. After the bootstrap server is active, view the logs to verify that the Ignition files were received:

   $ openstack console log show "$INFRA_ID-bootstrap"

21.5.18. Creating the control plane machines on RHOSP

Create three control plane machines by using the Ignition config files that you generated. Red Hat provides an Ansible playbook that you run to simplify this process.

Prerequisites

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The infrastructure ID from the installation program’s metadata file is set as an environment variable ($INFRA_ID).
- The `inventory.yaml`, `common.yaml`, and `control-plane.yaml` Ansible playbooks are in a common directory.
- You have the three Ignition files that were created in "Creating control plane Ignition config files".

Procedure

1. On a command line, change the working directory to the location of the playbooks.

2. If the control plane Ignition config files aren’t already in your working directory, copy them into it.

3. On a command line, run the `control-plane.yaml` playbook:

   $ ansible-playbook -i inventory.yaml control-plane.yaml

4. Run the following command to monitor the bootstrapping process:

   $ openshift-install wait-for bootstrap-complete

   You will see messages that confirm that the control plane machines are running and have joined the cluster:

   INFO API v1.27.3 up
   INFO Waiting up to 30m0s for bootstrapping to complete...
   ... INFO It is now safe to remove the bootstrap resources

21.5.19. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.
Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

Procedure

1. Export the `kubeadmin` credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   ``

   Example output

   ```text
   system:admin
   ```

21.5.20. Deleting bootstrap resources from RHOSP

Delete the bootstrap resources that you no longer need.

Prerequisites

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The `inventory.yaml`, `common.yaml`, and `down-bootstrap.yaml` Ansible playbooks are in a common directory.
- The control plane machines are running.
  - If you do not know the status of the machines, see "Verifying cluster status".

Procedure

1. On a command line, change the working directory to the location of the playbooks.

2. On a command line, run the `down-bootstrap.yaml` playbook:

   ```bash
   $ ansible-playbook -i inventory.yaml down-bootstrap.yaml
   ```

   The bootstrap port, server, and floating IP address are deleted.
**WARNING**

If you did not disable the bootstrap Ignition file URL earlier, do so now.

---

### 21.5.21. Creating compute machines on RHOSP

After standing up the control plane, create compute machines. Red Hat provides an Ansible playbook that you run to simplify this process.

**Prerequisites**

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The `inventory.yaml`, `common.yaml`, and `compute-nodes.yaml` Ansible playbooks are in a common directory.
- The `metadata.json` file that the installation program created is in the same directory as the Ansible playbooks.
- The control plane is active.

**Procedure**

1. On a command line, change the working directory to the location of the playbooks.
2. On a command line, run the playbook:

   ```bash
   $ ansible-playbook -i inventory.yaml compute-nodes.yaml
   ```

**Next steps**

- Approve the certificate signing requests for the machines.

### 21.5.22. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

**Prerequisites**

- You added machines to your cluster.

**Procedure**

1. Confirm that the cluster recognizes the machines:

   ```bash
   $ oc get nodes
   ```
Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>64m</td>
<td>v1.27.3</td>
</tr>
</tbody>
</table>

The output lists all of the machines that you created.

NOTE

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the Pending or Approved status for each machine that you added to the cluster:

```bash
$ oc get csr
```

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-8b2br</td>
<td>15m</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-8vnps</td>
<td>15m</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Pending</td>
</tr>
</tbody>
</table>

In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

NOTE

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.
NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the `oc exec`, `oc rsh`, and `oc logs` commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the `node-bootstrapper` service account in the `system:node` or `system:admin` groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

  ```bash
  $ oc adm certificate approve <csr_name>
  ```

  `<csr_name>` is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

  ```bash
  $ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
  ```

NOTE

Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```bash
$ oc get csr
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-c57lv</td>
<td>5m26s</td>
<td>system:node:ip-10-0-95-157.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
</tbody>
</table>

5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

  ```bash
  $ oc adm certificate approve <csr_name>
  ```

  `<csr_name>` is the name of a CSR from the list of current CSRs.
To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs oc adm certificate approve
```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>74m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>worker-0</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>worker-1</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.27.3</td>
</tr>
</tbody>
</table>

**NOTE**

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

**Additional information**

- For more information on CSRs, see [Certificate Signing Requests](#).

### 21.5.23. Verifying a successful installation

Verify that the OpenShift Container Platform installation is complete.

**Prerequisites**

- You have the installation program (**openshift-install**)

**Procedure**

- On a command line, enter:

```
$ openshift-install --log-level debug wait-for install-complete
```

The program outputs the console URL, as well as the administrator’s login information.

### 21.5.24. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager Hybrid Cloud Console](#).

After you confirm that your [OpenShift Cluster Manager Hybrid Cloud Console](#) inventory is correct,
either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service

21.5.25. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- If you need to enable external access to node ports, configure ingress cluster traffic by using a node port.
- If you did not configure RHOSP to accept application traffic over floating IP addresses, configure RHOSP access with floating IP addresses.

21.6. INSTALLING A CLUSTER ON OPENSTACK WITH KURYR ON YOUR OWN INFRASTRUCTURE

**IMPORTANT**

Kuryr is a deprecated feature. Deprecated functionality is still included in OpenShift Container Platform and continues to be supported; however, it will be removed in a future release of this product and is not recommended for new deployments.

For the most recent list of major functionality that has been deprecated or removed within OpenShift Container Platform, refer to the Deprecated and removed features section of the OpenShift Container Platform release notes.

In OpenShift Container Platform version 4.14, you can install a cluster on Red Hat OpenStack Platform (RHOSP) that runs on user-provisioned infrastructure.

Using your own infrastructure allows you to integrate your cluster with existing infrastructure and modifications. The process requires more labor on your part than installer-provisioned installations, because you must create all RHOSP resources, like Nova servers, Neutron ports, and security groups. However, Red Hat provides Ansible playbooks to help you in the deployment process.

21.6.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You verified that OpenShift Container Platform 4.14 is compatible with your RHOSP version by using the Supported platforms for OpenShift clusters section. You can also compare platform support across different versions by viewing the OpenShift Container Platform on RHOSP support matrix.
You have an RHOSP account where you want to install OpenShift Container Platform.

You understand performance and scalability practices for cluster scaling, control plane sizing, and etc. For more information, see Recommended practices for scaling the cluster.

On the machine from which you run the installation program, you have:

- A single directory in which you can keep the files you create during the installation process
- Python 3

### 21.6.2. About Kuryr SDN

**IMPORTANT**

Kuryr is a deprecated feature. Deprecated functionality is still included in OpenShift Container Platform and continues to be supported; however, it will be removed in a future release of this product and is not recommended for new deployments.

For the most recent list of major functionality that has been deprecated or removed within OpenShift Container Platform, refer to the Deprecated and removed features section of the OpenShift Container Platform release notes.

Kuryr is a container network interface (CNI) plugin solution that uses the Neutron and Octavia Red Hat OpenStack Platform (RHOSP) services to provide networking for pods and Services.

Kuryr and OpenShift Container Platform integration is primarily designed for OpenShift Container Platform clusters running on RHOSP VMs. Kuryr improves the network performance by plugging OpenShift Container Platform pods into RHOSP SDN. In addition, it provides interconnectivity between pods and RHOSP virtual instances.

Kuryr components are installed as pods in OpenShift Container Platform using the openshift-kuryr namespace:

- **kuryr-controller** - a single service instance installed on a master node. This is modeled in OpenShift Container Platform as a Deployment object.

- **kuryr-cni** - a container installing and configuring Kuryr as a CNI driver on each OpenShift Container Platform node. This is modeled in OpenShift Container Platform as a DaemonSet object.

The Kuryr controller watches the OpenShift Container Platform API server for pod, service, and namespace create, update, and delete events. It maps the OpenShift Container Platform API calls to corresponding objects in Neutron and Octavia. This means that every network solution that implements the Neutron trunk port functionality can be used to back OpenShift Container Platform via Kuryr. This includes open source solutions such as Open vSwitch (OVS) and Open Virtual Network (OVN) as well as Neutron-compatible commercial SDNs.

Kuryr is recommended for OpenShift Container Platform deployments on encapsulated RHOSP tenant networks to avoid double encapsulation, such as running an encapsulated OpenShift Container Platform SDN over an RHOSP network.

If you use provider networks or tenant VLANs, you do not need to use Kuryr to avoid double encapsulation. The performance benefit is negligible. Depending on your configuration, though, using Kuryr to avoid having two overlays might still be beneficial.
Kuryr is not recommended in deployments where all of the following criteria are true:

- The RHOSP version is less than 16.
- The deployment uses UDP services, or a large number of TCP services on few hypervisors.

or

- The `ovn-octavia` Octavia driver is disabled.
- The deployment uses a large number of TCP services on few hypervisors.

### 21.6.3. Resource guidelines for installing OpenShift Container Platform on RHOSP with Kuryr

When using Kuryr SDN, the pods, services, namespaces, and network policies are using resources from the RHOSP quota; this increases the minimum requirements. Kuryr also has some additional requirements on top of what a default install requires.

Use the following quota to satisfy a default cluster’s minimum requirements:

**Table 21.8. Recommended resources for a default OpenShift Container Platform cluster on RHOSP with Kuryr**

<table>
<thead>
<tr>
<th>Resource</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Floating IP addresses</td>
<td>3 - plus the expected number of Services of LoadBalancer type</td>
</tr>
<tr>
<td>Ports</td>
<td>1500 - 1 needed per Pod</td>
</tr>
<tr>
<td>Routers</td>
<td>1</td>
</tr>
<tr>
<td>Subnets</td>
<td>250 - 1 needed per Namespace/Project</td>
</tr>
<tr>
<td>Networks</td>
<td>250 - 1 needed per Namespace/Project</td>
</tr>
<tr>
<td>RAM</td>
<td>112 GB</td>
</tr>
<tr>
<td>vCPUs</td>
<td>28</td>
</tr>
<tr>
<td>Volume storage</td>
<td>275 GB</td>
</tr>
<tr>
<td>Instances</td>
<td>7</td>
</tr>
<tr>
<td>Security groups</td>
<td>250 - 1 needed per Service and per NetworkPolicy</td>
</tr>
<tr>
<td>Security group rules</td>
<td>1000</td>
</tr>
<tr>
<td>Server groups</td>
<td>2 - plus 1 for each additional availability zone in each machine pool</td>
</tr>
<tr>
<td>Resource</td>
<td>Value</td>
</tr>
<tr>
<td>----------------------</td>
<td>--------------------------------------------</td>
</tr>
<tr>
<td>Load balancers</td>
<td>100 - 1 needed per Service</td>
</tr>
<tr>
<td>Load balancer listeners</td>
<td>500 - 1 needed per Service-exposed port</td>
</tr>
<tr>
<td>Load balancer pools</td>
<td>500 - 1 needed per Service-exposed port</td>
</tr>
</tbody>
</table>

A cluster might function with fewer than recommended resources, but its performance is not guaranteed.

**IMPORTANT**

If RHOSP object storage (Swift) is available and operated by a user account with the `swiftoperator` role, it is used as the default backend for the OpenShift Container Platform image registry. In this case, the volume storage requirement is 175 GB. Swift space requirements vary depending on the size of the image registry.

**IMPORTANT**

If you are using Red Hat OpenStack Platform (RHOSP) version 16 with the Amphora driver rather than the OVN Octavia driver, security groups are associated with service accounts instead of user projects.

Take the following notes into consideration when setting resources:

- The number of ports that are required is larger than the number of pods. Kuryr uses ports pools to have pre-created ports ready to be used by pods and speed up the pods’ booting time.

- Each network policy is mapped into an RHOSP security group, and depending on the `NetworkPolicy` spec, one or more rules are added to the security group.

- Each service is mapped to an RHOSP load balancer. Consider this requirement when estimating the number of security groups required for the quota. If you are using RHOSP version 15 or earlier, or the `ovn-octavia` driver, each load balancer has a security group with the user project.

- The quota does not account for load balancer resources (such as VM resources), but you must consider these resources when you decide the RHOSP deployment’s size. The default installation will have more than 50 load balancers; the clusters must be able to accommodate them. If you are using RHOSP version 16 with the OVN Octavia driver enabled, only one load balancer VM is generated; services are load balanced through OVN flows.

An OpenShift Container Platform deployment comprises control plane machines, compute machines, and a bootstrap machine.

To enable Kuryr SDN, your environment must meet the following requirements:

- Run RHOSP 13+.
- Have Overcloud with Octavia.
- Use Neutron Trunk ports extension.
- Use **openvswitch** firewall driver if ML2/OVS Neutron driver is used instead of **ovs-hybrid**.

### 21.6.3.1. Increasing quota

When using Kuryr SDN, you must increase quotas to satisfy the Red Hat OpenStack Platform (RHOSP) resources used by pods, services, namespaces, and network policies.

#### Procedure

- Increase the quotas for a project by running the following command:

  ```bash
  $ sudo openstack quota set --secgroups 250 --secgroup-rules 1000 --ports 1500 --subnets 250 --networks 250 <project>
  ```

### 21.6.3.2. Configuring Neutron

Kuryr CNI leverages the Neutron Trunks extension to plug containers into the Red Hat OpenStack Platform (RHOSP) SDN, so you must use the **trunks** extension for Kuryr to properly work.

In addition, if you leverage the default ML2/OVS Neutron driver, the firewall must be set to **openvswitch** instead of **ovs_hybrid** so that security groups are enforced on trunk subports and Kuryr can properly handle network policies.

### 21.6.3.3. Configuring Octavia

Kuryr SDN uses Red Hat OpenStack Platform (RHOSP)'s Octavia LBaaS to implement OpenShift Container Platform services. Thus, you must install and configure Octavia components in RHOSP to use Kuryr SDN.

To enable Octavia, you must include the Octavia service during the installation of the RHOSP Overcloud, or upgrade the Octavia service if the Overcloud already exists. The following steps for enabling Octavia apply to both a clean install of the Overcloud or an Overcloud update.

#### NOTE

The following steps only capture the key pieces required during the deployment of RHOSP when dealing with Octavia. It is also important to note that registry methods vary.

This example uses the local registry method.

#### Procedure

1. If you are using the local registry, create a template to upload the images to the registry. For example:

   ```bash
   (undercloud) $ openstack overcloud container image prepare \
   -e /usr/share/openstack-tripleo-heat-templates/environments/services-docker/octavia.yaml \
   --namespace=registry.access.redhat.com/rhosp13 \
   --push-destination=<local-ip-from-undercloud.conf>:8787 \
   --prefix=openstack- \
   ```
2. Verify that the `local_registry_images.yaml` file contains the Octavia images. For example:

```yaml
...
- imagename: registry.access.redhat.com/rhosp13/openstack-octavia-api:13.0-43
  push_destination: <local-ip-from-undercloud.conf>:8787
- imagename: registry.access.redhat.com/rhosp13/openstack-octavia-health-manager:13.0-45
  push_destination: <local-ip-from-undercloud.conf>:8787
- imagename: registry.access.redhat.com/rhosp13/openstack-octavia-housekeeping:13.0-45
  push_destination: <local-ip-from-undercloud.conf>:8787
- imagename: registry.access.redhat.com/rhosp13/openstack-octavia-worker:13.0-44
  push_destination: <local-ip-from-undercloud.conf>:8787
...
```

**NOTE**

The Octavia container versions vary depending upon the specific RHOSP release installed.

3. Pull the container images from `registry.redhat.io` to the Undercloud node:

   ```shell
   (undercloud) $ sudo openstack overcloud container image upload
   --config-file /home/stack/local_registry_images.yaml
   --verbose
   
   This may take some time depending on the speed of your network and Undercloud disk.
   
4. Install or update your Overcloud environment with Octavia:

   ```shell
   $ openstack overcloud deploy --templates
   -e /usr/share/openstack-tripleo-heat-templates/environments/services-docker/octavia.yaml
   -e octavia_timeouts.yaml
   
   **NOTE**

   This command only includes the files associated with Octavia; it varies based on your specific installation of RHOSP. See the RHOSP documentation for further information. For more information on customizing your Octavia installation, see installation of Octavia using Director.

   **NOTE**

   When leveraging Kuryr SDN, the Overcloud installation requires the Neutron trunk extension. This is available by default on director deployments. Use the openvswitch firewall instead of the default ovs-hybrid when the Neutron backend is ML2/OVS. There is no need for modifications if the backend is ML2/OVN.

21.6.3.3.1. The Octavia OVN Driver
Octavia supports multiple provider drivers through the Octavia API.

To see all available Octavia provider drivers, on a command line, enter:

```
$ openstack loadbalancer provider list
```

Example output

```
+---------+-------------------------------------------------+
| name    | description                                     |
+---------+-------------------------------------------------+
| amphora | The Octavia Amphora driver.                     |
| octavia | Deprecated alias of the Octavia Amphora driver. |
| ovn     | Octavia OVN driver.                             |
+---------+-------------------------------------------------+
```

Beginning with RHOSP version 16, the Octavia OVN provider driver (ovn) is supported on OpenShift Container Platform on RHOSP deployments.

**ovn** is an integration driver for the load balancing that Octavia and OVN provide. It supports basic load balancing capabilities, and is based on OpenFlow rules. The driver is automatically enabled in Octavia by Director on deployments that use OVN Neutron ML2.

The Amphora provider driver is the default driver. If ovn is enabled, however, Kuryr uses it.

If Kuryr uses ovn instead of Amphora, it offers the following benefits:

- Decreased resource requirements. Kuryr does not require a load balancer VM for each service.
- Reduced network latency.
- Increased service creation speed by using OpenFlow rules instead of a VM for each service.
- Distributed load balancing actions across all nodes instead of centralized on Amphora VMs.

### 21.6.3.4. Known limitations of installing with Kuryr

Using OpenShift Container Platform with Kuryr SDN has several known limitations.

**RHOSP general limitations**

Using OpenShift Container Platform with Kuryr SDN has several limitations that apply to all versions and environments:

- **Service** objects with the **NodePort** type are not supported.

- Clusters that use the OVN Octavia provider driver support **Service** objects for which the **.spec.selector** property is unspecified only if the **.subsets.addresses** property of the **Endpoints** object includes the subnet of the nodes or pods.

- If the subnet on which machines are created is not connected to a router, or if the subnet is connected, but the router has no external gateway set, Kuryr cannot create floating IPs for **Service** objects with type **LoadBalancer**.

- Configuring the **sessionAffinity=ClientIP** property on **Service** objects does not have an effect. Kuryr does not support this setting.
RHOSP version limitations
Using OpenShift Container Platform with Kuryr SDN has several limitations that depend on the RHOSP version.

- RHOSP versions before 16 use the default Octavia load balancer driver (Amphora). This driver requires that one Amphora load balancer VM is deployed per OpenShift Container Platform service. Creating too many services can cause you to run out of resources. Deployments of later versions of RHOSP that have the OVN Octavia driver disabled also use the Amphora driver. They are subject to the same resource concerns as earlier versions of RHOSP.

- Kuryr SDN does not support automatic unidling by a service.

RHOSP upgrade limitations
As a result of the RHOSP upgrade process, the Octavia API might be changed, and upgrades to the Amphora images that are used for load balancers might be required.

You can address API changes on an individual basis.

If the Amphora image is upgraded, the RHOSP operator can handle existing load balancer VMs in two ways:

- Upgrade each VM by triggering a load balancer failover.
- Leave responsibility for upgrading the VMs to users.

If the operator takes the first option, there might be short downtimes during failovers.

If the operator takes the second option, the existing load balancers will not support upgraded Octavia API features, like UDP listeners. In this case, users must recreate their Services to use these features.

21.6.3.5. Control plane machines
By default, the OpenShift Container Platform installation process creates three control plane machines.

Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory and 4 vCPUs
- At least 100 GB storage space from the RHOSP quota

21.6.3.6. Compute machines
By default, the OpenShift Container Platform installation process creates three compute machines.

Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 8 GB memory and 2 vCPUs
• At least 100 GB storage space from the RHOSP quota

TIP

Compute machines host the applications that you run on OpenShift Container Platform; aim to run as many as you can.

21.6.3.7. Bootstrap machine

During installation, a bootstrap machine is temporarily provisioned to stand up the control plane. After the production control plane is ready, the bootstrap machine is deprovisioned.

The bootstrap machine requires:

• An instance from the RHOSP quota
• A port from the RHOSP quota
• A flavor with at least 16 GB memory and 4 vCPUs
• At least 100 GB storage space from the RHOSP quota

21.6.4. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

• Access OpenShift Cluster Manager Hybrid Cloud Console to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

• Access Quay.io to obtain the packages that are required to install your cluster.

• Obtain the packages that are required to perform cluster updates.

IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

21.6.5. Downloading playbook dependencies

The Ansible playbooks that simplify the installation process on user-provisioned infrastructure require several Python modules. On the machine where you will run the installer, add the modules’ repositories and then download them.

NOTE

These instructions assume that you are using Red Hat Enterprise Linux (RHEL) 8.
Prerequisites

- Python 3 is installed on your machine.

Procedure

1. On a command line, add the repositories:
   
   a. Register with Red Hat Subscription Manager:
      
      ```
      $ sudo subscription-manager register # If not done already
      ```
   
   b. Pull the latest subscription data:
      
      ```
      $ sudo subscription-manager attach --pool=$YOUR_POOLID # If not done already
      ```
   
   c. Disable the current repositories:
      
      ```
      $ sudo subscription-manager repos --disable=* # If not done already
      ```
   
   d. Add the required repositories:
      
      ```
      $ sudo subscription-manager repos \ 
      --enable=rhel-8-for-x86_64-baseos-rpms \ 
      --enable=openstack-16-tools-for-rhel-8-x86_64-rpms \ 
      --enable=ansible-2.9-for-rhel-8-x86_64-rpms \ 
      --enable=rhel-8-for-x86_64-appstream-rpms
      ```

2. Install the modules:
   
   ```
   $ sudo yum install python3-openstackclient ansible python3-openstacksdk python3-netaddr ansible-collections-openstack
   ```

3. Ensure that the `python` command points to `python3`:
   
   ```
   $ sudo alternatives --set python /usr/bin/python3
   ```

21.6.6. Downloading the installation playbooks

Download Ansible playbooks that you can use to install OpenShift Container Platform on your own Red Hat OpenStack Platform (RHOSP) infrastructure.

Prerequisites

- The curl command-line tool is available on your machine.

Procedure

- To download the playbooks to your working directory, run the following script from a command line:

  ```
  $ xargs -n 1 curl -O <<< 'https://raw.githubusercontent.com/openshift/installer/release-
  ```
The playbooks are downloaded to your machine.

**IMPORTANT**

During the installation process, you can modify the playbooks to configure your deployment.

Retain all playbooks for the life of your cluster. You must have the playbooks to remove your OpenShift Container Platform cluster from RHOSP.

**IMPORTANT**

You must match any edits you make in the `bootstrap.yaml`, `compute-nodes.yaml`, `control-plane.yaml`, `network.yaml`, and `security-groups.yaml` files to the corresponding playbooks that are prefixed with `down-`. For example, edits to the `bootstrap.yaml` file must be reflected in the `down-bootstrap.yaml` file, too. If you do not edit both files, the supported cluster removal process will fail.

### 21.6.7. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

**Prerequisites**

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.
Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

   **IMPORTANT**
   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   **IMPORTANT**
   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ tar -xvf openshift-install-linux.tar.gz
   ```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

21.6.8. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The ./openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.
IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

NOTE

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>  
```

Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

NOTE

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

```
$ cat ~/.ssh/id_ed25519.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `/openshift-install gather` command.

NOTE

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

a. If the ssh-agent process is not already running for your local user, start it as a background task:

```
$ eval "$($ssh-agent -s)"
```
NOTE
If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the `ssh-agent`:

   `$ ssh-add <path>/<file_name>`

   Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

Example output

   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

21.6.9. Creating the Red Hat Enterprise Linux CoreOS (RHCOS) image

The OpenShift Container Platform installation program requires that a Red Hat Enterprise Linux CoreOS (RHCOS) image be present in the Red Hat OpenStack Platform (RHOSP) cluster. Retrieve the latest RHCOS image, then upload it using the RHOSP CLI.

Prerequisites

- The RHOSP CLI is installed.

Procedure

   **IMPORTANT**

   The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available.

3. Download the Red Hat Enterprise Linux CoreOS (RHCOS) - OpenStack Image (QCOW)
4. Decompress the image.

**NOTE**
You must decompress the RHOSP image before the cluster can use it. The name of the downloaded file might not contain a compression extension, like `.gz` or `.tgz`. To find out if or how the file is compressed, in a command line, enter:

```
$ file <name_of_downloaded_file>
```

5. From the image that you downloaded, create an image that is named `rhcos` in your cluster by using the RHOSP CLI:

```
$ openstack image create --container-format=bare --disk-format=qcow2 --file rhcos-$(RHCOS_VERSION)-openstack.qcow2 rhcos
```

**IMPORTANT**
Depending on your RHOSP environment, you might be able to upload the image in either `.raw` or `.qcow2` formats. If you use Ceph, you must use the `.raw` format.

**WARNING**
If the installation program finds multiple images with the same name, it chooses one of them at random. To avoid this behavior, create unique names for resources in RHOSP.

After you upload the image to RHOSP, it is usable in the installation process.

### 21.6.10. Verifying external network access

The OpenShift Container Platform installation process requires external network access. You must provide an external network value to it, or deployment fails. Before you begin the process, verify that a network with the external router type exists in Red Hat OpenStack Platform (RHOSP).

**Prerequisites**

- Configure OpenStack’s networking service to have DHCP agents forward instances' DNS queries

**Procedure**

1. Using the RHOSP CLI, verify the name and ID of the 'External' network:

```
$ openstack network list --long -c ID -c Name -c "Router Type"
```

**Example output**
A network with an external router type appears in the network list. If at least one does not, see Creating a default floating IP network and Creating a default provider network.

NOTE

If the Neutron trunk service plugin is enabled, a trunk port is created by default. For more information, see Neutron trunk port.

21.6.11. Enabling access to the environment

At deployment, all OpenShift Container Platform machines are created in a Red Hat OpenStack Platform (RHOSP)-tenant network. Therefore, they are not accessible directly in most RHOSP deployments.

You can configure OpenShift Container Platform API and application access by using floating IP addresses (FIPs) during installation. You can also complete an installation without configuring FIPs, but the installer will not configure a way to reach the API or applications externally.

21.6.11.1. Enabling access with floating IP addresses

Create floating IP (FIP) addresses for external access to the OpenShift Container Platform API, cluster applications, and the bootstrap process.

Procedure

1. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the API FIP:

   ```
   $ openstack floating ip create --description "API <cluster_name>.<base_domain>" <external_network>
   ```

2. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the apps, or Ingress, FIP:

   ```
   $ openstack floating ip create --description "Ingress <cluster_name>.<base_domain>" <external_network>
   ```

3. By using the Red Hat OpenStack Platform (RHOSP) CLI, create the bootstrap FIP:

   ```
   $ openstack floating ip create --description "bootstrap machine" <external_network>
   ```

4. Add records that follow these patterns to your DNS server for the API and Ingress FIPs:

   ```
   api.<cluster_name>.<base_domain>. IN A <API_FIP>
   *.apps.<cluster_name>.<base_domain>. IN A <apps_FIP>
   ```
NOTE

If you do not control the DNS server, you can access the cluster by adding the cluster domain names such as the following to your /etc/hosts file:

- `<api_floating_ip> api.<cluster_name>.<base_domain>`
- `<application_floating_ip> grafana-openshift-monitoring.apps.<cluster_name>.<base_domain>`
- `<application_floating_ip> prometheus-k8s-openshift-monitoring.apps.<cluster_name>.<base_domain>`
- `<application_floating_ip> oauth-openshift.apps.<cluster_name>.<base_domain>`
- `<application_floating_ip> console-openshift-console.apps.<cluster_name>.<base_domain>`
- `<application_floating_ip> integrated-oauth-server-openshift-authentication.apps.<cluster_name>.<base_domain>`

The cluster domain names in the /etc/hosts file grant access to the web console and the monitoring interface of your cluster locally. You can also use the kubectl or oc. You can access the user applications by using the additional entries pointing to the `<application_floating_ip>`. This action makes the API and applications accessible to only you, which is not suitable for production deployment, but does allow installation for development and testing.

5. Add the FIPs to the inventory.yaml file as the values of the following variables:
   - `os_api_fip`
   - `os_bootstrap_fip`
   - `os_ingress_fip`

   If you use these values, you must also enter an external network as the value of the `os_external_network` variable in the inventory.yaml file.

TIP

You can make OpenShift Container Platform resources available outside of the cluster by assigning a floating IP address and updating your firewall configuration.

21.6.11.2. Completing installation without floating IP addresses

You can install OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) without providing floating IP addresses.

In the inventory.yaml file, do not define the following variables:

- `os_api_fip`
- `os_bootstrap_fip`
If you cannot provide an external network, you can also leave `os_external_network` blank. If you do not provide a value for `os_external_network`, a router is not created for you, and, without additional action, the installer will fail to retrieve an image from Glance. Later in the installation process, when you create network resources, you must configure external connectivity on your own.

If you run the installer with the `wait-for` command from a system that cannot reach the cluster API due to a lack of floating IP addresses or name resolution, installation fails. To prevent installation failure in these cases, you can use a proxy network or run the installer from a system that is on the same network as your machines.

**NOTE**

You can enable name resolution by creating DNS records for the API and Ingress ports. For example:

```
api.<cluster_name>.<base_domain>. IN A <api_port_IP>
*.apps.<cluster_name>.<base_domain>. IN A <ingress_port_IP>
```

If you do not control the DNS server, you can add the record to your `/etc/hosts` file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

### 21.6.12. Defining parameters for the installation program

The OpenShift Container Platform installation program relies on a file that is called `clouds.yaml`. The file describes Red Hat OpenStack Platform (RHOSP) configuration parameters, including the project name, log in information, and authorization service URLs.

**Procedure**

1. Create the `clouds.yaml` file:
   - If your RHOSP distribution includes the Horizon web UI, generate a `clouds.yaml` file in it.

     **IMPORTANT**

     Remember to add a password to the `auth` field. You can also keep secrets in a separate file from `clouds.yaml`.

     - If your RHOSP distribution does not include the Horizon web UI, or you do not want to use Horizon, create the file yourself. For detailed information about `clouds.yaml`, see Config files in the RHOSP documentation.

     ```yaml
     clouds:
     shiftstack:
     auth:
       project_name: shiftstack
       username: <username>
       password: <password>
       user_domain_name: Default
       project_domain_name: Default
     ```
If your RHOSP installation uses self-signed certificate authority (CA) certificates for endpoint authentication:

a. Copy the certificate authority file to your machine.

b. Add the `cacerts` key to the `clouds.yaml` file. The value must be an absolute, non-root-accessible path to the CA certificate:

```yaml
   clouds:
     shiftstack:
       ...  
     cacert: "/etc/pki/ca-trust/source/anchors/ca.crt.pem"
```

**TIP**

After you run the installer with a custom CA certificate, you can update the certificate by editing the value of the `ca-cert.pem` key in the `cloud-provider-config` keymap. On a command line, run:

```
$ oc edit configmap -n openshift-config cloud-provider-config
```

3. Place the `clouds.yaml` file in one of the following locations:

   a. The value of the `OS_CLIENT_CONFIG_FILE` environment variable
   
   b. The current directory
   
   c. A Unix-specific user configuration directory, for example `~/.config/openstack/clouds.yaml`
   
   d. A Unix-specific site configuration directory, for example `/etc/openstack/clouds.yaml`

   The installation program searches for `clouds.yaml` in that order.

21.6.13. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Red Hat OpenStack Platform (RHOSP).

**Prerequisites**

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Create the `install-config.yaml` file.

   a. Change to the directory that contains the installation program and run the following command:
a. Change to the directory that contains the installation program and run the following command:

```
$ ./openshift-install create install-config --dir <installation_directory> ¹
```

¹ For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

When specifying the directory:

- Verify that the directory has the `execute` permission. This permission is required to run Terraform binaries under the installation directory.

- Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

**NOTE**

Always delete the `~/.powervs` directory to avoid reusing a stale configuration. Run the following command:

```
$ rm -rf ~/.powervs
```

b. At the prompts, provide the configuration details for your cloud:

i. Optional: Select an SSH key to use to access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

ii. Select openstack as the platform to target.

iii. Specify the Red Hat OpenStack Platform (RHOSP) external network name to use for installing the cluster.

iv. Specify the floating IP address to use for external access to the OpenShift API.

v. Specify a RHOSP flavor with at least 16 GB RAM to use for control plane nodes and 8 GB RAM for compute nodes.

vi. Select the base domain to deploy the cluster to. All DNS records will be sub-domains of this base and will also include the cluster name.

vii. Enter a name for your cluster. The name must be 14 or fewer characters long.

2. Modify the `install-config.yaml` file. You can find more information about the available parameters in the "Installation configuration parameters" section.
3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

**IMPORTANT**

The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

You now have the file `install-config.yaml` in the directory that you specified.

**Additional resources**

- Installation configuration parameters for OpenStack

**21.6.13.1. Custom subnets in RHOSP deployments**

Optionally, you can deploy a cluster on a Red Hat OpenStack Platform (RHOSP) subnet of your choice. The subnet’s GUID is passed as the value of `platform.openstack.machinesSubnet` in the `install-config.yaml` file.

This subnet is used as the cluster’s primary subnet. By default, nodes and ports are created on it. You can create nodes and ports on a different RHOSP subnet by setting the value of the `platform.openstack.machinesSubnet` property to the subnet’s UUID.

Before you run the OpenShift Container Platform installer with a custom subnet, verify that your configuration meets the following requirements:

- The subnet that is used by `platform.openstack.machinesSubnet` has DHCP enabled.
- The CIDR of `platform.openstack.machinesSubnet` matches the CIDR of `networking.machineNetwork`.
- The installation program user has permission to create ports on this network, including ports with fixed IP addresses.

Clusters that use custom subnets have the following limitations:

- If you plan to install a cluster that uses floating IP addresses, the `platform.openstack.machinesSubnet` subnet must be attached to a router that is connected to the `externalNetwork` network.
- If the `platform.openstack.machinesSubnet` value is set in the `install-config.yaml` file, the installation program does not create a private network or subnet for your RHOSP machines.
- You cannot use the `platform.openstack.externalDNS` property at the same time as a custom subnet. To add DNS to a cluster that uses a custom subnet, configure DNS on the RHOSP network.

**NOTE**

By default, the API VIP takes x.x.x.5 and the Ingress VIP takes x.x.x.7 from your network’s CIDR block. To override these default values, set values for `platform.openstack.apiVIPs` and `platform.openstack.ingressVIPs` that are outside of the DHCP allocation pool.
IMPORTANT

The CIDR ranges for networks are not adjustable after cluster installation. Red Hat does not provide direct guidance on determining the range during cluster installation because it requires careful consideration of the number of created pods per namespace.

21.6.13.2. Sample customized install-config.yaml file for RHOSP with Kuryr

To deploy with Kuryr SDN instead of the default OVN-Kubernetes network plugin, you must modify the install-config.yaml file to include Kuryr as the desired networking.networkType. This sample install-config.yaml demonstrates all of the possible Red Hat OpenStack Platform (RHOSP) customization options.

IMPORTANT

This sample file is provided for reference only. You must obtain your install-config.yaml file by using the installation program.

```yaml
apiVersion: v1
baseDomain: example.com
controlPlane:
  name: master
  platform: {} 
  replicas: 3
compute:
  - name: worker
    platform:
      openstack:
        type: ml.large
        replicas: 3
metadata:
  name: example
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
      hostPrefix: 23
  machineNetwork:
    - cidr: 10.0.0.0/16
  serviceNetwork:
    - 172.30.0.0/16
  networkType: Kuryr
  platform:
    openstack:
      cloud: mycloud
      externalNetwork: external
      computeFlavor: m1.xlarge
      apiFloatingIP: 128.0.0.1
      trunkSupport: true
      octaviaSupport: true
      pullSecret: '\{"auths": ...\}'
      sshKey: ssh-ed25519 AAAA...
```
1. The Amphora Octavia driver creates two ports per load balancer. As a result, the service subnet that the installer creates is twice the size of the CIDR that is specified as the value of the `serviceNetwork` property. The larger range is required to prevent IP address conflicts.

2. The cluster network plugin to install. The supported values are Kuryr, OVNKubernetes, and OpenShiftSDN. The default value is OVNKubernetes.

3. Both `trunkSupport` and `octaviaSupport` are automatically discovered by the installer, so there is no need to set them. But if your environment does not meet both requirements, Kuryr SDN will not properly work. Trunks are needed to connect the pods to the RHOSP network and Octavia is required to create the OpenShift Container Platform services.

21.6.13.3. Cluster deployment on RHOSP provider networks

You can deploy your OpenShift Container Platform clusters on Red Hat OpenStack Platform (RHOSP) with a primary network interface on a provider network. Provider networks are commonly used to give projects direct access to a public network that can be used to reach the internet. You can also share provider networks among projects as part of the network creation process.

RHOSP provider networks map directly to an existing physical network in the data center. A RHOSP administrator must create them.

In the following example, OpenShift Container Platform workloads are connected to a data center by using a provider network:
OpenShift Container Platform clusters that are installed on provider networks do not require tenant networks or floating IP addresses. The installer does not create these resources during installation.

Example provider network types include flat (untagged) and VLAN (802.1Q tagged).

NOTE

A cluster can support as many provider network connections as the network type allows. For example, VLAN networks typically support up to 4096 connections.

You can learn more about provider and tenant networks in the RHOSP documentation.

21.6.13.3.1. RHOSP provider network requirements for cluster installation

Before you install an OpenShift Container Platform cluster, your Red Hat OpenStack Platform (RHOSP) deployment and provider network must meet a number of conditions:

- The RHOSP networking service (Neutron) is enabled and accessible through the RHOSP networking API.
- The RHOSP networking service has the port security and allowed address pairs extensions enabled.
• The provider network can be shared with other tenants.

**TIP**

Use the `openstack network create` command with the `--share` flag to create a network that can be shared.

• The RHOSP project that you use to install the cluster must own the provider network, as well as an appropriate subnet.

**TIP**

To create a network for a project that is named "openshift," enter the following command:

```bash
$ openstack network create --project openshift
```

To create a subnet for a project that is named "openshift," enter the following command:

```bash
$ openstack subnet create --project openshift
```

To learn more about creating networks on RHOSP, read the provider networks documentation.

If the cluster is owned by the admin user, you must run the installer as that user to create ports on the network.

**IMPORTANT**

Provider networks must be owned by the RHOSP project that is used to create the cluster. If they are not, the RHOSP Compute service (Nova) cannot request a port from that network.

• Verify that the provider network can reach the RHOSP metadata service IP address, which is 169.254.169.254 by default.

Depending on your RHOSP SDN and networking service configuration, you might need to provide the route when you create the subnet. For example:

```bash
$ openstack subnet create --dhcp --host-route
destination=169.254.169.254/32,gateway=192.0.2.2 ...
```

• Optional: To secure the network, create role-based access control (RBAC) rules that limit network access to a single project.

### 21.6.13.3.2. Deploying a cluster that has a primary interface on a provider network

You can deploy an OpenShift Container Platform cluster that has its primary network interface on an Red Hat OpenStack Platform (RHOSP) provider network.

**Prerequisites**

• Your Red Hat OpenStack Platform (RHOSP) deployment is configured as described by “RHOSP provider network requirements for cluster installation”.

3046
Procedure

1. In a text editor, open the `install-config.yaml` file.

2. Set the value of the `platform.openstack.apiVIPs` property to the IP address for the API VIP.

3. Set the value of the `platform.openstack.ingressVIPs` property to the IP address for the Ingress VIP.

4. Set the value of the `platform.openstack.machinesSubnet` property to the UUID of the provider network subnet.

5. Set the value of the `networking.machineNetwork.cidr` property to the CIDR block of the provider network subnet.

**IMPORTANT**

The `platform.openstack.apiVIPs` and `platform.openstack.ingressVIPs` properties must both be unassigned IP addresses from the `networking.machineNetwork.cidr` block.

Section of an installation configuration file for a cluster that relies on a RHOSP provider network

```yaml
... 
platform:
  openstack:
    apiVIPs:  
      - 192.0.2.13
    ingressVIPs:  
      - 192.0.2.23
    machinesSubnet: fa806b2f-ac49-4bce-b9db-124bc64209bf

# ...

networking:
  machineNetwork:
    - cidr: 192.0.2.0/24
```

1, 2 In OpenShift Container Platform 4.12 and later, the `apiVIP` and `ingressVIP` configuration settings are deprecated. Instead, use a list format to enter values in the `apiVIPs` and `ingressVIPs` configuration settings.

**WARNING**

You cannot set the `platform.openstack.externalNetwork` or `platform.openstack.externalDNS` parameters while using a provider network for the primary network interface.

When you deploy the cluster, the installer uses the `install-config.yaml` file to deploy the cluster on the provider network.
You can add additional networks, including provider networks, to the `platform.openstack.additionalNetworkIDs` list.

After you deploy your cluster, you can attach pods to additional networks. For more information, see [Understanding multiple networks](#).

### 21.6.13.4. Kuryr ports pools

A Kuryr ports pool maintains a number of ports on standby for pod creation. Keeping ports on standby minimizes pod creation time. Without ports pools, Kuryr must explicitly request port creation or deletion whenever a pod is created or deleted.

The Neutron ports that Kuryr uses are created in subnets that are tied to namespaces. These pod ports are also added as subports to the primary port of OpenShift Container Platform cluster nodes.

Because Kuryr keeps each namespace in a separate subnet, a separate ports pool is maintained for each namespace-worker pair.

Prior to installing a cluster, you can set the following parameters in the `cluster-network-03-config.yml` manifest file to configure ports pool behavior:

- **enablePortPoolsPrepopulation** parameter controls pool prepopulation, which forces Kuryr to add Neutron ports to the pools when the first pod that is configured to use the dedicated network for pods is created in a namespace. The default value is `false`.

- **poolMinPorts** parameter is the minimum number of free ports that are kept in the pool. The default value is `1`.

- **poolMaxPorts** parameter is the maximum number of free ports that are kept in the pool. A value of `0` disables that upper bound. This is the default setting. If your OpenStack port quota is low, or you have a limited number of IP addresses on the pod network, consider setting this option to ensure that unneeded ports are deleted.

- **poolBatchPorts** parameter defines the maximum number of Neutron ports that can be created at once. The default value is `3`.

### 21.6.13.5. Adjusting Kuryr ports pools during installation

During installation, you can configure how Kuryr manages Red Hat OpenStack Platform (RHOSP) Neutron ports to control the speed and efficiency of pod creation.

**Prerequisites**

- Create and modify the `install-config.yaml` file.

**Procedure**

1. From a command line, create the manifest files:

   ```bash
   $ ./openshift-install create manifests --dir <installation_directory>
   ```
1. For `<installation_directory>`, specify the name of the directory that contains the `install-config.yaml` file for your cluster.

2. Create a file that is named `cluster-network-03-config.yml` in the `<installation_directory>/manifests/` directory:

   ```bash
   $ touch <installation_directory>/manifests/cluster-network-03-config.yml
   ```

   For `<installation_directory>`, specify the directory name that contains the `manifests/` directory for your cluster.

   After creating the file, several network configuration files are in the `manifests/` directory, as shown:

   ```bash
   $ ls <installation_directory>/manifests/cluster-network-*
   cluster-network-01-crd.yml
   cluster-network-02-config.yml
   cluster-network-03-config.yml
   ```

3. Open the `cluster-network-03-config.yml` file in an editor, and enter a custom resource (CR) that describes the Cluster Network Operator configuration that you want:

   ```bash
   $ oc edit networks.operator.openshift.io cluster
   ```

4. Edit the settings to meet your requirements. The following file is provided as an example:

   ```json
   apiVersion: operator.openshift.io/v1
   kind: Network
   metadata:
     name: cluster
   spec:
     clusterNetwork:
       - cidr: 10.128.0.0/14
         hostPrefix: 23
     serviceNetwork:
       - 172.30.0.0/16
     defaultNetwork:
       type: Kuryr
       kuryrConfig:
         enablePortPoolsPrepopulation: false
         poolMinPorts: 1
         poolBatchPorts: 3
         poolMaxPorts: 5
         openstackServiceNetwork: 172.30.0.0/16
   ```

   Set `enablePortPoolsPrepopulation` to `true` to make Kuryr create new Neutron ports when the first pod on the network for pods is created in a namespace. This setting raises the Neutron ports quota but can reduce the time that is required to spawn pods. The default value is `false`. 
Kuryr creates new ports for a pool if the number of free ports in that pool is lower than the value of `poolMinPorts`. The default value is 1.

`poolBatchPorts` controls the number of new ports that are created if the number of free ports is lower than the value of `poolMinPorts`. The default value is 3.

If the number of free ports in a pool is higher than the value of `poolMaxPorts`, Kuryr deletes them until the number matches that value. Setting this value to 0 disables this upper bound, preventing pools from shrinking. The default value is 0.

The `openStackServiceNetwork` parameter defines the CIDR range of the network from which IP addresses are allocated to RHOSP Octavia’s LoadBalancers.

If this parameter is used with the Amphora driver, Octavia takes two IP addresses from this network for each load balancer: one for OpenShift and the other for VRRP connections. Because these IP addresses are managed by OpenShift Container Platform and Neutron respectively, they must come from different pools. Therefore, the value of `openStackServiceNetwork` must be at least twice the size of the value of `serviceNetwork`, and the value of `serviceNetwork` must overlap entirely with the range that is defined by `openStackServiceNetwork`.

The CNO verifies that VRRP IP addresses that are taken from the range that is defined by this parameter do not overlap with the range that is defined by the `serviceNetwork` parameter.

If this parameter is not set, the CNO uses an expanded value of `serviceNetwork` that is determined by decrementing the prefix size by 1.

5. Save the `cluster-network-03-config.yml` file, and exit the text editor.

6. Optional: Back up the `manifests/cluster-network-03-config.yml` file. The installation program deletes the `manifests/` directory while creating the cluster.

### 21.6.13.6. Setting a custom subnet for machines

The IP range that the installation program uses by default might not match the Neutron subnet that you create when you install OpenShift Container Platform. If necessary, update the CIDR value for new machines by editing the installation configuration file.

**Prerequisites**

- You have the `install-config.yaml` file that was generated by the OpenShift Container Platform installation program.

**Procedure**

1. On a command line, browse to the directory that contains `install-config.yaml`.

2. From that directory, either run a script to edit the `install-config.yaml` file or update the file manually:
   - To set the value by using a script, run:
     ```
     $ python -c 'import yaml; path = "install-config.yaml";
     ```
To set the value manually, open the file and set the value of `networking.machineCIDR` to something that matches your intended Neutron subnet.

21.6.13.7. Emptying compute machine pools

To proceed with an installation that uses your own infrastructure, set the number of compute machines in the installation configuration file to zero. Later, you create these machines manually.

**Prerequisites**

- You have the `install-config.yaml` file that was generated by the OpenShift Container Platform installation program.

**Procedure**

1. On a command line, browse to the directory that contains `install-config.yaml`.
2. From that directory, either run a script to edit the `install-config.yaml` file or update the file manually:
   - To set the value by using a script, run:

     ```python
     $ python -c 'import yaml; path = "install-config.yaml"; data = yaml.safe_load(open(path)); data["compute"][0]["replicas"] = 0; open(path, "w").write(yaml.dump(data, default_flow_style=False))'
     ```
   - To set the value manually, open the file and set the value of `compute.<first entry>.replicas` to 0.

21.6.13.8. Modifying the network type

By default, the installation program selects the `OpenShiftSDN` network type. To use Kuryr instead, change the value in the installation configuration file that the program generated.

**Prerequisites**

- You have the file `install-config.yaml` that was generated by the OpenShift Container Platform installation program

**Procedure**

1. In a command prompt, browse to the directory that contains `install-config.yaml`.
2. From that directory, either run a script to edit the `install-config.yaml` file or update the file manually:
To set the value by using a script, run:

```
$ python -c 'import yaml;
  path = "install-config.yaml";
  data = yaml.safe_load(open(path));
  data["networking"]['networkType'] = "Kuryr";
  open(path, "w").write(yaml.dump(data, default_flow_style=False))'
```

To set the value manually, open the file and set `networking.networkType` to "Kuryr".

21.6.14. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

**IMPORTANT**

- The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

**Prerequisites**

- You obtained the OpenShift Container Platform installation program.
- You created the `install-config.yaml` installation configuration file.

**Procedure**

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

   ```
   $ ./openshift-install create manifests --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.
2. Remove the Kubernetes manifest files that define the control plane machines, compute machine sets, and control plane machine sets:

```
$ rm -f openshift/99_openshift-cluster-api_master-machines-*yaml openshift/99_openshift-
cluster-api_worker-machineset-*yaml openshift/99_openshift-machine-api_master-control-
plane-machine-set.yaml
```

Because you create and manage these resources yourself, you do not have to initialize them.

- You can preserve the compute machine set files to create compute machines by using the machine API, but you must update references to them to match your environment.

3. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:

a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.

b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.

c. Save and exit the file.

4. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

```
$ ./openshift-install create ignition-configs --dir <installation_directory> 1
```

   For `<installation_directory>`, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The `kubeadmin-password` and `kubeconfig` files are created in the `./<installation_directory>/auth` directory:

```
├── auth
│   ├── kubeadmin-password
│   └── kubeconfig
├── bootstrap.ign
├── master.ign
├── metadata.json
└── worker.ign
```

5. Export the metadata file’s `infraID` key as an environment variable:

```
$ export INFRA_ID=$(jq -r .infraID metadata.json)
```

TIP

Extract the `infraID` key from `metadata.json` and use it as a prefix for all of the RHOSP resources that you create. By doing so, you avoid name conflicts when making multiple deployments in the same project.
21.6.15. Preparing the bootstrap Ignition files

The OpenShift Container Platform installation process relies on bootstrap machines that are created from a bootstrap Ignition configuration file.

Edit the file and upload it. Then, create a secondary bootstrap Ignition configuration file that Red Hat OpenStack Platform (RHOSP) uses to download the primary file.

Prerequisites

- You have the bootstrap Ignition file that the installer program generates, bootstrap.ign.
- The infrastructure ID from the installer’s metadata file is set as an environment variable ($INFRA_ID).
  - If the variable is not set, see Creating the Kubernetes manifest and Ignition config files
- You have an HTTP(S)-accessible way to store the bootstrap Ignition file.
  - The documented procedure uses the RHOSP image service (Glance), but you can also use the RHOSP storage service (Swift), Amazon S3, an internal HTTP server, or an ad hoc Nova server.

Procedure

1. Run the following Python script. The script modifies the bootstrap Ignition file to set the hostname and, if available, CA certificate file when it runs:

```python
import base64
import json
import os

with open('bootstrap.ign', 'r') as f:
    ignition = json.load(f)

files = ignition['storage'].get('files', [])

infra_id = os.environ.get('INFRA_ID', 'openshift').encode()
hostname_b64 = base64.standard_b64encode(infra_id + b'-bootstrap
').decode().strip()
files.append(
    {'path': '/etc/hostname',
     'mode': 420,
     'contents': {
         'source': 'data:text/plain;charset=utf-8;base64,' + hostname_b64
     }})

ca_cert_path = os.environ.get('OS_CACERT', '')
if ca_cert_path:
    with open(ca_cert_path, 'r') as f:
        ca_cert = f.read().encode()
        ca_cert_b64 = base64.standard_b64encode(ca_cert).decode().strip()

    files.append(
        {
```

3054
2. Using the RHOSP CLI, create an image that uses the bootstrap Ignition file:

```
$ openstack image create --disk-format=raw --container-format=bare --file bootstrap.ign <image_name>
```

3. Get the image’s details:

```
$ openstack image show <image_name>
```

Make a note of the file value; it follows the pattern v2/images/<image_ID>/file.

**NOTE**

Verify that the image you created is active.

4. Retrieve the image service’s public address:

```
$ openstack catalog show image
```

5. Combine the public address with the image file value and save the result as the storage location. The location follows the pattern <image_service_public_URL>/v2/images/<image_ID>/file.

6. Generate an auth token and save the token ID:

```
$ openstack token issue -c id -f value
```

7. Insert the following content into a file called $INFRA_ID-bootstrap-ignition.json and edit the placeholders to match your own values:

```json
{
    "ignition": {
        "config": {
            "merge": [{
                "source": "<storage_url>" ,
                "httpHeaders": [{
                    "name": "X-Auth-Token",
                    "value": "<token_ID>"
                }]
            }]
        }
    },
```
Replace the value of `ignition.config.merge.source` with the bootstrap Ignition file storage URL.

Set `name` in `httpHeaders` to "X-Auth-Token".

Set `value` in `httpHeaders` to your token’s ID.

If the bootstrap Ignition file server uses a self-signed certificate, include the base64-encoded certificate.

8. Save the secondary Ignition config file.

The bootstrap Ignition data will be passed to RHOSP during installation.

**WARNING**

The bootstrap Ignition file contains sensitive information, like `clouds.yaml` credentials. Ensure that you store it in a secure place, and delete it after you complete the installation process.

### 21.6.16. Creating control plane Ignition config files on RHOSP

Installing OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) on your own infrastructure requires control plane Ignition config files. You must create multiple config files.

**NOTE**

As with the bootstrap Ignition configuration, you must explicitly define a hostname for each control plane machine.

**Prerequisites**

- The infrastructure ID from the installation program’s metadata file is set as an environment variable (`$INFRA_ID`).
  - If the variable is not set, see "Creating the Kubernetes manifest and Ignition config files".

**Procedure**
On a command line, run the following Python script:

```bash
$ for index in $(seq 0 2); do
    MASTER_HOSTNAME="$INFRA_ID-master-$index"
    python -c "import base64, json, sys;
    ignition = json.load(sys.stdin);
    storage = ignition.get('storage', {});
    files = storage.get('files', []);
    files.append({'path': '/etc/hostname', 'mode': 420, 'contents': {'source':
        'data:text/plain;charset=utf-8;base64,' + base64.standard_b64encode(b'$MASTER_HOSTNAME').decode().strip(), 'verification': {}},'filesystem': 'root'});
    storage['files'] = files;
    ignition['storage'] = storage
    json.dump(ignition, sys.stdout)" <master.ign >"$INFRA_ID-master-$index-ignition.json"
done
```

You now have three control plane Ignition files: `<INFRA_ID>-master-0-ignition.json`, `<INFRA_ID>-master-1-ignition.json`, and `<INFRA_ID>-master-2-ignition.json`.

### 21.6.17. Creating network resources on RHOSP

Create the network resources that an OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) installation on your own infrastructure requires. To save time, run supplied Ansible playbooks that generate security groups, networks, subnets, routers, and ports.

**Prerequisites**

- Python 3 is installed on your machine.
- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".

**Procedure**

1. Optional: Add an external network value to the `inventory.yaml` playbook:

   **Example external network value in the inventory.yaml Ansible playbook**

   ```yaml
   ...
   # The public network providing connectivity to the cluster. If not
   # provided, the cluster external connectivity must be provided in another
   # way.
   ...
   # Required for os_api_fip, os_ingress_fip, os_bootstrap_fip.
   os_external_network: 'external'
   ...
   ```

   **IMPORTANT**

   If you did not provide a value for `os_external_network` in the `inventory.yaml` file, you must ensure that VMs can access Glance and an external connection yourself.
2. Optional: Add external network and floating IP (FIP) address values to the `inventory.yaml` playbook:

**Example FIP values in the `inventory.yaml` Ansible playbook**

```yaml
...
# OpenShift API floating IP address. If this value is non-empty, the
# corresponding floating IP will be attached to the Control Plane to
# serve the OpenShift API.
os_api_fip: '203.0.113.23'

# OpenShift Ingress floating IP address. If this value is non-empty, the
# corresponding floating IP will be attached to the worker nodes to serve
# the applications.
os_ingress_fip: '203.0.113.19'

# If this value is non-empty, the corresponding floating IP will be
# attached to the bootstrap machine. This is needed for collecting logs
# in case of install failure.
os_bootstrap_fip: '203.0.113.20'
```

**IMPORTANT**

If you do not define values for `os_api_fip` and `os_ingress_fip`, you must perform postinstallation network configuration.

If you do not define a value for `os_bootstrap_fip`, the installer cannot download debugging information from failed installations.

See “Enabling access to the environment” for more information.

3. On a command line, create security groups by running the `security-groups.yaml` playbook:

```bash
$ ansible-playbook -i inventory.yaml security-groups.yaml
```

4. On a command line, create a network, subnet, and router by running the `network.yaml` playbook:

```bash
$ ansible-playbook -i inventory.yaml network.yaml
```

5. Optional: If you want to control the default resolvers that Nova servers use, run the RHOSP CLI command:

```bash
$ openstack subnet set --dns-nameserver <server_1> --dns-nameserver <server_2> "$INFRA_ID-nodes"
```

### 21.6.18. Creating the bootstrap machine on RHOSP

Create a bootstrap machine and give it the network access it needs to run on Red Hat OpenStack Platform (RHOSP). Red Hat provides an Ansible playbook that you run to simplify this process.

**Prerequisites**
• You downloaded the modules in "Downloading playbook dependencies".

• You downloaded the playbooks in "Downloading the installation playbooks".

• The inventory.yaml, common.yaml, and bootstrap.yaml Ansible playbooks are in a common directory.

• The metadata.json file that the installation program created is in the same directory as the Ansible playbooks.

Procedure

1. On a command line, change the working directory to the location of the playbooks.

2. On a command line, run the bootstrap.yaml playbook:

   $ ansible-playbook -i inventory.yaml bootstrap.yaml

3. After the bootstrap server is active, view the logs to verify that the Ignition files were received:

   $ openstack console log show "$INFRA_ID-bootstrap"

21.6.19. Creating the control plane machines on RHOSP

Create three control plane machines by using the Ignition config files that you generated. Red Hat provides an Ansible playbook that you run to simplify this process.

Prerequisites

• You downloaded the modules in "Downloading playbook dependencies".

• You downloaded the playbooks in "Downloading the installation playbooks".

• The infrastructure ID from the installation program’s metadata file is set as an environment variable ($INFRA_ID).

• The inventory.yaml, common.yaml, and control-plane.yaml Ansible playbooks are in a common directory.

• You have the three Ignition files that were created in "Creating control plane Ignition config files".

Procedure

1. On a command line, change the working directory to the location of the playbooks.

2. If the control plane Ignition config files aren’t already in your working directory, copy them into it.

3. On a command line, run the control-plane.yaml playbook:

   $ ansible-playbook -i inventory.yaml control-plane.yaml

4. Run the following command to monitor the bootstrapping process:

   $
21.6.20. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster kubeconfig file. The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the oc CLI.

Procedure

1. Export the kubeadmin credentials:

   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig

   For <installation_directory>, specify the path to the directory that you stored the installation files in.

2. Verify you can run oc commands successfully using the exported configuration:

   $ oc whoami

   Example output

   system:admin

21.6.21. Deleting bootstrap resources from RHOSP

Delete the bootstrap resources that you no longer need.

Prerequisites

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The inventory.yaml, common.yaml, and down-bootstrap.yaml Ansible playbooks are in a common directory.
- The control plane machines are running.
  - If you do not know the status of the machines, see "Verifying cluster status".

**Procedure**

1. On a command line, change the working directory to the location of the playbooks.
2. On a command line, run the `down-bootstrap.yaml` playbook:

   ```
   $ ansible-playbook -i inventory.yaml down-bootstrap.yaml
   ```

   The bootstrap port, server, and floating IP address are deleted.

   **WARNING**

   If you did not disable the bootstrap Ignition file URL earlier, do so now.

**21.6.22. Creating compute machines on RHOSP**

After standing up the control plane, create compute machines. Red Hat provides an Ansible playbook that you run to simplify this process.

**Prerequisites**

- You downloaded the modules in "Downloading playbook dependencies".
- You downloaded the playbooks in "Downloading the installation playbooks".
- The `inventory.yaml`, `common.yaml`, and `compute-nodes.yaml` Ansible playbooks are in a common directory.
- The `metadata.json` file that the installation program created is in the same directory as the Ansible playbooks.
- The control plane is active.

**Procedure**

1. On a command line, change the working directory to the location of the playbooks.
2. On a command line, run the playbook:

   ```
   $ ansible-playbook -i inventory.yaml compute-nodes.yaml
   ```

**Next steps**

- Approve the certificate signing requests for the machines.
## 21.6.23. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

### Prerequisites

- You added machines to your cluster.

### Procedure

1. Confirm that the cluster recognizes the machines:

   ```
   $ oc get nodes
   ```

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>64m</td>
<td>v1.27.3</td>
</tr>
</tbody>
</table>

   The output lists all of the machines that you created.

   **NOTE**

   The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

   ```
   $ oc get csr
   ```

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-8b2br</td>
<td>15m</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-8vnps</td>
<td>15m</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Pending</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

   In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:
NOTE

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the machine-approver if the Kubelet requests a new certificate with identical parameters.

NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the `oc exec`, `oc rsh`, and `oc logs` commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the node-bootstrapper service account in the `system:node` or `system:admin` groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

  ```bash
  $ oc adm certificate approve <csr_name>  
  ```

  `<csr_name>` is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

  ```bash
  $ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
  ```

NOTE

Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

  ```bash
  $ oc get csr
  ```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-c57lv</td>
<td>5m26s</td>

</table>
OpenShift Container Platform 4.14 Installing

5. If the remaining CSRs are not approved, and are in the Pending status, approve the CSRs for
your cluster machines:
To approve them individually, run the following command for each valid CSR:
$ oc adm certificate approve <csr_name> 1
1

<csr_name> is the name of a CSR from the list of current CSRs.

To approve all pending CSRs, run the following command:
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}
{{end}}{{end}}' | xargs oc adm certificate approve
6. After all client and server CSRs have been approved, the machines have the Ready status.
Verify this by running the following command:
$ oc get nodes

Example output
NAME
master-0
master-1
master-2
worker-0
worker-1

STATUS ROLES AGE VERSION
Ready master 73m v1.27.3
Ready master 73m v1.27.3
Ready master 74m v1.27.3
Ready worker 11m v1.27.3
Ready worker 11m v1.27.3

NOTE
It can take a few minutes after approval of the server CSRs for the machines to
transition to the Ready status.
Additional information
For more information on CSRs, see Certificate Signing Requests .

21.6.24. Verifying a successful installation
Verify that the OpenShift Container Platform installation is complete.
Prerequisites
You have the installation program (openshift-install)
Procedure
On a command line, enter:
$ openshift-install --log-level debug wait-for install-complete
The program outputs the console URL, as well as the administrator’s login information.

3064


21.6.25. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager Hybrid Cloud Console.

After you confirm that your OpenShift Cluster Manager Hybrid Cloud Console inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service

21.6.26. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- If you need to enable external access to node ports, configure ingress cluster traffic by using a node port.
- If you did not configure RHOSP to accept application traffic over floating IP addresses, configure RHOSP access with floating IP addresses.

21.7. INSTALLING A CLUSTER ON OPENSTACK IN A RESTRICTED NETWORK

In OpenShift Container Platform 4.14, you can install a cluster on Red Hat OpenStack Platform (RHOSP) in a restricted network by creating an internal mirror of the installation release content.

21.7.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You verified that OpenShift Container Platform 4.14 is compatible with your RHOSP version by using the Supported platforms for OpenShift clusters section. You can also compare platform support across different versions by viewing the OpenShift Container Platform on RHOSP support matrix.
- You created a registry on your mirror host and obtained the imageContentSources data for your version of OpenShift Container Platform.

IMPORTANT

Because the installation media is on the mirror host, you can use that computer to complete all installation steps.
You understand performance and scalability practices for cluster scaling, control plane sizing, and etcd. For more information, see Recommended practices for scaling the cluster.

You have the metadata service enabled in RHOSP.

21.7.2. About installations in restricted networks

In OpenShift Container Platform 4.14, you can perform an installation that does not require an active connection to the internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service’s Route 53 DNS and IAM services, require internet access. Depending on your network, you might require less internet access for an installation on bare metal hardware, Nutanix, or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift image registry and contains the installation media. You can create this registry on a mirror host, which can access both the internet and your closed network, or by using other methods that meet your restrictions.

21.7.2.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The ClusterVersion status includes an Unable to retrieve available updates error.
- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

21.7.3. Resource guidelines for installing OpenShift Container Platform on RHOSP

To support an OpenShift Container Platform installation, your Red Hat OpenStack Platform (RHOSP) quota must meet the following requirements:

<table>
<thead>
<tr>
<th>Resource</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Floating IP addresses</td>
<td>3</td>
</tr>
<tr>
<td>Ports</td>
<td>15</td>
</tr>
<tr>
<td>Routers</td>
<td>1</td>
</tr>
<tr>
<td>Subnets</td>
<td>1</td>
</tr>
<tr>
<td>RAM</td>
<td>88 GB</td>
</tr>
<tr>
<td>vCPUs</td>
<td>22</td>
</tr>
</tbody>
</table>
A cluster might function with fewer than recommended resources, but its performance is not guaranteed.

**IMPORTANT**

If RHOSP object storage (Swift) is available and operated by a user account with the `swiftoperator` role, it is used as the default backend for the OpenShift Container Platform image registry. In this case, the volume storage requirement is 175 GB. Swift space requirements vary depending on the size of the image registry.

**NOTE**

By default, your security group and security group rule quotas might be low. If you encounter problems, run `openstack quota set --secgroups 3 --secgroup-rules 60 <project>` as an administrator to increase them.

An OpenShift Container Platform deployment comprises control plane machines, compute machines, and a bootstrap machine.

### 21.7.3.1. Control plane machines

By default, the OpenShift Container Platform installation process creates three control plane machines.

Each machine requires:

- An instance from the RHOSP quota
- A port from the RHOSP quota
- A flavor with at least 16 GB memory and 4 vCPUs
- At least 100 GB storage space from the RHOSP quota

### 21.7.3.2. Compute machines

By default, the OpenShift Container Platform installation process creates three compute machines.

Each machine requires:
• An instance from the RHOSP quota
• A port from the RHOSP quota
• A flavor with at least 8 GB memory and 2 vCPUs
• At least 100 GB storage space from the RHOSP quota

TIP
Compute machines host the applications that you run on OpenShift Container Platform; aim to run as many as you can.

21.7.3.3. Bootstrap machine
During installation, a bootstrap machine is temporarily provisioned to stand up the control plane. After the production control plane is ready, the bootstrap machine is deprovisioned.

The bootstrap machine requires:
• An instance from the RHOSP quota
• A port from the RHOSP quota
• A flavor with at least 16 GB memory and 4 vCPUs
• At least 100 GB storage space from the RHOSP quota

21.7.4. Internet access for OpenShift Container Platform
In OpenShift Container Platform 4.14, you require access to the internet to obtain the images that are necessary to install your cluster.

You must have internet access to:
• Access OpenShift Cluster Manager Hybrid Cloud Console to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
• Access Quay.io to obtain the packages that are required to install your cluster.
• Obtain the packages that are required to perform cluster updates.

21.7.5. Enabling Swift on RHOSP
Swift is operated by a user account with the swiftoperator role. Add the role to an account before you run the installation program.
IMPORTANT

If the Red Hat OpenStack Platform (RHOSP) object storage service, commonly known as Swift, is available, OpenShift Container Platform uses it as the image registry storage. If it is unavailable, the installation program relies on the RHOSP block storage service, commonly known as Cinder.

If Swift is present and you want to use it, you must enable access to it. If it is not present, or if you do not want to use it, skip this section.

IMPORTANT

RHOSP 17 sets the `rgw_max_attr_size` parameter of Ceph RGW to 256 characters. This setting causes issues with uploading container images to the OpenShift Container Platform registry. You must set the value of `rgw_max_attr_size` to at least 1024 characters.

Before installation, check if your RHOSP deployment is affected by this problem. If it is, reconfigure Ceph RGW.

Prerequisites

- You have a RHOSP administrator account on the target environment.
- The Swift service is installed.
- On Ceph RGW, the `account in url` option is enabled.

Procedure

To enable Swift on RHOSP:

1. As an administrator in the RHOSP CLI, add the `swiftoperator` role to the account that will access Swift:

   ```
   $ openstack role add --user <user> --project <project> swiftoperator
   ```

   Your RHOSP deployment can now use Swift for the image registry.

21.7.6. Defining parameters for the installation program

The OpenShift Container Platform installation program relies on a file that is called `clouds.yaml`. The file describes Red Hat OpenStack Platform (RHOSP) configuration parameters, including the project name, log in information, and authorization service URLs.

Procedure

1. Create the `clouds.yaml` file:

   - If your RHOSP distribution includes the Horizon web UI, generate a `clouds.yaml` file in it.

   IMPORTANT

   Remember to add a password to the `auth` field. You can also keep secrets in a separate file from `clouds.yaml`. 
If your RHOSP distribution does not include the Horizon web UI, or you do not want to use Horizon, create the file yourself. For detailed information about clouds.yaml, see Config files in the RHOSP documentation.

```yaml
clouds:
  shiftstack:
    auth:
      project_name: shiftstack
      username: <username>
      password: <password>
      user_domain_name: Default
      project_domain_name: Default
  dev-env:
    region_name: RegionOne
    auth:
      username: <username>
      password: <password>
      project_name: 'devonly'
```

2. If your RHOSP installation uses self-signed certificate authority (CA) certificates for endpoint authentication:
   a. Copy the certificate authority file to your machine.
   b. Add the cacerts key to the clouds.yaml file. The value must be an absolute, non-root-accessible path to the CA certificate:

```yaml
clouds:
  shiftstack:
    ...  
    cacert: "/etc/pki/ca-trust/source/anchors/ca.crt.pem"
```

**TIP**

After you run the installer with a custom CA certificate, you can update the certificate by editing the value of the ca-cert.pem key in the cloud-provider-config keymap. On a command line, run:

```
$ oc edit configmap -n openshift-config cloud-provider-config
```

3. Place the clouds.yaml file in one of the following locations:
   a. The value of the OS_CLIENT_CONFIG_FILE environment variable
   b. The current directory
   c. A Unix-specific user configuration directory, for example ~/.config/openstack/clouds.yaml
   d. A Unix-specific site configuration directory, for example /etc/openstack/clouds.yaml
   The installation program searches for clouds.yaml in that order.

### 21.7.7. Setting OpenStack Cloud Controller Manager options
Optionally, you can edit the OpenStack Cloud Controller Manager (CCM) configuration for your cluster. This configuration controls how OpenShift Container Platform interacts with Red Hat OpenStack Platform (RHOSP).

For a complete list of configuration parameters, see the "OpenStack Cloud Controller Manager reference guide" page in the "Installing on OpenStack" documentation.

**Procedure**

1. If you have not already generated manifest files for your cluster, generate them by running the following command:

   ```
   $ openshift-install --dir <destination_directory> create manifests
   ```

2. In a text editor, open the cloud-provider configuration manifest file. For example:

   ```
   $ vi openshift/manifests/cloud-provider-config.yaml
   ```

3. Modify the options according to the CCM reference guide.

   Configuring Octavia for load balancing is a common case for clusters that do not use Kuryr. For example:

   ```yaml
   #...
   [LoadBalancer]
   lb-provider = "amphora"  
   floating-network-id="d3deb660-4190-40a3-91f1-37326fe6ec4a"  
   create-monitor = True  
   monitor-delay = 10s  
   monitor-timeout = 10s  
   monitor-max-retries = 1
   #...
   ```

   - **1**: This property sets the Octavia provider that your load balancer uses. It accepts "ovn" or "amphora" as values. If you choose to use OVN, you must also set `lb-method` to `SOURCE_IP_PORT`.

   - **2**: This property is required if you want to use multiple external networks with your cluster. The cloud provider creates floating IP addresses on the network that is specified here.

   - **3**: This property controls whether the cloud provider creates health monitors for Octavia load balancers. Set the value to `True` to create health monitors. As of RHOSP 16.2, this feature is only available for the Amphora provider.

   - **4**: This property sets the frequency with which endpoints are monitored. The value must be in the `time.ParseDuration()` format. This property is required if the value of the `create-monitor` property is `True`.

   - **5**: This property sets the time that monitoring requests are open before timing out. The value must be in the `time.ParseDuration()` format. This property is required if the value of the `create-monitor` property is `True`.

   - **6**: This property defines how many successful monitoring requests are required before a load balancer is marked as online. The value must be an integer. This property is required if the value of the `create-monitor` property is `True`.
IMPORTANT

Prior to saving your changes, verify that the file is structured correctly. Clusters might fail if properties are not placed in the appropriate section.

IMPORTANT

You must set the value of the create-monitor property to True if you use services that have the value of the .spec.externalTrafficPolicy property set to Local. The OVN Octavia provider in RHOSP 16.2 does not support health monitors. Therefore, services that have ETP parameter values set to Local might not respond when the lb-provider value is set to "ovn".

IMPORTANT

For installations that use Kuryr, Kuryr handles relevant services. There is no need to configure Octavia load balancing in the cloud provider.

4. Save the changes to the file and proceed with installation.

TIP

You can update your cloud provider configuration after you run the installer. On a command line, run:

```
$ oc edit configmap -n openshift-config cloud-provider-config
```

After you save your changes, your cluster will take some time to reconfigure itself. The process is complete if none of your nodes have a SchedulingDisabled status.

### 21.7.8. Creating the RHCOS image for restricted network installations

Download the Red Hat Enterprise Linux CoreOS (RHCOS) image to install OpenShift Container Platform on a restricted network Red Hat OpenStack Platform (RHOSP) environment.

**Prerequisites**

- Obtain the OpenShift Container Platform installation program. For a restricted network installation, the program is on your mirror registry host.

**Procedure**

2. Under Version, select the most recent release of OpenShift Container Platform 4.14 for RHEL 8.
3. Download the Red Hat Enterprise Linux CoreOS (RHCOS) - OpenStack Image (QCOW) image.

4. Decompress the image.

**NOTE**

You must decompress the image before the cluster can use it. The name of the downloaded file might not contain a compression extension, like .gz or .tgz. To find out if or how the file is compressed, in a command line, enter:

```
$ file <name_of_downloaded_file>
```

5. Upload the image that you decompressed to a location that is accessible from the bastion server, like Glance. For example:

```
$ openstack image create --file rhcos-44.81.202003110027-0-openstack.x86_64.qcow2 --disk-format qcow2 rhcos-${RHCOS_VERSION}
```

**IMPORTANT**

Depending on your RHOSP environment, you might be able to upload the image in either .raw or .qcow2 formats. If you use Ceph, you must use the .raw format.

**WARNING**

If the installation program finds multiple images with the same name, it chooses one of them at random. To avoid this behavior, create unique names for resources in RHOSP.

The image is now available for a restricted installation. Note the image name or location for use in OpenShift Container Platform deployment.

### 21.7.9. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Red Hat OpenStack Platform (RHOSP).

**Prerequisites**
You have the OpenShift Container Platform installation program and the pull secret for your cluster. For a restricted network installation, these files are on your mirror host.

You have the **imageContentSources** values that were generated during mirror registry creation.

You have obtained the contents of the certificate for your mirror registry.

You have retrieved a Red Hat Enterprise Linux CoreOS (RHCOS) image and uploaded it to an accessible location.

**Procedure**

1. Create the `install-config.yaml` file.
   
   a. Change to the directory that contains the installation program and run the following command:

   ```bash
   $ ./openshift-install create install-config --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

   When specifying the directory:

   - Verify that the directory has the **execute** permission. This permission is required to run Terraform binaries under the installation directory.

   - Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

   ```
   NOTE
   Always delete the `~/.powervs` directory to avoid reusing a stale configuration. Run the following command:
   ```

   ```bash
   $ rm -rf ~/.powervs
   ```

   b. At the prompts, provide the configuration details for your cloud:

   i. Optional: Select an SSH key to use to access your cluster machines.

   ```
   NOTE
   For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.
   ```

   ii. Select `openstack` as the platform to target.
iii. Specify the Red Hat OpenStack Platform (RHOSP) external network name to use for installing the cluster.

iv. Specify the floating IP address to use for external access to the OpenShift API.

v. Specify a RHOSP flavor with at least 16 GB RAM to use for control plane nodes and 8 GB RAM for compute nodes.

vi. Select the base domain to deploy the cluster to. All DNS records will be sub-domains of this base and will also include the cluster name.

vii. Enter a name for your cluster. The name must be 14 or fewer characters long.

2. In the install-config.yaml file, set the value of platform.openstack.clusterOSImage to the image location or name. For example:

   ```yaml
   platform:
     openstack:
       clusterOSImage: http://mirror.example.com/images/rhcos-43.81.201912131630.0-
       openstack.x86_64.qcow2.gz?
       sha256=febbd68e8a1f2a245ca19522c16c86f67f9ac8e4e0c1f0a812b068b16f7265d
   ```

3. Edit the install-config.yaml file to give the additional information that is required for an installation in a restricted network.

   a. Update the pullSecret value to contain the authentication information for your registry:

   ```yaml
   pullSecret: 
   
   For `<mirror_host_name>`, specify the registry domain name that you specified in the certificate for your mirror registry, and for `<credentials>`, specify the base64-encoded user name and password for your mirror registry.

   b. Add the additionalTrustBundle parameter and value.

   ```yaml
   additionalTrustBundle: |
   
   The value must be the contents of the certificate file that you used for your mirror registry. The certificate file can be an existing, trusted certificate authority, or the self-signed certificate that you generated for the mirror registry.

   c. Add the image content resources, which resemble the following YAML excerpt:

   ```yaml
   imageContentSources:
     - mirrors:
       - `<mirror_host_name>:5000/<repo_name>/release
         source: quay.io/openshift-release-dev/ocp-release
     - mirrors:
       - `<mirror_host_name>:5000/<repo_name>/release
         source: registry.redhat.io/ocp/release
   ```
For these values, use the `imageContentSources` that you recorded during mirror registry creation.

d. Optional: Set the publishing strategy to `Internal`:

```
publish: Internal
```

By setting this option, you create an internal Ingress Controller and a private load balancer.

**IMPORTANT**

Azure Firewall *does not work seamlessly* with Azure Public Load balancers. Thus, when using Azure Firewall for restricting internet access, the `publish` field in `install-config.yaml` should be set to `Internal`.

4. Make any other modifications to the `install-config.yaml` file that you require. You can find more information about the available parameters in the Installation configuration parameters section.

5. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

**IMPORTANT**

The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

Additional resources

- Installation configuration parameters for OpenStack

**21.7.9.1. Configuring the cluster-wide proxy during installation**

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**NOTE**

Kuryr installations default to HTTP proxies.

**Prerequisites**

- For Kuryr installations on restricted networks that use the `Proxy` object, the proxy must be able to reply to the router that the cluster uses. To add a static route for the proxy configuration, from a command line as the root user, enter:

```
$ ip route add <cluster_network_cidr> via <installer_subnet_gateway>
```

- The restricted subnet must have a gateway that is defined and available to be linked to the `Router` resource that Kuryr creates.

- You have an existing `install-config.yaml` file.
You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the Proxy object’s spec.noProxy field to bypass the proxy if necessary.

**NOTE**

The Proxy object status.noProxy field is populated with the values of the networking.machineNetwork[].cidr, networking.clusterNetwork[].cidr, and networking.serviceNetwork[] fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object status.noProxy field is also populated with the instance metadata endpoint (169.254.169.254).

**Procedure**

1. Edit your install-config.yaml file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port>
  httpsProxy: https://<username>:<pswd>@<ip>:<port>
  noProxy: example.com
additionalTrustBundle:
  ---BEGIN CERTIFICATE-----
  <MY_TRUSTED_CA_CERT>
  -----END CERTIFICATE-----
additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle>
```

   1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.
   2. A proxy URL to use for creating HTTPS connections outside the cluster.
   3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.
   4. If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the trustedCA field of the Proxy object. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.
   5. Optional: The policy to determine the configuration of the Proxy object to reference the user-ca-bundle config map in the trustedCA field. The allowed values are Proxyonly and Always. Use Proxyonly to reference the user-ca-bundle config map only when http/https proxy is configured. Use Always to always reference the user-ca-bundle config map. The default value is Proxyonly.
NOTE

The installation program does not support the proxy `readinessEndpoints` field.

NOTE

If the installer times out, restart and then complete the deployment by using the `wait-for` command of the installer. For example:

```
$ ./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

NOTE

Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

21.7.9.2. Sample customized `install-config.yaml` file for restricted OpenStack installations

This sample `install-config.yaml` demonstrates all of the possible Red Hat OpenStack Platform (RHOSP) customization options.

IMPORTANT

This sample file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program.

```yaml
apiVersion: v1
baseDomain: example.com
controlPlane:
  name: master
  platform: {}
  replicas: 3
compute:
- name: worker
  platform:
    openstack:
      type: ml.large
      replicas: 3
metadata:
  name: example
networking:
  clusterNetwork:
  - cidr: 10.128.0.0/14
    hostPrefix: 23
  machineNetwork:
  - cidr: 10.0.0.0/16
  serviceNetwork:
```

3078
21.7.10. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the 

```
~/.ssh/authorized_keys
```

list for the `core` user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user `core`. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.
Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   $ ssh-keygen -t ed25519 -N " -f <path>/<file_name>

   Specify the path and file name, such as ~/.ssh/id_ed25519, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   $ cat <path>/<file_name>.pub

   For example, run the following to view the ~/.ssh/id_ed25519.pub public key:

   $ cat ~/.ssh/id_ed25519.pub

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the ./openshift-install gather command.

   **NOTE**

   On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.

   a. If the ssh-agent process is not already running for your local user, start it as a background task:

   $ eval "$(ssh-agent -s)"

   **Example output**

   Agent pid 31874

   **NOTE**

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the ssh-agent:
Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

### 21.7.11. Enabling access to the environment

At deployment, all OpenShift Container Platform machines are created in a Red Hat OpenStack Platform (RHOSP)-tenant network. Therefore, they are not accessible directly in most RHOSP deployments.

You can configure OpenShift Container Platform API and application access by using floating IP addresses (FIPs) during installation. You can also complete an installation without configuring FIPs, but the installer will not configure a way to reach the API or applications externally.

#### 21.7.11.1. Enabling access with floating IP addresses

Create floating IP (FIP) addresses for external access to the OpenShift Container Platform API and cluster applications.

**Procedure**

1. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the API FIP:

   ```
   $ openstack floating ip create --description "API <cluster_name>.<base_domain>" <external_network>
   ```

2. Using the Red Hat OpenStack Platform (RHOSP) CLI, create the apps, or Ingress, FIP:

   ```
   $ openstack floating ip create --description "Ingress <cluster_name>.<base_domain>" <external_network>
   ```

3. Add records that follow these patterns to your DNS server for the API and Ingress FIPs:

   ```
   API_FIP
   apps_FIP
   ```
NOTE

If you do not control the DNS server, you can access the cluster by adding the cluster domain names such as the following to your /etc/hosts file:

- `<api_floating_ip> api.<cluster_name>.<base_domain>`
- `<application_floating_ip> grafana-openshift-monitoring.apps.<cluster_name>.<base_domain>`
- `<application_floating_ip> prometheus-k8s-openshift-monitoring.apps.<cluster_name>.<base_domain>`
- `<application_floating_ip> oauth-openshift.apps.<cluster_name>.<base_domain>`
- `<application_floating_ip> console-openshift-console.apps.<cluster_name>.<base_domain>`
- `<application_floating_ip> integrated-oauth-server-openshift-authentication.apps.<cluster_name>.<base_domain>`

The cluster domain names in the /etc/hosts file grant access to the web console and the monitoring interface of your cluster locally. You can also use the kubectl or oc. You can access the user applications by using the additional entries pointing to the `<application_floating_ip>`. This action makes the API and applications accessible to only you, which is not suitable for production deployment, but does allow installation for development and testing.

4. Add the FIPs to the `install-config.yaml` file as the values of the following parameters:

- `platform.openstack.ingressFloatingIP`
- `platform.openstack.apiFloatingIP`

If you use these values, you must also enter an external network as the value of the `platform.openstack.externalNetwork` parameter in the `install-config.yaml` file.

TIP

You can make OpenShift Container Platform resources available outside of the cluster by assigning a floating IP address and updating your firewall configuration.

21.7.11.2. Completing installation without floating IP addresses

You can install OpenShift Container Platform on Red Hat OpenStack Platform (RHOSP) without providing floating IP addresses.

In the `install-config.yaml` file, do not define the following parameters:

- `platform.openstack.ingressFloatingIP`
- `platform.openstack.apiFloatingIP`

If you cannot provide an external network, you can also leave `platform.openstack.externalNetwork` blank. If you do not provide a value for `platform.openstack.externalNetwork`, a router is not created for
you, and, without additional action, the installer will fail to retrieve an image from Glance. You must configure external connectivity on your own.

If you run the installer from a system that cannot reach the cluster API due to a lack of floating IP addresses or name resolution, installation fails. To prevent installation failure in these cases, you can use a proxy network or run the installer from a system that is on the same network as your machines.

**NOTE**

You can enable name resolution by creating DNS records for the API and Ingress ports. For example:

```shell
api.<cluster_name>.<base_domain>. IN A <api_port_IP>
*.apps.<cluster_name>.<base_domain>. IN A <ingress_port_IP>
```

If you do not control the DNS server, you can add the record to your `/etc/hosts` file. This action makes the API accessible to only you, which is not suitable for production deployment but does allow installation for development and testing.

### 21.7.12. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

**Prerequisites**

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.

- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.

**Procedure**

- Change to the directory that contains the installation program and initialize the cluster deployment:

```shell
$ ./openshift-install create cluster --dir <installation_directory> \\
    --log-level=info
```

1. For `<installation_directory>`, specify the location of your customized `./install-config.yaml` file.

2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

**Verification**

When the cluster deployment completes successfully:
- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the `kubeadmin` user.

- Credential information also outputs to `<installation_directory>/openshift_install.log`.

**IMPORTANT**

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

**Example output**

```
... INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for `Recovering from expired control plane certificates` for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

### 21.7.13. Verifying cluster status

You can verify your OpenShift Container Platform cluster’s status during or after installation.

**Procedure**

1. In the cluster environment, export the administrator’s kubeconfig file:

   ```
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   **1** For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server.
2. View the control plane and compute machines created after a deployment:

   $ oc get nodes

3. View your cluster's version:

   $ oc get clusterversion

4. View your Operators' status:

   $ oc get clusteroperator

5. View all running pods in the cluster:

   $ oc get pods -A

21.7.14. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster kubeconfig file. The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the oc CLI.

Procedure

1. Export the kubeadmin credentials:

   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig

   1 For <installation_directory>, specify the path to the directory that you stored the installation files in.

2. Verify you can run oc commands successfully using the exported configuration:

   $ oc whoami

   Example output

   system:admin

Additional resources

- See Accessing the web console for more details about accessing and understanding the OpenShift Container Platform web console.
21.7.15. Disabling the default OperatorHub catalog sources

Operator catalogs that source content provided by Red Hat and community projects are configured for
OperatorHub by default during an OpenShift Container Platform installation. In a restricted network
environment, you must disable the default catalogs as a cluster administrator.

Procedure

- Disable the sources for the default catalogs by adding `disableAllDefaultSources: true` to the
  `OperatorHub` object:

  ```
  $ oc patch OperatorHub cluster --type json \\
  -p '[{"op": "add", "path": "/spec/disableAllDefaultSources", "value": true}]'
  ```

TIP

Alternatively, you can use the web console to manage catalog sources. From the Administration →
Cluster Settings → Configuration → OperatorHub page, click the Sources tab, where you can create,
update, delete, disable, and enable individual sources.

21.7.16. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics
about cluster health and the success of updates, requires internet access. If your cluster is connected to
the internet, Telemetry runs automatically, and your cluster is registered to
OpenShift Cluster Manager
Hybrid Cloud Console.

After you confirm that your OpenShift Cluster Manager Hybrid Cloud Console inventory is correct,
either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use
subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-
cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service

21.7.17. Next steps

- Customize your cluster.

- If the mirror registry that you used to install your cluster has a trusted CA, add it to the cluster by
  configuring additional trust stores.

- If necessary, you can opt out of remote health reporting.

- If necessary, see Registering your disconnected cluster

- Configure image streams for the Cluster Samples Operator and the must-gather tool.

- Learn how to use Operator Lifecycle Manager (OLM) on restricted networks.

- If you did not configure RHOSP to accept application traffic over floating IP addresses,
  configure RHOSP access with floating IP addresses.
21.8. OPENSTACK CLOUD CONTROLLER MANAGER REFERENCE GUIDE

21.8.1. The OpenStack Cloud Controller Manager

Beginning with OpenShift Container Platform 4.12, clusters that run on Red Hat OpenStack Platform (RHOSP) were switched from the legacy OpenStack cloud provider to the external OpenStack Cloud Controller Manager (CCM). This change follows the move in Kubernetes from in-tree, legacy cloud providers to external cloud providers that are implemented by using the Cloud Controller Manager.

To preserve user-defined configurations for the legacy cloud provider, existing configurations are mapped to new ones as part of the migration process. It searches for a configuration called `cloud-provider-config` in the `openshift-config` namespace.

**NOTE**

The config map name `cloud-provider-config` is not statically configured. It is derived from the `spec.cloudConfig.name` value in the `infrastructure/cluster` CRD.

Found configurations are synchronized to the `cloud-conf` config map in the `openshift-cloud-controller-manager` namespace.

As part of this synchronization, the OpenStack CCM Operator alters the new config map such that its properties are compatible with the external cloud provider. The file is changed in the following ways:

- The entire `[BlockStorage]` section is removed. External cloud providers no longer perform storage operations. Block storage configuration is managed by the Cinder CSI driver.

Additionally, the CCM Operator enforces a number of default options. Values for these options are always overridden as follows:

```
[Global]
use-clouds = true
clouds-file = /etc/openstack/secret/clouds.yaml
cloud = openstack
...

[LoadBalancer]
enabled = true
```

1. If the network is configured to use Kuryr, this value is `false`.

The `clouds-value` value, `/etc/openstack/secret/clouds.yaml`, is mapped to the `openstack-cloud-credentials` config in the `openshift-cloud-controller-manager` namespace. You can modify the RHOSP cloud in this file as you do any other `clouds.yaml` file.

21.8.2. The OpenStack Cloud Controller Manager (CCM) config map
An OpenStack CCM config map defines how your cluster interacts with your RHOSP cloud. By default, this configuration is stored under the `cloud.conf` key in the `cloud-conf` config map in the `openshift-cloud-controller-manager` namespace.

**IMPORTANT**

The `cloud-conf` config map is generated from the `cloud-provider-config` config map in the `openshift-config` namespace.

To change the settings that are described by the `cloud-conf` config map, modify the `cloud-provider-config` config map.

As part of this synchronization, the CCM Operator overrides some options. For more information, see "The RHOSP Cloud Controller Manager".

For example:

**An example `cloud-conf` config map**

```yaml
apiVersion: v1
data:
  cloud.conf: |
    [Global]
    secret-name = openstack-credentials
    secret-namespace = kube-system
    region = regionOne
    [LoadBalancer]
    enabled = True
kind: ConfigMap
metadata:
  creationTimestamp: "2022-12-20T17:01:08Z"
  name: cloud-conf
  namespace: openshift-cloud-controller-manager
  resourceVersion: "2519"
  uid: cbbeedaf-41ed-41c2-9f37-4885732d3677
```

1 Set global options by using a `clouds.yaml` file rather than modifying the config map.

The following options are present in the config map. Except when indicated otherwise, they are mandatory for clusters that run on RHOSP.

**21.8.2.1. Load balancer options**

CCM supports several load balancer options for deployments that use Octavia.

**NOTE**

Neutron-LBaaS support is deprecated.
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>enabled</strong></td>
<td>Whether or not to enable the <code>LoadBalancer</code> type of services integration. The default value is <code>true</code>.</td>
</tr>
<tr>
<td><strong>floating-network-id</strong></td>
<td>Optional. The external network used to create floating IP addresses for load balancer virtual IP addresses (VIPs). If there are multiple external networks in the cloud, this option must be set or the user must specify <code>loadbalancer.openstack.org/floating-network-id</code> in the service annotation.</td>
</tr>
<tr>
<td><strong>floating-subnet-id</strong></td>
<td>Optional. The external network subnet used to create floating IP addresses for the load balancer VIP. Can be overridden by the service annotation <code>loadbalancer.openstack.org/floating-subnet-id</code>.</td>
</tr>
<tr>
<td><strong>floating-subnet</strong></td>
<td>Optional. A name pattern (glob or regular expression if starting with ~) for the external network subnet used to create floating IP addresses for the load balancer VIP. Can be overridden by the service annotation <code>loadbalancer.openstack.org/floating-subnet</code>. If multiple subnets match the pattern, the first one with available IP addresses is used.</td>
</tr>
<tr>
<td><strong>floating-subnet-tags</strong></td>
<td>Optional. Tags for the external network subnet used to create floating IP addresses for the load balancer VIP. Can be overridden by the service annotation <code>loadbalancer.openstack.org/floating-subnet-tags</code>. If multiple subnets match these tags, the first one with available IP addresses is used. If the RHOSP network is configured with sharing disabled, for example, with the <code>--no-share</code> flag used during creation, this option is unsupported. Set the network to share to use this option.</td>
</tr>
</tbody>
</table>
### lb-method

The load balancing algorithm used to create the load balancer pool. For the Amphora provider the value can be **ROUND_ROBIN**, **LEAST_CONNECTIONS**, or **SOURCE_IP**. The default value is **ROUND_ROBIN**.

For the OVN provider, only the **SOURCE_IP_PORT** algorithm is supported.

For the Amphora provider, if using the **LEAST_CONNECTIONS** or **SOURCE_IP** methods, configure the `create-monitor` option as `true` in the `cloud-provider-config` config map on the `openshift-config` namespace and `ETP:Local` on the load-balancer type service to allow balancing algorithm enforcement in the client to service endpoint connections.

### lb-provider

Optional. Used to specify the provider of the load balancer, for example, *amphora* or *octavia*. Only the Amphora and Octavia providers are supported.

### lb-version

Optional. The load balancer API version. Only "v2" is supported.

### subnet-id

The ID of the Networking service subnet on which load balancer VIPs are created.

### network-id

The ID of the Networking service network on which load balancer VIPs are created. Unnecessary if `subnet-id` is set.

### create-monitor

Whether or not to create a health monitor for the service load balancer. A health monitor is required for services that declare `externalTrafficPolicy: Local`. The default value is `false`.

This option is unsupported if you use RHOSP earlier than version 17 with the *ovn* provider.

### monitor-delay

The interval in seconds by which probes are sent to members of the load balancer. The default value is 5.

### monitor-max-retries

The number of successful checks that are required to change the operating status of a load balancer member to **ONLINE**. The valid range is 1 to 10, and the default value is 1.
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>monitor-timeout</td>
<td>The time in seconds that a monitor waits to connect to the back end before it times out. The default value is 3.</td>
</tr>
<tr>
<td>internal-lb</td>
<td>Whether or not to create an internal load balancer without floating IP addresses. The default value is false.</td>
</tr>
<tr>
<td>LoadBalancerClass &quot;ClassName&quot;</td>
<td>This is a config section that comprises a set of options:</td>
</tr>
<tr>
<td></td>
<td>- floating-network-id</td>
</tr>
<tr>
<td></td>
<td>- floating-subnet-id</td>
</tr>
<tr>
<td></td>
<td>- floating-subnet</td>
</tr>
<tr>
<td></td>
<td>- floating-subnet-tags</td>
</tr>
<tr>
<td></td>
<td>- network-id</td>
</tr>
<tr>
<td></td>
<td>- subnet-id</td>
</tr>
<tr>
<td>max-shared-lb</td>
<td>The maximum number of services that can share a load balancer. The default value is 2.</td>
</tr>
</tbody>
</table>

### 21.8.2.2. Options that the Operator overrides

The CCM Operator overrides the following options, which you might recognize from configuring RHOSP. Do not configure them yourself. They are included in this document for informational purposes only.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>auth-url</td>
<td>The RHOSP Identity service URL. For example, <a href="http://128.110.154.166/identity">http://128.110.154.166/identity</a>.</td>
</tr>
<tr>
<td>os-endpoint-type</td>
<td>The type of endpoint to use from the service catalog.</td>
</tr>
<tr>
<td>username</td>
<td>The Identity service user name.</td>
</tr>
<tr>
<td>password</td>
<td>The Identity service user password.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>domain-id</td>
<td>The Identity service user domain ID.</td>
</tr>
<tr>
<td>domain-name</td>
<td>The Identity service user domain name.</td>
</tr>
<tr>
<td>tenant-id</td>
<td>The Identity service project ID. Leave this option unset if you are using Identity service application credentials.</td>
</tr>
<tr>
<td></td>
<td>In version 3 of the Identity API, which changed the identifier <code>tenant</code> to <code>project</code>, the value of <code>tenant-id</code> is automatically mapped to the project construct in the API.</td>
</tr>
<tr>
<td>tenant-name</td>
<td>The Identity service project name.</td>
</tr>
<tr>
<td>tenant-domain-id</td>
<td>The Identity service project domain ID.</td>
</tr>
<tr>
<td>tenant-domain-name</td>
<td>The Identity service project domain name.</td>
</tr>
<tr>
<td>user-domain-id</td>
<td>The Identity service user domain ID.</td>
</tr>
<tr>
<td>user-domain-name</td>
<td>The Identity service user domain name.</td>
</tr>
<tr>
<td>use-clouds</td>
<td>Whether or not to fetch authorization credentials from a <code>clouds.yaml</code> file. Options set in this section are prioritized over values read from the <code>clouds.yaml</code> file.</td>
</tr>
<tr>
<td></td>
<td>CCM searches for the file in the following places:</td>
</tr>
<tr>
<td></td>
<td>1. The value of the <code>clouds-file</code> option.</td>
</tr>
<tr>
<td></td>
<td>2. A file path stored in the environment variable <code>OS_CLIENT_CONFIG_FILE</code>.</td>
</tr>
<tr>
<td></td>
<td>3. The directory <code>pkg/openstack</code>.</td>
</tr>
<tr>
<td></td>
<td>4. The directory <code>~/.config/openstack</code>.</td>
</tr>
<tr>
<td></td>
<td>5. The directory <code>/etc/openstack</code>.</td>
</tr>
<tr>
<td>clouds-file</td>
<td>The file path of a <code>clouds.yaml</code> file. It is used if the <code>use-clouds</code> option is set to <code>true</code>.</td>
</tr>
<tr>
<td>cloud</td>
<td>The named cloud in the <code>clouds.yaml</code> file that you want to use. It is used if the <code>use-clouds</code> option is set to <code>true</code>.</td>
</tr>
</tbody>
</table>
21.9. UNINSTALLING A CLUSTER ON OPENSTACK

You can remove a cluster that you deployed to Red Hat OpenStack Platform (RHOSP).

21.9.1. Removing a cluster that uses installer-provisioned infrastructure

You can remove a cluster that uses installer-provisioned infrastructure from your cloud.

NOTE

After uninstallation, check your cloud provider for any resources not removed properly, especially with User Provisioned Infrastructure (UPI) clusters. There might be resources that the installer did not create or that the installer is unable to access.

Prerequisites

- You have a copy of the installation program that you used to deploy the cluster.
- You have the files that the installation program generated when you created your cluster.

Procedure

1. From the directory that contains the installation program on the computer that you used to install the cluster, run the following command:

   ```bash
   $ ./openshift-install destroy cluster \
   --dir <installation_directory> --log-level info
   ```

   1 For `<installation_directory>`, specify the path to the directory that you stored the installation files in.
   2 To view different details, specify `warn`, `debug`, or `error` instead of `info`.

   NOTE

   You must specify the directory that contains the cluster definition files for your cluster. The installation program requires the `metadata.json` file in this directory to delete the cluster.

2. Optional: Delete the `<installation_directory>` directory and the OpenShift Container Platform installation program.

21.10. UNINSTALLING A CLUSTER ON RHOSP FROM YOUR OWN INFRASTRUCTURE

You can remove a cluster that you deployed to Red Hat OpenStack Platform (RHOSP) on user-provisioned infrastructure.

21.10.1. Downloading playbook dependencies
The Ansible playbooks that simplify the removal process on user-provisioned infrastructure require several Python modules. On the machine where you will run the process, add the modules' repositories and then download them.

**NOTE**

These instructions assume that you are using Red Hat Enterprise Linux (RHEL) 8.

**Prerequisites**

- Python 3 is installed on your machine.

**Procedure**

1. On a command line, add the repositories:
   
a. Register with Red Hat Subscription Manager:
      
      ```
      $ sudo subscription-manager register # If not done already
      ```
   
b. Pull the latest subscription data:
      
      ```
      $ sudo subscription-manager attach --pool=$YOUR_POOLID # If not done already
      ```
   
c. Disable the current repositories:
      
      ```
      $ sudo subscription-manager repos --disable=* # If not done already
      ```
   
d. Add the required repositories:
      
      ```
      $ sudo subscription-manager repos 
      --enable=rhel-8-for-x86_64-baseos-rpms 
      --enable=openstack-16-tools-for-rhel-8-x86_64-rpms 
      --enable=ansible-2.9-for-rhel-8-x86_64-rpms 
      --enable=rhel-8-for-x86_64-appstream-rpms
      ```

2. Install the modules:

   ```
   $ sudo yum install python3-openstackclient ansible python3-openstacksdk
   ```

3. Ensure that the `python` command points to `python3`:

   ```
   $ sudo alternatives --set python /usr/bin/python3
   ```

**21.10.2. Removing a cluster from RHOSP that uses your own infrastructure**

You can remove an OpenShift Container Platform cluster on Red Hat OpenStack Platform (RHOSP) that uses your own infrastructure. To complete the removal process quickly, run several Ansible playbooks.

**Prerequisites**

- Python 3 is installed on your machine.
You downloaded the modules in "Downloading playbook dependencies."

You have the playbooks that you used to install the cluster.

You modified the playbooks that are prefixed with `down-` to reflect any changes that you made to their corresponding installation playbooks. For example, changes to the `bootstrap.yaml` file are reflected in the `down-bootstrap.yaml` file.

All of the playbooks are in a common directory.

Procedure

1. On a command line, run the playbooks that you downloaded:

   $ ansible-playbook -i inventory.yaml
   down-bootstrap.yaml
   down-control-plane.yaml
   down-compute-nodes.yaml
   down-load-balancers.yaml
   down-network.yaml
   down-security-groups.yaml

2. Remove any DNS record changes you made for the OpenShift Container Platform installation.

OpenShift Container Platform is removed from your infrastructure.

21.11. INSTALLATION CONFIGURATION PARAMETERS FOR OPENSTACK

Before you deploy an OpenShift Container Platform cluster on Red Hat OpenStack Platform (RHOSP), you provide parameters to customize your cluster and the platform that hosts it. When you create the `install-config.yaml` file, you provide values for the required parameters through the command line. You can then modify the `install-config.yaml` file to customize your cluster further.

21.11.1. Available installation configuration parameters for OpenStack

The following tables specify the required, optional, and OpenStack-specific installation configuration parameters that you can set as part of the installation process.

NOTE

After installation, you cannot modify these parameters in the `install-config.yaml` file.

21.11.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

Table 21.10. Required parameters
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion:</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is <code>v1</code>. The installation program may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>baseDomain:</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the baseDomain and metadata.name parameter values that uses the <code>&lt;metadata.name&gt;</code>, <code>&lt;baseDomain&gt;</code> format.</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
</tr>
<tr>
<td>metadata:</td>
<td>Kubernetes resource <code>ObjectMeta</code>, from which only the name parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata:</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of <code>{{.metadata.name}}</code>, <code>{{.baseDomain}}</code>.</td>
<td>String of lowercase letters, hyphens (‐), and periods (.), such as dev. The string must be 14 characters or fewer long.</td>
</tr>
<tr>
<td>platform:</td>
<td>The configuration for the specific platform upon which to perform the installation: alibabacloud, aws, baremetal, azure, gcp, ibmcloud, nutanix, openstack, powervs, vsphere, or {}. For additional information about platform. &lt;platform&gt; parameters, consult the table for your specific platform that follows.</td>
<td>Object</td>
</tr>
</tbody>
</table>
Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.

```
{
  "auths": {
    "cloud.openshift.com": {
      "auth": "b3Blb=",
      "email": "you@example.com"
    },
    "quay.io": {
      "auth": "b3Blb=",
      "email": "you@example.com"
    }
  }
}
```

### 21.11.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

**NOTE**

Globalnet is not supported with Red Hat OpenShift Data Foundation disaster recovery solutions. For regional disaster recovery scenarios, ensure that you use a nonoverlapping range of private IP addresses for the cluster and service networks in each cluster.

OpenShift Container Platform 4.14 Installing

3098
### 21.11.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking: machineNetwork: cidr:</td>
<td>Required if you use <code>networking.machineNetwork</code>. An IP address block. The default value is <code>10.0.0.0/16</code> for all platforms other than libvirt and IBM Power® Virtual Server. For libvirt, the default value is <code>192.168.126.0/24</code>. For IBM Power® Virtual Server, the default value is <code>192.168.0.0/24</code>.</td>
<td>An IP network block in CIDR notation. For example, <code>10.0.0.0/16</code>.</td>
</tr>
<tr>
<td><strong>NOTE</strong></td>
<td>Set the <code>networking.machineNetwork</code> to match the CIDR that the preferred NIC resides in.</td>
<td></td>
</tr>
</tbody>
</table>

#### Table 21.12. Optional parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle:</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>capabilities:</td>
<td>Controls the installation of optional core cluster components. You can reduce the footprint of your OpenShift Container Platform cluster by disabling optional components. For more information, see the &quot;Cluster capabilities&quot; page in <em>Installing</em>.</td>
<td>String array</td>
</tr>
<tr>
<td>capabilities: baselineCapabilitySet:</td>
<td>Selects an initial set of optional capabilities to enable. Valid values are <code>None</code>, <code>v4.11</code>, <code>v4.12</code> and <code>vCurrent</code>. The default value is <code>vCurrent</code>.</td>
<td>String</td>
</tr>
<tr>
<td>capabilities: additionalEnabledCapabilities:</td>
<td>Extends the set of optional capabilities beyond what you specify in <code>baselineCapabilitySet</code>. You may specify multiple capabilities in this parameter.</td>
<td>String array</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------------------------------</td>
</tr>
<tr>
<td>cpuPartitioningMode:</td>
<td>Enables workload partitioning, which isolates OpenShift Container Platform services, cluster management workloads, and infrastructure pods to run on a reserved set of CPUs. Workload partitioning can only be enabled during installation and cannot be disabled after installation. While this field enables workload partitioning, it does not configure workloads to use specific CPUs. For more information, see the Workload partitioning page in the Scalability and Performance section.</td>
<td>None or AllNodes. None is the default value.</td>
</tr>
<tr>
<td>compute:</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of MachinePool objects.</td>
</tr>
<tr>
<td>compute: architecture:</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, clusters with varied architectures are not supported. All pools must specify the same architecture. Valid values are <strong>amd64</strong> (the default).</td>
<td>String</td>
</tr>
<tr>
<td>compute: hyperthreading:</td>
<td>Whether to enable or disable simultaneous multithreading, or <strong>hyperthreading</strong>, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
</tbody>
</table>

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>compute:</td>
<td>Required if you use compute. The name of the machine pool.</td>

<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-----------------------------</td>
</tr>
<tr>
<td>controlPlane:</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>hyperthreading:</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td></td>
</tr>
<tr>
<td>controlPlane:</td>
<td>Required if you use <code>controlPlane</code>. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td>name:</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>controlPlane: platform:</td>
<td>alibabacloud, aws, azure, gcp, ibmcloud, nutanix, openstack, powervs, vsphere, or {}</td>
</tr>
<tr>
<td></td>
<td>Required if you use <code>controlPlane</code>. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the <code>compute.platform</code> parameter value.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>controlPlane: replicas:</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
<tr>
<td></td>
<td>The number of control plane machines to provision.</td>
<td></td>
</tr>
<tr>
<td>credentialsMode:</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual or an empty string (&quot;&quot;&quot;&quot;).[1]</td>
</tr>
</tbody>
</table>
Enable or disable FIPS mode. The default is `false` (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

### IMPORTANT

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see [Installing the system in FIPS mode](#). When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures.

### NOTE

If you are using Azure File storage, you cannot enable FIPS mode.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>imageContentSources:</td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects. Includes a <code>source</code> and, optionally, <code>mirrors</code>, as described in the following rows of this table.</td>
</tr>
<tr>
<td>imageContentSources: source:</td>
<td>Required if you use <code>imageContentSources</code>. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td>imageContentSources: mirrors:</td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
<tr>
<td>publish:</td>
<td>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</td>
<td><strong>Internal</strong> or <strong>External</strong>. The default value is <strong>External</strong>. Setting this field to <strong>Internal</strong> is not supported on non-cloud platforms.</td>
</tr>
<tr>
<td>sshKey:</td>
<td>The SSH key to authenticate access to your cluster machines.</td>
<td>For example, <code>sshKey: ssh-ed25519 AAAA...</code></td>
</tr>
</tbody>
</table>

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

1. Not all CCO modes are supported for all cloud providers. For more information about CCO modes, see the "Managing cloud provider credentials" entry in the `Authentication and authorization` content.
## 21.11.4. Additional Red Hat OpenStack Platform (RHOSP) configuration parameters

Additional RHOSP configuration parameters are described in the following table:

**Table 21.13. Additional RHOSP parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>compute: platform: openstack:</td>
<td>For compute machines, the size in gigabytes of the root volume. If you do not set this value, machines use ephemeral storage.</td>
<td>Integer, for example <strong>30</strong>.</td>
</tr>
<tr>
<td>rootVolume: size:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>compute: platform: openstack:</td>
<td>For compute machines, the root volume types.</td>
<td>A list of strings, for example, {<strong>performance-host1</strong>, <strong>performance-host2</strong>, <strong>performance-host3</strong>}. [1]</td>
</tr>
<tr>
<td>rootVolume: types:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>compute: platform: openstack:</td>
<td>For compute machines, the root volume's type. This property is deprecated and is replaced by <code>compute.platform.openstack.rootVolume.types</code>.</td>
<td>String, for example, <strong>performance</strong>. [2]</td>
</tr>
<tr>
<td>rootVolume: type:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>compute: platform: openstack:</td>
<td>For compute machines, the Cinder availability zone to install root volumes on. If you do not set a value for this parameter, the installation program selects the default availability zone. This parameter is mandatory when <code>compute.platform.openstack.zones</code> is defined.</td>
<td>A list of strings, for example <code>[&quot;zone-1&quot;, &quot;zone-2&quot;]</code></td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td>controlPlane: platform: openstack: rootVolume: types:</td>
<td>For control plane machines, the root volume types.</td>
<td>A list of strings, for example, {performance-host1, performance-host2, performance-host3}. [1]</td>
</tr>
<tr>
<td>controlPlane: platform: openstack: rootVolume: type:</td>
<td>For control plane machines, the root volume’s type. This property is deprecated and is replaced by compute.platform.openstack.rootVolume.types.</td>
<td>String, for example, performance. [2]</td>
</tr>
<tr>
<td>controlPlane: platform: openstack: rootVolume: zones:</td>
<td>For control plane machines, the Cinder availability zone to install root volumes on. If you do not set this value, the installation program selects the default availability zone. This parameter is mandatory when controlPlane.platform.openstack.zones is defined.</td>
<td>A list of strings, for example [&quot;zone-1&quot;, &quot;zone-2&quot;].</td>
</tr>
<tr>
<td>platform: openstack: cloud:</td>
<td>The name of the RHOSP cloud to use from the list of clouds in the clouds.yaml file.</td>
<td>String, for example MyCloud.</td>
</tr>
<tr>
<td>platform: openstack: externalNetwork:</td>
<td>The RHOSP external network name to be used for installation.</td>
<td>String, for example external.</td>
</tr>
</tbody>
</table>
### platform: openstack: computeFlavor:

The RHOSP flavor to use for control plane and compute machines.

This property is deprecated. To use a flavor as the default for all machine pools, add it as the value of the `type` key in the `platform.openstack.defaultMachinePlatform` property. You can also set a flavor value for each machine pool individually.

String, for example `m1.xlarge`.

---

1. If the machine pool defines `zones`, the count of types can either be a single item or match the number of items in `zones`. For example, the count of types cannot be 2 if there are 3 items in `zones`.

2. If you have any existing reference to this property, the installer populates the corresponding value in the `controlPlane.platform.openstack.rootVolume.types` field.

### 21.11.1.5. Optional RHOSP configuration parameters

Optional RHOSP configuration parameters are described in the following table:

**Table 21.14. Optional RHOSP parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>compute: platform: openstack: additionalNetworkIDs:</td>
<td>Additional networks that are associated with compute machines. Allowed address pairs are not created for additional networks.</td>
<td>A list of one or more UUIDs as strings. For example, <code>fa806b2f-ac49-4bce-b9db-124bc64209bf</code>.</td>
</tr>
<tr>
<td>compute: platform: openstack: additionalSecurityGroupIDs:</td>
<td>Additional security groups that are associated with compute machines.</td>
<td>A list of one or more UUIDs as strings. For example, <code>7ee219f3-d2e9-48a1-96c2-e7429f1b0da7</code>.</td>
</tr>
</tbody>
</table>
compute:
  platform:
    openstack:
      zones:

On clusters that use Kuryr, RHOSP Octavia does not support availability zones. Load balancers and, if you are using the Amphora provider driver, OpenShift Container Platform services that rely on Amphora VMs, are not created according to the value of this property.

A list of strings. For example, ["zone-1", "zone-2"].

compute:
  platform:
    openstack:
      serverGroupPolicy:

A server group policy to apply to the machine pool. For example, soft-affinity.

Server group policy to apply to the group that will contain the compute machines in the pool. You cannot change server group policies or affiliations after creation. Supported options include anti-affinity, soft-affinity, and soft-anti-affinity. The default value is soft-anti-affinity.

An affinity policy prevents migrations and therefore affects RHOSP upgrades. The affinity policy is not supported.

If you use a strict anti-affinity policy, an additional RHOSP host is required during instance migration.
<table>

<tr>
<td>controlPlane: platform: openstack: serverGroupPolicy:</td>
<td>Server group policy to apply to the group that will contain the control plane machines in the pool. You cannot change server group policies or affiliations after creation. Supported options include anti-affinity, soft-affinity, and soft-anti-affinity. The default value is soft-anti-affinity. An affinity policy prevents migrations, and therefore affects RHOSP upgrades. The affinity policy is not supported. If you use a strict anti-affinity policy, an additional RHOSP host is required during instance migration.</td>
<td>A server group policy to apply to the machine pool. For example, <strong>soft-affinity</strong>.</td>
</tr>
<tr>
<td>platform: openstack: clusterOSImage:</td>
<td>The location from which the installation program downloads the RHOS image. You must set this parameter to perform an installation in a restricted network.</td>
<td>An HTTP or HTTPS URL, optionally with an SHA-256 checksum. For example, <strong><a href="http://mirror.example.com/images/rhcos-43.81.201912131630.0-openstack.x86_64.qcow2.gz?sha256=ffebbd68e8a1f2a245ca19522c16c86f7f9ac8e40c1f0a812b068b16f7265d">http://mirror.example.com/images/rhcos-43.81.201912131630.0-openstack.x86_64.qcow2.gz?sha256=ffebbd68e8a1f2a245ca19522c16c86f7f9ac8e40c1f0a812b068b16f7265d</a></strong>. The value can also be the name of an existing Glance image, for example <strong>my-rhcos</strong>.</td>
</tr>
</tbody>
</table>
### Properties to add to the installer-uploaded ClusterOSImage in Glance

This property is ignored if `platform.openstack.clusterOSImage` is set to an existing Glance image.

You can use this property to exceed the default persistent volume (PV) limit for RHOSP of 26 PVs per node. To exceed the limit, set the `hw_scsi_model` property value to `virtio-scsi` and the `hw_disk_bus` value to `scsi`.

You can also use this property to enable the QEMU guest agent by including the `hw_qemu_guest_agent` property with a value of `yes`.

<table>

The first item in networking.machineNetwork must match the value of machinesSubnet. If you deploy to a custom subnet, you cannot specify an external DNS server to the OpenShift Container Platform installer. Instead, add DNS to the subnet in RHOSP.</td>
<td>A UUID as a string. For example, fa806b2f-ac49-4bce-b9db-124bc64209bf.</td>
</tr>
</tbody>
</table>
CHAPTER 22. INSTALLING ON VSPHERE

22.1. PREPARING TO INSTALL ON VSPHERE

22.1.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- If you use a firewall and plan to use Telemetry, you configured the firewall to allow the sites required by your cluster.
- You reviewed your VMware platform licenses. Red Hat does not place any restrictions on your VMware licenses, but some VMware infrastructure components require licensing.

22.1.2. Choosing a method to install OpenShift Container Platform on vSphere

You can install OpenShift Container Platform with the Assisted Installer. This method requires no setup for the installer, and is ideal for connected environments like vSphere. Installing with the Assisted Installer also provides integration with vSphere, enabling autoscaling. See Installing an on-premise cluster using the Assisted Installer for additional details.

You can also install OpenShift Container Platform on vSphere by using installer-provisioned or user-provisioned infrastructure. Installer-provisioned infrastructure is ideal for installing in environments with air-gapped/restricted networks, where the installation program provisions the underlying infrastructure for the cluster. You can also install OpenShift Container Platform on infrastructure that you provide. If you do not use infrastructure that the installation program provisions, you must manage and maintain the cluster resources yourself.

See the Installation process for more information about installer-provisioned and user-provisioned installation processes.

IMPORTANT

The steps for performing a user-provisioned infrastructure installation are provided as an example only. Installing a cluster with infrastructure you provide requires knowledge of the vSphere platform and the installation process of OpenShift Container Platform. Use the user-provisioned infrastructure installation instructions as a guide; you are free to create the required resources through other methods.

22.1.2.1. Installer-provisioned infrastructure installation of OpenShift Container Platform on vSphere

Installer-provisioned infrastructure allows the installation program to preconfigure and automate the provisioning of resources required by OpenShift Container Platform.

- Installing a cluster on vSphere You can install OpenShift Container Platform on vSphere by using installer-provisioned infrastructure installation with no customization.
- **Installing a cluster on vSphere with customizations** You can install OpenShift Container Platform on vSphere by using installer-provisioned infrastructure installation with the default customization options.

- **Installing a cluster on vSphere with network customizations** You can install OpenShift Container Platform on installer-provisioned vSphere infrastructure, with network customizations. You can customize your OpenShift Container Platform network configuration during installation, so that your cluster can coexist with your existing IP address allocations and adhere to your network requirements.

- **Installing a cluster on vSphere in a restricted network** You can install a cluster on VMware vSphere infrastructure in a restricted network by creating an internal mirror of the installation release content. You can use this method to deploy OpenShift Container Platform on an internal network that is not visible to the internet.

**22.1.2.2. User-provisioned infrastructure installation of OpenShift Container Platform on vSphere**

User-provisioned infrastructure requires the user to provision all resources required by OpenShift Container Platform.

- xref:[Installing a cluster on vSphere with user-provisioned infrastructure] You can install OpenShift Container Platform on VMware vSphere infrastructure that you provision.

- **Installing a cluster on vSphere with network customizations with user-provisioned infrastructure** You can install OpenShift Container Platform on VMware vSphere infrastructure that you provision with customized network configuration options.

- **Installing a cluster on vSphere in a restricted network with user-provisioned infrastructure** OpenShift Container Platform can be installed on VMware vSphere infrastructure that you provision in a restricted network.

**22.1.3. VMware vSphere infrastructure requirements**

You must install the OpenShift Container Platform cluster on a VMware vSphere version 7.0 Update 2 or later instance that meets the requirements for the components that you use.

**NOTE**

OpenShift Container Platform version 4.14 supports VMware vSphere version 8.0.

You can host the VMware vSphere infrastructure on-premise or on a VMware Cloud Verified provider that meets the requirements outlined in the following tables:

**Table 22.1. Version requirements for vSphere virtual environments**

<table>
<thead>
<tr>
<th>Virtual environment product</th>
<th>Required version</th>
</tr>
</thead>
<tbody>
<tr>
<td>VMware virtual hardware</td>
<td>15 or later</td>
</tr>
<tr>
<td>vSphere ESXi hosts</td>
<td>7.0 Update 2 or later</td>
</tr>
<tr>
<td>vCenter host</td>
<td>7.0 Update 2 or later</td>
</tr>
</tbody>
</table>
IMPORTANT

You must ensure that the time on your ESXi hosts is synchronized before you install OpenShift Container Platform. See Edit Time Configuration for a Host in the VMware documentation.

Table 22.2. Minimum supported vSphere version for VMware components

<table>
<thead>
<tr>
<th>Component</th>
<th>Minimum supported versions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hypervisor</td>
<td>vSphere 7.0 Update 2 and later with virtual hardware version 15</td>
<td>This version is the minimum version that Red Hat Enterprise Linux CoreOS (RHCOS) supports. For more information about supported hardware on the latest version of Red Hat Enterprise Linux (RHEL) that is compatible with RHCOS, see Hardware on the Red Hat Customer Portal.</td>
</tr>
<tr>
<td>Storage with in-tree drivers</td>
<td>vSphere 7.0 Update 2 and later</td>
<td>This plugin creates vSphere storage by using the in-tree storage drivers for vSphere included in OpenShift Container Platform.</td>
</tr>
<tr>
<td>Optional: Networking (NSX-T)</td>
<td>vSphere 7.0 Update 2 and later</td>
<td>vSphere 7.0 Update 2 is required for OpenShift Container Platform. For more information about the compatibility of NSX and OpenShift Container Platform, see the Release Notes section of VMware’s NSX container plugin documentation.</td>
</tr>
</tbody>
</table>

IMPORTANT

To ensure the best performance conditions for your cluster workloads that operate on Oracle® Cloud Infrastructure and on the Oracle® Cloud VMware Solution (OCVS) service, ensure volume performance units (VPUs) for your block volume are sized for your workloads.

The following list provides some guidance in selecting the VPUs needed for specific performance needs:

- Test or proof of concept environment: 100 GB, and 20 to 30 VPUs.
- Base-production environment: 500 GB, and 60 VPUs.
- Heavy-use production environment: More than 500 GB, and 100 or more VPUs.

Consider allocating additional VPUs to give enough capacity for updates and scaling activities. See Block Volume Performance Levels in the Oracle documentation.
22.1.4. VMware vSphere CSI Driver Operator requirements

To install the vSphere CSI Driver Operator, the following requirements must be met:

- VMware vSphere version 7.0 Update 2 or later
- vCenter 7.0 Update 2 or later
- Virtual machines of hardware version 15 or later
- No third-party vSphere CSI driver already installed in the cluster

If a third-party vSphere CSI driver is present in the cluster, OpenShift Container Platform does not overwrite it. The presence of a third-party vSphere CSI driver prevents OpenShift Container Platform from updating to OpenShift Container Platform 4.13 or later.

**NOTE**

The VMware vSphere CSI Driver Operator is supported only on clusters deployed with `platform: vsphere` in the installation manifest.

Additional resources

- To remove a third-party vSphere CSI driver, see Removing a third-party vSphere CSI Driver .

22.1.5. Configuring the vSphere connection settings

- **Updating the vSphere connection settings following an installation** For installations on vSphere using the Assisted Installer, you must manually update the vSphere connection settings to complete the installation. For installer-provisioned or user-provisioned infrastructure installations on vSphere, you can optionally validate or modify the vSphere connection settings at any time.

22.1.6. Uninstalling an installer-provisioned infrastructure installation of OpenShift Container Platform on vSphere

- **Uninstalling a cluster on vSphere that uses installer-provisioned infrastructure** You can remove a cluster that you deployed on VMware vSphere infrastructure that used installer-provisioned infrastructure.

22.2. INSTALLING A CLUSTER ON VSPHERE

In OpenShift Container Platform version 4.14, you can install a cluster on your VMware vSphere instance by using installer-provisioned infrastructure.

**NOTE**

OpenShift Container Platform supports deploying a cluster to a single VMware vCenter only. Deploying a cluster with machines/machine sets on multiple vCenters is not supported.

22.2.1. Prerequisites
You reviewed details about the OpenShift Container Platform installation and update processes.

You read the documentation on selecting a cluster installation method and preparing it for users.

You provisioned persistent storage for your cluster. To deploy a private image registry, your storage must provide ReadWriteMany access modes.

The OpenShift Container Platform installer requires access to port 443 on the vCenter and ESXi hosts. You verified that port 443 is accessible.

If you use a firewall, you confirmed with the administrator that port 443 is accessible. Control plane nodes must be able to reach vCenter and ESXi hosts on port 443 for the installation to succeed.

If you use a firewall, you configured it to allow the sites that your cluster requires access to.

**NOTE**
Be sure to also review this site list if you are configuring a proxy.

### 22.2.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager Hybrid Cloud Console to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- Access Quay.io to obtain the packages that are required to install your cluster.

- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 22.2.3. VMware vSphere infrastructure requirements

You must install the OpenShift Container Platform cluster on a VMware vSphere version 7.0 Update 2 or later instance that meets the requirements for the components that you use.

**NOTE**

OpenShift Container Platform version 4.14 supports VMware vSphere version 8.0.
You can host the VMware vSphere infrastructure on-premise or on a VMware Cloud Verified provider that meets the requirements outlined in the following tables:

### Table 22.3. Version requirements for vSphere virtual environments

<table>
<thead>
<tr>
<th>Virtual environment product</th>
<th>Required version</th>
</tr>
</thead>
<tbody>
<tr>
<td>VMware virtual hardware</td>
<td>15 or later</td>
</tr>
<tr>
<td>vSphere ESXi hosts</td>
<td>7.0 Update 2 or later</td>
</tr>
<tr>
<td>vCenter host</td>
<td>7.0 Update 2 or later</td>
</tr>
</tbody>
</table>

**IMPORTANT**

You must ensure that the time on your ESXi hosts is synchronized before you install OpenShift Container Platform. See [Edit Time Configuration for a Host](#) in the VMware documentation.

### Table 22.4. Minimum supported vSphere version for VMware components

<table>
<thead>
<tr>
<th>Component</th>
<th>Minimum supported versions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hypervisor</td>
<td>vSphere 7.0 Update 2 and later with virtual hardware version 15</td>
<td>This version is the minimum version that Red Hat Enterprise Linux CoreOS (RHCOS) supports. For more information about supported hardware on the latest version of Red Hat Enterprise Linux (RHEL) that is compatible with RHCOS, see <a href="#">Hardware</a> on the Red Hat Customer Portal.</td>
</tr>
<tr>
<td>Storage with in-tree drivers</td>
<td>vSphere 7.0 Update 2 and later</td>
<td>This plugin creates vSphere storage by using the in-tree storage drivers for vSphere included in OpenShift Container Platform.</td>
</tr>
<tr>
<td>Optional: Networking (NSX-T)</td>
<td>vSphere 7.0 Update 2 and later</td>
<td>vSphere 7.0 Update 2 is required for OpenShift Container Platform. For more information about the compatibility of NSX and OpenShift Container Platform, see the Release Notes section of VMware’s <a href="#">NSX container plugin documentation</a>.</td>
</tr>
</tbody>
</table>
To ensure the best performance conditions for your cluster workloads that operate on Oracle® Cloud Infrastructure and on the Oracle® Cloud VMware Solution (OCVS) service, ensure volume performance units (VPUs) for your block volume are sized for your workloads.

The following list provides some guidance in selecting the VPUs needed for specific performance needs:

- Test or proof of concept environment: 100 GB, and 20 to 30 VPUs.
- Base-production environment: 500 GB, and 60 VPUs.
- Heavy-use production environment: More than 500 GB, and 100 or more VPUs.

Consider allocating additional VPUs to give enough capacity for updates and scaling activities. See Block Volume Performance Levels in the Oracle documentation.

### 22.2.4. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate.

Review the following details about the required network ports.

#### Table 22.5. Ports used for all-machine to all-machine communications

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Port</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ICMP</td>
<td>N/A</td>
<td>Network reachability tests</td>
</tr>
<tr>
<td>TCP</td>
<td>1936</td>
<td>Metrics</td>
</tr>
<tr>

<td>Host level services, including the node exporter on ports <strong>9100-9101</strong>.</td>
</tr>
<tr>
<td>TCP</td>
<td>500</td>
<td>IPsec IKE packets</td>
</tr>
<tr>
<td>TCP</td>
<td>4500</td>
<td>IPsec NAT-T packets</td>
</tr>
</tbody>
</table>
### 22.2.5. VMware vSphere CSI Driver Operator requirements

To install the vSphere CSI Driver Operator, the following requirements must be met:

- VMware vSphere version 7.0 Update 2 or later
- vCenter 7.0 Update 2 or later
- Virtual machines of hardware version 15 or later
- No third-party vSphere CSI driver already installed in the cluster

If a third-party vSphere CSI driver is present in the cluster, OpenShift Container Platform does not overwrite it. The presence of a third-party vSphere CSI driver prevents OpenShift Container Platform from updating to OpenShift Container Platform 4.13 or later.

**NOTE**

The VMware vSphere CSI Driver Operator is supported only on clusters deployed with platform: vsphere in the installation manifest.

**Additional resources**

- To remove a third-party vSphere CSI driver, see [Removing a third-party vSphere CSI Driver](#).
- To update the hardware version for your vSphere nodes, see [Updating hardware on nodes running in vSphere](#).

### 22.2.6. vCenter requirements
Before you install an OpenShift Container Platform cluster on your vCenter that uses infrastructure that the installer provisions, you must prepare your environment.

**Required vCenter account privileges**
To install an OpenShift Container Platform cluster in a vCenter, the installation program requires access to an account with privileges to read and create the required resources. Using an account that has global administrative privileges is the simplest way to access all of the necessary permissions.

If you cannot use an account with global administrative privileges, you must create roles to grant the privileges necessary for OpenShift Container Platform cluster installation. While most of the privileges are always required, some are required only if you plan for the installation program to provision a folder to contain the OpenShift Container Platform cluster on your vCenter instance, which is the default behavior. You must create or amend vSphere roles for the specified objects to grant the required privileges.

An additional role is required if the installation program is to create a vSphere virtual machine folder.

### Example 22.1. Roles and privileges required for installation in vSphere API

<table>
<thead>

</tbody>
</table>

For more information about creating an account with only the required privileges, see [vSphere Permissions and User Management Tasks](#) in the vSphere documentation.

**Using OpenShift Container Platform with vMotion**

If you intend on using vMotion in your vSphere environment, consider the following before installing an OpenShift Container Platform cluster.

- OpenShift Container Platform generally supports compute-only vMotion, where *generally* implies that you meet all VMware best practices for vMotion. To help ensure the uptime of your compute and control plane nodes, ensure that you follow the VMware best practices for vMotion, and use VMware anti-affinity rules to improve the availability of OpenShift Container Platform during maintenance or hardware issues.

For more information about vMotion and anti-affinity rules, see the VMware vSphere documentation for [vMotion networking requirements](#) and [VM anti-affinity rules](#).

- Using Storage vMotion can cause issues and is not supported. If you are using vSphere volumes in your pods, migrating a VM across datastores, either manually or through Storage vMotion, causes invalid references within OpenShift Container Platform persistent volume (PV) objects that can result in data loss.

- OpenShift Container Platform does not support selective migration of VMDKs across datastores, using datastore clusters for VM provisioning or for dynamic or static provisioning of PVs, or using a datastore that is part of a datastore cluster for dynamic or static provisioning of...
IMPORTANT

You can specify the path of any datastore that exists in a datastore cluster. By default, Storage Distributed Resource Scheduler (SDRS), which uses Storage vMotion, is automatically enabled for a datastore cluster. Red Hat does not support Storage vMotion, so you must disable Storage DRS to avoid data loss issues for your OpenShift Container Platform cluster.

If you must specify VMs across multiple datastores, use a datastore object to specify a failure domain in your cluster’s install-config.yaml configuration file. For more information, see "VMware vSphere region and zone enablement".

Cluster resources
When you deploy an OpenShift Container Platform cluster that uses installer-provisioned infrastructure, the installation program must be able to create several resources in your vCenter instance.

A standard OpenShift Container Platform installation creates the following vCenter resources:

- 1 Folder
- 1 Tag category
- 1 Tag
- Virtual machines:
  - 1 template
  - 1 temporary bootstrap node
  - 3 control plane nodes
  - 3 compute machines

Although these resources use 856 GB of storage, the bootstrap node is destroyed during the cluster installation process. A minimum of 800 GB of storage is required to use a standard cluster.

If you deploy more compute machines, the OpenShift Container Platform cluster will use more storage.

Cluster limits
Available resources vary between clusters. The number of possible clusters within a vCenter is limited primarily by available storage space and any limitations on the number of required resources. Be sure to consider both limitations to the vCenter resources that the cluster creates and the resources that you require to deploy a cluster, such as IP addresses and networks.

Networking requirements
Use Dynamic Host Configuration Protocol (DHCP) for the network and ensure that the DHCP server is configured to provide persistent IP addresses to the cluster machines.

NOTE

You do not need to use the DHCP for the network if you want to provision nodes with static IP addresses.
Configure the default gateway to use the DHCP server. All nodes must be in the same VLAN. You cannot scale the cluster using a second VLAN as a Day 2 operation.

You must use the Dynamic Host Configuration Protocol (DHCP) for the network and ensure that the DHCP server is configured to provide persistent IP addresses to the cluster machines. In the DHCP lease, you must configure the DHCP to use the default gateway. All nodes must be in the same VLAN. You cannot scale the cluster using a second VLAN as a Day 2 operation.

Additionally, you must create the following networking resources before you install the OpenShift Container Platform cluster:

**NOTE**

It is recommended that each OpenShift Container Platform node in the cluster must have access to a Network Time Protocol (NTP) server that is discoverable via DHCP. Installation is possible without an NTP server. However, asynchronous server clocks will cause errors, which NTP server prevents.

**Required IP Addresses**

For a network that uses DHCP, an installer-provisioned vSphere installation requires two static IP addresses:

- The **API** address is used to access the cluster API.
- The **Ingress** address is used for cluster ingress traffic.

You must provide these IP addresses to the installation program when you install the OpenShift Container Platform cluster.

**DNS records**

You must create DNS records for two static IP addresses in the appropriate DNS server for the vCenter instance that hosts your OpenShift Container Platform cluster. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the cluster base domain that you specify when you install the cluster. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>`.

**Table 22.8. Required DNS records**

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>API VIP</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>This DNS A/AAAA or CNAME record must point to the load balancer for the control plane machines. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>
Ingress VIP

A wildcard DNS A/AAAA or CNAME record that points to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ingress</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A wildcard DNS A/AAAA or CNAME record that points to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>

### Static IP addresses for vSphere nodes

You can provision bootstrap, control plane, and compute nodes to be configured with static IP addresses in environments where Dynamic Host Configuration Protocol (DHCP) does not exist. To configure this environment, you must provide values to the `platform.vsphere.hosts.role` parameter in the `install-config.yaml` file.

**IMPORTANT**

Static IP addresses for vSphere nodes is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see [Technology Preview Features Support Scope](#).

By default, the installation program is configured to use the DHCP for the network, but this network has limited configurable capabilities.

After you define one or more machine pools in your `install-config.yaml` file, you can define network definitions for nodes on your network. Ensure that the number of network definitions matches the number of machine pools that you configured for your cluster.

The following example shows a network configuration for a node with the role `compute`:

```
---
platform:
  vsphere:
    hosts:
      - role: compute
        networkDevice:
          ipAddrs:
            - 192.168.204.10/24
          gateway: 192.168.204.1
```
Valid network definition values include **bootstrap**, **control-plane**, and **compute**. You must list at least one **bootstrap** network definition in your **install-config.yaml** configuration file.

Lists IPv4, IPv6, or both IP addresses that the installation program passes to the network interface. The machine API controller assigns all configured IP addresses to the default network interface.

The default gateway for the network interface.

Lists up to 3 DNS nameservers.

---

### IMPORTANT

To enable the Technology Preview feature of static IP addresses for vSphere nodes for your cluster, you must include **featureSet:TechPreviewNoUpgrade** as the initial entry in the **install-config.yaml** file.

After you deployed your cluster to run nodes with static IP addresses, you can scale a machine to use one of these static IP addresses. Additionally, you can use a machine set to configure a machine to use one of the configured static IP addresses.

- Scaling machines to use static IP addresses
- Using a machine set to scale machines with configured static IP addresses

### 22.2.7. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the **core** user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user **core**. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

### IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

### NOTE

You must use a local key, not one that you configured with platform-specific approaches such as **AWS key pairs**.
Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>
   ```

   Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

   **NOTE**
   If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   ```bash
   $ cat <path>/<file_name>.pub
   ```

   For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

   ```bash
   $ cat ~/.ssh/id_ed25519.pub
   ```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

   **NOTE**
   On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

   a. If the `ssh-agent` process is not already running for your local user, start it as a background task:

   ```bash
   $ eval "$(ssh-agent -s)"
   ```

   **Example output**

   ```bash
   Agent pid 31874
   ```

   **NOTE**
   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the `ssh-agent`:
$ ssh-add <path>/<file_name>

Specify the path and file name for your SSH private key, such as ~/.ssh/id_ed25519

Example output

Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

22.2.8. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

Prerequisites

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space.

**IMPORTANT**

If you attempt to run the installation program on macOS, a known issue related to the golang compiler causes the installation of the OpenShift Container Platform cluster to fail. For more information about this issue, see the section named “Known Issues” in the OpenShift Container Platform 4.14 release notes document.

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.
IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ tar -xvf openshift-install-linux.tar.gz
   ```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

22.2.9. Adding vCenter root CA certificates to your system trust

Because the installation program requires access to your vCenter’s API, you must add your vCenter’s trusted root CA certificates to your system trust before you install an OpenShift Container Platform cluster.

Procedure

1. From the vCenter home page, download the vCenter’s root CA certificates. Click Download trusted root CA certificates in the vSphere Web Services SDK section. The `<vCenter>/certs/download.zip` file downloads.

2. Extract the compressed file that contains the vCenter root CA certificates. The contents of the compressed file resemble the following file structure:

```
certs
  └── lin
    └── 108f4d17.0
         └── 108f4d17.r1
              └── 7e757f6a.0
                   └── 8e4f8471.0
                        └── 8e4f8471.r0
    └── mac
         └── 108f4d17.0
              └── 108f4d17.r1
                   └── 7e757f6a.0
                        └── 8e4f8471.0
                             └── 8e4f8471.r0
     └── win
          └── 108f4d17.0.crt
               └── 108f4d17.r1.crt
                    └── 7e757f6a.0.crt
                         └── 8e4f8471.0.crt
                              └── 8e4f8471.r0.crt
```
3 directories, 15 files
3. Add the files for your operating system to the system trust. For example, on a Fedora operating system, run the following command:

```
# cp certs/lin/* /etc/pki/ca-trust/source/anchors
```

4. Update your system trust. For example, on a Fedora operating system, run the following command:

```
# update-ca-trust extract
```

### 22.2.10. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

**Prerequisites**

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.
- Optional: Before you create the cluster, configure an external load balancer in place of the default load balancer.

**IMPORTANT**

You do not need to specify API and Ingress static addresses for your installation program. If you choose this configuration, you must take additional actions to define network targets that accept an IP address from each referenced vSphere subnet. See the section “Configuring an external load balancer”.

**Procedure**

1. Change to the directory that contains the installation program and initialize the cluster deployment:

```
$ ./openshift-install create cluster --dir <installation_directory> \ ①
   --log-level=info ②
```

   **①** For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

   **②** To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

When specifying the directory:
- Verify that the directory has the `execute` permission. This permission is required to run Terraform binaries under the installation directory.

- Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Provide values at the prompts:
   a. Optional: Select an SSH key to use to access your cluster machines.

      **NOTE**

      For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

   b. Select `vsphere` as the platform to target.

   c. Specify the name of your vCenter instance.

   d. Specify the user name and password for the vCenter account that has the required permissions to create the cluster.

      The installation program connects to your vCenter instance.

      **IMPORTANT**

      Some VMware vCenter Single Sign-On (SSO) environments with Active Directory (AD) integration might primarily require you to use the traditional login method, which requires the `<domain>\` construct.

      To ensure that vCenter account permission checks complete properly, consider using the User Principal Name (UPN) login method, such as `<username>@<fully_qualified_domainname>`.

   e. Select the data center in your vCenter instance to connect to.

   f. Select the default vCenter datastore to use.

      **NOTE**

      Datastore and cluster names cannot exceed 60 characters; therefore, ensure the combined string length does not exceed the 60 character limit.

   g. Select the vCenter cluster to install the OpenShift Container Platform cluster in. The installation program uses the root resource pool of the vSphere cluster as the default resource pool.

   h. Select the network in the vCenter instance that contains the virtual IP addresses and DNS records that you configured.
i. Enter the virtual IP address that you configured for control plane API access.

j. Enter the virtual IP address that you configured for cluster ingress.

k. Enter the base domain. This base domain must be the same one that you used in the DNS records that you configured.

l. Enter a descriptive name for your cluster. The cluster name must be the same one that you used in the DNS records that you configured.

**NOTE**

Datastore and cluster names cannot exceed 60 characters; therefore, ensure the combined string length does not exceed the 60 character limit.

m. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

**Verification**

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the *kubeadmin* user.

- Credential information also outputs to `<installation_directory>/.openshift_install.log`.

**IMPORTANT**

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

**Example output**

```
... INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```
IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

22.2.11. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of **oc**.

Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

**Procedure**

2. Select the architecture from the **Product Variant** drop-down list.

3. Select the appropriate version from the **Version** drop-down list.

4. Click **Download Now** next to the **OpenShift v4.14 Linux Client** entry and save the file.

5. Unpack the archive:

   ```
   $ tar xvf <file>
   ```

6. Place the **oc** binary in a directory that is on your **PATH**.

   To check your **PATH**, execute the following command:

   ```
   $ echo $PATH
   ```

**Verification**

- After you install the OpenShift CLI, it is available using the **oc** command:

  ```
  $ oc <command>
  ```
Installing the OpenShift CLI on Windows
You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

Procedure

2. Select the appropriate version from the Version drop-down list.

3. Click Download Now next to the OpenShift v4.14 Windows Client entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the oc binary to a directory that is on your PATH.
   To check your PATH, open the command prompt and execute the following command:

   \C:\> path

Verification

- After you install the OpenShift CLI, it is available using the oc command:

  \C:\> oc <command>

Installing the OpenShift CLI on macOS
You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.

Procedure

2. Select the appropriate version from the Version drop-down list.

3. Click Download Now next to the OpenShift v4.14 macOS Client entry and save the file.

   **NOTE**
   For macOS arm64, choose the OpenShift v4.14 macOS arm64 Client entry.

4. Unpack and unzip the archive.

5. Move the oc binary to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:

   $ echo $PATH

Verification

- After you install the OpenShift CLI, it is available using the oc command:
22.2.12. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster kubeconfig file. The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the oc CLI.

**Procedure**

1. Export the kubeadmin credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run oc commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   ```

   **Example output**

   system:admin

22.2.13. Creating registry storage

After you install the cluster, you must create storage for the registry Operator.

22.2.13.1. Image registry removed during installation

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as Removed. This allows openshift-installer to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the managementState from Removed to Managed.

22.2.13.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.
Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the **Recreate** rollout strategy during upgrades.

### 22.2.13.2.1. Configuring registry storage for VMware vSphere

As a cluster administrator, following installation you must configure your registry to use storage.

#### Prerequisites

- Cluster administrator permissions.
- A cluster on VMware vSphere.
- Persistent storage provisioned for your cluster, such as Red Hat OpenShift Data Foundation.

**IMPORTANT**

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. **ReadWriteOnce** access also requires that the registry uses the **Recreate** rollout strategy. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have "100Gi" capacity.

**IMPORTANT**

Testing shows issues with using the NFS server on RHEL as storage backend for core services. This includes the OpenShift Container Registry and Quay, Prometheus for monitoring storage, and Elasticsearch for logging storage. Therefore, using RHEL NFS to back PVs used by core services is not recommended.

Other NFS implementations on the marketplace might not have these issues. Contact the individual NFS implementation vendor for more information on any testing that was possibly completed against these OpenShift Container Platform core components.

#### Procedure

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

   **NOTE**

   When you use shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

   ```bash
   $ oc get pod -n openshift-image-registry -l docker-registry=default
   ```
[Example output]

No resources found in openshift-image-registry namespace

[NOTE]

If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

$ oc edit configs.imageregistry.operator.openshift.io

[Example output]

storage:
pvc:
  claim: 1

1 Leave the claim field blank to allow the automatic creation of an image-registry-storage persistent volume claim (PVC). The PVC is generated based on the default storage class. However, be aware that the default storage class might provide ReadWriteOnce (RWO) volumes, such as a RADOS Block Device (RBD), which can cause issues when you replicate to more than one replica.

4. Check the clusteroperator status:

$ oc get clusteroperator image-registry

[Example output]

NAME         VERSION   AVAILABLE PROGRESSING DEGRADED  SINCE  MESSAGE
image-registry 4.7      True   False   False      6h50m

22.2.13.2.2. Configuring block registry storage for VMware vSphere

To allow the image registry to use block storage types such as vSphere Virtual Machine Disk (VMDK) during upgrades as a cluster administrator, you can use the Recreate rollout strategy.

[IMPORTANT]

Block storage volumes are supported but not recommended for use with image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

[Procedure]

1. To set the image registry storage as a block storage type, patch the registry so that it uses the Recreate rollout strategy and runs with only 1 replica:
2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.

   a. Create a `pvc.yaml` file with the following contents to define a VMware vSphere PersistentVolumeClaim object:

   ```yaml
   kind: PersistentVolumeClaim
   apiVersion: v1
   metadata:
     name: image-registry-storage
     namespace: openshift-image-registry
   spec:
     accessModes:
     - ReadWriteOnce
     resources:
       requests:
         storage: 100Gi
   ```

   1. A unique name that represents the `PersistentVolumeClaim` object.
   2. The namespace for the `PersistentVolumeClaim` object, which is `openshift-image-registry`.
   3. The access mode of the persistent volume claim. With `ReadWriteOnce`, the volume can be mounted with read and write permissions by a single node.
   4. The size of the persistent volume claim.

   b. Create the `PersistentVolumeClaim` object from the file:

   ```bash
   $ oc create -f pvc.yaml -n openshift-image-registry
   ```

3. Edit the registry configuration so that it references the correct PVC:

   ```bash
   $ oc edit config.imageregistry.operator.openshift.io -o yaml
   ```

   **Example output**

   ```yaml
   storage:
     pvc:
       claim:
   ```

   1. By creating a custom PVC, you can leave the `claim` field blank for the default automatic creation of an `image-registry-storage` PVC.

For instructions about configuring registry storage so that it references the correct PVC, see Configuring the registry for vSphere.

### 22.2.14. Backing up VMware vSphere volumes
OpenShift Container Platform provisions new volumes as independent persistent disks to freely attach and detach the volume on any node in the cluster. As a consequence, it is not possible to back up volumes that use snapshots, or to restore volumes from snapshots. See Snapshot Limitations for more information.

**Procedure**

To create a backup of persistent volumes:

1. Stop the application that is using the persistent volume.
2. Clone the persistent volume.
3. Restart the application.
4. Create a backup of the cloned volume.
5. Delete the cloned volume.

### 22.2.15. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager Hybrid Cloud Console.

After you confirm that your OpenShift Cluster Manager Hybrid Cloud Console inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- See About remote health monitoring for more information about the Telemetry service

### 22.2.16. Configuring an external load balancer

You can configure an OpenShift Container Platform cluster to use an external load balancer in place of the default load balancer.

**IMPORTANT**

Configuring an external load balancer depends on your vendor’s load balancer.

The information and examples in this section are for guideline purposes only. Consult the vendor documentation for more specific information about the vendor’s load balancer.

Red Hat supports the following services for an external load balancer:

- OpenShift API
- Ingress Controller

You can choose to configure one or both of these services for an external load balancer. Configuring only the Ingress Controller service is a common configuration option.
The following configuration options are supported for external load balancers:

- Use a node selector to map the Ingress Controller to a specific set of nodes. You must assign a static IP address to each node in this set, or configure each node to receive the same IP address from the Dynamic Host Configuration Protocol (DHCP). Infrastructure nodes commonly receive this type of configuration.

- Target all IP addresses on a subnet. This configuration can reduce maintenance overhead, because you can create and destroy nodes within those networks without reconfiguring the load balancer targets. If you deploy your ingress pods by using a machine set on a smaller network, such as a /27 or /28, you can simplify your load balancer targets.

**TIP**

You can list all IP addresses that exist in a network by checking the machine config pool’s resources.

**Considerations**

- For a front-end IP address, you can use the same IP address for the front-end IP address, the Ingress Controller’s load balancer, and API load balancer. Check the vendor’s documentation for this capability.

- For a back-end IP address, ensure that an IP address for an OpenShift Container Platform control plane node does not change during the lifetime of the external load balancer. You can achieve this by completing one of the following actions:
  - Assign a static IP address to each control plane node.
  - Configure each node to receive the same IP address from the DHCP every time the node requests a DHCP lease. Depending on the vendor, the DHCP lease might be in the form of an IP reservation or a static DHCP assignment.

- Manually define each node that runs the Ingress Controller in the external load balancer for the Ingress Controller back-end service. For example, if the Ingress Controller moves to an undefined node, a connection outage can occur.

**OpenShift API prerequisites**

- You defined a front-end IP address.

- TCP ports 6443 and 22623 are exposed on the front-end IP address of your load balancer. Check the following items:
  - Port 6443 provides access to the OpenShift API service.
  - Port 22623 can provide ignition startup configurations to nodes.

- The front-end IP address and port 6443 are reachable by all users of your system with a location external to your OpenShift Container Platform cluster.

- The front-end IP address and port 22623 are reachable only by OpenShift Container Platform nodes.

- The load balancer backend can communicate with OpenShift Container Platform control plane nodes on port 6443 and 22623.
Ingress Controller prerequisites

- You defined a front-end IP address.
- TCP ports 443 and 80 are exposed on the front-end IP address of your load balancer.
- The front-end IP address, port 80 and port 443 are reachable by all users of your system with a location external to your OpenShift Container Platform cluster.
- The front-end IP address, port 80 and port 443 are reachable to all nodes that operate in your OpenShift Container Platform cluster.
- The load balancer backend can communicate with OpenShift Container Platform nodes that run the Ingress Controller on ports 80, 443, and 1936.

Prerequisite for health check URL specifications

You can configure most load balancers by setting health check URLs that determine if a service is available or unavailable. OpenShift Container Platform provides these health checks for the OpenShift API, Machine Configuration API, and Ingress Controller backend services.

The following examples demonstrate health check specifications for the previously listed backend services:

Example of a Kubernetes API health check specification

Path: HTTPS:6443/readyz
Healthy threshold: 2
Unhealthy threshold: 2
Timeout: 10
Interval: 10

Example of a Machine Config API health check specification

Path: HTTPS:22623/healthz
Healthy threshold: 2
Unhealthy threshold: 2
Timeout: 10
Interval: 10

Example of an Ingress Controller health check specification

Path: HTTP:1936/healthz/ready
Healthy threshold: 2
Unhealthy threshold: 2
Timeout: 5
Interval: 10

Procedure

1. Configure the HAProxy Ingress Controller, so that you can enable access to the cluster from your load balancer on ports 6443, 443, and 80:

   Example HAProxy configuration
### 2. Use the `curl` CLI command to verify that the external load balancer and its resources are operational:

a. Verify that the cluster machine configuration API is accessible to the Kubernetes API server resource, by running the following command and observing the response:

```bash
# ...
listen my-cluster-api-6443
bind 192.168.1.100:6443
mode tcp
balance roundrobin
option httpchk
http-check connect
http-check send meth GET uri /readyz
http-check expect status 200
   server my-cluster-master-2 192.168.1.101:6443 check inter 10s rise 2 fall 2
   server my-cluster-master-0 192.168.1.102:6443 check inter 10s rise 2 fall 2
   server my-cluster-master-1 192.168.1.103:6443 check inter 10s rise 2 fall 2

listen my-cluster-machine-config-api-22623
bind 192.168.1.1000.0.0.0:22623
mode tcp
balance roundrobin
option httpchk
http-check connect
http-check send meth GET uri /healthz
http-check expect status 200
   server my-cluster-master-2 192.0168.21.2101:22623 check inter 10s rise 2 fall 2
   server my-cluster-master-0 192.168.1.1020.2.3:22623 check inter 10s rise 2 fall 2
   server my-cluster-master-1 192.168.1.1030.2.1:22623 check inter 10s rise 2 fall 2

listen my-cluster-apps-443
bind 192.168.1.100:443
mode tcp
balance roundrobin
option httpchk
http-check connect
http-check send meth GET uri /healthz/ready
http-check expect status 200
   server my-cluster-worker-0 192.168.1.111:443 check port 1936 inter 10s rise 2 fall 2
   server my-cluster-worker-1 192.168.1.112:443 check port 1936 inter 10s rise 2 fall 2
   server my-cluster-worker-2 192.168.1.113:443 check port 1936 inter 10s rise 2 fall 2

listen my-cluster-apps-80
bind 192.168.1.100:80
mode tcp
balance roundrobin
option httpchk
http-check connect
http-check send meth GET uri /healthz/ready
http-check expect status 200
   server my-cluster-worker-0 192.168.1.111:80 check port 1936 inter 10s rise 2 fall 2
   server my-cluster-worker-1 192.168.1.112:80 check port 1936 inter 10s rise 2 fall 2
   server my-cluster-worker-2 192.168.1.113:80 check port 1936 inter 10s rise 2 fall 2
# ...
```
If the configuration is correct, you receive a JSON object in response:

```json
{
    "major": "1",
    "minor": "11+",
    "gitVersion": "v1.11.0+ad103ed",
    "gitCommit": "ad103ed",
    "gitTreeState": "clean",
    "buildDate": "2019-01-09T06:44:10Z",
    "goVersion": "go1.10.3",
    "compiler": "gc",
    "platform": "linux/amd64"
}
```

b. Verify that the cluster machine configuration API is accessible to the Machine config server resource, by running the following command and observing the output:

```
$ curl -v https://<loadbalancer_ip_address>:22623/healthz --insecure
```

If the configuration is correct, the output from the command shows the following response:

```
HTTP/1.1 200 OK
Content-Length: 0
```

c. Verify that the controller is accessible to the Ingress Controller resource on port 80, by running the following command and observing the output:

```
$ curl -l -L -H "Host: console-openshift-console.apps.<cluster_name>.<base_domain>" http://<load_balancer_front_end_IP_address>
```

If the configuration is correct, the output from the command shows the following response:

```
HTTP/1.1 302 Found
content-length: 0
location: https://console-openshift-console.apps.ocp4.private.opequon.net/
cache-control: no-cache
```

d. Verify that the controller is accessible to the Ingress Controller resource on port 443, by running the following command and observing the output:

```
```

If the configuration is correct, the output from the command shows the following response:

```
HTTP/1.1 200 OK
referrer-policy: strict-origin-when-cross-origin
set-cookie: csrf-token=UlYWOyQ62LWjw2h003xtYSKlh1a0Py2hhctw0WmV2YEdhJjFyQwWcGBsja261dG
LgajO0nxzVErhiXt6QepA7g==; Path=/; Secure; SameSite=Lax
```
3. Configure the DNS records for your cluster to target the front-end IP addresses of the external load balancer. You must update records to your DNS server for the cluster API and applications over the load balancer.

**Examples of modified DNS records**

```
<load_balancer_ip_address> A api.<cluster_name>.<base_domain>
A record pointing to Load Balancer Front End

<load_balancer_ip_address> A apps.<cluster_name>.<base_domain>
A record pointing to Load Balancer Front End
```

**IMPORTANT**

DNS propagation might take some time for each DNS record to become available. Ensure that each DNS record propagates before validating each record.

4. Use the curl CLI command to verify that the external load balancer and DNS record configuration are operational:

   a. Verify that you can access the cluster API, by running the following command and observing the output:

   ```
   $ curl https://api.<cluster_name>.<base_domain>:6443/version --insecure
   ```

   If the configuration is correct, you receive a JSON object in response:

   ```
   {
   "major": "1",
   "minor": "11+",
   "gitVersion": "v1.11.0+ad103ed",
   "gitCommit": "ad103ed",
   "gitTreeState": "clean",
   "buildDate": "2019-01-09T06:44:10Z",
   "goVersion": "go1.10.3",
   "compiler": "gc",
   "platform": "linux/amd64"
   }
   ```

   b. Verify that you can access the cluster machine configuration, by running the following command and observing the output:
If the configuration is correct, the output from the command shows the following response:

```
HTTP/1.1 200 OK
Content-Length: 0
```

c. Verify that you can access each cluster application on port 443, by running the following command and observing the output:

```
$ curl -v https://api.<cluster_name>.<base_domain>:22623/healthz --insecure
```

If the configuration is correct, the output from the command shows the following response:

```
HTTP/1.1 200 OK
Content-Length: 0
```

d. Verify that you can access each cluster application on port 443, by running the following command and observing the output:

```
$ curl https://console-openshift-console.apps.<cluster_name>.<base_domain> -I -L --insecure
```

If the configuration is correct, the output from the command shows the following response:

```
HTTP/1.1 200 OK
```

```
referrer-policy: strict-origin-when-cross-origin
set-cookie: csrf-token=UlYWOyQ62LWjw2h003xtYSKlh1a0Py2hhctw0WmV2YEdhJjFyQwWcGBsja261dG
LgaYOOxzVErhiXt6QepA7g==; Path=/; Secure; SameSite=Lax
```
22.2.17. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- Set up your registry and configure registry storage.
- Optional: View the events from the vSphere Problem Detector Operator to determine if the cluster has permission or storage configuration issues.

22.3. INSTALLING A CLUSTER ON VSPHERE WITH CUSTOMIZATIONS

In OpenShift Container Platform version 4.14, you can install a cluster on your VMware vSphere instance by using installer-provisioned infrastructure. To customize the installation, you modify parameters in the `install-config.yaml` file before you install the cluster.

**NOTE**

OpenShift Container Platform supports deploying a cluster to a single VMware vCenter only. Deploying a cluster with machines/machine sets on multiple vCenters is not supported.

22.3.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You provisioned persistent storage for your cluster. To deploy a private image registry, your storage must provide ReadWriteMany access modes.
- The OpenShift Container Platform installer requires access to port 443 on the vCenter and ESXi hosts. You verified that port 443 is accessible.
- If you use a firewall, you confirmed with the administrator that port 443 is accessible. Control plane nodes must be able to reach vCenter and ESXi hosts on port 443 for the installation to succeed.
- If you use a firewall, you configured it to allow the sites that your cluster requires access to.

**NOTE**

Be sure to also review this site list if you are configuring a proxy.

22.3.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.
You must have internet access to:

- Access OpenShift Cluster Manager Hybrid Cloud Console to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 22.3.3. VMware vSphere infrastructure requirements

You must install the OpenShift Container Platform cluster on a VMware vSphere version 7.0 Update 2 or later instance that meets the requirements for the components that you use.

**NOTE**

OpenShift Container Platform version 4.14 supports VMware vSphere version 8.0.

You can host the VMware vSphere infrastructure on-premise or on a VMware Cloud Verified provider that meets the requirements outlined in the following tables:

<table>
<thead>
<tr>
<th>Virtual environment product</th>
<th>Required version</th>
</tr>
</thead>
<tbody>
<tr>
<td>VMware virtual hardware</td>
<td>15 or later</td>
</tr>
<tr>
<td>vSphere ESXi hosts</td>
<td>7.0 Update 2 or later</td>
</tr>
<tr>
<td>vCenter host</td>
<td>7.0 Update 2 or later</td>
</tr>
</tbody>
</table>

**IMPORTANT**

You must ensure that the time on your ESXi hosts is synchronized before you install OpenShift Container Platform. See [Edit Time Configuration for a Host](#) in the VMware documentation.

<p>| Table 22.10. Minimum supported vSphere version for VMware components |</p>
<table>
<thead>
<tr>
<th>Component</th>
<th>Minimum supported versions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hypervisor</td>
<td>vSphere 7.0 Update 2 and later with virtual hardware version 15</td>
<td>This version is the minimum version that Red Hat Enterprise Linux CoreOS (RHCOS) supports. For more information about supported hardware on the latest version of Red Hat Enterprise Linux (RHEL) that is compatible with RHCOS, see <a href="#">Hardware</a> on the Red Hat Customer Portal.</td>
</tr>
<tr>
<td>Storage with in-tree drivers</td>
<td>vSphere 7.0 Update 2 and later</td>
<td>This plugin creates vSphere storage by using the in-tree storage drivers for vSphere included in OpenShift Container Platform.</td>
</tr>
<tr>
<td>Optional: Networking (NSX-T)</td>
<td>vSphere 7.0 Update 2 and later</td>
<td>vSphere 7.0 Update 2 is required for OpenShift Container Platform. For more information about the compatibility of NSX and OpenShift Container Platform, see the Release Notes section of VMware’s NSX container plugin documentation.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

To ensure the best performance conditions for your cluster workloads that operate on Oracle® Cloud Infrastructure and on the Oracle® Cloud VMware Solution (OCVS) service, ensure volume performance units (VPUs) for your block volume are sized for your workloads.

The following list provides some guidance in selecting the VPUs needed for specific performance needs:

- Test or proof of concept environment: 100 GB, and 20 to 30 VPUs.
- Base-production environment: 500 GB, and 60 VPUs.
- Heavy-use production environment: More than 500 GB, and 100 or more VPUs.

Consider allocating additional VPUs to give enough capacity for updates and scaling activities. See [Block Volume Performance Levels](#) in the Oracle documentation.

### 22.3.4. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate.
Review the following details about the required network ports.

### Table 22.11. Ports used for all-machine to all-machine communications

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Port</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ICMP</td>
<td>N/A</td>

<th>Protocol</th>
<th>Port</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>2379-2380</td>
<td>etcd server and peer ports</td>
</tr>
</tbody>
</table>

### 22.3.5. VMware vSphere CSI Driver Operator requirements

To install the vSphere CSI Driver Operator, the following requirements must be met:
VMware vSphere version 7.0 Update 2 or later

vCenter 7.0 Update 2 or later

Virtual machines of hardware version 15 or later

No third-party vSphere CSI driver already installed in the cluster

If a third-party vSphere CSI driver is present in the cluster, OpenShift Container Platform does not overwrite it. The presence of a third-party vSphere CSI driver prevents OpenShift Container Platform from updating to OpenShift Container Platform 4.13 or later.

**NOTE**

The VMware vSphere CSI Driver Operator is supported only on clusters deployed with **platform: vsphere** in the installation manifest.

Additional resources

- To remove a third-party vSphere CSI driver, see Removing a third-party vSphere CSI Driver.
- To update the hardware version for your vSphere nodes, see Updating hardware on nodes running in vSphere.

### 22.3.6. vCenter requirements

Before you install an OpenShift Container Platform cluster on your vCenter that uses infrastructure that the installer provisions, you must prepare your environment.

**Required vCenter account privileges**

To install an OpenShift Container Platform cluster in a vCenter, the installation program requires access to an account with privileges to read and create the required resources. Using an account that has global administrative privileges is the simplest way to access all of the necessary permissions.

If you cannot use an account with global administrative privileges, you must create roles to grant the privileges necessary for OpenShift Container Platform cluster installation. While most of the privileges are always required, some are required only if you plan for the installation program to provision a folder to contain the OpenShift Container Platform cluster on your vCenter instance, which is the default behavior. You must create or amend vSphere roles for the specified objects to grant the required privileges.

An additional role is required if the installation program is to create a vSphere virtual machine folder.

**Example 22.4. Roles and privileges required for installation in vSphere API**

<table>
<thead>

For more information about creating an account with only the required privileges, see vSphere Permissions and User Management Tasks in the vSphere documentation.

Using OpenShift Container Platform with vMotion
If you intend on using vMotion in your vSphere environment, consider the following before installing an OpenShift Container Platform cluster.

- OpenShift Container Platform generally supports compute-only vMotion, where generally implies that you meet all VMware best practices for vMotion.

To help ensure the uptime of your compute and control plane nodes, ensure that you follow the VMware best practices for vMotion, and use VMware anti-affinity rules to improve the availability of OpenShift Container Platform during maintenance or hardware issues.

For more information about vMotion and anti-affinity rules, see the VMware vSphere documentation for vMotion networking requirements and VM anti-affinity rules.

- Using Storage vMotion can cause issues and is not supported. If you are using vSphere volumes in your pods, migrating a VM across datastores, either manually or through Storage vMotion, causes invalid references within OpenShift Container Platform persistent volume (PV) objects that can result in data loss.

- OpenShift Container Platform does not support selective migration of VMDKs across datastores, using datastore clusters for VM provisioning or for dynamic or static provisioning of PVs, or using a datastore that is part of a datastore cluster for dynamic or static provisioning of PVs.

**IMPORTANT**

You can specify the path of any datastore that exists in a datastore cluster. By default, Storage Distributed Resource Scheduler (SDRS), which uses Storage vMotion, is automatically enabled for a datastore cluster. Red Hat does not support Storage vMotion, so you must disable Storage DRS to avoid data loss issues for your OpenShift Container Platform cluster.

If you must specify VMs across multiple datastores, use a datastore object to specify a failure domain in your cluster’s install-config.yaml configuration file. For more information, see “VMware vSphere region and zone enablement”.

Cluster resources
When you deploy an OpenShift Container Platform cluster that uses installer-provisioned infrastructure, the installation program must be able to create several resources in your vCenter instance.

A standard OpenShift Container Platform installation creates the following vCenter resources:

- 1 Folder
Virtual machines:
- 1 template
- 1 temporary bootstrap node
- 3 control plane nodes
- 3 compute machines

Although these resources use 856 GB of storage, the bootstrap node is destroyed during the cluster installation process. A minimum of 800 GB of storage is required to use a standard cluster.

If you deploy more compute machines, the OpenShift Container Platform cluster will use more storage.

**Cluster limits**
Available resources vary between clusters. The number of possible clusters within a vCenter is limited primarily by available storage space and any limitations on the number of required resources. Be sure to consider both limitations to the vCenter resources that the cluster creates and the resources that you require to deploy a cluster, such as IP addresses and networks.

**Networking requirements**
Use Dynamic Host Configuration Protocol (DHCP) for the network and ensure that the DHCP server is configured to provide persistent IP addresses to the cluster machines.

**NOTE**
You do not need to use the DHCP for the network if you want to provision nodes with static IP addresses.

Configure the default gateway to use the DHCP server. All nodes must be in the same VLAN. You cannot scale the cluster using a second VLAN as a Day 2 operation.

You must use the Dynamic Host Configuration Protocol (DHCP) for the network and ensure that the DHCP server is configured to provide persistent IP addresses to the cluster machines. In the DHCP lease, you must configure the DHCP to use the default gateway. All nodes must be in the same VLAN. You cannot scale the cluster using a second VLAN as a Day 2 operation.

Additionally, you must create the following networking resources before you install the OpenShift Container Platform cluster:

**NOTE**
It is recommended that each OpenShift Container Platform node in the cluster must have access to a Network Time Protocol (NTP) server that is discoverable via DHCP. Installation is possible without an NTP server. However, asynchronous server clocks will cause errors, which NTP server prevents.

**Required IP Addresses**
For a network that uses DHCP, an installer-provisioned vSphere installation requires two static IP addresses:
- The **API** address is used to access the cluster API.
- The **Ingress** address is used for cluster ingress traffic.

You must provide these IP addresses to the installation program when you install the OpenShift Container Platform cluster.

**DNS records**

You must create DNS records for two static IP addresses in the appropriate DNS server for the vCenter instance that hosts your OpenShift Container Platform cluster. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the cluster base domain that you specify when you install the cluster. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>`.

### Table 22.14. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>API VIP</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>This DNS A/AAAA or CNAME record must point to the load balancer for the control plane machines. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Ingress VIP</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A wildcard DNS A/AAAA or CNAME record that points to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**Static IP addresses for vSphere nodes**

You can provision bootstrap, control plane, and compute nodes to be configured with static IP addresses in environments where Dynamic Host Configuration Protocol (DHCP) does not exist. To configure this environment, you must provide values to the `platform.vsphere.hosts.role` parameter in the `install-config.yaml` file.

**IMPORTANT**

Static IP addresses for vSphere nodes is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see [Technology Preview Features Support Scope](#).
By default, the installation program is configured to use the DHCP for the network, but this network has limited configurable capabilities.

After you define one or more machine pools in your `install-config.yaml` file, you can define network definitions for nodes on your network. Ensure that the number of network definitions matches the number of machine pools that you configured for your cluster.

The following example shows a network configuration for a node with the role `compute`:

```yaml
---
platform:
  vsphere:
    hosts:
      - role: compute
        networkDevice:
          ipAddrs:
            - 192.168.204.10/24
          gateway: 192.168.204.1
          nameservers:
            - 192.168.204.1
---
```

1. Valid network definition values include `bootstrap`, `control-plane`, and `compute`. You must list at least one `bootstrap` network definition in your `install-config.yaml` configuration file.

2. Lists IPv4, IPv6, or both IP addresses that the installation program passes to the network interface. The machine API controller assigns all configured IP addresses to the default network interface.

3. The default gateway for the network interface.

4. Lists up to 3 DNS nameservers.

**IMPORTANT**

To enable the Technology Preview feature of static IP addresses for vSphere nodes for your cluster, you must include `featureSet:TechPreviewNoUpgrade` as the initial entry in the `install-config.yaml` file.

After you deployed your cluster to run nodes with static IP addresses, you can scale a machine to use one of these static IP addresses. Additionally, you can use a machine set to configure a machine to use one of the configured static IP addresses.

- Scaling machines to use static IP addresses
- Using a machine set to scale machines with configured static IP addresses

### 22.3.7. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the `core` user on each node, which enables password-less authentication.
After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```sh
dsso@node1:~$ ssh-keygen -t ed25519 -N " -f <path>/<file_name>
   ```

   Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   ```sh
   $ cat <path>/<file_name>.pub
   ```

   For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

   ```sh
   $ cat ~/.ssh/id_ed25519.pub
   ```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.
NOTE

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

a. If the `ssh-agent` process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

Example output

```
Agent pid 31874
```

NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the `ssh-agent`:

```
$ ssh-add <path>/<file_name>
```

Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

22.3.8. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

Prerequisites

- You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space.

IMPORTANT

If you attempt to run the installation program on macOS, a known issue related to the `golang` compiler causes the installation of the OpenShift Container Platform cluster to fail. For more information about this issue, see the section named “Known Issues” in the OpenShift Container Platform 4.14 release notes document.
Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**
The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

**IMPORTANT**
Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ tar -xvf openshift-install-linux.tar.gz
   ```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

22.3.9. Adding vCenter root CA certificates to your system trust

Because the installation program requires access to your vCenter’s API, you must add your vCenter’s trusted root CA certificates to your system trust before you install an OpenShift Container Platform cluster.

**Procedure**

1. From the vCenter home page, download the vCenter’s root CA certificates. Click Download trusted root CA certificates in the vSphere Web Services SDK section. The `<vCenter>/certs/download.zip` file downloads.

2. Extract the compressed file that contains the vCenter root CA certificates. The contents of the compressed file resemble the following file structure:

   ```
   certs
   └── lin
       ├── 108f4d17.0
       └── 108f4d17.r1
   ```
3. Add the files for your operating system to the system trust. For example, on a Fedora operating system, run the following command:

```bash
# cp certs/lin/* /etc/pki/ca-trust/source/anchors
```

4. Update your system trust. For example, on a Fedora operating system, run the following command:

```bash
# update-ca-trust extract
```

### 22.3.10. VMware vSphere region and zone enablement

You can deploy an OpenShift Container Platform cluster to multiple vSphere datacenters that run in a single VMware vCenter. Each datacenter can run multiple clusters. This configuration reduces the risk of a hardware failure or network outage that can cause your cluster to fail.

**IMPORTANT**

The VMware vSphere region and zone enablement feature requires the vSphere Container Storage Interface (CSI) driver as the default storage driver in the cluster. As a result, the feature only available on a newly installed cluster.

A cluster that was upgraded from a previous release defaults to using the in-tree vSphere driver, so you must enable CSI automatic migration for the cluster. You can then configure multiple regions and zones for the upgraded cluster.

The default installation configuration deploys a cluster to a single vSphere datacenter. If you want to deploy a cluster to multiple vSphere datacenters, you must create an installation configuration file that enables the region and zone feature.

The default `install-config.yaml` file includes `vcenters` and `failureDomains` fields, where you can specify multiple vSphere datacenters and clusters for your OpenShift Container Platform cluster. You can leave these fields blank if you want to install an OpenShift Container Platform cluster in a vSphere environment that consists of single datacenter.

The following list describes terms associated with defining zones and regions for your cluster:
• **Failure domain**: Establishes the relationships between a region and zone. You define a failure domain by using vCenter objects, such as a **datastore** object. A failure domain defines the vCenter location for OpenShift Container Platform cluster nodes.

• **Region**: Specifies a vCenter datacenter. You define a region by using a tag from the **openshift-region** tag category.

• **Zone**: Specifies a vCenter cluster. You define a zone by using a tag from the **openshift-zone** tag category.

**NOTE**

If you plan on specifying more than one failure domain in your **install-config.yaml** file, you must create tag categories, zone tags, and region tags in advance of creating the configuration file.

You must create a vCenter tag for each vCenter datacenter, which represents a region. Additionally, you must create a vCenter tag for each cluster than runs in a datacenter, which represents a zone. After you create the tags, you must attach each tag to their respective datacenters and clusters.

The following table outlines an example of the relationship among regions, zones, and tags for a configuration with multiple vSphere datacenters running in a single VMware vCenter.

<table>
<thead>
<tr>
<th>Datacenter (region)</th>
<th>Cluster (zone)</th>
<th>Tags</th>
</tr>
</thead>
<tbody>
<tr>
<td>us-east</td>
<td>us-east-1</td>
<td>us-east-1a</td>

<td>us-west-2a</td>
</tr>
<tr>
<td></td>
<td></td>
<td>us-west-2b</td>
</tr>
</tbody>
</table>

**Additional resources**

- **Additional VMware vSphere configuration parameters**
- **Deprecated VMware vSphere configuration parameters**
- **vSphere automatic migration**
- **VMware vSphere CSI Driver Operator**
22.3.11. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on VMware vSphere.

Prerequisites

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Create the `install-config.yaml` file.
   a. Change to the directory that contains the installation program and run the following command:

   ```
   $ ./openshift-install create install-config --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

   When specifying the directory:

   - Verify that the directory has the `execute` permission. This permission is required to run Terraform binaries under the installation directory.
   - Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

   ```
   NOTE
   Always delete the `~/.powervs` directory to avoid reusing a stale configuration. Run the following command:
   ```

   ```
   $ rm -rf ~/.powervs
   ```

   b. At the prompts, provide the configuration details for your cloud:

   i. Optional: Select an SSH key to use to access your cluster machines.

   ```
   NOTE
   For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.
   ```

   ii. Select `vsphere` as the platform to target.

   iii. Specify the name of your vCenter instance.
iv. Specify the user name and password for the vCenter account that has the required permissions to create the cluster.
The installation program connects to your vCenter instance.

v. Select the data center in your vCenter instance to connect to.

**NOTE**
After you create the installation configuration file, you can modify the file to create a multiple vSphere datacenters environment. This means that you can deploy an OpenShift Container Platform cluster to multiple vSphere datacenters that run in a single VMware vCenter. For more information about creating this environment, see the section named VMware vSphere region and zone enablement.

vi. Select the default vCenter datastore to use.

**WARNING**
You can specify the path of any datastore that exists in a datastore cluster. By default, Storage Distributed Resource Scheduler (SDRS), which uses Storage vMotion, is automatically enabled for a datastore cluster. Red Hat does not support Storage vMotion, so you must disable Storage DRS to avoid data loss issues for your OpenShift Container Platform cluster.

You cannot specify more than one datastore path. If you must specify VMs across multiple datastores, use a datastore object to specify a failure domain in your cluster’s install-config.yaml configuration file. For more information, see "VMware vSphere region and zone enablement".

vii. Select the vCenter cluster to install the OpenShift Container Platform cluster in. The installation program uses the root resource pool of the vSphere cluster as the default resource pool.

viii. Select the network in the vCenter instance that contains the virtual IP addresses and DNS records that you configured.

ix. Enter the virtual IP address that you configured for control plane API access.

x. Enter the virtual IP address that you configured for cluster ingress.

xi. Enter the base domain. This base domain must be the same one that you used in the DNS records that you configured.

xii. Enter a descriptive name for your cluster.
The cluster name you enter must match the cluster name you specified when configuring the DNS records.
2. Modify the `install-config.yaml` file. You can find more information about the available parameters in the "Installation configuration parameters" section.

**NOTE**

If you are installing a three-node cluster, be sure to set the `compute.replicas` parameter to 0. This ensures that the cluster's control planes are schedulable. For more information, see "Installing a three-node cluster on vSphere".

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

**IMPORTANT**

The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

Additional resources

- Installation configuration parameters

### 22.3.11.1. Sample install-config.yaml file for an installer-provisioned VMware vSphere cluster

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute:
  - architecture: x86_64
    name: <worker_node>
    platform: {}  # 1
    replicas: 3  # 2
controlPlane:
  architecture: x86_64
  name: <parent_node>
  platform: {}  # 3
  replicas: 3
metadata:
  creationTimestamp: null
  name: test  # 4
platform:
  vsphere:  
  apiVIPs:  # 5
    - 10.0.0.1
failureDomains:
  - name: <failure_domain_name>
    region: <default_region_name>
    server: <fullyQualified_domain_name>
topology:
  computeCluster: "/<datacenter>/host/<cluster>
  datacenter: <datacenter>
  datastore: "/<datacenter>/datastore/<datastore>"  # 7
```
The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, -, and the first line of the controlPlane section must not. Only one control plane pool is used.

The cluster name that you specified in your DNS records.

Optional: Provides additional configuration for the machine pool parameters for the compute and control plane machines.

Establishes the relationships between a region and zone. You define a failure domain by using vCenter objects, such as a datastore object. A failure domain defines the vCenter location for OpenShift Container Platform cluster nodes.

The path to the vSphere datastore that holds virtual machine files, templates, and ISO images.

**IMPORTANT**

You can specify the path of any datastore that exists in a datastore cluster. By default, Storage vMotion is automatically enabled for a datastore cluster. Red Hat does not support Storage vMotion, so you must disable Storage vMotion to avoid data loss issues for your OpenShift Container Platform cluster.

If you must specify VMs across multiple datastores, use a datastore object to specify a failure domain in your cluster’s install-config.yaml configuration file. For more information, see "VMware vSphere region and zone enablement".

Optional: Provides an existing resource pool for machine creation. If you do not specify a value, the installation program uses the root resource pool of the vSphere cluster.

The vSphere disk provisioning method.
In OpenShift Container Platform 4.12 and later, the `apiVIP` and `ingressVIP` configuration settings are deprecated. Instead, use a list format to enter values in the `apiVIPs` and `ingressVIPs` configuration settings.

### 22.3.11.2. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

#### Prerequisites

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

#### Procedure

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port>  # 1
  httpsProxy: https://<username>:<pswd>@<ip>:<port>  # 2
noProxy: example.com  # 3
additionalTrustBundle: |
  -----BEGIN CERTIFICATE-----
  <MY_TRUSTED_CA_CERT>
  -----END CERTIFICATE-----
additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle>  # 5
```

1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.
2. A proxy URL to use for creating HTTPS connections outside the cluster.
3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For
If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the `trustedCA` field of the `Proxy` object. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

Optional: The policy to determine the configuration of the `Proxy` object to reference the `user-ca-bundle` config map in the `trustedCA` field. The allowed values are `Proxyonly` and `Always`. Use `Proxyonly` to reference the `user-ca-bundle` config map only when `http/https` proxy is configured. Use `Always` to always reference the `user-ca-bundle` config map. The default value is `Proxyonly`.

**NOTE**

The installation program does not support the proxy `readinessEndpoints` field.

**NOTE**

If the installer times out, restart and then complete the deployment by using the `wait-for` command of the installer. For example:

```
$ ./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

**NOTE**

Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

### 22.3.11.3. Configuring regions and zones for a VMware vCenter

You can modify the default installation configuration file, so that you can deploy an OpenShift Container Platform cluster to multiple vSphere datacenters that run in a single VMware vCenter.

The default `install-config.yaml` file configuration from the previous release of OpenShift Container Platform is deprecated. You can continue to use the deprecated default configuration, but the `openshift-installer` will prompt you with a warning message that indicates the use of deprecated fields in the configuration file.
**IMPORTANT**

The example uses the `govc` command. The `govc` command is an open source command available from VMware; it is not available from Red Hat. The Red Hat support team does not maintain the `govc` command. Instructions for downloading and installing `govc` are found on the VMware documentation website.

**Prerequisites**

- You have an existing `install-config.yaml` installation configuration file.

**IMPORTANT**

You must specify at least one failure domain for your OpenShift Container Platform cluster, so that you can provision datacenter objects for your VMware vCenter server. Consider specifying multiple failure domains if you need to provision virtual machine nodes in different datacenters, clusters, datastores, and other components.

**Procedure**

1. Enter the following `govc` command-line tool commands to create the `openshift-region` and `openshift-zone` vCenter tag categories:

   **IMPORTANT**

   If you specify different names for the `openshift-region` and `openshift-zone` vCenter tag categories, the installation of the OpenShift Container Platform cluster fails.

   ```
   $ govc tags.category.create -d "OpenShift region" openshift-region
   $ govc tags.category.create -d "OpenShift zone" openshift-zone
   ```

2. To create a region tag for each region vSphere datacenter where you want to deploy your cluster, enter the following command in your terminal:

   ```
   $ govc tags.create -c <region_tag_category> <region_tag>
   ```

3. To create a zone tag for each vSphere cluster where you want to deploy your cluster, enter the following command:

   ```
   $ govc tags.create -c <zone_tag_category> <zone_tag>
   ```

4. Attach region tags to each vCenter datacenter object by entering the following command:

   ```
   $ govc tags.attach -c <region_tag_category> <region_tag_1> /<datacenter_1>
   ```

5. Attach the zone tags to each vCenter datacenter object by entering the following command:

   ```
   $ govc tags.attach -c <zone_tag_category> <zone_tag_1> /<datacenter_1>/host/vcs-mdcnc-workload-1
   ```
6. Change to the directory that contains the installation program and initialize the cluster deployment according to your chosen installation requirements.

Sample install-config.yaml file with multiple datacenters defined in a vSphere center

```yaml
---
compute:
  ---
  vsphere:
    zones:
      - "<machine_pool_zone_1>"
      - "<machine_pool_zone_2>"

---
controlPlane:
  ---
  vsphere:
    zones:
      - "<machine_pool_zone_1>"
      - "<machine_pool_zone_2>"

---
platform:
  vsphere:
    vcenters:
      ---
      datacenters:
        - <datacenter1_name>
        - <datacenter2_name>
      failureDomains:
        - name: <machine_pool_zone_1>
          region: <region_tag_1>
          zone: <zone_tag_1>
          server: <fully_qualified_domain_name>
          topology:
            datacenter: <datacenter1>
            computeCluster: "/<datacenter1>/host/<cluster1>"
            networks:
              - <VM_Network1_name>
              datastore: "/<datacenter1>/datastore/<datastore1>"
              resourcePool: "/<datacenter1>/host/<cluster1>/Resources/<resourcePool1>"
              folder: "/<datacenter1>/vm/<folder1>"
        - name: <machine_pool_zone_2>
          region: <region_tag_2>
          zone: <zone_tag_2>
          server: <fully_qualified_domain_name>
          topology:
            datacenter: <datacenter2>
            computeCluster: "/<datacenter2>/host/<cluster2>"
            networks:
              - <VM_Network2_name>
              datastore: "/<datacenter2>/datastore/<datastore2>"
              resourcePool: "/<datacenter2>/host/<cluster2>/Resources/<resourcePool2>"
              folder: "/<datacenter2>/vm/<folder2>"
---
```

22.3.12. Deploying the cluster
You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

**Prerequisites**

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.
- Optional: Before you create the cluster, configure an external load balancer in place of the default load balancer.

**IMPORTANT**

You do not need to specify API and Ingress static addresses for your installation program. If you choose this configuration, you must take additional actions to define network targets that accept an IP address from each referenced vSphere subnet. See the section "Configuring an external load balancer".

**Procedure**

- Change to the directory that contains the installation program and initialize the cluster deployment:

  ```bash
  $ ./openshift-install create cluster --dir <installation_directory> --log-level=info
  ```

  1. For `<installation_directory>`, specify the location of your customized `.install-config.yaml` file.
  2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

**Verification**

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the `kubeadmin` user.
- Credential information also outputs to `<installation_directory>/openshift_install.log`.

**IMPORTANT**

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.
Example output

```
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

**22.3.13. Installing the OpenShift CLI by downloading the binary**

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of **oc**.

**Installing the OpenShift CLI on Linux**

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

**Procedure**

2. Select the architecture from the **Product Variant** drop-down list.
3. Select the appropriate version from the **Version** drop-down list.
4. Click **Download Now** next to the **OpenShift v4.14 Linux Client** entry and save the file.
5. Unpack the archive:

   ```bash
   $ tar xvf <file>
   ```
6. Place the `oc` binary in a directory that is on your `PATH`. To check your `PATH`, execute the following command:

```bash
$ echo $PATH
```

**Verification**

- After you install the OpenShift CLI, it is available using the `oc` command:

```bash
$ oc <command>
```

**Installing the OpenShift CLI on Windows**

You can install the OpenShift CLI (`oc`) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version from the Version drop-down list.
3. Click Download Now next to the OpenShift v4.14 Windows Client entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the `oc` binary to a directory that is on your `PATH`. To check your `PATH`, open the command prompt and execute the following command:

```bash
C:\> path
```

**Verification**

- After you install the OpenShift CLI, it is available using the `oc` command:

```bash
C:\> oc <command>
```

**Installing the OpenShift CLI on macOS**

You can install the OpenShift CLI (`oc`) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version from the Version drop-down list.
3. Click Download Now next to the OpenShift v4.14 macOS Client entry and save the file.

   **NOTE**

   For macOS arm64, choose the OpenShift v4.14 macOS arm64 Client entry.

4. Unpack and unzip the archive.
5. Move the `oc` binary to a directory on your PATH. To check your PATH, open a terminal and execute the following command:

```
$ echo $PATH
```

**Verification**

- After you install the OpenShift CLI, it is available using the `oc` command:

```
$ oc <command>
```

### 22.3.14. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

```
$ export KUBEECONFIG=<installation_directory>/auth/kubeconfig
```

   1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

```
$ oc whoami
```

   **Example output**

```
system:admin
```

### 22.3.15. Creating registry storage

After you install the cluster, you must create storage for the registry Operator.

#### 22.3.15.1. Image registry removed during installation

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as Removed. This allows `openshift-installer` to complete installations on these platform types.
After installation, you must edit the Image Registry Operator configuration to switch the managementState from Removed to Managed.

22.3.15.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the Recreate rollout strategy during upgrades.

22.3.15.2.1. Configuring registry storage for VMware vSphere

As a cluster administrator, following installation you must configure your registry to use storage.

Prerequisites

- Cluster administrator permissions.
- A cluster on VMware vSphere.
- Persistent storage provisioned for your cluster, such as Red Hat OpenShift Data Foundation.

**IMPORTANT**

OpenShift Container Platform supports ReadWriteOnce access for image registry storage when you have only one replica. ReadWriteOnce access also requires that the registry uses the Recreate rollout strategy. To deploy an image registry that supports high availability with two or more replicas, ReadWriteMany access is required.

- Must have "100Gi" capacity.

**IMPORTANT**

Testing shows issues with using the NFS server on RHEL as storage backend for core services. This includes the OpenShift Container Registry and Quay, Prometheus for monitoring storage, and Elasticsearch for logging storage. Therefore, using RHEL NFS to back PVs used by core services is not recommended.

Other NFS implementations on the marketplace might not have these issues. Contact the individual NFS implementation vendor for more information on any testing that was possibly completed against these OpenShift Container Platform core components.

Procedure

1. To configure your registry to use storage, change the spec.storage.pvc in the configs.imageregistry/cluster resource.
NOTE
When you use shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

   $ oc get pod -n openshift-image-registry -l docker-registry=default

**Example output**

   No resources found in openshift-image-registry namespace

   **NOTE**
   If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

   $ oc edit configs.imageregistry.operator.openshift.io

**Example output**

   storage:
   pvc:
   claim: 1

   Leave the claim field blank to allow the automatic creation of an image-registry-storage persistent volume claim (PVC). The PVC is generated based on the default storage class. However, be aware that the default storage class might provide ReadWriteOnce (RWO) volumes, such as a RADOS Block Device (RBD), which can cause issues when you replicate to more than one replica.

4. Check the clusteroperator status:

   $ oc get clusteroperator image-registry

**Example output**

   NAME             VERSION      AVAILABLE PROGRESSING DEGRADED
   SINCE     MESSAGE           True     False     False     6h50m

22.3.15.2.2. Configuring block registry storage for VMware vSphere

To allow the image registry to use block storage types such as vSphere Virtual Machine Disk (VMDK) during upgrades as a cluster administrator, you can use the Recreate rollout strategy.
IMPORTANT

Block storage volumes are supported but not recommended for use with image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

Procedure

1. To set the image registry storage as a block storage type, patch the registry so that it uses the `Recreate` rollout strategy and runs with only 1 replica:

   ```bash
   $ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec":
   {"rolloutStrategy":"Recreate","replicas":1}}'
   ```

2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.

   a. Create a `pvc.yaml` file with the following contents to define a VMware vSphere `PersistentVolumeClaim` object:

   ```yaml
   kind: PersistentVolumeClaim
   apiVersion: v1
   metadata:
     name: image-registry-storage
     namespace: openshift-image-registry
   spec:
     accessModes:
     - ReadWriteOnce
     resources:
       requests:
         storage: 100Gi
   ```

   1. A unique name that represents the `PersistentVolumeClaim` object.
   2. The namespace for the `PersistentVolumeClaim` object, which is `openshift-image-registry`.
   3. The access mode of the persistent volume claim. With `ReadWriteOnce`, the volume can be mounted with read and write permissions by a single node.
   4. The size of the persistent volume claim.

   b. Create the `PersistentVolumeClaim` object from the file:

   ```bash
   $ oc create -f pvc.yaml -n openshift-image-registry
   ```

3. Edit the registry configuration so that it references the correct PVC:

   ```bash
   $ oc edit config.imageregistry.operator.openshift.io -o yaml
   ```

Example output
By creating a custom PVC, you can leave the **claim** field blank for the default automatic creation of an **image-registry-storage** PVC.

For instructions about configuring registry storage so that it references the correct PVC, see Configuring the registry for vSphere.

### 22.3.16. Backing up VMware vSphere volumes

OpenShift Container Platform provisions new volumes as independent persistent disks to freely attach and detach the volume on any node in the cluster. As a consequence, it is not possible to back up volumes that use snapshots, or to restore volumes from snapshots. See Snapshot Limitations for more information.

**Procedure**

To create a backup of persistent volumes:

1. Stop the application that is using the persistent volume.
2. Clone the persistent volume.
3. Restart the application.
4. Create a backup of the cloned volume.
5. Delete the cloned volume.

### 22.3.17. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to **OpenShift Cluster Manager Hybrid Cloud Console**.

After you confirm that your **OpenShift Cluster Manager Hybrid Cloud Console** inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use **subscription watch** to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- See About remote health monitoring for more information about the Telemetry service

### 22.3.18. Configuring an external load balancer

You can configure an OpenShift Container Platform cluster to use an external load balancer in place of the default load balancer.
IMPORTANT

Configuring an external load balancer depends on your vendor’s load balancer.

The information and examples in this section are for guideline purposes only. Consult the vendor documentation for more specific information about the vendor’s load balancer.

Red Hat supports the following services for an external load balancer:

- OpenShift API
- Ingress Controller

You can choose to configure one or both of these services for an external load balancer. Configuring only the Ingress Controller service is a common configuration option.

The following configuration options are supported for external load balancers:

- Use a node selector to map the Ingress Controller to a specific set of nodes. You must assign a static IP address to each node in this set, or configure each node to receive the same IP address from the Dynamic Host Configuration Protocol (DHCP). Infrastructure nodes commonly receive this type of configuration.

- Target all IP addresses on a subnet. This configuration can reduce maintenance overhead, because you can create and destroy nodes within those networks without reconfiguring the load balancer targets. If you deploy your ingress pods by using a machine set on a smaller network, such as a /27 or /28, you can simplify your load balancer targets.

TIP

You can list all IP addresses that exist in a network by checking the machine config pool’s resources.

Considerations

- For a front-end IP address, you can use the same IP address for the front-end IP address, the Ingress Controller’s load balancer, and API load balancer. Check the vendor’s documentation for this capability.

- For a back-end IP address, ensure that an IP address for an OpenShift Container Platform control plane node does not change during the lifetime of the external load balancer. You can achieve this by completing one of the following actions:
  - Assign a static IP address to each control plane node.
  - Configure each node to receive the same IP address from the DHCP every time the node requests a DHCP lease. Depending on the vendor, the DHCP lease might be in the form of an IP reservation or a static DHCP assignment.

- Manually define each node that runs the Ingress Controller in the external load balancer for the Ingress Controller back-end service. For example, if the Ingress Controller moves to an undefined node, a connection outage can occur.

OpenShift API prerequisites

- You defined a front-end IP address.
TCP ports 6443 and 22623 are exposed on the front-end IP address of your load balancer. Check the following items:

- Port 6443 provides access to the OpenShift API service.
- Port 22623 can provide ignition startup configurations to nodes.

- The front-end IP address and port 6443 are reachable by all users of your system with a location external to your OpenShift Container Platform cluster.
- The front-end IP address and port 22623 are reachable only by OpenShift Container Platform nodes.
- The load balancer backend can communicate with OpenShift Container Platform control plane nodes on port 6443 and 22623.

**Ingress Controller prerequisites**

- You defined a front-end IP address.
- TCP ports 443 and 80 are exposed on the front-end IP address of your load balancer.
- The front-end IP address, port 80 and port 443 are reachable by all users of your system with a location external to your OpenShift Container Platform cluster.
- The front-end IP address, port 80 and port 443 are reachable to all nodes that operate in your OpenShift Container Platform cluster.
- The load balancer backend can communicate with OpenShift Container Platform nodes that run the Ingress Controller on ports 80, 443, and 1936.

**Prerequisite for health check URL specifications**

You can configure most load balancers by setting health check URLs that determine if a service is available or unavailable. OpenShift Container Platform provides these health checks for the OpenShift API, Machine Configuration API, and Ingress Controller backend services.

The following examples demonstrate health check specifications for the previously listed backend services:

**Example of a Kubernetes API health check specification**

```
Path: HTTPS:6443/readyz
Healthy threshold: 2
Unhealthy threshold: 2
Timeout: 10
Interval: 10
```

**Example of a Machine Config API health check specification**

```
Path: HTTPS:22623/healthz
Healthy threshold: 2
Unhealthy threshold: 2
Timeout: 10
Interval: 10
```
Example of an Ingress Controller health check specification

- Path: HTTP:1936/healthz/ready
- Healthy threshold: 2
- Unhealthy threshold: 2
- Timeout: 5
- Interval: 10

Procedure

1. Configure the HAProxy Ingress Controller, so that you can enable access to the cluster from your load balancer on ports 6443, 443, and 80:

   **Example HAProxy configuration**

   ```
   #...
   listen my-cluster-api-6443
      bind 192.168.1.100:6443
      mode tcp
      balance roundrobin
      option httpchk
      http-check connect
      http-check send meth GET uri /readyz
      http-check expect status 200
      server my-cluster-master-2 192.168.1.101:6443 check inter 10s rise 2 fall 2
      server my-cluster-master-0 192.168.1.102:6443 check inter 10s rise 2 fall 2
      server my-cluster-master-1 192.168.1.103:6443 check inter 10s rise 2 fall 2

   listen my-cluster-machine-config-api-22623
      bind 192.168.1.100.0.0.0:22623
      mode tcp
      balance roundrobin
      option httpchk
      http-check connect
      http-check send meth GET uri /healthz
      http-check expect status 200
      server my-cluster-master-2 192.0168.21.2101:22623 check inter 10s rise 2 fall 2
      server my-cluster-master-0 192.168.1.1020.2.3:22623 check inter 10s rise 2 fall 2
      server my-cluster-master-1 192.168.1.1030.2.1:22623 check inter 10s rise 2 fall 2

   listen my-cluster-apps-443
      bind 192.168.1.100:443
      mode tcp
      balance roundrobin
      option httpchk
      http-check connect
      http-check send meth GET uri /healthz/ready
      http-check expect status 200
      server my-cluster-worker-0 192.168.1.111:443 check port 1936 inter 10s rise 2 fall 2
      server my-cluster-worker-1 192.168.1.112:443 check port 1936 inter 10s rise 2 fall 2
      server my-cluster-worker-2 192.168.1.113:443 check port 1936 inter 10s rise 2 fall 2

   listen my-cluster-apps-80
      bind 192.168.1.100:80
      mode tcp
   ```
2. Use the `curl` CLI command to verify that the external load balancer and its resources are operational:

a. Verify that the cluster machine configuration API is accessible to the Kubernetes API server resource, by running the following command and observing the response:

```
$ curl https://<loadbalancer_ip_address>:6443/version --insecure
```

If the configuration is correct, you receive a JSON object in response:

```
{
  "major": "1",
  "minor": "11+",
  "gitVersion": "v1.11.0+ad103ed",
  "gitCommit": "ad103ed",
  "gitTreeState": "clean",
  "buildDate": "2019-01-09T06:44:10Z",
  "goVersion": "go1.10.3",
  "compiler": "gc",
  "platform": "linux/amd64"
}
```

b. Verify that the cluster machine configuration API is accessible to the Machine config server resource, by running the following command and observing the output:

```
$ curl -v https://<loadbalancer_ip_address>:22623/healthz --insecure
```

If the configuration is correct, the output from the command shows the following response:

```
HTTP/1.1 200 OK
Content-Length: 0
```

c. Verify that the controller is accessible to the Ingress Controller resource on port 80, by running the following command and observing the output:

```
$ curl -I -L -H "Host: console-openshift-console.apps.<cluster_name>.<base_domain>" http://<load_balancer_front_end_IP_address>
```

If the configuration is correct, the output from the command shows the following response:

```
HTTP/1.1 302 Found
Content-Length: 0
Location: https://console-openshift-console.apps.ocp4.private.opequon.net/
Cache-Control: no-cache
```
d. Verify that the controller is accessible to the Ingress Controller resource on port 443, by running the following command and observing the output:

```bash
```

If the configuration is correct, the output from the command shows the following response:

```
HTTP/1.1 200 OK
referrer-policy: strict-origin-when-cross-origin
set-cookie: csrf-token=UlYWOyQ62LWjw2h003xtYSKlh1a0Py2hhctw0WmV2YEdhJjfYQwWcGBsja261dG
LgaYO0nxzVERhiXt6QepA7g==; Path=/; Secure; SameSite=Lax
x-content-type-options: nosniff
x-dns-prefetch-control: off
x-frame-options: DENY
x-xss-protection: 1; mode=block
date: Wed, 04 Oct 2023 16:29:38 GMT
content-type: text/html; charset=utf-8
set-cookie: 1e2670d92730b515ce3a1bb65da45062=1bf5e9573c9a2760c964ed1659cc1673; path=/; HttpOnly; Secure; SameSite=None
cache-control: private
```

3. Configure the DNS records for your cluster to target the front-end IP addresses of the external load balancer. You must update records to your DNS server for the cluster API and applications over the load balancer.

**Examples of modified DNS records**

```
<load_balancer_ip_address> A api.<cluster_name>.<base_domain>
A record pointing to Load Balancer Front End

<load_balancer_ip_address> A apps.<cluster_name>.<base_domain>
A record pointing to Load Balancer Front End
```

**IMPORTANT**

DNS propagation might take some time for each DNS record to become available. Ensure that each DNS record propagates before validating each record.

4. Use the `curl` CLI command to verify that the external load balancer and DNS record configuration are operational:

a. Verify that you can access the cluster API, by running the following command and observing the output:

```bash
$ curl https://api.<cluster_name>.<base_domain>:6443/version --insecure
```

If the configuration is correct, you receive a JSON object in response:
b. Verify that you can access the cluster machine configuration, by running the following command and observing the output:

```
$ curl -v https://api.<cluster_name>.<base_domain>:22623/healthz --insecure
```

If the configuration is correct, the output from the command shows the following response:

```
HTTP/1.1 200 OK
Content-Length: 0
```

c. Verify that you can access each cluster application on port, by running the following command and observing the output:

```
$ curl http://console-openshift-console.apps.<cluster_name>.<base_domain> -I -L --insecure
```

If the configuration is correct, the output from the command shows the following response:

```
HTTP/1.1 302 Found
content-length: 0
location: https://console-openshift-console.apps.<cluster-name>.<base domain>/
cache-control: no-cacheHTTP/1.1 200 OK
caller-policy: strict-origin-when-cross-origin
set-cookie: csrftoken=39HoZgzidNzJkJkg/JuLJMeoKNXllfVVv2YgZc09c3TBOBU4Ni6kDXaJH1LdicNhN1UsQWzon4Dor9GWGfopaTEQ==; Path=/; Secure
x-content-type-options: nosniff
x-dns-prefetch-control: off
x-frame-options: DENY

cache-control: private
```

d. Verify that you can access each cluster application on port 443, by running the following command and observing the output:

```
$ curl https://console-openshift-console.apps.<cluster_name>.<base_domain> -I -L --insecure
```

If the configuration is correct, the output from the command shows the following response:

```
HTTP/1.1 200 OK
referrer-policy: strict-origin-when-cross-origin
set-cookie: csrf-token=UlYWOyQ62LWjw2h003xtYSKlh1a0Py2hhctw0WmV2YEdhJiFyQwWcGBsja261dGLgaYO0nxzVERhiXt6QepA7g==; Path=/; Secure; SameSite=Lax

cache-control: private
```

22.3.19. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- Set up your registry and configure registry storage.
- Optional: View the events from the vSphere Problem Detector Operator to determine if the cluster has permission or storage configuration issues.

22.4. INSTALLING A CLUSTER ON VSPHERE WITH NETWORK CUSTOMIZATIONS

In OpenShift Container Platform version 4.14, you can install a cluster on your VMware vSphere instance by using installer-provisioned infrastructure with customized network configuration options. By customizing your network configuration, your cluster can coexist with existing IP address allocations in your environment and integrate with existing MTU and VXLAN configurations. To customize the installation, you modify parameters in the `install-config.yaml` file before you install the cluster.

You must set most of the network configuration parameters during installation, and you can modify only `kubeProxy` configuration parameters in a running cluster.

**NOTE**

OpenShift Container Platform supports deploying a cluster to a single VMware vCenter only. Deploying a cluster with machines/machine sets on multiple vCenters is not supported.

22.4.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
You read the documentation on selecting a cluster installation method and preparing it for users.

You provisioned persistent storage for your cluster. To deploy a private image registry, your storage must provide ReadWriteMany access modes.

The OpenShift Container Platform installer requires access to port 443 on the vCenter and ESXi hosts. You verified that port 443 is accessible.

If you use a firewall, confirm with the administrator that port 443 is accessible. Control plane nodes must be able to reach vCenter and ESXi hosts on port 443 for the installation to succeed.

If you use a firewall, you configured it to allow the sites that your cluster requires access to.

NOTE
Be sure to also review this site list if you are configuring a proxy.

22.4.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager Hybrid Cloud Console to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- Access Quay.io to obtain the packages that are required to install your cluster.

- Obtain the packages that are required to perform cluster updates.

IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

22.4.3. VMware vSphere infrastructure requirements

You must install the OpenShift Container Platform cluster on a VMware vSphere version 7.0 Update 2 or later instance that meets the requirements for the components that you use.

NOTE
OpenShift Container Platform version 4.14 supports VMware vSphere version 8.0.

You can host the VMware vSphere infrastructure on-premise or on a VMware Cloud Verified provider that meets the requirements outlined in the following tables:

Table 22.15. Version requirements for vSphere virtual environments
Virtual environment product | Required version
--- | ---
VMware virtual hardware | 15 or later
vSphere ESXi hosts | 7.0 Update 2 or later
vCenter host | 7.0 Update 2 or later

**IMPORTANT**

You must ensure that the time on your ESXi hosts is synchronized before you install OpenShift Container Platform. See **Edit Time Configuration for a Host** in the VMware documentation.

Table 22.16. Minimum supported vSphere version for VMware components

<table>
<thead>
<tr>
<th>Component</th>
<th>Minimum supported versions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hypervisor</td>
<td>vSphere 7.0 Update 2 and later with virtual hardware version 15</td>
<td>This version is the minimum version that Red Hat Enterprise Linux CoreOS (RHCOS) supports. For more information about supported hardware on the latest version of Red Hat Enterprise Linux (RHEL) that is compatible with RHCOS, see Hardware on the Red Hat Customer Portal.</td>
</tr>
<tr>
<td>Storage with in-tree drivers</td>
<td>vSphere 7.0 Update 2 and later</td>
<td>This plugin creates vSphere storage by using the in-tree storage drivers for vSphere included in OpenShift Container Platform.</td>
</tr>
<tr>
<td>Optional: Networking (NSX-T)</td>
<td>vSphere 7.0 Update 2 and later</td>
<td>vSphere 7.0 Update 2 is required for OpenShift Container Platform. For more information about the compatibility of NSX and OpenShift Container Platform, see the Release Notes section of VMware’s NSX container plugin documentation.</td>
</tr>
</tbody>
</table>
IMPORTANT

To ensure the best performance conditions for your cluster workloads that operate on Oracle® Cloud Infrastructure and on the Oracle® Cloud VMware Solution (OCVS) service, ensure volume performance units (VPUs) for your block volume are sized for your workloads.

The following list provides some guidance in selecting the VPUs needed for specific performance needs:

- Test or proof of concept environment: 100 GB, and 20 to 30 VPUs.
- Base-production environment: 500 GB, and 60 VPUs.
- Heavy-use production environment: More than 500 GB, and 100 or more VPUs.

Consider allocating additional VPUs to give enough capacity for updates and scaling activities. See Block Volume Performance Levels in the Oracle documentation.

22.4.4. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate.

Review the following details about the required network ports.

Table 22.17. Ports used for all-machine to all-machine communications

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Port</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ICMP</td>

<td>etcd server and peer ports</td>
</tr>
</tbody>
</table>

22.4.5. VMware vSphere CSI Driver Operator requirements

To install the vSphere CSI Driver Operator, the following requirements must be met:

- VMware vSphere version 7.0 Update 2 or later
- vCenter 7.0 Update 2 or later
- Virtual machines of hardware version 15 or later
- No third-party vSphere CSI driver already installed in the cluster

If a third-party vSphere CSI driver is present in the cluster, OpenShift Container Platform does not overwrite it. The presence of a third-party vSphere CSI driver prevents OpenShift Container Platform from updating to OpenShift Container Platform 4.13 or later.

**NOTE**

The VMware vSphere CSI Driver Operator is supported only on clusters deployed with `platform: vsphere` in the installation manifest.

Additional resources

- To remove a third-party vSphere CSI driver, see [Removing a third-party vSphere CSI Driver](#).
- To update the hardware version for your vSphere nodes, see [Updating hardware on nodes running in vSphere](#).

22.4.6. vCenter requirements
Before you install an OpenShift Container Platform cluster on your vCenter that uses infrastructure that the installer provisions, you must prepare your environment.

**Required vCenter account privileges**
To install an OpenShift Container Platform cluster in a vCenter, the installation program requires access to an account with privileges to read and create the required resources. Using an account that has global administrative privileges is the simplest way to access all of the necessary permissions.

If you cannot use an account with global administrative privileges, you must create roles to grant the privileges necessary for OpenShift Container Platform cluster installation. While most of the privileges are always required, some are required only if you plan for the installation program to provision a folder to contain the OpenShift Container Platform cluster on your vCenter instance, which is the default behavior. You must create or amend vSphere roles for the specified objects to grant the required privileges.

An additional role is required if the installation program is to create a vSphere virtual machine folder.

### Example 22.7. Roles and privileges required for installation in vSphere API

<table>
<thead>
<tr>
<th>vSphere object for role</th>
<th>When required</th>
<th>Required privileges in vSphere API</th>
</tr>
</thead>
<tbody>
<tr>

<td>&quot;Virtual machine&quot;.&quot;Edit Inventory&quot;.&quot;Remove&quot;</td>
</tr>
</tbody>
</table>

22. INSTALLING ON VSPHERE
<table>
<thead>
<tr>
<th>vSphere object for role</th>
<th>When required</th>
<th>Required privileges in vCenter GUI</th>
</tr>
</thead>
<tbody>
<tr>
<td>vSphere vCenter Datacenter</td>
<td>If the installation program creates the virtual machine folder. For UPI, <code>VirtualMachine.Inventory.Create</code> and <code>VirtualMachine.Inventory.Delete</code> privileges are optional if your cluster does not use the Machine API.</td>
<td>&quot;vSphere Tagging&quot;.&quot;Assign or Unassign vSphere Tag on Object&quot; &quot;Resource.&quot;Assign virtual machine to resource pool&quot; &quot;VApp.Import&quot; &quot;Virtual machine&quot;.&quot;Change Configuration&quot;.&quot;Add existing disk&quot; &quot;Virtual machine&quot;.&quot;Change Configuration&quot;.&quot;Add new disk&quot; &quot;Virtual machine&quot;.&quot;Change Configuration&quot;.&quot;Add or remove device&quot; &quot;Virtual machine&quot;.&quot;Change Configuration&quot;.&quot;Advanced configuration&quot; &quot;Virtual machine&quot;.&quot;Change Configuration&quot;.&quot;Set annotation&quot; &quot;Virtual machine&quot;.&quot;Change Configuration&quot;.&quot;Change CPU count&quot; &quot;Virtual machine&quot;.&quot;Change Configuration&quot;.&quot;Extend virtual disk&quot; &quot;Virtual machine&quot;.&quot;Change Configuration&quot;.&quot;Acquire disk lease&quot; &quot;Virtual machine&quot;.&quot;Change Configuration&quot;.&quot;Modify device settings&quot; &quot;Virtual machine&quot;.&quot;Change Configuration&quot;.&quot;Change Memory&quot; &quot;Virtual machine&quot;.&quot;Change Configuration&quot;.&quot;Remove disk&quot; &quot;Virtual machine&quot;.&quot;Change Configuration&quot;.&quot;Rename&quot; &quot;Virtual machine&quot;.&quot;Change Configuration&quot;.&quot;Reset guest information&quot;</td>
</tr>
</tbody>
</table>
Additionally, the user requires some **ReadOnly** permissions, and some of the roles require permission to propagate the permissions to child objects. These settings vary depending on whether or not you install the cluster into an existing folder.

**Example 22.9. Required permissions and propagation settings**

<table>
<thead>
<tr>
<th>vSphere object</th>
<th>When required</th>
<th>Propagate to children</th>
<th>Permissions required</th>
</tr>
</thead>
<tbody>
<tr>
<td>vSphere vCenter</td>
<td>Always</td>
<td>False</td>
<td>Listed required privileges</td>
</tr>
</tbody>
</table>
Using OpenShift Container Platform with vMotion

If you intend on using vMotion in your vSphere environment, consider the following before installing an OpenShift Container Platform cluster.

- OpenShift Container Platform generally supports compute-only vMotion, where *generally* implies that you meet all VMware best practices for vMotion. To help ensure the uptime of your compute and control plane nodes, ensure that you follow the VMware best practices for vMotion, and use VMware anti-affinity rules to improve the availability of OpenShift Container Platform during maintenance or hardware issues.

  For more information about vMotion and anti-affinity rules, see the VMware vSphere documentation for [vMotion networking requirements](https://www.vmware.com/support/pubs/doc.html?docid=doc-428452) and [VM anti-affinity rules](https://www.vmware.com/support/pubs/doc.html?docid=doc-428455).

- Using Storage vMotion can cause issues and is not supported. If you are using vSphere volumes in your pods, migrating a VM across datastores, either manually or through Storage vMotion, causes invalid references within OpenShift Container Platform persistent volume (PV) objects that can result in data loss.

- OpenShift Container Platform does not support selective migration of VMDKs across datastores, using datastore clusters for VM provisioning or for dynamic or static provisioning of PVs, or using a datastore that is part of a datastore cluster for dynamic or static provisioning of
IMPORTANT

You can specify the path of any datastore that exists in a datastore cluster. By default, Storage Distributed Resource Scheduler (SDRS), which uses Storage vMotion, is automatically enabled for a datastore cluster. Red Hat does not support Storage vMotion, so you must disable Storage DRS to avoid data loss issues for your OpenShift Container Platform cluster.

If you must specify VMs across multiple datastores, use a datastore object to specify a failure domain in your cluster’s install-config.yaml configuration file. For more information, see "VMware vSphere region and zone enablement".

Cluster resources
When you deploy an OpenShift Container Platform cluster that uses installer-provisioned infrastructure, the installation program must be able to create several resources in your vCenter instance.

A standard OpenShift Container Platform installation creates the following vCenter resources:

- 1 Folder
- 1 Tag category
- 1 Tag
- Virtual machines:
  - 1 template
  - 1 temporary bootstrap node
  - 3 control plane nodes
  - 3 compute machines

Although these resources use 856 GB of storage, the bootstrap node is destroyed during the cluster installation process. A minimum of 800 GB of storage is required to use a standard cluster.

If you deploy more compute machines, the OpenShift Container Platform cluster will use more storage.

Cluster limits
Available resources vary between clusters. The number of possible clusters within a vCenter is limited primarily by available storage space and any limitations on the number of required resources. Be sure to consider both limitations to the vCenter resources that the cluster creates and the resources that you require to deploy a cluster, such as IP addresses and networks.

Networking requirements
Use Dynamic Host Configuration Protocol (DHCP) for the network and ensure that the DHCP server is configured to provide persistent IP addresses to the cluster machines.

NOTE
You do not need to use the DHCP for the network if you want to provision nodes with static IP addresses.
Configure the default gateway to use the DHCP server. All nodes must be in the same VLAN. You cannot scale the cluster using a second VLAN as a Day 2 operation.

You must use the Dynamic Host Configuration Protocol (DHCP) for the network and ensure that the DHCP server is configured to provide persistent IP addresses to the cluster machines. In the DHCP lease, you must configure the DHCP to use the default gateway. All nodes must be in the same VLAN. You cannot scale the cluster using a second VLAN as a Day 2 operation.

Additionally, you must create the following networking resources before you install the OpenShift Container Platform cluster:

**NOTE**

It is recommended that each OpenShift Container Platform node in the cluster must have access to a Network Time Protocol (NTP) server that is discoverable via DHCP. Installation is possible without an NTP server. However, asynchronous server clocks will cause errors, which NTP server prevents.

**Required IP Addresses**

For a network that uses DHCP, an installer-provisioned vSphere installation requires two static IP addresses:

- The **API** address is used to access the cluster API.
- The **Ingress** address is used for cluster ingress traffic.

You must provide these IP addresses to the installation program when you install the OpenShift Container Platform cluster.

**DNS records**

You must create DNS records for two static IP addresses in the appropriate DNS server for the vCenter instance that hosts your OpenShift Container Platform cluster. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the cluster base domain that you specify when you install the cluster. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>.

**Table 22.20. Required DNS records**

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>API VIP</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>This DNS A/AAAA or CNAME record must point to the load balancer for the control plane machines. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>
Ingress VIP

*.apps.<cluster_name>.<base_domain>.

A wildcard DNS A/AAAA or CNAME record that points to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ingress VIP</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A wildcard DNS A/AAAA or CNAME record that points to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>

Static IP addresses for vSphere nodes
You can provision bootstrap, control plane, and compute nodes to be configured with static IP addresses in environments where Dynamic Host Configuration Protocol (DHCP) does not exist. To configure this environment, you must provide values to the `platform.vsphere.hosts.role` parameter in the `install-config.yaml` file.

### IMPORTANT

Static IP addresses for vSphere nodes is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see Technology Preview Features Support Scope.

By default, the installation program is configured to use the DHCP for the network, but this network has limited configurable capabilities.

After you define one or more machine pools in your `install-config.yaml` file, you can define network definitions for nodes on your network. Ensure that the number of network definitions matches the number of machine pools that you configured for your cluster.

The following example shows a network configuration for a node with the role `compute`:

```yaml
---
platform:
  vsphere:
    hosts:
      - role: compute
        networkDevice:
          ipAddrs:
            - 192.168.204.10/24
          gateway: 192.168.204.1
```
Valid network definition values include bootstrap, control-plane, and compute. You must list at least one bootstrap network definition in your install-config.yaml configuration file.

Lists IPv4, IPv6, or both IP addresses that the installation program passes to the network interface. The machine API controller assigns all configured IP addresses to the default network interface.

The default gateway for the network interface.

Lists up to 3 DNS nameservers.

IMPORTANT

To enable the Technology Preview feature of static IP addresses for vSphere nodes for your cluster, you must include featureSet:TechPreviewNoUpgrade as the initial entry in the install-config.yaml file.

After you deployed your cluster to run nodes with static IP addresses, you can scale a machine to use one of these static IP addresses. Additionally, you can use a machine set to configure a machine to use one of the configured static IP addresses.

- Scaling machines to use static IP addresses
- Using a machine set to scale machines with configured static IP addresses

22.4.7. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The ./openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

NOTE

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.
Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N " -f <path>/<file_name>
   ```

   Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

   **NOTE**
   If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   ```bash
   $ cat <path>/<file_name>.pub
   ```

   For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

   ```bash
   $ cat ~/.ssh/id_ed25519.pub
   ```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

   **NOTE**
   On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

   a. If the ssh-agent process is not already running for your local user, start it as a background task:

   ```bash
   $ eval "$(ssh-agent -s)"
   ```

   **Example output**

   ```bash
   Agent pid 31874
   ```

   **NOTE**
   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the ssh-agent:
Specify the path and file name for your SSH private key, such as ~/.ssh/id_ed25519

Example output

Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

Next steps

• When you install OpenShift Container Platform, provide the SSH public key to the installation program.

22.4.8. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

Prerequisites

• You have a machine that runs Linux, for example Red Hat Enterprise Linux 8, with 500 MB of local disk space.

IMPORTANT

If you attempt to run the installation program on macOS, a known issue related to the golang compiler causes the installation of the OpenShift Container Platform cluster to fail. For more information about this issue, see the section named “Known Issues” in the OpenShift Container Platform 4.14 release notes document.

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.
IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   $ tar -xvf openshift-install-linux.tar.gz

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

22.4.9. Adding vCenter root CA certificates to your system trust

Because the installation program requires access to your vCenter’s API, you must add your vCenter’s trusted root CA certificates to your system trust before you install an OpenShift Container Platform cluster.

Procedure

1. From the vCenter home page, download the vCenter’s root CA certificates. Click Download trusted root CA certificates in the vSphere Web Services SDK section. The <vCenter>/certs/download.zip file downloads.

2. Extract the compressed file that contains the vCenter root CA certificates. The contents of the compressed file resemble the following file structure:

   ```
   certs
   └── lin
       ├── 108f4d17.0
       │    └── 108f4d17.r1
       │         └── 7e7576a.0
       │             └── 8e4f8471.0
       │                 └── 8e4f8471.r0
       └── mac
           ├── 108f4d17.0
           │    └── 108f4d17.r1
           │         └── 7e7576a.0
           │             └── 8e4f8471.0
           │                 └── 8e4f8471.r0
           └── win
               ├── 108f4d17.0.crt
               │    └── 108f4d17.r1.crt
               │         └── 7e7576a.0.crt
               │             └── 8e4f8471.0.crt
               │                 └── 8e4f8471.r0.crt
   3 directories, 15 files
   ```
3. Add the files for your operating system to the system trust. For example, on a Fedora operating system, run the following command:

```
# cp certs/lin/* /etc/pki/ca-trust/source/anchors
```

4. Update your system trust. For example, on a Fedora operating system, run the following command:

```
# update-ca-trust extract
```

### 22.4.10. VMware vSphere region and zone enablement

You can deploy an OpenShift Container Platform cluster to multiple vSphere datacenters that run in a single VMware vCenter. Each datacenter can run multiple clusters. This configuration reduces the risk of a hardware failure or network outage that can cause your cluster to fail.

**IMPORTANT**

The VMware vSphere region and zone enablement feature requires the vSphere Container Storage Interface (CSI) driver as the default storage driver in the cluster. As a result, the feature only available on a newly installed cluster.

A cluster that was upgraded from a previous release defaults to using the in-tree vSphere driver, so you must enable CSI automatic migration for the cluster. You can then configure multiple regions and zones for the upgraded cluster.

The default installation configuration deploys a cluster to a single vSphere datacenter. If you want to deploy a cluster to multiple vSphere datacenters, you must create an installation configuration file that enables the region and zone feature.

The default `install-config.yaml` file includes `vcenters` and `failureDomains` fields, where you can specify multiple vSphere datacenters and clusters for your OpenShift Container Platform cluster. You can leave these fields blank if you want to install an OpenShift Container Platform cluster in a vSphere environment that consists of single datacenter.

The following list describes terms associated with defining zones and regions for your cluster:

- **Failure domain**: Establishes the relationships between a region and zone. You define a failure domain by using vCenter objects, such as a `datastore` object. A failure domain defines the vCenter location for OpenShift Container Platform cluster nodes.

- **Region**: Specifies a vCenter datacenter. You define a region by using a tag from the `openshift-region` tag category.

- **Zone**: Specifies a vCenter cluster. You define a zone by using a tag from the `openshift-zone` tag category.

**NOTE**

If you plan on specifying more than one failure domain in your `install-config.yaml` file, you must create tag categories, zone tags, and region tags in advance of creating the configuration file.
You must create a vCenter tag for each vCenter datacenter, which represents a region. Additionally, you must create a vCenter tag for each cluster that runs in a datacenter, which represents a zone. After you create the tags, you must attach each tag to their respective datacenters and clusters.

The following table outlines an example of the relationship among regions, zones, and tags for a configuration with multiple vSphere datacenters running in a single VMware vCenter.

<table>
<thead>
<tr>
<th>Datacenter (region)</th>
<th>Cluster (zone)</th>
<th>Tags</th>
</tr>
</thead>
<tbody>
<tr>
<td>us-east</td>
<td>us-east-1</td>
<td>us-east-1a</td>
</tr>
<tr>

</tbody>
</table>

Additional resources

- Additional VMware vSphere configuration parameters
- Deprecated VMware vSphere configuration parameters
- vSphere automatic migration
- VMware vSphere CSI Driver Operator

22.4.11. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on VMware vSphere.

Prerequisites

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Create the `install-config.yaml` file.
   a. Change to the directory that contains the installation program and run the following command:
For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

When specifying the directory:

- Verify that the directory has the `execute` permission. This permission is required to run Terraform binaries under the installation directory.

- Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

**NOTE**

Always delete the `~/.powervs` directory to avoid reusing a stale configuration. Run the following command:

```
$ rm -rf ~/.powervs
```

b. At the prompts, provide the configuration details for your cloud:

i. Optional: Select an SSH key to use to access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

ii. Select `vsphere` as the platform to target.

iii. Specify the name of your vCenter instance.

iv. Specify the user name and password for the vCenter account that has the required permissions to create the cluster. The installation program connects to your vCenter instance.

v. Select the data center in your vCenter instance to connect to.

**NOTE**

After you create the installation configuration file, you can modify the file to create a multiple vSphere datacenters environment. This means that you can deploy an OpenShift Container Platform cluster to multiple vSphere datacenters that run in a single VMware vCenter. For more information about creating this environment, see the section named `VMware vSphere region and zone enablement`.
vi. Select the default vCenter datastore to use.

**WARNING**

You can specify the path of any datastore that exists in a datastore cluster. By default, Storage Distributed Resource Scheduler (SDRS), which uses Storage vMotion, is automatically enabled for a datastore cluster. Red Hat does not support Storage vMotion, so you must disable Storage DRS to avoid data loss issues for your OpenShift Container Platform cluster.

You cannot specify more than one datastore path. If you must specify VMs across multiple datastores, use a `datastore` object to specify a failure domain in your cluster’s `install-config.yaml` configuration file. For more information, see “VMware vSphere region and zone enablement”.

vii. Select the vCenter cluster to install the OpenShift Container Platform cluster in. The installation program uses the root resource pool of the vSphere cluster as the default resource pool.

viii. Select the network in the vCenter instance that contains the virtual IP addresses and DNS records that you configured.

ix. Enter the virtual IP address that you configured for control plane API access.

x. Enter the virtual IP address that you configured for cluster ingress.

xi. Enter the base domain. This base domain must be the same one that you used in the DNS records that you configured.

xii. Enter a descriptive name for your cluster. The cluster name you enter must match the cluster name you specified when configuring the DNS records.

2. Modify the `install-config.yaml` file. You can find more information about the available parameters in the “Installation configuration parameters” section.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

**IMPORTANT**

The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

**Additional resources**

- Installation configuration parameters
22.4.11.1. Sample install-config.yaml file for an installer-provisioned VMware vSphere cluster

You can customize the install-config.yaml file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute:
  - architecture: amd64
    name: <worker_node>
    platform: {}
    replicas: 3
controlPlane:
  architecture: amd64
  name: <parent_node>
  platform: {}
  replicas: 3
metadata:
  creationTimestamp: null
  name: test
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
      hostPrefix: 23
  machineNetwork:
    - cidr: 10.0.0.0/16
  networkType: OVNKubernetes
  serviceNetwork:
    - 172.30.0.0/16
platform:
  vsphere:
  apiVIPs:
    - 10.0.0.1
  failureDomains:
    - name: <failure_domain_name>
      region: <default_region_name>
      server: <fullyQualifiedDomainName>
      topology:
        computeCluster: "/<datacenter>/host/<cluster>"
        datacenter: <datacenter>
        datastore: "/<datacenter>/datastore/<datastore>"
  networks:
  - <VM_Network_name>
  resourcePool: "/<datacenter>/host/<cluster>/Resources/<resourcePool>"
  folder: "/<datacenter_name>/vm/<folder_name>/<subfolder_name>"
  zone: <default_zone_name>
  ingressVIPs:
  - 10.0.0.2
vcenters:
  - <datacenter>
    password: <password>
    port: 443
    server: <fullyQualifiedDomainName>
```
The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, -, and the first line of the controlPlane section must not. Only one control plane pool is used.

The cluster name that you specified in your DNS records.

Optional: Provides additional configuration for the machine pool parameters for the compute and control plane machines.

Establishes the relationships between a region and zone. You define a failure domain by using vCenter objects, such as a datastore object. A failure domain defines the vCenter location for OpenShift Container Platform cluster nodes.

The path to the vSphere datastore that holds virtual machine files, templates, and ISO images.

**IMPORTANT**

You can specify the path of any datastore that exists in a datastore cluster. By default, Storage vMotion is automatically enabled for a datastore cluster. Red Hat does not support Storage vMotion, so you must disable Storage vMotion to avoid data loss issues for your OpenShift Container Platform cluster.

If you must specify VMs across multiple datastores, use a datastore object to specify a failure domain in your cluster’s install-config.yaml configuration file. For more information, see "VMware vSphere region and zone enablement".

Optional: Provides an existing resource pool for machine creation. If you do not specify a value, the installation program uses the root resource pool of the vSphere cluster.

The vSphere disk provisioning method.

The cluster network plugin to install. The supported values are OVNKubernetes and OpenShiftSDN. The default value is OVNKubernetes.

**NOTE**

In OpenShift Container Platform 4.12 and later, the apiVIP and ingressVIP configuration settings are deprecated. Instead, use a list format to enter values in the apiVIPs and ingressVIPs configuration settings.

22.4.11.2. Configuring the cluster-wide proxy during installation
Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**Prerequisites**

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

**Procedure**

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
     httpProxy: http://<username>:<pswd>@<ip>:<port>  #1
     httpsProxy: https://<username>:<pswd>@<ip>:<port>  #2
     noProxy: example.com  #3
     additionalTrustBundle: |
       -----BEGIN CERTIFICATE-----
       <MY_TRUSTED_CA_CERT>
       -----END CERTIFICATE-----
     additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle>  #5
   
   #1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.
   #2 A proxy URL to use for creating HTTPS connections outside the cluster.
   #3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, `.y.com` matches `x.y.com`, but not `y.com`. Use * to bypass the proxy for all destinations. You must include vCenter’s IP address and the IP range that you use for its machines.
   #4 If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges these contents with the Red Hat
Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the trustedCA field of the Proxy object. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

Optional: The policy to determine the configuration of the Proxy object to reference the user-ca-bundle config map in the trustedCA field. The allowed values are Proxyonly and Always. Use Proxyonly to reference the user-ca-bundle config map only when http/https proxy is configured. Use Always to always reference the user-ca-bundle config map. The default value is Proxyonly.

NOTE
The installation program does not support the proxy readinessEndpoints field.

NOTE
If the installer times out, restart and then complete the deployment by using the wait-for command of the installer. For example:

```
$ ./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

NOTE
Only the Proxy object named cluster is supported, and no additional proxies can be created.

22.4.11.3. Optional: Deploying with dual-stack networking

For dual-stack networking in OpenShift Container Platform clusters, you can configure IPv4 and IPv6 address endpoints for cluster nodes. To configure IPv4 and IPv6 address endpoints for cluster nodes, edit the machineNetwork, clusterNetwork, and serviceNetwork configuration settings in the install-config.yaml file. Each setting must have two CIDR entries each. For a cluster with the IPv4 family as the primary address family, specify the IPv4 setting first. For a cluster with the IPv6 family as the primary address family, specify the IPv4 setting first.

```yaml
machineNetwork:
  - cidr: {{ extcidrnet }}
  - cidr: {{ extcidrnet6 }}
clusterNetwork:
  - cidr: 10.128.0.0/14
    hostPrefix: 23
  - cidr: fd02::/48
    hostPrefix: 64
serviceNetwork:
  - 172.30.0.0/16
  - fd03::/112
```
To provide an interface to the cluster for applications that use IPv4 and IPv6 addresses, configure IPv4 and IPv6 virtual IP (VIP) address endpoints for the Ingress VIP and API VIP services. To configure IPv4 and IPv6 address endpoints, edit the `apiVIPs` and `ingressVIPs` configuration settings in the `install-config.yaml` file. The `apiVIPs` and `ingressVIPs` configuration settings use a list format. The order of the list indicates the primary and secondary VIP address for each service.

```yaml
platform:
  vsphere:
    apiVIPs:
    - <api_ipv4>
    - <api_ipv6>
    ingressVIPs:
    - <wildcard_ipv4>
    - <wildcard_ipv6>
```

**NOTE**

For a cluster with dual-stack networking configuration, you must assign both IPv4 and IPv6 addresses to the same interface.

### 22.4.11.4. Configuring regions and zones for a VMware vCenter

You can modify the default installation configuration file, so that you can deploy an OpenShift Container Platform cluster to multiple vSphere datacenters that run in a single VMware vCenter.

The default `install-config.yaml` file configuration from the previous release of OpenShift Container Platform is deprecated. You can continue to use the deprecated default configuration, but the `openshift-installer` will prompt you with a warning message that indicates the use of deprecated fields in the configuration file.

**IMPORTANT**

The example uses the `govc` command. The `govc` command is an open source command available from VMware; it is not available from Red Hat. The Red Hat support team does not maintain the `govc` command. Instructions for downloading and installing `govc` are found on the VMware documentation website.

**Prerequisites**

- You have an existing `install-config.yaml` installation configuration file.

**IMPORTANT**

You must specify at least one failure domain for your OpenShift Container Platform cluster, so that you can provision datacenter objects for your VMware vCenter server. Consider specifying multiple failure domains if you need to provision virtual machine nodes in different datacenters, clusters, datastores, and other components.

**Procedure**

1. Enter the following `govc` command-line tool commands to create the `openshift-region` and `openshift-zone` vCenter tag categories:
IMPORTANT

If you specify different names for the `openshift-region` and `openshift-zone` vCenter tag categories, the installation of the OpenShift Container Platform cluster fails.

1. Change to the directory that contains the installation program and initialize the cluster deployment according to your chosen installation requirements.

2. To create a region tag for each region vSphere datacenter where you want to deploy your cluster, enter the following command in your terminal:

   `$ govc tags.category.create -d "OpenShift region" openshift-region`

3. To create a zone tag for each vSphere cluster where you want to deploy your cluster, enter the following command:

   `$ govc tags.category.create -d "OpenShift zone" openshift-zone`

4. Attach region tags to each vCenter datacenter object by entering the following command:

   `$ govc tags.create -c <region_tag_category> <region_tag>`

5. Attach the zone tags to each vCenter datacenter object by entering the following command:

   `$ govc tags.attach -c <region_tag_category> <region_tag_1> /<datacenter_1>`

6. Change to the directory that contains the installation program and initialize the cluster deployment according to your chosen installation requirements.

Sample `install-config.yaml` file with multiple datacenters defined in a vSphere center

```yaml
---
compute:
  ---
  vsphere:
    zones:
      - "<machine_pool_zone_1>"
      - "<machine_pool_zone_2>"
  ---
controlPlane:
  ---
  vsphere:
    zones:
      - "<machine_pool_zone_1>"
      - "<machine_pool_zone_2>"
  ---
platform:
  vsphere:
    vcenters:
  ---
```
22.4.12. Network configuration phases

There are two phases prior to OpenShift Container Platform installation where you can customize the network configuration.

Phase 1

You can customize the following network-related fields in the `install-config.yaml` file before you create the manifest files:

- `networking.networkType`
- `networking.clusterNetwork`
- `networking.serviceNetwork`
- `networking.machineNetwork`

For more information on these fields, refer to `Installation configuration parameters`.

**NOTE**

Set the `networking.machineNetwork` to match the CIDR that the preferred NIC resides in.
IMPORTANT

The CIDR range 172.17.0.0/16 is reserved by libVirt. You cannot use this range or any range that overlaps with this range for any networks in your cluster.

Phase 2

After creating the manifest files by running `openshift-install create manifests`, you can define a customized Cluster Network Operator manifest with only the fields you want to modify. You can use the manifest to specify advanced network configuration.

You cannot override the values specified in phase 1 in the `install-config.yaml` file during phase 2. However, you can further customize the network plugin during phase 2.

22.4.13. Specifying advanced network configuration

You can use advanced network configuration for your network plugin to integrate your cluster into your existing network environment. You can specify advanced network configuration only before you install the cluster.

IMPORTANT

Customizing your network configuration by modifying the OpenShift Container Platform manifest files created by the installation program is not supported. Applying a manifest file that you create, as in the following procedure, is supported.

Prerequisites

- You have created the `install-config.yaml` file and completed any modifications to it.

Procedure

1. Change to the directory that contains the installation program and create the manifests:

   ```sh
dir <installation_directory>
```

2. Create a stub manifest file for the advanced network configuration that is named `cluster-network-03-config.yml` in the `<installation_directory>/manifests/` directory:

   ```yaml
   apiVersion: operator.openshift.io/v1
   kind: Network
   metadata:
       name: cluster
   spec:
   ```

3. Specify the advanced network configuration for your cluster in the `cluster-network-03-config.yml` file, such as in the following examples:

   Specify a different VXLAN port for the OpenShift SDN network provider
Enable IPsec for the OVN-Kubernetes network provider

```yaml
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
  name: cluster
spec:
defaultNetwork:
  openshiftSDNConfig:
    vxlanPort: 4800

apiVersion: operator.openshift.io/v1
kind: Network
metadata:
  name: cluster
spec:
defaultNetwork:
  ovnKubernetesConfig:
    ipsecConfig: {}
```

4. Optional: Back up the `manifests/cluster-network-03-config.yml` file. The installation program consumes the `manifests/` directory when you create the Ignition config files.

5. Remove the Kubernetes manifest files that define the control plane machines and compute machineSets:

   ```bash
   $ rm -f openshift/99_openshift-cluster-api_master-machines-*.yaml openshift/99_openshift-cluster-api_worker-machineset-*.yaml
   ```

   Because you create and manage these resources yourself, you do not have to initialize them.

   - You can preserve the MachineSet files to create compute machines by using the machine API, but you must update references to them to match your environment.

22.4.14. Cluster Network Operator configuration

The configuration for the cluster network is specified as part of the Cluster Network Operator (CNO) configuration and stored in a custom resource (CR) object that is named `cluster`. The CR specifies the fields for the `Network` API in the `operator.openshift.io` API group.

The CNO configuration inherits the following fields during cluster installation from the `Network` API in the `Network.config.openshift.io` API group and these fields cannot be changed:

- `clusterNetwork`
  - IP address pools from which pod IP addresses are allocated.

- `serviceNetwork`
  - IP address pool for services.

- `defaultNetwork.type`
  - Cluster network plugin, such as OpenShift SDN or OVN-Kubernetes.

You can specify the cluster network plugin configuration for your cluster by setting the fields for the `defaultNetwork` object in the CNO object named `cluster`. 

The fields for the Cluster Network Operator (CNO) are described in the following table:

Table 22.21. Cluster Network Operator configuration object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>metadata.name</td>
<td>string</td>
<td>The name of the CNO object. This name is always cluster.</td>
</tr>
<tr>
<td>spec.clusterNetwork</td>
<td>array</td>
<td>A list specifying the blocks of IP addresses from which pod IP addresses are allocated and the subnet prefix length assigned to each individual node in the cluster. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>spec:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- clusterNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- cidr: 10.128.0.0/19</td>
</tr>
<tr>
<td></td>
<td></td>
<td>hostPrefix: 23</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- cidr: 10.128.32.0/19</td>
</tr>
<tr>
<td></td>
<td></td>
<td>hostPrefix: 23</td>
</tr>
<tr>
<td>spec.serviceNetwork</td>
<td>array</td>
<td>A block of IP addresses for services. The OpenShift SDN and OVN-Kubernetes network plugins support only a single IP address block for the service network. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>spec:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- serviceNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- 172.30.0.0/14</td>
</tr>
<tr>
<td>spec.defaultNetwork</td>
<td>object</td>
<td>Configures the network plugin for the cluster network.</td>
</tr>
<tr>
<td>spec.kubeProxyConfig</td>
<td>object</td>
<td>The fields for this object specify the kube-proxy configuration. If you are using the OVN-Kubernetes cluster network plugin, the kube-proxy configuration has no effect.</td>
</tr>
</tbody>
</table>

defaultNetwork object configuration

The values for the defaultNetwork object are defined in the following table:

Table 22.22. defaultNetwork object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
Either OpenShiftSDN or OVNKubernetes. The Red Hat OpenShift Networking network plugin is selected during installation. This value cannot be changed after cluster installation.

NOTE

OpenShift Container Platform uses the OVN-Kubernetes network plugin by default.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>string</td>
<td>Either OpenShiftSDN or OVNKubernetes. The Red Hat OpenShift Networking network plugin is selected during installation. This value cannot be changed after cluster installation.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>openshiftSDNConfig</td>
<td>object</td>
<td>This object is only valid for the OpenShift SDN network plugin.</td>
</tr>
<tr>
<td>ovnKubernetesConfig</td>
<td>object</td>
<td>This object is only valid for the OVN-Kubernetes network plugin.</td>
</tr>
</tbody>
</table>

Configuration for the OpenShift SDN network plugin

The following table describes the configuration fields for the OpenShift SDN network plugin:

Table 22.23. openshiftSDNConfig object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mode</td>
<td>string</td>
<td>Configures the network isolation mode for OpenShift SDN. The default value is NetworkPolicy. The values Multitenant and Subnet are available for backwards compatibility with OpenShift Container Platform 3.x but are not recommended. This value cannot be changed after cluster installation.</td>
</tr>
</tbody>
</table>
The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.

If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.

If your cluster requires different MTU values for different nodes, you must set this value to 50 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1450.

This value cannot be changed after cluster installation.

The port to use for all VXLAN packets. The default value is 4789. This value cannot be changed after cluster installation.

If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number.

On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port 9000 and port 9999.

Example OpenShift SDN configuration

defaultNetwork:
  type: OpenShiftSDN
  openshiftSDNConfig:
    mode: NetworkPolicy
    mtu: 1450
    vxlanPort: 4789

Configuration for the OVN-Kubernetes network plugin

The following table describes the configuration fields for the OVN-Kubernetes network plugin:

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>defaultNetwork</td>
<td></td>
<td></td>
</tr>
<tr>
<td>type</td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshiftSDNConfig</td>
<td></td>
<td></td>
</tr>
<tr>
<td>mode</td>
<td></td>
<td></td>
</tr>
<tr>
<td>mtu</td>
<td>integer</td>
<td></td>
</tr>
<tr>
<td>vxlanPort</td>
<td>integer</td>
<td></td>
</tr>
</tbody>
</table>

Table 22.24. ovnKubernetesConfig object
The maximum transmission unit (MTU) for the Geneve (Generic Network Virtualization Encapsulation) overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.

If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.

If your cluster requires different MTU values for different nodes, you must set this value to 100 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1400.

The port to use for all Geneve packets. The default value is 6081. This value cannot be changed after cluster installation.

Specify an empty object to enable IPsec encryption.

Specify a configuration object for customizing network policy audit logging. If unset, the defaults audit log settings are used.

Optional: Specify a configuration object for customizing how egress traffic is sent to the node gateway.

NOTE

While migrating egress traffic, you can expect some disruption to workloads and service traffic until the Cluster Network Operator (CNO) successfully rolls out the changes.
If your existing network infrastructure overlaps with the 100.64.0.0/16 IPv4 subnet, you can specify a different IP address range for internal use by OVN-Kubernetes. You must ensure that the IP address range does not overlap with any other subnet used by your OpenShift Container Platform installation. The IP address range must be larger than the maximum number of nodes that can be added to the cluster. For example, if the clusterNetwork.cidr value is 10.128.0.0/14 and the clusterNetwork.hostPrefix value is /23, then the maximum number of nodes is $2^{23-14}=512$.

This field cannot be changed after installation.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>v4InternalSubnet</td>
<td></td>
<td>The default value is 100.64.0.0/16.</td>
</tr>
</tbody>
</table>
If your existing network infrastructure overlaps with the `fd98::/48` IPv6 subnet, you can specify a different IP address range for internal use by OVN-Kubernetes. You must ensure that the IP address range does not overlap with any other subnet used by your OpenShift Container Platform installation. The IP address range must be larger than the maximum number of nodes that can be added to the cluster.

This field cannot be changed after installation.

The default value is `fd98::/48`.

### Table 22.25. `policyAuditConfig` object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>rateLimit</code></td>
<td>integer</td>
<td>The maximum number of messages to generate every second per node. The default value is 20 messages per second.</td>
</tr>
<tr>
<td><code>maxFileSize</code></td>
<td>integer</td>
<td>The maximum size for the audit log in bytes. The default value is 50000000 or 50 MB.</td>
</tr>
</tbody>
</table>
destination | string | One of the following additional audit log targets:

libc
   The libc syslog() function of the journald process on the host.
udp:<host>:<port>
   A syslog server. Replace <host>:<port> with the host and port of the syslog server.
unix:<file>
   A Unix Domain Socket file specified by <file>.
null
   Do not send the audit logs to any additional target.

syslogFacility | string | The syslog facility, such as kern, as defined by RFC5424. The default value is local0.

Table 22.26. gatewayConfig object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>routingViaHost</td>
<td>boolean</td>
<td>Set this field to true to send egress traffic from pods to the host networking stack. For highly-specialized installations and applications that rely on manually configured routes in the kernel routing table, you might want to route egress traffic to the host networking stack. By default, egress traffic is processed in OVN to exit the cluster and is not affected by specialized routes in the kernel routing table. The default value is false. This field has an interaction with the Open vSwitch hardware offloading feature. If you set this field to true, you do not receive the performance benefits of the offloading because egress traffic is processed by the host networking stack.</td>
</tr>
<tr>
<td>ipForwarding</td>
<td>object</td>
<td>You can control IP forwarding for all traffic on OVN-Kubernetes managed interfaces by using the ipForwarding specification in the Network resource. Specify Restricted to only allow IP forwarding for Kubernetes related traffic. Specify Global to allow forwarding of all IP traffic. For new installations, the default is Restricted. For updates to OpenShift Container Platform 4.14, the default is Global.</td>
</tr>
</tbody>
</table>

Example OVN-Kubernetes configuration with IPSec enabled

```yaml
defaultNetwork:
  type: OVNKubernetes
  ovnKubernetesConfig:
    mtu: 1400
    genevePort: 6081
    ipsecConfig: {}```
kubeProxyConfig object configuration
The values for the kubeProxyConfig object are defined in the following table:

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>iptablesSyncPeriod</td>
<td>string</td>
<td>The refresh period for iptables rules. The default value is 30s. Valid suffixes include s, m, and h and are described in the Go time package documentation.</td>
</tr>
<tr>
<td>proxyArguments.iptables-min-sync-period</td>
<td>array</td>
<td>The minimum duration before refreshing iptables rules. This field ensures that the refresh does not happen too frequently. Valid suffixes include s, m, and h and are described in the Go time package. The default value is:</td>
</tr>
</tbody>
</table>

```
kubeProxyConfig:
  proxyArguments:
    iptables-min-sync-period:
      - 0s
```

22.4.15. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

IMPORTANT
You can run the create cluster command of the installation program only once, during initial installation.

Prerequisites

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.
- Optional: Before you create the cluster, configure an external load balancer in place of the default load balancer.
IMPORTANT

You do not need to specify API and Ingress static addresses for your installation program. If you choose this configuration, you must take additional actions to define network targets that accept an IP address from each referenced vSphere subnet. See the section "Configuring an external load balancer".

Procedure

- Change to the directory that contains the installation program and initialize the cluster deployment:

  
  
  ```bash
  $ ./openshift-install create cluster --dir <installation_directory> \  
  --log-level=info
  ```

  1 For `<installation_directory>`, specify the location of your customized `./install-config.yaml` file.

  2 To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

Verification

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the `kubeadmin` user.

- Credential information also outputs to `<installation_directory>/.openshift_install.log`.

IMPORTANT

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

Example output

```
... INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export
KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```
The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

22.4.16. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

IMPORTANT

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of oc.

Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure

2. Select the architecture from the Product Variant drop-down list.

3. Select the appropriate version from the Version drop-down list.

4. Click Download Now next to the OpenShift v4.14 Linux Client entry and save the file.

5. Unpack the archive:

   $ tar xvf <file>

6. Place the oc binary in a directory that is on your PATH.

   To check your PATH, execute the following command:

   $ echo $PATH

Verification

- After you install the OpenShift CLI, it is available using the oc command:

   $ oc <command>
Installing the OpenShift CLI on Windows
You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

Procedure
2. Select the appropriate version from the Version drop-down list.
3. Click Download Now next to the OpenShift v4.14 Windows Client entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the oc binary to a directory that is on your PATH.
   To check your PATH, open the command prompt and execute the following command:

   C:\> path

Verification
- After you install the OpenShift CLI, it is available using the oc command:

   C:\> oc <command>

Installing the OpenShift CLI on macOS
You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.

Procedure
2. Select the appropriate version from the Version drop-down list.
3. Click Download Now next to the OpenShift v4.14 macOS Client entry and save the file.
4. Unpack and unzip the archive.
5. Move the oc binary to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:

   $ echo $PATH

Verification
- After you install the OpenShift CLI, it is available using the oc command:

   $ echo $PATH
22.4.17. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

   ```
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```
   $ oc whoami
   ```

   **Example output**

   ```
   system:admin
   ```

22.4.18. Creating registry storage

After you install the cluster, you must create storage for the registry Operator.

22.4.18.1. Image registry removed during installation

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as Removed. This allows `openshift-installer` to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the `managementState` from Removed to Managed.

22.4.18.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.
Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the `Recreate` rollout strategy during upgrades.

22.4.18.2.1. Configuring registry storage for VMware vSphere

As a cluster administrator, following installation you must configure your registry to use storage.

**Prerequisites**

- Cluster administrator permissions.
- A cluster on VMware vSphere.
- Persistent storage provisioned for your cluster, such as Red Hat OpenShift Data Foundation.

**IMPORTANT**

OpenShift Container Platform supports `ReadWriteOnce` access for image registry storage when you have only one replica. `ReadWriteOnce` access also requires that the registry uses the `Recreate` rollout strategy. To deploy an image registry that supports high availability with two or more replicas, `ReadWriteMany` access is required.

- Must have "100Gi" capacity.

**IMPORTANT**

Testing shows issues with using the NFS server on RHEL as storage backend for core services. This includes the OpenShift Container Registry and Quay, Prometheus for monitoring storage, and Elasticsearch for logging storage. Therefore, using RHEL NFS to back PVs used by core services is not recommended.

Other NFS implementations on the marketplace might not have these issues. Contact the individual NFS implementation vendor for more information on any testing that was possibly completed against these OpenShift Container Platform core components.

**Procedure**

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

   **NOTE**

   When you use shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

   ```
   $ oc get pod -n openshift-image-registry -l docker-registry=default
   ```
Example output

No resources found in openshift-image-registry namespace

NOTE

If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

   $ oc edit configs.imageregistry.operator.openshift.io

Example output

storage:
pvc:
  claim: 1

Leave the claim field blank to allow the automatic creation of an image-registry-storage persistent volume claim (PVC). The PVC is generated based on the default storage class. However, be aware that the default storage class might provide ReadWriteOnce (RWO) volumes, such as a RADOS Block Device (RBD), which can cause issues when you replicate to more than one replica.

4. Check the clusteroperator status:

   $ oc get clusteroperator image-registry

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
<th>SINCE</th>
<th>MESSAGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>image-registry</td>

<td>True</td>
<td>False</td>
<td>False</td>
<td>6h50m</td>
<td></td>
</tr>
</tbody>
</table>

22.4.18.2.2. Configuring block registry storage for VMware vSphere

To allow the image registry to use block storage types such as vSphere Virtual Machine Disk (VMDK) during upgrades as a cluster administrator, you can use the Recreate rollout strategy.

IMPORTANT

Block storage volumes are supported but not recommended for use with image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

Procedure

1. To set the image registry storage as a block storage type, patch the registry so that it uses the Recreate rollout strategy and runs with only 1 replica:
Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.

a. Create a `pvc.yaml` file with the following contents to define a VMware vSphere PersistentVolumeClaim object:

```yaml
kind: PersistentVolumeClaim
apiVersion: v1
metadata:
  name: image-registry-storage
  namespace: openshift-image-registry
spec:
  accessModes:
  - ReadWriteOnce
  resources:
    requests:
      storage: 100Gi
```

1. A unique name that represents the `PersistentVolumeClaim` object.
2. The namespace for the `PersistentVolumeClaim` object, which is `openshift-image-registry`.
3. The access mode of the persistent volume claim. With `ReadWriteOnce`, the volume can be mounted with read and write permissions by a single node.
4. The size of the persistent volume claim.

b. Create the `PersistentVolumeClaim` object from the file:

```bash
$ oc create -f pvc.yaml -n openshift-image-registry
```

3. Edit the registry configuration so that it references the correct PVC:

```bash
$ oc edit config.imageregistry.operator.openshift.io -o yaml
```

**Example output**

```yaml
storage:
pvc:
  claim: 1
```

1. By creating a custom PVC, you can leave the `claim` field blank for the default automatic creation of an `image-registry-storage` PVC.

For instructions about configuring registry storage so that it references the correct PVC, see Configuring the registry for vSphere.

**22.4.19. Backing up VMware vSphere volumes**
OpenShift Container Platform provisions new volumes as independent persistent disks to freely attach and detach the volume on any node in the cluster. As a consequence, it is not possible to back up volumes that use snapshots, or to restore volumes from snapshots. See Snapshot Limitations for more information.

**Procedure**

To create a backup of persistent volumes:

1. Stop the application that is using the persistent volume.
2. Clone the persistent volume.
3. Restart the application.
4. Create a backup of the cloned volume.
5. Delete the cloned volume.

**22.4.20. Telemetry access for OpenShift Container Platform**

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager Hybrid Cloud Console.

After you confirm that your OpenShift Cluster Manager Hybrid Cloud Console inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- See About remote health monitoring for more information about the Telemetry service

**22.4.21. Configuring an external load balancer**

You can configure an OpenShift Container Platform cluster to use an external load balancer in place of the default load balancer.

**IMPORTANT**

Configuring an external load balancer depends on your vendor’s load balancer.

The information and examples in this section are for guideline purposes only. Consult the vendor documentation for more specific information about the vendor’s load balancer.

Red Hat supports the following services for an external load balancer:

- OpenShift API
- Ingress Controller

You can choose to configure one or both of these services for an external load balancer. Configuring only the Ingress Controller service is a common configuration option.
The following configuration options are supported for external load balancers:

- Use a node selector to map the Ingress Controller to a specific set of nodes. You must assign a static IP address to each node in this set, or configure each node to receive the same IP address from the Dynamic Host Configuration Protocol (DHCP). Infrastructure nodes commonly receive this type of configuration.

- Target all IP addresses on a subnet. This configuration can reduce maintenance overhead, because you can create and destroy nodes within those networks without reconfiguring the load balancer targets. If you deploy your ingress pods by using a machine set on a smaller network, such as a /27 or /28, you can simplify your load balancer targets.

  **TIP**

  You can list all IP addresses that exist in a network by checking the machine config pool’s resources.

**Considerations**

- For a front-end IP address, you can use the same IP address for the front-end IP address, the Ingress Controller’s load balancer, and API load balancer. Check the vendor’s documentation for this capability.

- For a back-end IP address, ensure that an IP address for an OpenShift Container Platform control plane node does not change during the lifetime of the external load balancer. You can achieve this by completing one of the following actions:
  - Assign a static IP address to each control plane node.
  - Configure each node to receive the same IP address from the DHCP every time the node requests a DHCP lease. Depending on the vendor, the DHCP lease might be in the form of an IP reservation or a static DHCP assignment.

- Manually define each node that runs the Ingress Controller in the external load balancer for the Ingress Controller back-end service. For example, if the Ingress Controller moves to an undefined node, a connection outage can occur.

**OpenShift API prerequisites**

- You defined a front-end IP address.

- TCP ports 6443 and 22623 are exposed on the front-end IP address of your load balancer. Check the following items:
  - Port 6443 provides access to the OpenShift API service.
  - Port 22623 can provide ignition startup configurations to nodes.

- The front-end IP address and port 6443 are reachable by all users of your system with a location external to your OpenShift Container Platform cluster.

- The front-end IP address and port 22623 are reachable only by OpenShift Container Platform nodes.

- The load balancer backend can communicate with OpenShift Container Platform control plane nodes on port 6443 and 22623.
Ingress Controller prerequisites

- You defined a front-end IP address.
- TCP ports 443 and 80 are exposed on the front-end IP address of your load balancer.
- The front-end IP address, port 80 and port 443 are reachable by all users of your system with a location external to your OpenShift Container Platform cluster.
- The front-end IP address, port 80 and port 443 are reachable to all nodes that operate in your OpenShift Container Platform cluster.
- The load balancer backend can communicate with OpenShift Container Platform nodes that run the Ingress Controller on ports 80, 443, and 1936.

Prerequisite for health check URL specifications

You can configure most load balancers by setting health check URLs that determine if a service is available or unavailable. OpenShift Container Platform provides these health checks for the OpenShift API, Machine Configuration API, and Ingress Controller backend services.

The following examples demonstrate health check specifications for the previously listed backend services:

Example of a Kubernetes API health check specification

Path: HTTPS:6443/readyz
Healthy threshold: 2
Unhealthy threshold: 2
Timeout: 10
Interval: 10

Example of a Machine Config API health check specification

Path: HTTPS:22623/healthz
Healthy threshold: 2
Unhealthy threshold: 2
Timeout: 10
Interval: 10

Example of an Ingress Controller health check specification

Path: HTTP:1936/healthz/ready
Healthy threshold: 2
Unhealthy threshold: 2
Timeout: 5
Interval: 10

Procedure

1. Configure the HAProxy Ingress Controller, so that you can enable access to the cluster from your load balancer on ports 6443, 443, and 80:

   Example HAProxy configuration
2. Use the `curl` CLI command to verify that the external load balancer and its resources are operational:

   a. Verify that the cluster machine configuration API is accessible to the Kubernetes API server resource, by running the following command and observing the response:
If the configuration is correct, you receive a JSON object in response:

```
{
  "major": "1",
  "minor": "11+",
  "gitVersion": "v1.11.0+ad103ed",
  "gitCommit": "ad103ed",
  "gitTreeState": "clean",
  "buildDate": "2019-01-09T06:44:10Z",
  "goVersion": "go1.10.3",
  "compiler": "gc",
  "platform": "linux/amd64"
}
```

b. Verify that the cluster machine configuration API is accessible to the Machine config server resource, by running the following command and observing the output:

```
$ curl -v https://<loadbalancer_ip_address>:22623/healthz --insecure
```
If the configuration is correct, the output from the command shows the following response:

```
HTTP/1.1 200 OK
Content-Length: 0
```

c. Verify that the controller is accessible to the Ingress Controller resource on port 80, by running the following command and observing the output:

```
$ curl -I -L -H "Host: console-openshift-console.apps.<cluster_name>.<base_domain>" http://<load_balancer_front_end_IP_address>
```
If the configuration is correct, the output from the command shows the following response:

```
HTTP/1.1 302 Found
content-length: 0
location: https://console-openshift-console.apps.ocp4.private.opequon.net/
cache-control: no-cache
```

d. Verify that the controller is accessible to the Ingress Controller resource on port 443, by running the following command and observing the output:

```
```
If the configuration is correct, the output from the command shows the following response:

```
HTTP/1.1 200 OK
referrer-policy: strict-origin-when-cross-origin
set-cookie: csrftoken=ULYWOyQ62LWjw2h003xtYSKh1a0Py2hhctw0WmV2YEdhJfYQwWcGBsja261dGLgaYO0nxzVErhiXt6QepA7g==; Path=/; Secure; SameSite=Lax
```
3. Configure the DNS records for your cluster to target the front-end IP addresses of the external load balancer. You must update records to your DNS server for the cluster API and applications over the load balancer.

**Examples of modified DNS records**

- `<load_balancer_ip_address> A api.<cluster_name>.<base_domain>`
  A record pointing to Load Balancer Front End

- `<load_balancer_ip_address> A apps.<cluster_name>.<base_domain>`
  A record pointing to Load Balancer Front End

**IMPORTANT**

DNS propagation might take some time for each DNS record to become available. Ensure that each DNS record propagates before validating each record.

4. Use the `curl` CLI command to verify that the external load balancer and DNS record configuration are operational:

   a. Verify that you can access the cluster API, by running the following command and observing the output:

   ```bash
   $ curl https://api.<cluster_name>.<base_domain>:6443/version --insecure
   ```

   If the configuration is correct, you receive a JSON object in response:

   ```json
   {
     "major": "1",
     "minor": "11+",
     "gitVersion": "v1.11.0+ad103ed",
     "gitCommit": "ad103ed",
     "gitTreeState": "clean",
     "buildDate": "2019-01-09T06:44:10Z",
     "goVersion": "go1.10.3",
     "compiler": "gc",
     "platform": "linux/amd64"
   }
   ```

   b. Verify that you can access the cluster machine configuration, by running the following command and observing the output:
$ curl -v https://api.<cluster_name>.<base_domain>:22623/healthz --insecure

If the configuration is correct, the output from the command shows the following response:

HTTP/1.1 200 OK
Content-Length: 0

c. Verify that you can access each cluster application on port, by running the following command and observing the output:

$ curl http://console-openshift-console.apps.<cluster_name>.<base_domain> -I -L --insecure

If the configuration is correct, the output from the command shows the following response:

HTTP/1.1 302 Found
content-length: 0
location: https://console-openshift-console.apps.<cluster_name>.<base_domain>/
cache-control: no-cacheHTTP/1.1 200 OK
referrer-policy: strict-origin-when-cross-origin

3252
22.4.22. Configuring network components to run on the control plane

You can configure networking components to run exclusively on the control plane nodes. By default, OpenShift Container Platform allows any node in the machine config pool to host the ingressVIP virtual IP address. However, some environments deploy worker nodes in separate subnets from the control plane nodes, which requires configuring the ingressVIP virtual IP address to run on the control plane nodes.

**NOTE**

You can scale the remote workers by creating a worker machineset in a separate subnet.

**IMPORTANT**

When deploying remote workers in separate subnets, you must place the ingressVIP virtual IP address exclusively with the control plane nodes.

---

**Internet access**

---

**Procedure**

1. Change to the directory storing the `install-config.yaml` file:

   ```bash
   $ cd ~/clusterconfigs
   ```

2. Switch to the `manifests` subdirectory:

   ```bash
   $ cd manifests
   ```

3. Create a file named `cluster-network-avoid-workers-99-config.yaml`:

   ```bash
   -
   ```
4. Open the `cluster-network-avoid-workers-99-config.yaml` file in an editor and enter a custom resource (CR) that describes the Operator configuration:

```yaml
apiVersion: machineconfiguration.openshift.io/v1
kind: MachineConfig
metadata:
  name: 50-worker-fix-mpi-rwn
labels:
  machineconfiguration.openshift.io/role: worker
spec:
  config:
    ignition:
      version: 3.2.0
    storage:
      files:
        - path: /etc/kubernetes/manifests/keepalived.yaml
          mode: 0644
          contents:
            source: data:
```

This manifest places the `ingressVIP` virtual IP address on the control plane nodes. Additionally, this manifest deploys the following processes on the control plane nodes only:

- **openshift-ingress-operator**
- **keepalived**

6. Create a `manifests/cluster-ingress-default-ingresscontroller.yaml` file:

```yaml
apiVersion: operator.openshift.io/v1
kind: IngressController
metadata:
  name: default
namespace: openshift-ingress-operator
spec:
  nodePlacement:
    nodeSelector:
      matchLabels:
        node-role.kubernetes.io/master: ""
```

7. Consider backing up the `manifests` directory. The installer deletes the `manifests/` directory when creating the cluster.

8. Modify the `cluster-scheduler-02-config.yml` manifest to make the control plane nodes schedulable by setting the `mastersSchedulable` field to `true`. Control plane nodes are not schedulable by default. For example:

```bash
$ sed -i "s;mastersSchedulable: false,mastersSchedulable: true;g" clusterconfigs/manifests/cluster-scheduler-02-config.yaml
```
NOTE
If control plane nodes are not schedulable after completing this procedure, deploying the cluster will fail.

22.4.23. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- Set up your registry and configure registry storage.
- Optional: View the events from the vSphere Problem Detector Operator to determine if the cluster has permission or storage configuration issues.

22.5. INSTALLING A CLUSTER ON VSPHERE WITH USER-PROVISIONED INFRASTRUCTURE

In OpenShift Container Platform version 4.14, you can install a cluster on VMware vSphere infrastructure that you provision.

NOTE
OpenShift Container Platform supports deploying a cluster to a single VMware vCenter only. Deploying a cluster with machines/machine sets on multiple vCenters is not supported.

IMPORTANT
The steps for performing a user-provisioned infrastructure installation are provided as an example only. Installing a cluster with infrastructure you provide requires knowledge of the vSphere platform and the installation process of OpenShift Container Platform. Use the user-provisioned infrastructure installation instructions as a guide; you are free to create the required resources through other methods.

22.5.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You provisioned persistent storage for your cluster. To deploy a private image registry, your storage must provide ReadWriteMany access modes.
- Completing the installation requires that you upload the Red Hat Enterprise Linux CoreOS (RHCOS) OVA on vSphere hosts. The machine from which you complete this process requires access to port 443 on the vCenter and ESXi hosts. You verified that port 443 is accessible.
- If you use a firewall, you confirmed with the administrator that port 443 is accessible. Control plane nodes must be able to reach vCenter and ESXi hosts on port 443 for the installation to succeed.
If you use a firewall, you configured it to allow the sites that your cluster requires access to.

**NOTE**

Be sure to also review this site list if you are configuring a proxy.

### 22.5.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- **Access** [OpenShift Cluster Manager Hybrid Cloud Console](https://openshift.redhat.com) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- **Access** [Quay.io](https://quay.io) to obtain the packages that are required to install your cluster.

- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 22.5.3. VMware vSphere infrastructure requirements

You must install the OpenShift Container Platform cluster on a VMware vSphere version 7.0 Update 2 or later instance that meets the requirements for the components that you use.

**NOTE**

OpenShift Container Platform version 4.14 supports VMware vSphere version 8.0.

You can host the VMware vSphere infrastructure on-premise or on a [VMware Cloud Verified provider](https://www.vmware.com/cloud-verified) that meets the requirements outlined in the following tables:

**Table 22.28. Version requirements for vSphere virtual environments**

<table>
<thead>
<tr>
<th>Virtual environment product</th>
<th>Required version</th>
</tr>
</thead>
<tbody>
<tr>
<td>VMware virtual hardware</td>
<td>15 or later</td>
</tr>
<tr>
<td>vSphere ESXi hosts</td>
<td>7.0 Update 2 or later</td>
</tr>
<tr>
<td>vCenter host</td>
<td>7.0 Update 2 or later</td>
</tr>
</tbody>
</table>
IMPORTANT

You must ensure that the time on your ESXi hosts is synchronized before you install OpenShift Container Platform. See Edit Time Configuration for a Host in the VMware documentation.

Table 22.29. Minimum supported vSphere version for VMware components

<table>
<thead>
<tr>
<th>Component</th>
<th>Minimum supported versions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hypervisor</td>
<td>vSphere 7.0 Update 2 and later with virtual hardware version 15</td>
<td>This version is the minimum version that Red Hat Enterprise Linux CoreOS (RHCOS) supports. For more information about supported hardware on the latest version of Red Hat Enterprise Linux (RHEL) that is compatible with RHCOS, see Hardware on the Red Hat Customer Portal.</td>
</tr>
<tr>
<td>Storage with in-tree drivers</td>
<td>vSphere 7.0 Update 2 and later</td>
<td>This plugin creates vSphere storage by using the in-tree storage drivers for vSphere included in OpenShift Container Platform.</td>
</tr>
<tr>
<td>Optional: Networking (NSX-T)</td>
<td>vSphere 7.0 Update 2 and later</td>
<td>vSphere 7.0 Update 2 is required for OpenShift Container Platform. For more information about the compatibility of NSX and OpenShift Container Platform, see the Release Notes section of VMware’s NSX container plugin documentation.</td>
</tr>
</tbody>
</table>

IMPORTANT

To ensure the best performance conditions for your cluster workloads that operate on Oracle® Cloud Infrastructure and on the Oracle® Cloud VMware Solution (OCVS) service, ensure volume performance units (VPUs) for your block volume are sized for your workloads.

The following list provides some guidance in selecting the VPUs needed for specific performance needs:

- Test or proof of concept environment: 100 GB, and 20 to 30 VPUs.
- Base-production environment: 500 GB, and 60 VPUs.
- Heavy-use production environment: More than 500 GB, and 100 or more VPUs.

Consider allocating additional VPUs to give enough capacity for updates and scaling activities. See Block Volume Performance Levels in the Oracle documentation.
22.5.4. VMware vSphere CSI Driver Operator requirements

To install the vSphere CSI Driver Operator, the following requirements must be met:

- VMware vSphere version 7.0 Update 2 or later
- vCenter 7.0 Update 2 or later
- Virtual machines of hardware version 15 or later
- No third-party vSphere CSI driver already installed in the cluster

If a third-party vSphere CSI driver is present in the cluster, OpenShift Container Platform does not overwrite it. The presence of a third-party vSphere CSI driver prevents OpenShift Container Platform from updating to OpenShift Container Platform 4.13 or later.

**NOTE**

The VMware vSphere CSI Driver Operator is supported only on clusters deployed with `platform: vsphere` in the installation manifest.

Additional resources

- To remove a third-party vSphere CSI driver, see Removing a third-party vSphere CSI Driver.
- To update the hardware version for your vSphere nodes, see Updating hardware on nodes running in vSphere.

22.5.5. Requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

This section describes the requirements for deploying OpenShift Container Platform on user-provisioned infrastructure.

22.5.5.1. vCenter requirements

Before you install an OpenShift Container Platform cluster on your vCenter that uses infrastructure that you provided, you must prepare your environment.

**Required vCenter account privileges**

To install an OpenShift Container Platform cluster in a vCenter, your vSphere account must include privileges for reading and creating the required resources. Using an account that has global administrative privileges is the simplest way to access all of the necessary permissions.

**Example 22.10. Roles and privileges required for installation in vSphere API**

<table>

Using OpenShift Container Platform with vMotion
If you intend on using vMotion in your vSphere environment, consider the following before installing an OpenShift Container Platform cluster.

- OpenShift Container Platform generally supports compute-only vMotion, where generally implies that you meet all VMware best practices for vMotion. To help ensure the uptime of your compute and control plane nodes, ensure that you follow the VMware best practices for vMotion, and use VMware anti-affinity rules to improve the availability of OpenShift Container Platform during maintenance or hardware issues.

  For more information about vMotion and anti-affinity rules, see the VMware vSphere documentation for vMotion networking requirements and VM anti-affinity rules.

- Using Storage vMotion can cause issues and is not supported. If you are using vSphere volumes in your pods, migrating a VM across datastores, either manually or through Storage vMotion, causes invalid references within OpenShift Container Platform persistent volume (PV) objects that can result in data loss.

- OpenShift Container Platform does not support selective migration of VMDKs across datastores, using datastore clusters for VM provisioning or for dynamic or static provisioning of PVs, or using a datastore that is part of a datastore cluster for dynamic or static provisioning of PVs.

**IMPORTANT**

You can specify the path of any datastore that exists in a datastore cluster. By default, Storage Distributed Resource Scheduler (SDRS), which uses Storage vMotion, is automatically enabled for a datastore cluster. Red Hat does not support Storage vMotion, so you must disable Storage DRS to avoid data loss issues for your OpenShift Container Platform cluster.

If you must specify VMs across multiple datastores, use a datastore object to specify a failure domain in your cluster’s `install-config.yaml` configuration file. For more information, see “VMware vSphere region and zone enablement”.

Cluster resources
When you deploy an OpenShift Container Platform cluster that uses infrastructure that you provided, you must create the following resources in your vCenter instance:

- 1 Folder
- 1 Tag category
1 Tag
- Virtual machines:
  - 1 template
  - 1 temporary bootstrap node
  - 3 control plane nodes
  - 3 compute machines

Although these resources use 856 GB of storage, the bootstrap node is destroyed during the cluster installation process. A minimum of 800 GB of storage is required to use a standard cluster.

If you deploy more compute machines, the OpenShift Container Platform cluster will use more storage.

Cluster limits
Available resources vary between clusters. The number of possible clusters within a vCenter is limited primarily by available storage space and any limitations on the number of required resources. Be sure to consider both limitations to the vCenter resources that the cluster creates and the resources that you require to deploy a cluster, such as IP addresses and networks.

Networking requirements
Use Dynamic Host Configuration Protocol (DHCP) for the network and ensure that the DHCP server is configured to provide persistent IP addresses to the cluster machines.

NOTE
You do not need to use the DHCP for the network if you want to provision nodes with static IP addresses.

Configure the default gateway to use the DHCP server. All nodes must be in the same VLAN. You cannot scale the cluster using a second VLAN as a Day 2 operation.

You must use the Dynamic Host Configuration Protocol (DHCP) for the network and ensure that the DHCP server is configured to provide persistent IP addresses to the cluster machines. In the DHCP lease, you must configure the DHCP to use the default gateway. All nodes must be in the same VLAN. You cannot scale the cluster using a second VLAN as a Day 2 operation.

Additionally, you must create the following networking resources before you install the OpenShift Container Platform cluster:

NOTE
It is recommended that each OpenShift Container Platform node in the cluster must have access to a Network Time Protocol (NTP) server that is discoverable via DHCP. Installation is possible without an NTP server. However, asynchronous server clocks will cause errors, which NTP server prevents.

Required IP Addresses
DNS records
You must create DNS records for two static IP addresses in the appropriate DNS server for the vCenter instance that hosts your OpenShift Container Platform cluster. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the cluster base domain that you specify when you install the
cluster. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>`.

Table 22.30. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>API VIP</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>This DNS A/AAAA or CNAME record must point to the load balancer for the control plane machines. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Ingress VIP</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A wildcard DNS A/AAAA or CNAME record that points to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>

Additional resources

- Creating a compute machine set on vSphere

22.5.5.2. Required machines for cluster installation

The smallest OpenShift Container Platform clusters require the following hosts:

Table 22.31. Minimum required hosts

<table>
<thead>
<tr>
<th>Hosts</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>One temporary bootstrap machine</td>
<td>The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.</td>
</tr>
<tr>
<td>Three control plane machines</td>
<td>The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.</td>
</tr>
<tr>
<td>At least two compute machines, which are also known as worker machines</td>
<td>The workloads requested by OpenShift Container Platform users run on the compute machines.</td>
</tr>
</tbody>
</table>
To maintain high availability of your cluster, use separate physical hosts for these cluster machines.

The bootstrap and control plane machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system. However, the compute machines can choose between Red Hat Enterprise Linux CoreOS (RHCOS), Red Hat Enterprise Linux (RHEL) 8.6 and later.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 9.2 and inherits all of its hardware certifications and requirements. See Red Hat Enterprise Linux technology capabilities and limits.

### 22.5.5.3. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

<table>
<thead>
<tr>
<th>Machine</th>
<th>Operating System</th>
<th>vCPU</th>
<th>Virtual RAM</th>
<th>Storage</th>
<th>Input/Output Per Second (IOPS)[1]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS, RHEL 8.6 and later [2]</td>
<td>2</td>
<td>8 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
</tbody>
</table>

1. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.

2. As with all user-provisioned installations, if you choose to use RHEL compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and has been removed in OpenShift Container Platform 4.10 and later.

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

### Additional resources

- Optimizing storage

### 22.5.5.4. Requirements for encrypting virtual machines

You can encrypt your virtual machines prior to installing OpenShift Container Platform 4.14 by meeting the following requirements.
You have configured a Standard key provider in vSphere. For more information, see Adding a KMS to vCenter Server.

**IMPORTANT**
The Native key provider in vCenter is not supported. For more information, see vSphere Native Key Provider Overview.

- You have enabled host encryption mode on all of the ESXi hosts that are hosting the cluster. For more information, see Enabling host encryption mode.
- You have a vSphere account which has all cryptographic privileges enabled. For more information, see Cryptographic Operations Privileges.

When you deploy the OVF template in the section titled "Installing RHCOS and starting the OpenShift Container Platform bootstrap process", select the option to "Encrypt this virtual machine" when you are selecting storage for the OVF template. After completing cluster installation, create a storage class that uses the encryption storage policy you used to encrypt the virtual machines.

### Additional resources
- Creating an encrypted storage class

#### 22.5.5.5. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The kube-controller-manager only approves the kubelet client CSRs. The machine-approver cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

#### 22.5.5.6. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in initramfs during boot to fetch their Ignition config files.

During the initial boot, the machines require an IP address configuration that is set either through a DHCP server or statically by providing the required boot options. After a network connection is established, the machines download their Ignition config files from an HTTP or HTTPS server. The Ignition config files are then used to set the exact state of each machine. The Machine Config Operator completes more changes to the machines, such as the application of new certificates or keys, after installation.

It is recommended to use a DHCP server for long-term management of the cluster machines. Ensure that the DHCP server is configured to provide persistent IP addresses, DNS server information, and hostnames to the cluster machines.
NOTE

If a DHCP service is not available for your user-provisioned infrastructure, you can instead provide the IP networking configuration and the address of the DNS server to the nodes at RHCOS install time. These can be passed as boot arguments if you are installing from an ISO image. See the Installing RHCOS and starting the OpenShift Container Platform bootstrap process section for more information about static IP provisioning and advanced networking options.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

22.5.5.6.1. Setting the cluster node hostnames through DHCP

On Red Hat Enterprise Linux CoreOS (RHCOS) machines, the hostname is set through NetworkManager. By default, the machines obtain their hostname through DHCP. If the hostname is not provided by DHCP, set statically through kernel arguments, or another method, it is obtained through a reverse DNS lookup. Reverse DNS lookup occurs after the network has been initialized on a node and can take time to resolve. Other system services can start prior to this and detect the hostname as localhost or similar. You can avoid this by using DHCP to provide the hostname for each cluster node.

Additionally, setting the hostnames through DHCP can bypass any manual DNS record name configuration errors in environments that have a DNS split-horizon implementation.

22.5.5.6.2. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

IMPORTANT

In connected OpenShift Container Platform environments, all nodes are required to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

Table 22.33. Ports used for all-machine to all-machine communications

</tr>
</tbody>
</table>

Ethernet adaptor hardware address requirements
When provisioning VMs for the cluster, the ethernet interfaces configured for each VM must use a MAC address from the VMware Organizationally Unique Identifier (OUI) allocation ranges:

- 00:05:69:00:00:00 to 00:05:69:FF:FF
- 00:0c:29:00:00:00 to 00:0c:29:FF:FF
- 00:1c:14:00:00:00 to 00:1c:14:FF:FF
- 00:50:56:00:00:00 to 00:50:56:3F:FF

If a MAC address outside the VMware OUI is used, the cluster installation will not succeed.

NTP configuration for user-provisioned infrastructure
OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a
disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for Configuring chrony time service.

If a DHCP server provides NTP server information, the chrony time service on the Red Hat Enterprise Linux CoreOS (RHCOS) machines read the information and can sync the clock with the NTP servers.

**Additional resources**

- Configuring chrony time service

### 22.5.5.7. User-provisioned DNS requirements

In OpenShift Container Platform deployments, DNS name resolution is required for the following components:

- The Kubernetes API
- The OpenShift Container Platform application wildcard
- The bootstrap, control plane, and compute machines

Reverse DNS resolution is also required for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the hostnames for all the nodes, unless the hostnames are provided by DHCP. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

**NOTE**

It is recommended to use a DHCP server to provide the hostnames to each cluster node. See the DHCP recommendations for user-provisioned infrastructure section for more information.

The following DNS records are required for a user-provisioned OpenShift Container Platform cluster and they must be in place before installation. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>..

**Table 22.36. Required DNS records**

<table>
<thead>
<tr>
<th>Component</th>

<tr>
<td>IMPORTANT</td>
<td>The API server must be able to resolve the worker nodes by the hostnames that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.</td>
<td></td>
</tr>
<tr>
<td>Routes</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A wildcard DNS A/AAAA or CNAME record that refers to the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster. For example, console-openshift-console.apps.&lt;cluster_name&gt;.&lt;base_domain&gt; is used as a wildcard route to the OpenShift Container Platform console.</td>
</tr>
<tr>
<td>Bootstrap machine</td>
<td>bootstrap.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Control plane</td>
<td>&lt;master&gt;&lt;n&gt;..&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Compute machines</td>
<td>&lt;worker&gt;&lt;n&gt;..&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>NOTE</td>
<td>In OpenShift Container Platform 4.4 and later, you do not need to specify etcd host and SRV records in your DNS configuration.</td>
<td></td>
</tr>
<tr>
<td>TIP</td>
<td>You can use the dig command to verify name and reverse name resolution. See the section on Validating DNS resolution for user-provisioned infrastructure for detailed validation steps.</td>
<td></td>

</table>
22.5.5.7.1. Example DNS configuration for user-provisioned clusters

This section provides A and PTR record configuration samples that meet the DNS requirements for deploying OpenShift Container Platform on user-provisioned infrastructure. The samples are not meant to provide advice for choosing one DNS solution over another.

In the examples, the cluster name is `ocp4` and the base domain is `example.com`.

Example DNS A record configuration for a user-provisioned cluster

The following example is a BIND zone file that shows sample A records for name resolution in a user-provisioned cluster.

```
Example 22.13. Sample DNS zone database

$TTL 1W
@ IN SOA ns1.example.com. root (2019070700 ; serial 3H ; refresh (3 hours) 30M ; retry (30 minutes) 2W ; expiry (2 weeks) 1W ) ; minimum (1 week)
IN NS ns1.example.com.

7.1.168.192.in-addr.arpa. IN PTR worker1.ocp4.example.com. 8
;
;EOF
```

1 Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer.
2 Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer and is used for internal cluster communications.
3 Provides reverse DNS resolution for the bootstrap machine.
4, 5, 6 Provides reverse DNS resolution for the control plane machines.
Provides reverse DNS resolution for the compute machines.

**NOTE**

A PTR record is not required for the OpenShift Container Platform application wildcard.

### 22.5.5.8. Load balancing requirements for user-provisioned infrastructure

Before you install OpenShift Container Platform, you must provision the API and application Ingress load balancing infrastructure. In production scenarios, you can deploy the API and application Ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

**NOTE**

If you want to deploy the API and application Ingress load balancers with a Red Hat Enterprise Linux (RHEL) instance, you must purchase the RHEL subscription separately.

The load balancing infrastructure must meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:

   - **Layer 4 load balancing only.** This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.

   - **A stateless load balancing algorithm.** The options vary based on the load balancer implementation.

   **IMPORTANT**

   Do not configure session persistence for an API load balancer. Configuring session persistence for a Kubernetes API server might cause performance issues from excess application traffic for your OpenShift Container Platform cluster and the Kubernetes API that runs inside the cluster.

Configure the following ports on both the front and back of the load balancers:

**Table 22.37. API load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the /readyz endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
</tbody>
</table>
22623

Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>

**NOTE**

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the `/readyz` endpoint to the removal of the API server instance from the pool. Within the time frame after `/readyz` returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application Ingress load balancer**: Provides an ingress point for application traffic flowing in from outside the cluster. A working configuration for the Ingress router is required for an OpenShift Container Platform cluster.

Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

**TIP**

If the true IP address of the client can be seen by the application Ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

Configure the following ports on both the front and back of the load balancers:

**Table 22.38. Application Ingress load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>
**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application Ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

22.5.5.8.1. Example load balancer configuration for user-provisioned clusters

This section provides an example API and application Ingress load balancer configuration that meets the load balancing requirements for user-provisioned clusters. The sample is an `/etc/haproxy/haproxy.cfg` configuration for an HAProxy load balancer. The example is not meant to provide advice for choosing one load balancing solution over another.

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

**NOTE**

If you are using HAProxy as a load balancer and SELinux is set to `enforcing`, you must ensure that the HAProxy service can bind to the configured TCP port by running `setsebool -P haproxy_connect_any=1`.

### Example 22.15. Sample API and application Ingress load balancer configuration

```plaintext
global
  log 127.0.0.1 local2
  pidfile /var/run/haproxy.pid
  maxconn 4000
daemon
defaults
mode http
log global
dontlognull
option http-server-close
option redispatch
retries 3
timeout http-request 10s
timeout queue 1m
timeout connect 10s
timeout client 1m
timeout server 1m
timeout http-keep-alive 10s
timeout check 10s
maxconn 3000
listen api-server-6443
  bind *:6443
  mode tcp
  server bootstrap bootstrap.ocp4.example.com:6443 check inter 1s backup
  server master0 master0.ocp4.example.com:6443 check inter 1s
  server master1 master1.ocp4.example.com:6443 check inter 1s
  server master2 master2.ocp4.example.com:6443 check inter 1s
listen machine-config-server-22623
```

3280
Port 6443 handles the Kubernetes API traffic and points to the control plane machines.

The bootstrap entries must be in place before the OpenShift Container Platform cluster installation and they must be removed after the bootstrap process is complete.

Port 22623 handles the machine config server traffic and points to the control plane machines.

Port 443 handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

Port 80 handles the HTTP traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

NOTE

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application Ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

TIP

If you are using HAProxy as a load balancer, you can check that the haproxy process is listening on ports 6443, 22623, 443, and 80 by running `netstat -nltpu` on the HAProxy node.

22.5.6. Preparing the user-provisioned infrastructure

Before you install OpenShift Container Platform on user-provisioned infrastructure, you must prepare the underlying infrastructure.

This section provides details about the high-level steps required to set up your cluster infrastructure in preparation for an OpenShift Container Platform installation. This includes configuring IP networking and network connectivity for your cluster nodes, enabling the required ports through your firewall, and
setting up the required DNS and load balancing infrastructure.

After preparation, your cluster infrastructure must meet the requirements outlined in the Requirements for a cluster with user-provisioned infrastructure section.

Prerequisites

- You have reviewed the OpenShift Container Platform 4.x Tested Integrations page.
- You have reviewed the infrastructure requirements detailed in the Requirements for a cluster with user-provisioned infrastructure section.

Procedure

1. If you are using DHCP to provide the IP networking configuration to your cluster nodes, configure your DHCP service.
   
a. Add persistent IP addresses for the nodes to your DHCP server configuration. In your configuration, match the MAC address of the relevant network interface to the intended IP address for each node.

b. When you use DHCP to configure IP addressing for the cluster machines, the machines also obtain the DNS server information through DHCP. Define the persistent DNS server address that is used by the cluster nodes through your DHCP server configuration.

   **NOTE**

   If you are not using a DHCP service, you must provide the IP networking configuration and the address of the DNS server to the nodes at RHCOS install time. These can be passed as boot arguments if you are installing from an ISO image. See the Installing RHCOS and starting the OpenShift Container Platform bootstrap process section for more information about static IP provisioning and advanced networking options.

c. Define the hostnames of your cluster nodes in your DHCP server configuration. See the Setting the cluster node hostnames through DHCP section for details about hostname considerations.

   **NOTE**

   If you are not using a DHCP service, the cluster nodes obtain their hostname through a reverse DNS lookup.

2. Ensure that your network infrastructure provides the required network connectivity between the cluster components. See the Networking requirements for user-provisioned infrastructure section for details about the requirements.

3. Configure your firewall to enable the ports required for the OpenShift Container Platform cluster components to communicate. See Networking requirements for user-provisioned infrastructure section for details about the ports that are required.
IMPORTANT

By default, port 1936 is accessible for an OpenShift Container Platform cluster, because each control plane node needs access to this port.

Avoid using the Ingress load balancer to expose this port, because doing so might result in the exposure of sensitive information, such as statistics and metrics, related to Ingress Controllers.

4. Setup the required DNS infrastructure for your cluster.
   a. Configure DNS name resolution for the Kubernetes API, the application wildcard, the bootstrap machine, the control plane machines, and the compute machines.
   b. Configure reverse DNS resolution for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.
      See the User-provisioned DNS requirements section for more information about the OpenShift Container Platform DNS requirements.

5. Validate your DNS configuration.
   a. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses in the responses correspond to the correct components.
   b. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names in the responses correspond to the correct components.
      See the Validating DNS resolution for user-provisioned infrastructure section for detailed DNS validation steps.

6. Provision the required API and application ingress load balancing infrastructure. See the Load balancing requirements for user-provisioned infrastructure section for more information about the requirements.

   NOTE

   Some load balancing solutions require the DNS name resolution for the cluster nodes to be in place before the load balancing is initialized.

22.5.7. Validating DNS resolution for user-provisioned infrastructure

You can validate your DNS configuration before installing OpenShift Container Platform on user-provisioned infrastructure.

IMPORTANT

The validation steps detailed in this section must succeed before you install your cluster.

Prerequisites

- You have configured the required DNS records for your user-provisioned infrastructure.

Procedure
1. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses contained in the responses correspond to the correct components.

   a. Perform a lookup against the Kubernetes API record name. Check that the result points to the IP address of the API load balancer:

   ```
   $ dig +noall +answer @<nameserver_ip> api.<cluster_name>.<base_domain>
   ```

   1. Replace `<nameserver_ip>` with the IP address of the nameserver, `<cluster_name>` with your cluster name, and `<base_domain>` with your base domain name.

   **Example output**

   ```
   api.ocp4.example.com. 604800 IN A 192.168.1.5
   ```

   b. Perform a lookup against the Kubernetes internal API record name. Check that the result points to the IP address of the API load balancer:

   ```
   $ dig +noall +answer @<nameserver_ip> api-int.<cluster_name>.<base_domain>
   ```

   **Example output**

   ```
   api-int.ocp4.example.com. 604800 IN A 192.168.1.5
   ```

   c. Test an example `*.apps.<cluster_name>.<base_domain>` DNS wildcard lookup. All of the application wildcard lookups must resolve to the IP address of the application ingress load balancer:

   ```
   $ dig +noall +answer @<nameserver_ip> random.apps.<cluster_name>.<base_domain>
   ```

   **Example output**

   ```
   random.apps.ocp4.example.com. 604800 IN A 192.168.1.5
   ```

   **NOTE**

   In the example outputs, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

   You can replace `random` with another wildcard value. For example, you can query the route to the OpenShift Container Platform console:

   ```
   $ dig +noall +answer @<nameserver_ip> console-openshift-console.apps.<cluster_name>.<base_domain>
   ```

   **Example output**
d. Run a lookup against the bootstrap DNS record name. Check that the result points to the IP address of the bootstrap node:

```bash
$ dig +noall +answer @<nameserver_ip> bootstrap.<cluster_name>.<base_domain>
```

**Example output**

```
bootstrap.ocp4.example.com. 604800 IN A 192.168.1.96
```

e. Use this method to perform lookups against the DNS record names for the control plane and compute nodes. Check that the results correspond to the IP addresses of each node.

2. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names contained in the responses correspond to the correct components.

a. Perform a reverse lookup against the IP address of the API load balancer. Check that the response includes the record names for the Kubernetes API and the Kubernetes internal API:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.5
```

**Example output**

```
5.1.168.192.in-addr.arpa. 604800 IN PTR api-int.ocp4.example.com. 1
5.1.168.192.in-addr.arpa. 604800 IN PTR api.ocp4.example.com. 2
```

1 Provides the record name for the Kubernetes internal API.
2 Provides the record name for the Kubernetes API.

**NOTE**

A PTR record is not required for the OpenShift Container Platform application wildcard. No validation step is needed for reverse DNS resolution against the IP address of the application ingress load balancer.

b. Perform a reverse lookup against the IP address of the bootstrap node. Check that the result points to the DNS record name of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.96
```

**Example output**

```
```

c. Use this method to perform reverse lookups against the IP addresses for the control plane and compute nodes. Check that the results correspond to the DNS record names of each node.
22.5.8. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The ./openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> 1

   1 Specify the path and file name, such as ~/.ssh/id_ed25519, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   $ cat <path>/<file_name>.pub

   For example, run the following to view the ~/.ssh/id_ed25519.pub public key:

   $ cat ~/.ssh/id_ed25519.pub
3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

**NOTE**

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

a. If the `ssh-agent` process is not already running for your local user, start it as a background task:

```bash
$ eval "$(ssh-agent -s)"
```

**Example output**

Agent pid 31874

**NOTE**

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the `ssh-agent`:

```bash
$ ssh-add <path>/<file_name>
```

Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

**Example output**

Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program. If you install a cluster on infrastructure that you provision, you must provide the key to the installation program.

**22.5.9. VMware vSphere region and zone enablement**

You can deploy an OpenShift Container Platform cluster to multiple vSphere datacenters that run in a single VMware vCenter. Each datacenter can run multiple clusters. This configuration reduces the risk of a hardware failure or network outage that can cause your cluster to fail.
IMPORTANT

The VMware vSphere region and zone enablement feature requires the vSphere Container Storage Interface (CSI) driver as the default storage driver in the cluster. As a result, the feature only available on a newly installed cluster.

A cluster that was upgraded from a previous release defaults to using the in-tree vSphere driver, so you must enable CSI automatic migration for the cluster. You can then configure multiple regions and zones for the upgraded cluster.

The default installation configuration deploys a cluster to a single vSphere datacenter. If you want to deploy a cluster to multiple vSphere datacenters, you must create an installation configuration file that enables the region and zone feature.

The default install-config.yaml file includes vcenters and failureDomains fields, where you can specify multiple vSphere datacenters and clusters for your OpenShift Container Platform cluster. You can leave these fields blank if you want to install an OpenShift Container Platform cluster in a vSphere environment that consists of single datacenter.

The following list describes terms associated with defining zones and regions for your cluster:

- Failure domain: Establishes the relationships between a region and zone. You define a failure domain by using vCenter objects, such as a datastore object. A failure domain defines the vCenter location for OpenShift Container Platform cluster nodes.

- Region: Specifies a vCenter datacenter. You define a region by using a tag from the openshift-region tag category.

- Zone: Specifies a vCenter cluster. You define a zone by using a tag from the openshift-zone tag category.

**NOTE**

If you plan on specifying more than one failure domain in your install-config.yaml file, you must create tag categories, zone tags, and region tags in advance of creating the configuration file.

You must create a vCenter tag for each vCenter datacenter, which represents a region. Additionally, you must create a vCenter tag for each cluster than runs in a datacenter, which represents a zone. After you create the tags, you must attach each tag to their respective datacenters and clusters.

The following table outlines an example of the relationship among regions, zones, and tags for a configuration with multiple vSphere datacenters running in a single VMware vCenter.

<table>
<thead>
<tr>
<th>Datacenter (region)</th>
<th>Cluster (zone)</th>
<th>Tags</th>
</tr>
</thead>
<tbody>
<tr>
<td>us-east</td>
<td>us-east-1</td>
<td>us-east-1a</td>
</tr>
<tr>
<td></td>
<td></td>
<td>us-east-1b</td>
</tr>
<tr>
<td></td>
<td>us-east-2</td>
<td>us-east-2a</td>
</tr>
<tr>
<td></td>
<td></td>
<td>us-east-2b</td>
</tr>
</tbody>
</table>
### Additional resources

- Additional VMware vSphere configuration parameters
- Deprecated VMware vSphere configuration parameters
- vSphere automatic migration
- VMware vSphere CSI Driver Operator

### 22.5.10. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

**Prerequisites**

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

**Procedure**

1. Access the **Infrastructure Provider** page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.
Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   $ tar -xvf openshift-install-linux.tar.gz

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 22.5.11. Manually creating the installation configuration file

For user-provisioned installations of OpenShift Container Platform, you manually generate your installation configuration file.

**Prerequisites**

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.
- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Create an installation directory to store your required installation assets in:

   $ mkdir <installation_directory>

   **IMPORTANT**

   You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample `install-config.yaml` file template that is provided and save it in the `<installation_directory>`.

   **NOTE**

   You must name this configuration file `install-config.yaml`. 
NOTE

For some platform types, you can alternatively run `./openshift-install create install-config --dir <installation_directory>` to generate an `install-config.yaml` file. You can provide details about your cluster configuration at the prompts.

3. If you are installing a three-node cluster, modify the `install-config.yaml` file by setting the `compute.replicas` parameter to 0. This ensures that the cluster’s control planes are schedulable. For more information, see "Installing a three-node cluster on vSphere".

4. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

IMPORTANT

The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.

Additional resources

- Installation configuration parameters

### 22.5.11.1. Sample `install-config.yaml` file for VMware vSphere

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
additionalTrustBundlePolicy: Proxyonly
apiVersion: v1
baseDomain: example.com
compute:  
  - architecture: amd64
    name: <worker_node>
    platform: {}
    replicas: 0
  controlPlane:  
    architecture: amd64
    name: <parent_node>
    platform: {}
    replicas: 3
metadata:  
  creationTimestamp: null
  name: test
networking:  
---
platform:  
vsphere:  
  failureDomains:  
    - name: <failure_domain_name>
      region: <default_region_name>
      server: <fully_qualified_domain_name>
      topology:  
        computeCluster: "<datacenter>/host/<cluster>"
      datacenter: <datacenter>
The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

The `controlPlane` section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the `compute` section must begin with a hyphen, -, and the first line of the `controlPlane` section must not. Both sections define a single machine pool, so only one control plane is used. OpenShift Container Platform does not support defining multiple compute pools.

You must set the value of the `replicas` parameter to 0. This parameter controls the number of workers that the cluster creates and manages for you, which are functions that the cluster does not perform when you use user-provisioned infrastructure. You must manually deploy worker machines for the cluster to use before you finish installing OpenShift Container Platform.

The number of control plane machines that you add to the cluster. Because the cluster uses this values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

The cluster name that you specified in your DNS records.

Establishes the relationships between a region and zone. You define a failure domain by using vCenter objects, such as a `datastore` object. A failure domain defines the vCenter location for OpenShift Container Platform cluster nodes.

The vSphere datacenter.

The path to the vSphere datastore that holds virtual machine files, templates, and ISO images.
10 Optional: For installer-provisioned infrastructure, the absolute path of an existing resource pool where the installation program creates the virtual machines, for example, 
  /<datacenter_name>/host/<cluster_name>/Resources/<resource_pool_name>/<optional_nested_resource_pool_name>. If you do not specify a value, resources are installed in the root of the cluster /example_datacenter/host/example_cluster/Resources.

11 Optional: For installer-provisioned infrastructure, the absolute path of an existing folder where the installation program creates the virtual machines, for example, 
  /<datacenter_name>/vm/<folder_name>/<subfolder_name>. If you do not provide this value, the installation program creates a top-level folder in the datacenter virtual machine folder that is named with the infrastructure ID. If you are providing the infrastructure for the cluster and you do not want to use the default StorageClass object, named thin, you can omit the folder parameter from the install-config.yaml file.

12 The password associated with the vSphere user.

13 The fully-qualified hostname or IP address of the vCenter server.

14 The vSphere disk provisioning method.

15 Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

IMPORTANT

You can specify the path of any datastore that exists in a datastore cluster. By default, Storage vMotion is automatically enabled for a datastore cluster. Red Hat does not support Storage vMotion, so you must disable Storage vMotion to avoid data loss issues for your OpenShift Container Platform cluster.

If you must specify VMs across multiple datastores, use a datastore object to specify a failure domain in your cluster’s install-config.yaml configuration file. For more information, see “VMware vSphere region and zone enablement”.

IMPORTANT

The Cluster Cloud Controller Manager Operator performs a connectivity check on a provided hostname or IP address. Ensure that you specify a hostname or an IP address to a reachable vCenter server. If you provide metadata to a non-existent vCenter server, installation of the cluster fails at the bootstrap stage.

IMPORTANT

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see Installing the system in FIPS mode. When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures.
The pull secret that you obtained from OpenShift Cluster Manager Hybrid Cloud Console. This pull secret allows you to authenticate with the services that are provided by the included authorities.

The public portion of the default SSH key for the core user in Red Hat Enterprise Linux CoreOS (RHCOS).

22.5.11.2. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

Prerequisites

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the Proxy object’s `spec.noProxy` field to bypass the proxy if necessary.

NOTE

The Proxy object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port> ¹
  httpsProxy: https://<username>:<pswd>@<ip>:<port> ²
  noProxy: example.com ³
additionalTrustBundle: |
  -----BEGIN CERTIFICATE-----
  <MY_TRUSTED_CA_CERT>
  -----END CERTIFICATE-----
additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle>
```

¹ A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.

² A proxy URL to use for creating HTTPS connections outside the cluster.
A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For

If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the `trustedCA` field of the `Proxy` object. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

Optional: The policy to determine the configuration of the `Proxy` object to reference the `user-ca-bundle` config map in the `trustedCA` field. The allowed values are `Proxyonly` and `Always`. Use `Proxyonly` to reference the `user-ca-bundle` config map only when http/https proxy is configured. Use `Always` to always reference the `user-ca-bundle` config map. The default value is `Proxyonly`.

**NOTE**
The installation program does not support the proxy `readinessEndpoints` field.

**NOTE**
If the installer times out, restart and then complete the deployment by using the `wait-for` command of the installer. For example:

```
$ ./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster–wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

**NOTE**
Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

### 22.5.11.3. Configuring regions and zones for a VMware vCenter

You can modify the default installation configuration file, so that you can deploy an OpenShift Container Platform cluster to multiple vSphere datacenters that run in a single VMware vCenter.

The default `install-config.yaml` file configuration from the previous release of OpenShift Container Platform is deprecated. You can continue to use the deprecated default configuration, but the `openshift-installer` will prompt you with a warning message that indicates the use of deprecated fields in the configuration file.
IMPORTANT

The example uses the `govc` command. The `govc` command is an open source command available from VMware; it is not available from Red Hat. The Red Hat support team does not maintain the `govc` command. Instructions for downloading and installing `govc` are found on the VMware documentation website.

Prerequisites

- You have an existing `install-config.yaml` installation configuration file.

IMPORTANT

You must specify at least one failure domain for your OpenShift Container Platform cluster, so that you can provision datacenter objects for your VMware vCenter server. Consider specifying multiple failure domains if you need to provision virtual machine nodes in different datacenters, clusters, datastores, and other components.

Procedure

1. Enter the following `govc` command-line tool commands to create the `openshift-region` and `openshift-zone` vCenter tag categories:

```
$ govc tags.category.create -d "OpenShift region" openshift-region
$ govc tags.category.create -d "OpenShift zone" openshift-zone
```

IMPORTANT

If you specify different names for the `openshift-region` and `openshift-zone` vCenter tag categories, the installation of the OpenShift Container Platform cluster fails.

2. To create a region tag for each region vSphere datacenter where you want to deploy your cluster, enter the following command in your terminal:

```
$ govc tags.create -c <region_tag_category> <region_tag>
```

3. To create a zone tag for each vSphere cluster where you want to deploy your cluster, enter the following command:

```
$ govc tags.create -c <zone_tag_category> <zone_tag>
```

4. Attach region tags to each vCenter datacenter object by entering the following command:

```
$ govc tags.attach -c <region_tag_category> <region_tag_1> /<datacenter_1>
```

5. Attach the zone tags to each vCenter datacenter object by entering the following command:

```
$ govc tags.attach -c <zone_tag_category> <zone_tag_1> /<datacenter_1>/host/vcs-mdcnc-workload-1
```
6. Change to the directory that contains the installation program and initialize the cluster deployment according to your chosen installation requirements.

Sample install-config.yaml file with multiple datacenters defined in a vSphere center

```yaml
---
compute:
  vsphere:
    zones:
      - "<machine_pool_zone_1>"
      - "<machine_pool_zone_2>"
---
controlPlane:
  vsphere:
    zones:
      - "<machine_pool_zone_1>"
      - "<machine_pool_zone_2>"
---
platform:
  vsphere:
    vcenters:
      - datacenters:
          - <datacenter1_name>
          - <datacenter2_name>
        failureDomains:
          - name: <machine_pool_zone_1>
            region: <region_tag_1>
            zone: <zone_tag_1>
            server: <fully_qualified_domain_name>
            topology:
              datacenter: <datacenter1>
              computeCluster: "/<datacenter1>/host/<cluster1>"
          networks:
            - <VM_Network1_name>
            datastore: "/<datacenter1>/datastore/<datastore1>"
            resourcePool: "/<datacenter1>/host/<cluster1>/Resources/<resourcePool1>"
            folder: "/<datacenter1>/vm/<folder1>"
          - name: <machine_pool_zone_2>
            region: <region_tag_2>
            zone: <zone_tag_2>
            server: <fully_qualified_domain_name>
            topology:
              datacenter: <datacenter2>
              computeCluster: "/<datacenter2>/host/<cluster2>"
          networks:
            - <VM_Network2_name>
            datastore: "/<datacenter2>/datastore/<datastore2>"
            resourcePool: "/<datacenter2>/host/<cluster2>/Resources/<resourcePool2>"
            folder: "/<datacenter2>/vm/<folder2>"
---
```

22.5.12. Creating the Kubernetes manifest and Ignition config files
Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

**IMPORTANT**

- The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

**Prerequisites**

- You obtained the OpenShift Container Platform installation program.

- You created the `install-config.yaml` installation configuration file.

**Procedure**

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

   ```bash
   $ ./openshift-install create manifests --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.

2. Remove the Kubernetes manifest files that define the control plane machines, compute machine sets, and control plane machine sets:

   ```bash
   ```

   Because you create and manage these resources yourself, you do not have to initialize them.

   - You can preserve the compute machine set files to create compute machines by using the machine API, but you must update references to them to match your environment.
**WARNING**

If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.

**IMPORTANT**

When you configure control plane nodes from the default unschedulable to schedulable, additional subscriptions are required. This is because control plane nodes then become compute nodes.

3. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:
   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.
   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.
   c. Save and exit the file.

4. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

   ```shell
   $ ./openshift-install create ignition-configs --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the same installation directory.

   Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The `kubeadmin-password` and `kubeconfig` files are created in the `./<installation_directory>/auth` directory:

   - `/auth`
     - `kubeadmin-password`
     - `kubeconfig`
     - `bootstrap.ign`
     - `master.ign`
     - `metadata.json`
     - `worker.ign`

22.5.13. Extracting the infrastructure name

The Ignition config files contain a unique cluster identifier that you can use to uniquely identify your cluster in VMware vSphere. If you plan to use the cluster identifier as the name of your virtual machine folder, you must extract it.

**Prerequisites**
You obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

You generated the Ignition config files for your cluster.

You installed the `jq` package.

**Procedure**

- To extract and view the infrastructure name from the Ignition config file metadata, run the following command:
  
  ```bash
  $ jq -r .infraID <installation_directory>/metadata.json
  ```

  For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

**Example output**

```
openshift-vw9j6
```

The output of this command is your cluster name and a random string.

### 22.5.14. Installing RHCOS and starting the OpenShift Container Platform bootstrap process

To install OpenShift Container Platform on user-provisioned infrastructure on VMware vSphere, you must install Red Hat Enterprise Linux CoreOS (RHCOS) on vSphere hosts. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS machines have rebooted.

**Prerequisites**

- You have obtained the Ignition config files for your cluster.
- You have access to an HTTP server that you can access from your computer and that the machines that you create can access.
- You have created a vSphere cluster.

**Procedure**

1. Upload the bootstrap Ignition config file, which is named `<installation_directory>/bootstrap.ign`, that the installation program created to your HTTP server. Note the URL of this file.

2. Save the following secondary Ignition config file for your bootstrap node to your computer as `<installation_directory>/merge-bootstrap.ign`:

```json
{
```
Specify the URL of the bootstrap Ignition config file that you hosted.

When you create the virtual machine (VM) for the bootstrap machine, you use this Ignition config file.

3. Locate the following Ignition config files that the installation program created:

   - `<installation_directory>/master.ign`
   - `<installation_directory>/worker.ign`
   - `<installation_directory>/merge-bootstrap.ign`

4. Convert the Ignition config files to Base64 encoding. Later in this procedure, you must add these files to the extra configuration parameter `guestinfo.ignition.config.data` in your VM. For example, if you use a Linux operating system, you can use the `base64` command to encode the files.

   ```
   $ base64 -w0 <installation_directory>/master.ign > <installation_directory>/master.64
   $ base64 -w0 <installation_directory>/worker.ign > <installation_directory>/worker.64
   $ base64 -w0 <installation_directory>/merge-bootstrap.ign > <installation_directory>/merge-bootstrap.64
   ```

   **IMPORTANT**

   If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

5. Obtain the RHCOS OVA image. Images are available from the RHCOS image mirror page.
IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must download an image with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image version that matches your OpenShift Container Platform version if it is available.

The filename contains the OpenShift Container Platform version number in the format rhcos-vmware.<architecture>.ova.

6. In the vSphere Client, create a folder in your datacenter to store your VMs.
   a. Click the VMs and Templates view.
   b. Right-click the name of your datacenter.
   c. Click New Folder → New VM and Template Folder.
   d. In the window that is displayed, enter the folder name. If you did not specify an existing folder in the install-config.yaml file, then create a folder with the same name as the infrastructure ID. You use this folder name so vCenter dynamically provisions storage in the appropriate location for its Workspace configuration.

7. In the vSphere Client, create a template for the OVA image and then clone the template as needed.

   NOTE

   In the following steps, you create a template and then clone the template for all of your cluster machines. You then provide the location for the Ignition config file for that cloned machine type when you provision the VMs.

   a. From the Hosts and Clusters tab, right-click your cluster name and select Deploy OVF Template.
   b. On the Select an OVF tab, specify the name of the RHCOS OVA file that you downloaded.
   c. On the Select a name and folder tab, set a Virtual machine name for your template, such as Template-RHCOS. Click the name of your vSphere cluster and select the folder you created in the previous step.
   d. On the Select a compute resource tab, click the name of your vSphere cluster.
   e. On the Select storage tab, configure the storage options for your VM.
      - Select Thin Provision or Thick Provision, based on your storage preferences.
      - Select the datastore that you specified in your install-config.yaml file.
      - If you want to encrypt your virtual machines, select Encrypt this virtual machine. See the section titled “Requirements for encrypting virtual machines” for more information.
   f. On the Select network tab, specify the network that you configured for the cluster, if available.
g. When creating the OVF template, do not specify values on the **Customize template** tab or configure the template any further.

**IMPORTANT**

Do not start the original VM template. The VM template must remain off and must be cloned for new RH COS machines. Starting the VM template configures the VM template as a VM on the platform, which prevents it from being used as a template that compute machine sets can apply configurations to.

8. Optional: Update the configured virtual hardware version in the VM template, if necessary. Follow [Upgrading a virtual machine to the latest hardware version](#) in the VMware documentation for more information.

**IMPORTANT**

It is recommended that you update the hardware version of the VM template to version 15 before creating VMs from it, if necessary. Using hardware version 13 for your cluster nodes running on vSphere is now deprecated. If your imported template defaults to hardware version 13, you must ensure that your ESXi host is on 6.7U3 or later before upgrading the VM template to hardware version 15. If your vSphere version is less than 6.7U3, you can skip this upgrade step; however, a future version of OpenShift Container Platform is scheduled to remove support for hardware version 13 and vSphere versions less than 6.7U3.

9. After the template deploys, deploy a VM for a machine in the cluster.

   a. Right-click the template name and click **Clone → Clone to Virtual Machine**

   b. On the **Select a name and folder** tab, specify a name for the VM. You might include the machine type in the name, such as `control-plane-0` or `compute-1`.

      **NOTE**

      Ensure that all virtual machine names across a vSphere installation are unique.

   c. On the **Select a name and folder** tab, select the name of the folder that you created for the cluster.

   d. On the **Select a compute resource** tab, select the name of a host in your datacenter.

   e. On the **Select clone options** tab, select **Customize this virtual machine’s hardware**

   f. On the **Customize hardware** tab, click **Advanced Parameters**.

**IMPORTANT**

The following configuration suggestions are for example purposes only. As a cluster administrator, you must configure resources according to the resource demands placed on your cluster. To best manage cluster resources, consider creating a resource pool from the cluster’s root resource pool.
Optional: Override default DHCP networking in vSphere. To enable static IP networking:

- Set your static IP configuration:

  **Example command**

  ```bash
  $ export IPCFG="ip=<ip>::<gateway>::<netmask>::<hostname>::<iface>::none
  nameserver=srv1 [nameserver=srv2 [nameserver=srv3 [...]]]"
  ```

  **Example command**

  ```bash
  $ export IPCFG="ip=192.168.100.101::192.168.100.254:255.255.255.0::none
  nameserver=8.8.8.8"
  ```

- Set the `guestinfo.afterburn.initrd.network-kargs` property before you boot a VM from an OVA in vSphere:

  **Example command**

  ```bash
  $ govc vm.change -vm "<vm_name>" -e "guestinfo.afterburn.initrd.network-kargs=${IPCFG}"
  ```

- Add the following configuration parameter names and values by specifying data in the **Attribute** and **Values** fields. Ensure that you select the **Add** button for each parameter that you create.

  - `guestinfo.ignition.config.data`: Locate the base-64 encoded files that you created previously in this procedure, and paste the contents of the base64-encoded Ignition config file for this machine type.

  - `guestinfo.ignition.config.data.encoding`: Specify `base64`.

  - `disk.EnableUUID`: Specify `TRUE`.

  - `stealclock.enable`: If this parameter was not defined, add it and specify `TRUE`.

  - Create a child resource pool from the cluster’s root resource pool. Perform resource allocation in this child resource pool.

  g. In the **Virtual Hardware** panel of the **Customize hardware** tab, modify the specified values as required. Ensure that the amount of RAM, CPU, and disk storage meets the minimum requirements for the machine type.

  h. Complete the remaining configuration steps. On clicking the **Finish** button, you have completed the cloning operation.

  i. From the **Virtual Machines** tab, right-click on your VM and then select **Power → Power On**.

  j. Check the console output to verify that Ignition ran.

  **Example command**

  ```text
  Ignition: ran on 2022/03/14 14:48:33 UTC (this boot)
  Ignition: user-provided config was applied
  ```
Next steps

- Create the rest of the machines for your cluster by following the preceding steps for each machine.

**IMPORTANT**

You must create the bootstrap and control plane machines at this time. Because some pods are deployed on compute machines by default, also create at least two compute machines before you install the cluster.

### 22.5.15. Adding more compute machines to a cluster in vSphere

You can add more compute machines to a user-provisioned OpenShift Container Platform cluster on VMware vSphere.

After your vSphere template deploys in your OpenShift Container Platform cluster, you can deploy a virtual machine (VM) for a machine in that cluster.

**NOTE**

If you are installing a three-node cluster, skip this step. A three-node cluster consists of three control plane machines, which also act as compute machines.

#### Prerequisites

- Obtain the base64-encoded Ignition file for your compute machines.
- You have access to the vSphere template that you created for your cluster.

#### Procedure

1. Right-click the template’s name and click **Clone → Clone to Virtual Machine**

2. On the **Select a name and folder** tab, specify a name for the VM. You might include the machine type in the name, such as **compute-1**.

   **NOTE**

   Ensure that all virtual machine names across a vSphere installation are unique.

3. On the **Select a name and folder** tab, select the name of the folder that you created for the cluster.

4. On the **Select a compute resource** tab, select the name of a host in your datacenter.

5. On the **Select storage** tab, select storage for your configuration and disk files.

6. On the **Select clone options** tab, select **Customize this virtual machine’s hardware**.

7. On the **Customize hardware** tab, click **Advanced Parameters**.

   - Add the following configuration parameter names and values by specifying data in the **Attribute** and **Values** fields. Ensure that you select the **Add** button for each parameter that you create.
- `guestinfo.ignition.config.data`: Paste the contents of the base64-encoded compute Ignition config file for this machine type.

- `guestinfo.ignition.config.data.encoding`: Specify `base64`.

- `disk.EnableUUID`: Specify `TRUE`.

8. In the `Virtual Hardware` panel of the `Customize hardware` tab, modify the specified values as required. Ensure that the amount of RAM, CPU, and disk storage meets the minimum requirements for the machine type. If many networks exist, select `Add New Device > Network Adapter`, and then enter your network information in the fields provided by the `New Network` menu item.

9. Complete the remaining configuration steps. On clicking the `Finish` button, you have completed the cloning operation.

10. From the `Virtual Machines` tab, right-click on your VM and then select `Power → Power On`.

**Next steps**

- Continue to create more compute machines for your cluster.

### 22.5.16. Disk partitioning

In most cases, data partitions are originally created by installing RHCOS, rather than by installing another operating system. In such cases, the OpenShift Container Platform installer should be allowed to configure your disk partitions.

However, there are two cases where you might want to intervene to override the default partitioning when installing an OpenShift Container Platform node:

- **Create separate partitions:** For greenfield installations on an empty disk, you might want to add separate storage to a partition. This is officially supported for making `/var` or a subdirectory of `/var`, such as `/var/lib/etcd`, a separate partition, but not both.

  **IMPORTANT**

  For disk sizes larger than 100GB, and especially disk sizes larger than 1TB, create a separate `/var` partition. See "Creating a separate `/var` partition" and this Red Hat Knowledgebase article for more information.

- **Retain existing partitions:** For a brownfield installation where you are reinstalling OpenShift Container Platform on an existing node and want to retain data partitions installed from your previous operating system, there are both boot arguments and options to `coreos-installer` that allow you to retain existing data partitions.

### Creating a separate `/var` partition

In general, disk partitioning for OpenShift Container Platform should be left to the installer. However, there are cases where you might want to create separate partitions in a part of the filesystem that you expect to grow.
OpenShift Container Platform supports the addition of a single partition to attach storage to either the
/var partition or a subdirectory of /var. For example:

- /var/lib/containers: Holds container-related content that can grow as more images and
  containers are added to a system.
- /var/lib/etcd: Holds data that you might want to keep separate for purposes such as
  performance optimization of etcd storage.
- /var: Holds data that you might want to keep separate for purposes such as auditing.

**IMPORTANT**

For disk sizes larger than 100GB, and especially larger than 1TB, create a separate
/var partition.

Storing the contents of a /var directory separately makes it easier to grow storage for those areas as
needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this
method, you will not have to pull all your containers again, nor will you have to copy massive log files
when you update systems.

Because /var must be in place before a fresh installation of Red Hat Enterprise Linux CoreOS (RHCOS),
the following procedure sets up the separate /var partition by creating a machine config manifest that is
inserted during the openshift-install preparation phases of an OpenShift Container Platform
installation.

**Procedure**

1. Create a directory to hold the OpenShift Container Platform installation files:
   
   ```shell
   $ mkdir $HOME/clusterconfig
   ```

2. Run openshift-install to create a set of files in the manifest and openshift subdirectories.
   Answer the system questions as you are prompted:
   
   ```shell
   $ openshift-install create manifests --dir $HOME/clusterconfig
   ? SSH Public Key ...
   $ ls $HOME/clusterconfig/openshift/
   99_kubeadmin-password-secret.yaml
   99_openshift-cluster-api_master-machines-0.yaml
   99_openshift-cluster-api_master-machines-1.yaml
   99_openshift-cluster-api_master-machines-2.yaml
   ...
   ```

3. Create a Butane config that configures the additional partition. For example, name the file
   $HOME/clusterconfig/98-var-partition.bu, change the disk device name to the name of the
   storage device on the worker systems, and set the storage size as appropriate. This example
   places the /var directory on a separate partition:
   
   ```yaml
   variant: openshift
   version: 4.14.0
   metadata:
     labels:
       machineconfiguration.openshift.io/role: worker
   ```
name: 98-var-partition
storage:
disks:
  - device: /dev/disk/by-id/<device_name> ¹
partitions:
  - label: var
    start_mib: <partition_start_offset> ²
    size_mib: <partition_size> ³
filesystems:
  - device: /dev/disk/by-partlabel/var
    path: /var
    format: xfs
    mount_options: [defaults, prjquota] ⁴
    with_mount_unit: true

¹ The storage device name of the disk that you want to partition.
² When adding a data partition to the boot disk, a minimum value of 25000 mebibytes is recommended. The root file system is automatically resized to fill all available space up to the specified offset. If no value is specified, or if the specified value is smaller than the recommended minimum, the resulting root file system will be too small, and future reinstalls of RHCOS might overwrite the beginning of the data partition.
³ The size of the data partition in mebibytes.
⁴ The `prjquota` mount option must be enabled for filesystems used for container storage.

**NOTE**

When creating a separate /var partition, you cannot use different instance types for worker nodes, if the different instance types do not have the same device name.

4. Create a manifest from the Butane config and save it to the `clusterconfig/openshift` directory. For example, run the following command:

```
$ butane $HOME/clusterconfig/98-var-partition.bu -o $HOME/clusterconfig/openshift/98-var-partition.yaml
```

5. Run `openshift-install` again to create Ignition configs from a set of files in the `manifest` and `openshift` subdirectories:

```
$ openshift-install create ignition-configs --dir $HOME/clusterconfig
$ ls $HOME/clusterconfig/auth bootstrap.ign master.ign metadata.json worker.ign
```

Now you can use the Ignition config files as input to the vSphere installation procedures to install Red Hat Enterprise Linux CoreOS (RHCOS) systems.

**22.5.17. Updating the bootloader using bootupd**

To update the bootloader by using `bootupd`, you must either install `bootupd` on RHCOS machines manually or provide a machine config with the enabled `systemd` unit. Unlike `grubby` or other
bootloader tools, **bootupd** does not manage kernel space configuration such as passing kernel arguments.

After you have installed **bootupd**, you can manage it remotely from the OpenShift Container Platform cluster.

**NOTE**

It is recommended that you use **bootupd** only on bare metal or virtualized hypervisor installations, such as for protection against the BootHole vulnerability.

**Manual install method**

You can manually install **bootupd** by using the **bootctl** command-line tool.

1. Inspect the system status:
   ```bash
   # bootupctl status
   ```

   **Example output for x86_64**
   ```plaintext
   Component EFI
   Installed: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
   Update: At latest version
   ```

   **Example output for aarch64**
   ```plaintext
   Component EFI
   Installed: grub2-efi-aa64-1:2.02-99.el8_4.1.aarch64,shim-aa64-15.4-2.el8_1.aarch64
   Update: At latest version
   ```

2. RHCOS images created without **bootupd** installed on them require an explicit adoption phase. If the system status is **Adoptable**, perform the adoption:
   ```bash
   # bootupctl adopt-and-update
   ```

   **Example output**
   ```plaintext
   Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
   ```

3. If an update is available, apply the update so that the changes take effect on the next reboot:
   ```bash
   # bootupctl update
   ```

   **Example output**
   ```plaintext
   Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
   ```

**Machine config method**

Another way to enable **bootupd** is by providing a machine config.
• Provide a machine config file with the enabled **systemd** unit, as shown in the following example:

**Example output**

```yaml
variant: rhcos
version: 1.1.0
systemd:
  units:
    - name: custom-bootupd-auto.service
      enabled: true
      contents: |
        [Unit]
        Description=Bootupd automatic update

        [Service]
        ExecStart=/usr/bin/bootupctl update
        RemainAfterExit=yes

        [Install]
        WantedBy=multi-user.target
```

**22.5.18. Installing the OpenShift CLI by downloading the binary**

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of **oc**.

**Installing the OpenShift CLI on Linux**

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

**Procedure**

2. Select the architecture from the **Product Variant** drop-down list.

3. Select the appropriate version from the **Version** drop-down list.

4. Click **Download Now** next to the **OpenShift v4.14 Linux Client** entry and save the file.

5. Unpack the archive:

   ```bash
   $ tar xvf <file>
   ```

6. Place the **oc** binary in a directory that is on your **PATH**.

   To check your **PATH**, execute the following command:

   ```bash
   $ echo $PATH
   ```
Verifications

- After you install the OpenShift CLI, it is available using the `oc` command:

  ```
  $ oc <command>
  ```

Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (`oc`) binary on Windows by using the following procedure.

Procedure

2. Select the appropriate version from the Version drop-down list.

3. Click Download Now next to the OpenShift v4.14 Windows Client entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the `oc` binary to a directory that is on your PATH.

To check your PATH, open the command prompt and execute the following command:

  ```
  C:\> path
  ```

Verifications

- After you install the OpenShift CLI, it is available using the `oc` command:

  ```
  C:\> oc <command>
  ```

Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (`oc`) binary on macOS by using the following procedure.

Procedure

2. Select the appropriate version from the Version drop-down list.

3. Click Download Now next to the OpenShift v4.14 macOS Client entry and save the file.

4. Unpack and unzip the archive.

5. Move the `oc` binary to a directory on your PATH.

To check your PATH, open a terminal and execute the following command:

  ```
  $ echo $PATH
  ```

**NOTE**

For macOS arm64, choose the OpenShift v4.14 macOS arm64 Client entry.
Verification

- After you install the OpenShift CLI, it is available using the `oc` command:

  ```bash
  $ oc <command>
  ```

22.5.19. Waiting for the bootstrap process to complete

The OpenShift Container Platform bootstrap process begins after the cluster nodes first boot into the persistent RHCOS environment that has been installed to disk. The configuration information provided through the Ignition config files is used to initialize the bootstrap process and install OpenShift Container Platform on the machines. You must wait for the bootstrap process to complete.

Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have obtained the installation program and generated the Ignition config files for your cluster.
- You installed RHCOS on your cluster machines and provided the Ignition config files that the OpenShift Container Platform installation program generated.
- Your machines have direct internet access or have an HTTP or HTTPS proxy available.

Procedure

1. Monitor the bootstrap process:

   ```bash
   $ ./openshift-install --dir <installation_directory> wait-for bootstrap-complete
   --log-level=info
   ```

   1 For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   2 To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

   **Example output**

   ```none
   INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
   INFO API v1.27.3 up
   INFO Waiting up to 30m0s for bootstrapping to complete...
   INFO It is now safe to remove the bootstrap resources
   ```

   The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After the bootstrap process is complete, remove the bootstrap machine from the load balancer.
IMPORTANT
You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the bootstrap machine itself.

22.5.20. Logging in to the cluster by using the CLI
You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites
- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

Procedure
1. Export the `kubeadmin` credentials:
   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```
   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:
   ```bash
   $ oc whoami
   system:admin
   ```

22.5.21. Approving the certificate signing requests for your machines
When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

Prerequisites
- You added machines to your cluster.

Procedure
1. Confirm that the cluster recognizes the machines:
   ```bash
   $ oc get nodes
   ```
   Example output
The output lists all of the machines that you created.

**NOTE**

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

   $ oc get csr

**Example output**

```
NAME        AGE     REQUESTOR                                                                 CONDITION
 csr-8b2br   15m     system:serviceaccount:openshift-machine-config-operator:node-bootstrapper   Pending
 csr-8vnps   15m     system:serviceaccount:openshift-machine-config-operator:node-bootstrapper   Pending
...
```

In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

**NOTE**

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.
NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the `oc exec`, `oc rsh`, and `oc logs` commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the `node-bootstrapper` service account in the `system:node` or `system:admin` groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

```bash
$ oc adm certificate approve <csr_name> ①
```

① `<csr_name>` is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```bash
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' xargs --no-run-if-empty oc adm certificate approve
```

NOTE

Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```bash
$ oc get csr
```

Example output

```
NAME        AGE     REQUESTOR            CONDITION
---         ----     ------------------ --------
csr-bfd72   5m26s   system:node:ip-10-0-50-126.us-east-2.compute.internal Pending
csr-c57lv   5m26s   system:node:ip-10-0-95-157.us-east-2.compute.internal Pending
...
```

5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

```bash
$ oc adm certificate approve <csr_name> ①
```

① `<csr_name>` is the name of a CSR from the list of current CSRs.
To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs oc adm certificate approve
```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>74m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>worker-0</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>worker-1</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.27.3</td>
</tr>
</tbody>
</table>

**NOTE**

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

**Additional information**

- For more information on CSRs, see [Certificate Signing Requests](#).

### 22.5.22. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

**Prerequisites**

- Your control plane has initialized.

**Procedure**

1. Watch the cluster components come online:

```
$ watch -n5 oc get clusteroperators
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
<th>SINCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>authentication</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>19m</td>
</tr>
<tr>
<td>baremetal</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>37m</td>
</tr>
<tr>
<td>cloud-credential</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>40m</td>
</tr>
<tr>
<td>cluster-autoscaler</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>37m</td>
</tr>
<tr>
<td>config-operator</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>38m</td>
</tr>
</tbody>
</table>
2. Configure the Operators that are not available.

22.5.22.1. Image registry removed during installation

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as **Removed**. This allows `openshift-installer` to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the `managementState` from **Removed** to **Managed**.

22.5.22.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the **Recreate** rollout strategy during upgrades.

22.5.22.2.1. Configuring registry storage for VMware vSphere

As a cluster administrator, following installation you must configure your registry to use storage.
Prerequisites

- Cluster administrator permissions.
- A cluster on VMware vSphere.
- Persistent storage provisioned for your cluster, such as Red Hat OpenShift Data Foundation.

**IMPORTANT**

OpenShift Container Platform supports *ReadWriteOnce* access for image registry storage when you have only one replica. *ReadWriteOnce* access also requires that the registry uses the *Recreate* rollout strategy. To deploy an image registry that supports high availability with two or more replicas, *ReadWriteMany* access is required.

- Must have "100Gi" capacity.

**IMPORTANT**

Testing shows issues with using the NFS server on RHEL as storage backend for core services. This includes the OpenShift Container Registry and Quay, Prometheus for monitoring storage, and Elasticsearch for logging storage. Therefore, using RHEL NFS to back PVs used by core services is not recommended.

Other NFS implementations on the marketplace might not have these issues. Contact the individual NFS implementation vendor for more information on any testing that was possibly completed against these OpenShift Container Platform core components.

Procedure

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

**NOTE**

When you use shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

   ```
   $ oc get pod -n openshift-image-registry -l docker-registry=default
   ```

   **Example output**

   ```
   No resources found in openshift-image-registry namespace
   ```

   **NOTE**

   If you do have a registry pod in your output, you do not need to continue with this procedure.
3. Check the registry configuration:

$ oc edit configs.imageregistry.operator.openshift.io

**Example output**

```
storage:
pvc:
  claim: 1
```

Leave the **claim** field blank to allow the automatic creation of an **image-registry-storage** persistent volume claim (PVC). The PVC is generated based on the default storage class. However, be aware that the default storage class might provide ReadWriteOnce (RWO) volumes, such as a RADOS Block Device (RBD), which can cause issues when you replicate to more than one replica.

4. Check the **clusteroperator** status:

$ oc get clusteroperator image-registry

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
<th>SINCE</th>
<th>MESSAGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>image-registry</td>
<td>4.7</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>6h50m</td>
<td></td>
</tr>
</tbody>
</table>

**22.5.22.2.2. Configuring storage for the image registry in non-production clusters**

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

**Procedure**

- To set the image registry storage to an empty directory:

```
$ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec":
{"storage":{"emptyDir":[]}}}'
```

**WARNING**

Configure this option for only non-production clusters.

If you run this command before the Image Registry Operator initializes its components, the **oc patch** command fails with the following error:

```
Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
```
Wait a few minutes and run the command again.

22.5.22.2.3. Configuring block registry storage for VMware vSphere

To allow the image registry to use block storage types such as vSphere Virtual Machine Disk (VMDK) during upgrades as a cluster administrator, you can use the **Recreate** rollout strategy.

**IMPORTANT**

Block storage volumes are supported but not recommended for use with image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

**Procedure**

1. To set the image registry storage as a block storage type, patch the registry so that it uses the **Recreate** rollout strategy and runs with only 1 replica:

   ```bash
   $ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec":
   {"rolloutStrategy":"Recreate","replicas":1}}'
   ```

2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.
   a. Create a **pvc.yaml** file with the following contents to define a VMware vSphere **PersistentVolumeClaim** object:

   ```yaml
   kind: PersistentVolumeClaim
   apiVersion: v1
   metadata:
     name: image-registry-storage
     namespace: openshift-image-registry
   spec:
     accessModes:
     - ReadWriteOnce
     resources:
       requests:
         storage: 100Gi
   ```

   1. A unique name that represents the **PersistentVolumeClaim** object.
   2. The namespace for the **PersistentVolumeClaim** object, which is **openshift-image-registry**.
   3. The access mode of the persistent volume claim. With **ReadWriteOnce**, the volume can be mounted with read and write permissions by a single node.
   4. The size of the persistent volume claim.

   b. Create the **PersistentVolumeClaim** object from the file:

   ```bash
   $ oc create -f pvc.yaml -n openshift-image-registry
   ```
3. Edit the registry configuration so that it references the correct PVC:

```
$ oc edit config.imageregistry.operator.openshift.io -o yaml
```

**Example output**

```
storage:
pvc:
  claim: 1
```

By creating a custom PVC, you can leave the `claim` field blank for the default automatic creation of an `image-registry-storage` PVC.

For instructions about configuring registry storage so that it references the correct PVC, see [Configuring the registry for vSphere](#).

### 22.5.23. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

**Prerequisites**

- Your control plane has initialized.
- You have completed the initial Operator configuration.

**Procedure**

1. Confirm that all the cluster components are online with the following command:

```
$ watch -n5 oc get clusteroperators
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>

</tbody>
</table>
Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```
$ ./openshift-install --dir <installation_directory> wait-for install-complete
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

**Example output**

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

2. Confirm that the Kubernetes API server is communicating with the pods.
   a. To view a list of all pods, use the following command:

```
$ oc get pods --all-namespaces
```
Example output

<table>
<thead>
<tr>
<th>NAMESPACE</th>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>openshift-apiserver-operator</td>
<td>openshift-apiserver-operator-85cb746d55-zqhs8</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td></td>
<td>Running 1 9m</td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apiserver-67b9g</td>
<td>1/1</td>
<td>Running 0</td>
</tr>
<tr>
<td></td>
<td>Running 3m</td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apiserver-ljcmx</td>
<td>1/1</td>
<td>Running 0</td>
</tr>
<tr>
<td></td>
<td>Running 1m</td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apiserver-z25h4</td>
<td>1/1</td>
<td>Running 0</td>
</tr>
<tr>
<td></td>
<td>Running 2m</td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-authentication-operator</td>
<td>authentication-operator-69d5d8bf84-vh2n8</td>
<td>1/1</td>
<td>Running 0</td>
</tr>
<tr>
<td></td>
<td>Running 0 5m</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

b. View the logs for a pod that is listed in the output of the previous command by using the following command:

```
$ oc logs <pod_name> -n <namespace>
```

1. Specify the pod name and namespace, as shown in the output of the previous command.

If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation.

See “Enabling multipathing with kernel arguments on RHCOS” in the Post-installation machine configuration tasks documentation for more information.

You can add extra compute machines after the cluster installation is completed by following Adding compute machines to vSphere.

### 22.5.24. Configuring vSphere DRS anti-affinity rules for control plane nodes

vSphere Distributed Resource Scheduler (DRS) anti-affinity rules can be configured to support higher availability of OpenShift Container Platform Control Plane nodes. Anti-affinity rules ensure that the vSphere Virtual Machines for the OpenShift Container Platform Control Plane nodes are not scheduled to the same vSphere Host.

**IMPORTANT**

- The following information applies to compute DRS only and does not apply to storage DRS.

- The `govc` command is an open-source command available from VMware; it is not available from Red Hat. The `govc` command is not supported by the Red Hat support.

- Instructions for downloading and installing `govc` are found on the VMware documentation website.
Create an anti-affinity rule by running the following command:

**Example command**

```
$ govc cluster.rule.create \
   -name openshift4-control-plane-group \
   -dc MyDatacenter -cluster MyCluster \
   -enable \
   -anti-affinity master-0 master-1 master-2
```

After creating the rule, your control plane nodes are automatically migrated by vSphere so they are not running on the same hosts. This might take some time while vSphere reconciles the new rule. Successful command completion is shown in the following procedure.

**NOTE**

The migration occurs automatically and might cause brief OpenShift API outage or latency until the migration finishes.

The vSphere DRS anti-affinity rules need to be updated manually in the event of a control plane VM name change or migration to a new vSphere Cluster.

**Procedure**

1. Remove any existing DRS anti-affinity rule by running the following command:

```
$ govc cluster.rule.remove \
   -name openshift4-control-plane-group \
   -dc MyDatacenter -cluster MyCluster
```

**Example Output**

```
[13-10-22 09:33:24] Reconfigure /MyDatacenter/host/MyCluster...OK
```

2. Create the rule again with updated names by running the following command:

```
$ govc cluster.rule.create \
   -name openshift4-control-plane-group \
   -dc MyDatacenter -cluster MyOtherCluster \
   -enable \
   -anti-affinity master-0 master-1 master-2
```

22.5.25. **Backing up VMware vSphere volumes**

OpenShift Container Platform provisions new volumes as independent persistent disks to freely attach and detach the volume on any node in the cluster. As a consequence, it is not possible to back up volumes that use snapshots, or to restore volumes from snapshots. See [Snapshot Limitations](#) for more information.

**Procedure**

To create a backup of persistent volumes:
1. Stop the application that is using the persistent volume.
2. Clone the persistent volume.
3. Restart the application.
4. Create a backup of the cloned volume.
5. Delete the cloned volume.

22.5.26. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager Hybrid Cloud Console.

After you confirm that your OpenShift Cluster Manager Hybrid Cloud Console inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources
- See About remote health monitoring for more information about the Telemetry service

22.5.27. Next steps
- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- Set up your registry and configure registry storage.
- Optional: View the events from the vSphere Problem Detector Operator to determine if the cluster has permission or storage configuration issues.
- Optional: if you created encrypted virtual machines, create an encrypted storage class.

22.6. INSTALLING A CLUSTER ON VSPHERE WITH NETWORK CUSTOMIZATIONS

In OpenShift Container Platform version 4.14, you can install a cluster on VMware vSphere infrastructure that you provision with customized network configuration options. By customizing your network configuration, your cluster can coexist with existing IP address allocations in your environment and integrate with existing MTU and VXLAN configurations.

NOTE

OpenShift Container Platform supports deploying a cluster to a single VMware vCenter only. Deploying a cluster with machines/machine sets on multiple vCenters is not supported.
You must set most of the network configuration parameters during installation, and you can modify only `kubeProxy` configuration parameters in a running cluster.

**IMPORTANT**

The steps for performing a user-provisioned infrastructure installation are provided as an example only. Installing a cluster with infrastructure you provide requires knowledge of the vSphere platform and the installation process of OpenShift Container Platform. Use the user-provisioned infrastructure installation instructions as a guide; you are free to create the required resources through other methods.

### 22.6.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- Completing the installation requires that you upload the Red Hat Enterprise Linux CoreOS (RHCOS) OVA on vSphere hosts. The machine from which you complete this process requires access to port 443 on the vCenter and ESXi hosts. Verify that port 443 is accessible.
- If you use a firewall, you confirmed with the administrator that port 443 is accessible. Control plane nodes must be able to reach vCenter and ESXi hosts on port 443 for the installation to succeed.
- If you use a firewall, you configured it to allow the sites that your cluster requires access to.

### 22.6.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager Hybrid Cloud Console to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 22.6.3. VMware vSphere infrastructure requirements
You must install the OpenShift Container Platform cluster on a VMware vSphere version 7.0 Update 2 or later instance that meets the requirements for the components that you use.

**NOTE**

OpenShift Container Platform version 4.14 supports VMware vSphere version 8.0.

You can host the VMware vSphere infrastructure on-premise or on a VMware Cloud Verified provider that meets the requirements outlined in the following tables:

**Table 22.39. Version requirements for vSphere virtual environments**

<table>
<thead>
<tr>
<th>Virtual environment product</th>
<th>Required version</th>
</tr>
</thead>
<tbody>
<tr>
<td>VMware virtual hardware</td>
<td>15 or later</td>
</tr>
<tr>
<td>vSphere ESXi hosts</td>
<td>7.0 Update 2 or later</td>
</tr>
<tr>
<td>vCenter host</td>
<td>7.0 Update 2 or later</td>
</tr>
</tbody>
</table>

**IMPORTANT**

You must ensure that the time on your ESXi hosts is synchronized before you install OpenShift Container Platform. See *Edit Time Configuration for a Host* in the VMware documentation.

**Table 22.40. Minimum supported vSphere version for VMware components**

<table>
<thead>
<tr>
<th>Component</th>
<th>Minimum supported versions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hypervisor</td>
<td>vSphere 7.0 Update 2 and later with virtual hardware version 15</td>
<td>This version is the minimum version that Red Hat Enterprise Linux CoreOS (RHCOS) supports. For more information about supported hardware on the latest version of Red Hat Enterprise Linux (RHEL) that is compatible with RHCOS, see Hardware on the Red Hat Customer Portal.</td>
</tr>
<tr>
<td>Storage with in-tree drivers</td>
<td>vSphere 7.0 Update 2 and later</td>
<td>This plugin creates vSphere storage by using the in-tree storage drivers for vSphere included in OpenShift Container Platform.</td>
</tr>
</tbody>
</table>
### IMPORTANT

To ensure the best performance conditions for your cluster workloads that operate on Oracle® Cloud Infrastructure and on the Oracle® Cloud VMware Solution (OCVS) service, ensure volume performance units (VPUs) for your block volume are sized for your workloads.

The following list provides some guidance in selecting the VPUs needed for specific performance needs:

- **Test or proof of concept environment**: 100 GB, and 20 to 30 VPUs.
- **Base-production environment**: 500 GB, and 60 VPUs.
- **Heavy-use production environment**: More than 500 GB, and 100 or more VPUs.

Consider allocating additional VPUs to give enough capacity for updates and scaling activities. See [Block Volume Performance Levels](https://docs.oracle.com/en-us/iaas/compute/index.html#block) in the Oracle documentation.

### 22.6.4. VMware vSphere CSI Driver Operator requirements

To install the vSphere CSI Driver Operator, the following requirements must be met:

- VMware vSphere version 7.0 Update 2 or later
- vCenter 7.0 Update 2 or later
- Virtual machines of hardware version 15 or later
- No third-party vSphere CSI driver already installed in the cluster

If a third-party vSphere CSI driver is present in the cluster, OpenShift Container Platform does not overwrite it. The presence of a third-party vSphere CSI driver prevents OpenShift Container Platform from updating to OpenShift Container Platform 4.13 or later.

### NOTE

The VMware vSphere CSI Driver Operator is supported only on clusters deployed with platform: vsphere in the installation manifest.

### Additional resources

- To remove a third-party vSphere CSI driver, see [Removing a third-party vSphere CSI Driver](https://docs.openshift.com/container-platform/4.13/install-guide/cluster-upgrade/removing-csi-driver.html).
22.6.5. Requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines. This section describes the requirements for deploying OpenShift Container Platform on user-provisioned infrastructure.

22.6.5.1. vCenter requirements

Before you install an OpenShift Container Platform cluster on your vCenter that uses infrastructure that you provided, you must prepare your environment.

**Required vCenter account privileges**

To install an OpenShift Container Platform cluster in a vCenter, your vSphere account must include privileges for reading and creating the required resources. Using an account that has global administrative privileges is the simplest way to access all of the necessary permissions.

**Example 22.16. Roles and privileges required for installation in vSphere API**

<table>
<thead>
<tr>
<th>vSphere object for role</th>

For more information about creating an account with only the required privileges, see [vSphere Permissions and User Management Tasks](#) in the vSphere documentation.

### Using OpenShift Container Platform with vMotion

If you intend on using vMotion in your vSphere environment, consider the following before installing an OpenShift Container Platform cluster.

- **OpenShift Container Platform generally supports compute-only vMotion**, where generally implies that you meet all VMware best practices for vMotion.
  
  To help ensure the uptime of your compute and control plane nodes, ensure that you follow the VMware best practices for vMotion, and use VMware anti-affinity rules to improve the availability of OpenShift Container Platform during maintenance or hardware issues.

  For more information about vMotion and anti-affinity rules, see the VMware vSphere documentation for [vMotion networking requirements](#) and [VM anti-affinity rules](#).

- **Using Storage vMotion can cause issues and is not supported.** If you are using vSphere volumes in your pods, migrating a VM across datastores, either manually or through Storage vMotion, causes invalid references within OpenShift Container Platform persistent volume (PV) objects that can result in data loss.

- **OpenShift Container Platform does not support selective migration of VMDKs across datastores**, using datastore clusters for VM provisioning or for dynamic or static provisioning of PVs, or using a datastore that is part of a datastore cluster for dynamic or static provisioning of PVs.

  **IMPORTANT**

  You can specify the path of any datastore that exists in a datastore cluster. By default, Storage Distributed Resource Scheduler (SDRS), which uses Storage vMotion, is automatically enabled for a datastore cluster. Red Hat does not support Storage vMotion, so you must disable Storage DRS to avoid data loss issues for your OpenShift Container Platform cluster.

  If you must specify VMs across multiple datastores, use a **datastore object** to specify a failure domain in your cluster’s `install-config.yaml` configuration file. For more information, see “VMware vSphere region and zone enablement”.

### Cluster resources

When you deploy an OpenShift Container Platform cluster that uses infrastructure that you provided, you must create the following resources in your vCenter instance:

- 1 Folder
- 1 Tag category
- 1 Tag
Virtual machines:
- 1 template
- 1 temporary bootstrap node
- 3 control plane nodes
- 3 compute machines

Although these resources use 856 GB of storage, the bootstrap node is destroyed during the cluster installation process. A minimum of 800 GB of storage is required to use a standard cluster.

If you deploy more compute machines, the OpenShift Container Platform cluster will use more storage.

**Cluster limits**
Available resources vary between clusters. The number of possible clusters within a vCenter is limited primarily by available storage space and any limitations on the number of required resources. Be sure to consider both limitations to the vCenter resources that the cluster creates and the resources that you require to deploy a cluster, such as IP addresses and networks.

**Networking requirements**
Use Dynamic Host Configuration Protocol (DHCP) for the network and ensure that the DHCP server is configured to provide persistent IP addresses to the cluster machines.

**NOTE**
You do not need to use the DHCP for the network if you want to provision nodes with static IP addresses.

Configure the default gateway to use the DHCP server. All nodes must be in the same VLAN. You cannot scale the cluster using a second VLAN as a Day 2 operation.

You must use the Dynamic Host Configuration Protocol (DHCP) for the network and ensure that the DHCP server is configured to provide persistent IP addresses to the cluster machines. In the DHCP lease, you must configure the DHCP to use the default gateway. All nodes must be in the same VLAN. You cannot scale the cluster using a second VLAN as a Day 2 operation.

Additionally, you must create the following networking resources before you install the OpenShift Container Platform cluster:

**NOTE**
It is recommended that each OpenShift Container Platform node in the cluster must have access to a Network Time Protocol (NTP) server that is discoverable via DHCP. Installation is possible without an NTP server. However, asynchronous server clocks will cause errors, which NTP server prevents.

**Required IP Addresses**

**DNS records**
You must create DNS records for two static IP addresses in the appropriate DNS server for the vCenter instance that hosts your OpenShift Container Platform cluster. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the cluster base domain that you specify when you install the cluster. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>`.
### Table 22.41. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>API VIP</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>This DNS A/AAAA or CNAME record must point to the load balancer for the control plane machines. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Ingress VIP</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A wildcard DNS A/AAAA or CNAME record that points to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>

### Additional resources
- Creating a compute machine set on vSphere

### 22.6.5.2. Required machines for cluster installation

The smallest OpenShift Container Platform clusters require the following hosts:

### Table 22.42. Minimum required hosts

<table>
<thead>
<tr>
<th>Hosts</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>One temporary bootstrap machine</td>
<td>The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.</td>
</tr>
<tr>
<td>Three control plane machines</td>
<td>The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.</td>
</tr>
<tr>
<td>At least two compute machines, which are also known as worker machines.</td>
<td>The workloads requested by OpenShift Container Platform users run on the compute machines.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

To maintain high availability of your cluster, use separate physical hosts for these cluster machines.
The bootstrap and control plane machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system. However, the compute machines can choose between Red Hat Enterprise Linux CoreOS (RHCOS), Red Hat Enterprise Linux (RHEL) 8.6 and later.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 9.2 and inherits all of its hardware certifications and requirements. See Red Hat Enterprise Linux technology capabilities and limits.

22.6.5.3. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

Table 22.43. Minimum resource requirements

<table>
<thead>
<tr>
<th>Machine</th>
<th>Operating System</th>
<th>vCPU</th>
<th>Virtual RAM</th>
<th>Storage</th>
<th>Input/Output Per Second (IOPS)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS, RHEL 8.6 and later</td>
<td>2</td>
<td>8 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
</tbody>
</table>

1. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.

2. As with all user-provisioned installations, if you choose to use RHEL compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and has been removed in OpenShift Container Platform 4.10 and later.

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

Additional resources

- Optimizing storage

22.6.5.4. Requirements for encrypting virtual machines

You can encrypt your virtual machines prior to installing OpenShift Container Platform 4.14 by meeting the following requirements.

- You have configured a Standard key provider in vSphere. For more information, see Adding a KMS to vCenter Server.
IMPORTANT

The Native key provider in vCenter is not supported. For more information, see vSphere Native Key Provider Overview.

- You have enabled host encryption mode on all of the ESXi hosts that are hosting the cluster. For more information, see Enabling host encryption mode.
- You have a vSphere account which has all cryptographic privileges enabled. For more information, see Cryptographic Operations Privileges.

When you deploy the OVF template in the section titled "Installing RHCOS and starting the OpenShift Container Platform bootstrap process", select the option to "Encrypt this virtual machine" when you are selecting storage for the OVF template. After completing cluster installation, create a storage class that uses the encryption storage policy you used to encrypt the virtual machines.

Additional resources

- Creating an encrypted storage class

22.6.5.5. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The kube-controller-manager only approves the kubelet client CSRs. The machine approver cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

22.6.5.6. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in initramfs during boot to fetch their Ignition config files.

During the initial boot, the machines require an IP address configuration that is set either through a DHCP server or statically by providing the required boot options. After a network connection is established, the machines download their Ignition config files from an HTTP or HTTPS server. The Ignition config files are then used to set the exact state of each machine. The Machine Config Operator completes more changes to the machines, such as the application of new certificates or keys, after installation.

It is recommended to use a DHCP server for long-term management of the cluster machines. Ensure that the DHCP server is configured to provide persistent IP addresses, DNS server information, and hostnames to the cluster machines.

NOTE

If a DHCP service is not available for your user-provisioned infrastructure, you can instead provide the IP networking configuration and the address of the DNS server to the nodes at RHCOS install time. These can be passed as boot arguments if you are installing from an ISO image. See the Installing RHCOS and starting the OpenShift Container Platform bootstrap process section for more information about static IP provisioning and advanced networking options.
The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

22.6.5.6.1. Setting the cluster node hostnames through DHCP

On Red Hat Enterprise Linux CoreOS (RHCOS) machines, the hostname is set through NetworkManager. By default, the machines obtain their hostname through DHCP. If the hostname is not provided by DHCP, set statically through kernel arguments, or another method, it is obtained through a reverse DNS lookup. Reverse DNS lookup occurs after the network has been initialized on a node and can take time to resolve. Other system services can start prior to this and detect the hostname as localhost or similar. You can avoid this by using DHCP to provide the hostname for each cluster node.

Additionally, setting the hostnames through DHCP can bypass any manual DNS record name configuration errors in environments that have a DNS split-horizon implementation.

22.6.5.6.2. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

**IMPORTANT**

In connected OpenShift Container Platform environments, all nodes are required to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

Table 22.44. Ports used for all-machine to all-machine communications

Ethernet adaptor hardware address requirements
When provisioning VMs for the cluster, the ethernet interfaces configured for each VM must use a MAC address from the VMware Organizationally Unique Identifier (OUI) allocation ranges:

- 00:05:69:00:00:00 to 00:05:69:FF:FF
- 00:0c:29:00:00:00 to 00:0c:29:FF:FF
- 00:1c:14:00:00:00 to 00:1c:14:FF:FF
- 00:50:56:00:00:00 to 00:50:56:3F:FF

If a MAC address outside the VMware OUI is used, the cluster installation will not succeed.

NTP configuration for user-provisioned infrastructure
OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for Configuring chrony time service.

If a DHCP server provides NTP server information, the chrony time service on the Red Hat Enterprise Linux CoreOS (RHCOS) machines read the information and can sync the clock with the NTP servers.

Additional resources
22.6.5.7. User-provisioned DNS requirements

In OpenShift Container Platform deployments, DNS name resolution is required for the following components:

- The Kubernetes API
- The OpenShift Container Platform application wildcard
- The bootstrap, control plane, and compute machines

Reverse DNS resolution is also required for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the hostnames for all the nodes, unless the hostnames are provided by DHCP. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

NOTE

It is recommended to use a DHCP server to provide the hostnames to each cluster node. See the DHCP recommendations for user-provisioned infrastructure section for more information.

The following DNS records are required for a user-provisioned OpenShift Container Platform cluster and they must be in place before installation. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>..<cluster_name>..<base_domain>`.`

Table 22.47. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes API</td>
<td>api.&lt;cluster_name&gt;..&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the API load balancer. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Component</td>
<td>Record</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>--------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| **api-int.<cluster_name>..<base_domain>** | A DNS A/AAAA or CNAME record, and a DNS PTR record, to internally identify the API load balancer. These records must be resolvable from all the nodes within the cluster. | **IMPORTANT**

The API server must be able to resolve the worker nodes by the hostnames that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods. |
| **Routes** | *.apps.<cluster_name>..<base_domain>** | A wildcard DNS A/AAAA or CNAME record that refers to the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.

For example, `console-openshift-console.apps.<cluster_name>..<base_domain>` is used as a wildcard route to the OpenShift Container Platform console. |
| **Bootstrap machine** | bootstrap.<cluster_name>..<base_domain>** | A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster. |
| **Control plane machines** | <master><n>..<cluster_name>..<base_domain>** | DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes. These records must be resolvable by the nodes within the cluster. |
| **Compute machines** | <worker><n>..<cluster_name>..<base_domain>** | DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster. |

**NOTE**

In OpenShift Container Platform 4.4 and later, you do not need to specify etcd host and SRV records in your DNS configuration.

**TIP**

You can use the `dig` command to verify name and reverse name resolution. See the section on *Validating DNS resolution for user-provisioned infrastructure* for detailed validation steps.
22.6.5.7.1. Example DNS configuration for user-provisioned clusters

This section provides A and PTR record configuration samples that meet the DNS requirements for deploying OpenShift Container Platform on user-provisioned infrastructure. The samples are not meant to provide advice for choosing one DNS solution over another.

In the examples, the cluster name is ocp4 and the base domain is example.com.

Example DNS A record configuration for a user-provisioned cluster

The following example is a BIND zone file that shows sample A records for name resolution in a user-provisioned cluster.

```

;EOF
```

1  Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer.

2  Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer and is used for internal cluster communications.

3  Provides reverse DNS resolution for the bootstrap machine.

4 5 6  Provides reverse DNS resolution for the control plane machines.
Provides reverse DNS resolution for the compute machines.

**NOTE**

A PTR record is not required for the OpenShift Container Platform application wildcard.

### 22.6.5.8. Load balancing requirements for user-provisioned infrastructure

Before you install OpenShift Container Platform, you must provision the API and application Ingress load balancing infrastructure. In production scenarios, you can deploy the API and application Ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

**NOTE**

If you want to deploy the API and application Ingress load balancers with a Red Hat Enterprise Linux (RHEL) instance, you must purchase the RHEL subscription separately.

The load balancing infrastructure must meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:

   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.

   - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

**IMPORTANT**

Do not configure session persistence for an API load balancer. Configuring session persistence for a Kubernetes API server might cause performance issues from excess application traffic for your OpenShift Container Platform cluster and the Kubernetes API that runs inside the cluster.

Configure the following ports on both the front and back of the load balancers:

**Table 22.48. API load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the /readyz endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
</tbody>
</table>
Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>

**NOTE**

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the `/readyz` endpoint to the removal of the API server instance from the pool. Within the time frame after `/readyz` returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application Ingress load balancer**: Provides an ingress point for application traffic flowing in from outside the cluster. A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

**TIP**

If the true IP address of the client can be seen by the application Ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

Configure the following ports on both the front and back of the load balancers:

**Table 22.49. Application Ingress load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>
NOTE

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application Ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

22.6.5.8.1. Example load balancer configuration for user-provisioned clusters

This section provides an example API and application Ingress load balancer configuration that meets the load balancing requirements for user-provisioned clusters. The sample is an /etc/haproxy/haproxy.cfg configuration for an HAProxy load balancer. The example is not meant to provide advice for choosing one load balancing solution over another.

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

NOTE

If you are using HAProxy as a load balancer and SELinux is set to enforcing, you must ensure that the HAProxy service can bind to the configured TCP port by running `setsebool -P haproxy_connect_any=1`.

Example 22.21. Sample API and application Ingress load balancer configuration

```
Example 22.21. Sample API and application Ingress load balancer configuration

global
    log 127.0.0.1 local2
    pidfile /var/run/haproxy.pid
    maxconn 4000
daemon
defaults
    mode http
    log global
doctrine dontlognull
    option http-server-close
    option redispatch
    retries 3
    timeout http-request 10s
    timeout queue 1m
    timeout connect 10s
    timeout client 1m
    timeout server 1m
    timeout http-keep-alive 10s
    timeout check 10s
    maxconn 3000
listen api-server-6443
    bind *:6443
    mode tcp
    server bootstrap bootstrap.ocp4.example.com:6443 check inter 1s backup
    server master0 master0.ocp4.example.com:6443 check inter 1s
    server master1 master1.ocp4.example.com:6443 check inter 1s
    server master2 master2.ocp4.example.com:6443 check inter 1s
listen machine-config-server-22623
```
Port 6443 handles the Kubernetes API traffic and points to the control plane machines.

The bootstrap entries must be in place before the OpenShift Container Platform cluster installation and they must be removed after the bootstrap process is complete.

Port 22623 handles the machine config server traffic and points to the control plane machines.

Port 443 handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

Port 80 handles the HTTP traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

NOTE
If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application Ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

TIP
If you are using HAProxy as a load balancer, you can check that the haproxy process is listening on ports 6443, 22623, 443, and 80 by running netstat -nltupe on the HAProxy node.

22.6.6. Preparing the user-provisioned infrastructure

Before you install OpenShift Container Platform on user-provisioned infrastructure, you must prepare the underlying infrastructure.

This section provides details about the high-level steps required to set up your cluster infrastructure in preparation for an OpenShift Container Platform installation. This includes configuring IP networking and network connectivity for your cluster nodes, enabling the required ports through your firewall, and
setting up the required DNS and load balancing infrastructure.

After preparation, your cluster infrastructure must meet the requirements outlined in the Requirements for a cluster with user-provisioned infrastructure section.

**Prerequisites**

- You have reviewed the OpenShift Container Platform 4.x Tested Integrations page.
- You have reviewed the infrastructure requirements detailed in the Requirements for a cluster with user-provisioned infrastructure section.

**Procedure**

1. If you are using DHCP to provide the IP networking configuration to your cluster nodes, configure your DHCP service.
   
   a. Add persistent IP addresses for the nodes to your DHCP server configuration. In your configuration, match the MAC address of the relevant network interface to the intended IP address for each node.

   b. When you use DHCP to configure IP addressing for the cluster machines, the machines also obtain the DNS server information through DHCP. Define the persistent DNS server address that is used by the cluster nodes through your DHCP server configuration.

   **NOTE**
   
   If you are not using a DHCP service, you must provide the IP networking configuration and the address of the DNS server to the nodes at RHCOS install time. These can be passed as boot arguments if you are installing from an ISO image. See the Installing RHCOS and starting the OpenShift Container Platform bootstrap process section for more information about static IP provisioning and advanced networking options.

   c. Define the hostnames of your cluster nodes in your DHCP server configuration. See the Setting the cluster node hostnames through DHCP section for details about hostname considerations.

   **NOTE**
   
   If you are not using a DHCP service, the cluster nodes obtain their hostname through a reverse DNS lookup.

2. Ensure that your network infrastructure provides the required network connectivity between the cluster components. See the Networking requirements for user-provisioned infrastructure section for details about the requirements.

3. Configure your firewall to enable the ports required for the OpenShift Container Platform cluster components to communicate. See Networking requirements for user-provisioned infrastructure section for details about the ports that are required.
IMPORTANT

By default, port 1936 is accessible for an OpenShift Container Platform cluster, because each control plane node needs access to this port.

Avoid using the Ingress load balancer to expose this port, because doing so might result in the exposure of sensitive information, such as statistics and metrics, related to Ingress Controllers.

4. Setup the required DNS infrastructure for your cluster.
   a. Configure DNS name resolution for the Kubernetes API, the application wildcard, the bootstrap machine, the control plane machines, and the compute machines.
   b. Configure reverse DNS resolution for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.
      See the User-provisioned DNS requirements section for more information about the OpenShift Container Platform DNS requirements.

5. Validate your DNS configuration.
   a. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses in the responses correspond to the correct components.
   b. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names in the responses correspond to the correct components.
      See the Validating DNS resolution for user-provisioned infrastructure section for detailed DNS validation steps.

6. Provision the required API and application ingress load balancing infrastructure. See the Load balancing requirements for user-provisioned infrastructure section for more information about the requirements.

NOTE

Some load balancing solutions require the DNS name resolution for the cluster nodes to be in place before the load balancing is initialized.

22.6.7. Validating DNS resolution for user-provisioned infrastructure

You can validate your DNS configuration before installing OpenShift Container Platform on user-provisioned infrastructure.

IMPORTANT

The validation steps detailed in this section must succeed before you install your cluster.

Prerequisites

- You have configured the required DNS records for your user-provisioned infrastructure.

Procedure
1. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses contained in the responses correspond to the correct components.

   a. Perform a lookup against the Kubernetes API record name. Check that the result points to the IP address of the API load balancer:

   ```
   $ dig +noall +answer @<nameserver_ip> api.<cluster_name>.<base_domain>  
   ```

   Replace `<nameserver_ip>` with the IP address of the nameserver, `<cluster_name>` with your cluster name, and `<base_domain>` with your base domain name.

   **Example output**

   ```
   api.ocp4.example.com. 604800 IN A 192.168.1.5
   ```

   b. Perform a lookup against the Kubernetes internal API record name. Check that the result points to the IP address of the API load balancer:

   ```
   $ dig +noall +answer @<nameserver_ip> api-int.<cluster_name>.<base_domain>
   ```

   **Example output**

   ```
   api-int.ocp4.example.com. 604800 IN A 192.168.1.5
   ```

   c. Test an example `*.apps.<cluster_name>.<base_domain>` DNS wildcard lookup. All of the application wildcard lookups must resolve to the IP address of the application ingress load balancer:

   ```
   $ dig +noall +answer @<nameserver_ip> random.apps.<cluster_name>.<base_domain>
   ```

   **Example output**

   ```
   random.apps.ocp4.example.com. 604800 IN A 192.168.1.5
   ```

   **NOTE**

   In the example outputs, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

   You can replace random with another wildcard value. For example, you can query the route to the OpenShift Container Platform console:

   ```
   $ dig +noall +answer @<nameserver_ip> console-openshift-console.apps.<cluster_name>.<base_domain>
   ```

   **Example output**
d. Run a lookup against the bootstrap DNS record name. Check that the result points to the IP address of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> bootstrap.<cluster_name>.<base_domain>
```

**Example output**

```
bootstrap.ocp4.example.com.  604800 IN A 192.168.1.96
```

e. Use this method to perform lookups against the DNS record names for the control plane and compute nodes. Check that the results correspond to the IP addresses of each node.

2. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names contained in the responses correspond to the correct components.

a. Perform a reverse lookup against the IP address of the API load balancer. Check that the response includes the record names for the Kubernetes API and the Kubernetes internal API:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.5
```

**Example output**

```
5.1.168.192.in-addr.arpa. 604800 IN PTR api-int.ocp4.example.com. 1
5.1.168.192.in-addr.arpa. 604800 IN PTR api.ocp4.example.com. 2
```

1 Provides the record name for the Kubernetes internal API.

2 Provides the record name for the Kubernetes API.

**NOTE**

A PTR record is not required for the OpenShift Container Platform application wildcard. No validation step is needed for reverse DNS resolution against the IP address of the application ingress load balancer.

b. Perform a reverse lookup against the IP address of the bootstrap node. Check that the result points to the DNS record name of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.96
```

**Example output**

```
```

c. Use this method to perform reverse lookups against the IP addresses for the control plane and compute nodes. Check that the results correspond to the DNS record names of each node.
22.6.8. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The ./openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>  
   ```

   Specify the path and file name, such as ~/.ssh/id_ed25519, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   ```
   $ cat <path>/<file_name>.pub
   ```

   For example, run the following to view the ~/.ssh/id_ed25519.pub public key:

   ```
   $ cat ~/.ssh/id_ed25519.pub
   ```
3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

   **NOTE**

   On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

   a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

   ```bash
   $ eval "$(ssh-agent -s)"
   
   Example output
   
   Agent pid 31874
   
   **NOTE**

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

   ```bash
   $ ssh-add <path>/<file_name>
   
   Example output
   
   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
   
   **Next steps**

   * When you install OpenShift Container Platform, provide the SSH public key to the installation program.

---

**22.6.9. VMware vSphere region and zone enablement**

You can deploy an OpenShift Container Platform cluster to multiple vSphere datacenters that run in a single VMware vCenter. Each datacenter can run multiple clusters. This configuration reduces the risk of a hardware failure or network outage that can cause your cluster to fail.
**IMPORTANT**

The VMware vSphere region and zone enablement feature requires the vSphere Container Storage Interface (CSI) driver as the default storage driver in the cluster. As a result, the feature only available on a newly installed cluster.

A cluster that was upgraded from a previous release defaults to using the in-tree vSphere driver, so you must enable CSI automatic migration for the cluster. You can then configure multiple regions and zones for the upgraded cluster.

The default installation configuration deploys a cluster to a single vSphere datacenter. If you want to deploy a cluster to multiple vSphere datacenters, you must create an installation configuration file that enables the region and zone feature.

The default `install-config.yaml` file includes `vcenters` and `failureDomains` fields, where you can specify multiple vSphere datacenters and clusters for your OpenShift Container Platform cluster. You can leave these fields blank if you want to install an OpenShift Container Platform cluster in a vSphere environment that consists of single datacenter.

The following list describes terms associated with defining zones and regions for your cluster:

- **Failure domain**: Establishes the relationships between a region and zone. You define a failure domain by using vCenter objects, such as a *datastore* object. A failure domain defines the vCenter location for OpenShift Container Platform cluster nodes.

- **Region**: Specifies a vCenter datacenter. You define a region by using a tag from the `openshift-region` tag category.

- **Zone**: Specifies a vCenter cluster. You define a zone by using a tag from the `openshift-zone` tag category.

**NOTE**

If you plan on specifying more than one failure domain in your `install-config.yaml` file, you must create tag categories, zone tags, and region tags in advance of creating the configuration file.

You must create a vCenter tag for each vCenter datacenter, which represents a region. Additionally, you must create a vCenter tag for each cluster than runs in a datacenter, which represents a zone. After you create the tags, you must attach each tag to their respective datacenters and clusters.

The following table outlines an example of the relationship among regions, zones, and tags for a configuration with multiple vSphere datacenters running in a single VMware vCenter.

<table>
<thead>
<tr>
<th>Datacenter (region)</th>
<th>Cluster (zone)</th>
<th>Tags</th>
</tr>
</thead>
<tbody>
<tr>
<td>us-east</td>
<td>us-east-1</td>
<td>us-east-1a</td>
</tr>
<tr>
<td></td>

<td>us-west-2b</td>
</tr>
</tbody>
</table>

**Additional resources**

- Additional VMware vSphere configuration parameters
- Deprecated VMware vSphere configuration parameters
- vSphere automatic migration
- VMware vSphere CSI Driver Operator

### 22.6.10. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

**Prerequisites**

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

**Procedure**

1. Access the **Infrastructure Provider** page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.
Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   $ tar -xvf openshift-install-linux.tar.gz

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

22.6.11. Manually creating the installation configuration file

For user-provisioned installations of OpenShift Container Platform, you manually generate your installation configuration file.

The Cluster Cloud Controller Manager Operator performs a connectivity check on a provided hostname or IP address. Ensure that you specify a hostname or an IP address to a reachable vCenter server. If you provide metadata to a non-existent vCenter server, installation of the cluster fails at the bootstrap stage.

Prerequisites

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.

- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Create an installation directory to store your required installation assets in:

   $ mkdir <installation_directory>

   You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.
2. Customize the sample `install-config.yaml` file template that is provided and save it in the `<installation_directory>`.

**NOTE**

You must name this configuration file `install-config.yaml`.

**NOTE**

For some platform types, you can alternatively run `./openshift-install create install-config --dir <installation_directory>` to generate an `install-config.yaml` file. You can provide details about your cluster configuration at the prompts.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

**IMPORTANT**

The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.

Additional resources

- Installation configuration parameters

### 22.6.11.1. Sample `install-config.yaml` file for VMware vSphere

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster's platform or modify the values of the required parameters.

```yaml
additionalTrustBundlePolicy: Proxyonly
apiVersion: v1
baseDomain: example.com
compute:
  - architecture: amd64
    name: <worker_node>
    platform: {}
    replicas: 0
controlPlane:
  architecture: amd64
  name: <parent_node>
  platform: {}
  replicas: 3
metadata:
  creationTimestamp: null
  name: test
networking:
  ---
  platform:
    vsphere:
      failureDomains:
        - name: <failure_domain_name>
          region: <default_region_name>
          server: <fully_qualified_domain_name>
```
The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

The **controlPlane** section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the `compute` section must begin with a hyphen, `-`, and the first line of the `controlPlane` section must not. Both sections define a single machine pool, so only one control plane is used. OpenShift Container Platform does not support defining multiple compute pools.

You must set the value of the `replicas` parameter to **0**. This parameter controls the number of workers that the cluster creates and manages for you, which are functions that the cluster does not perform when you use user-provisioned infrastructure. You must manually deploy worker machines for the cluster to use before you finish installing OpenShift Container Platform.

The number of control plane machines that you add to the cluster. Because the cluster uses this values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

The cluster name that you specified in your DNS records.

Establishes the relationships between a region and zone. You define a failure domain by using vCenter objects, such as a `datastore` object. A failure domain defines the vCenter location for OpenShift Container Platform cluster nodes.

The vSphere datacenter.

The path to the vSphere datastore that holds virtual machine files, templates, and ISO images.
IMPORTANT

You can specify the path of any datastore that exists in a datastore cluster. By default, Storage vMotion is automatically enabled for a datastore cluster. Red Hat does not support Storage vMotion, so you must disable Storage vMotion to avoid data loss issues for your OpenShift Container Platform cluster.

If you must specify VMs across multiple datastores, use a datastore object to specify a failure domain in your cluster’s install-config.yaml configuration file. For more information, see “VMware vSphere region and zone enablement.”

Optional: For installer-provisioned infrastructure, the absolute path of an existing resource pool where the installation program creates the virtual machines, for example, /<datacenter_name>/host/<cluster_name>/Resources/<resource_pool_name>/<optional_nested_resource_pool_name>. If you do not specify a value, resources are installed in the root of the cluster /example_datacenter/host/example_cluster/Resources.

Optional: For installer-provisioned infrastructure, the absolute path of an existing folder where the installation program creates the virtual machines, for example, /<datacenter_name>/vm/<folder_name>/<subfolder_name>. If you do not provide this value, the installation program creates a top-level folder in the datacenter virtual machine folder that is named with the infrastructure ID. If you are providing the infrastructure for the cluster and you do not want to use the default StorageClass object, named thin, you can omit the folder parameter from the install-config.yaml file.

The password associated with the vSphere user.

The fully-qualified hostname or IP address of the vCenter server.

IMPORTANT

The Cluster Cloud Controller Manager Operator performs a connectivity check on a provided hostname or IP address. Ensure that you specify a hostname or an IP address to a reachable vCenter server. If you provide metadata to a non-existent vCenter server, installation of the cluster fails at the bootstrap stage.

The vSphere disk provisioning method.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

IMPORTANT

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see Installing the system in FIPS mode. When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures.
The pull secret that you obtained from OpenShift Cluster Manager Hybrid Cloud Console. This pull secret allows you to authenticate with the services that are provided by the included authorities.

The public portion of the default SSH key for the core user in Red Hat Enterprise Linux CoreOS (RHCOS).

22.6.11.2. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the install-config.yaml file.

Prerequisites

- You have an existing install-config.yaml file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the Proxy object’s spec.noProxy field to bypass the proxy if necessary.

**NOTE**

The Proxy object status.noProxy field is populated with the values of the networking.machineNetwork[].cidr, networking.clusterNetwork[].cidr, and networking.serviceNetwork[] fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object status.noProxy field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your install-config.yaml file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port> 1
  httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
  noProxy: example.com 3
additionalTrustBundle: |
  -----BEGIN CERTIFICATE-----
  <MY_TRUSTED_CA_CERT>
  -----END CERTIFICATE-----
additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> 5
```

1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.

2. A proxy URL to use for creating HTTPS connections outside the cluster.
3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For

4. If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the trustedCA field of the Proxy object. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

5. Optional: The policy to determine the configuration of the Proxy object to reference the user-ca-bundle config map in the trustedCA field. The allowed values are Proxyonly and Always. Use Proxyonly to reference the user-ca-bundle config map only when http/https proxy is configured. Use Always to always reference the user-ca-bundle config map. The default value is Proxyonly.

NOTE

The installation program does not support the proxy readinessEndpoints field.

NOTE

If the installer times out, restart and then complete the deployment by using the wait-for command of the installer. For example:

```
$ ./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

NOTE

Only the Proxy object named cluster is supported, and no additional proxies can be created.

22.6.11.3. Configuring regions and zones for a VMware vCenter

You can modify the default installation configuration file, so that you can deploy an OpenShift Container Platform cluster to multiple vSphere datacenters that run in a single VMware vCenter.

The default install-config.yaml file configuration from the previous release of OpenShift Container Platform is deprecated. You can continue to use the deprecated default configuration, but the openshift-installer will prompt you with a warning message that indicates the use of deprecated fields in the configuration file.
IMPORTANT

The example uses the `govc` command. The `govc` command is an open source command available from VMware; it is not available from Red Hat. The Red Hat support team does not maintain the `govc` command. Instructions for downloading and installing `govc` are found on the VMware documentation website.

Prerequisites

- You have an existing `install-config.yaml` installation configuration file.

IMPORTANT

You must specify at least one failure domain for your OpenShift Container Platform cluster, so that you can provision datacenter objects for your VMware vCenter server. Consider specifying multiple failure domains if you need to provision virtual machine nodes in different datacenters, clusters, datastores, and other components.

Procedure

1. Enter the following `govc` command-line tool commands to create the `openshift-region` and `openshift-zone` vCenter tag categories:

   **IMPORTANT**
   If you specify different names for the `openshift-region` and `openshift-zone` vCenter tag categories, the installation of the OpenShift Container Platform cluster fails.

   ```bash
   $ govc tags.category.create -d "OpenShift region" openshift-region
   $ govc tags.category.create -d "OpenShift zone" openshift-zone
   ```

2. To create a region tag for each region vSphere datacenter where you want to deploy your cluster, enter the following command in your terminal:

   ```bash
   $ govc tags.create -c <region_tag_category> <region_tag>
   ```

3. To create a zone tag for each vSphere cluster where you want to deploy your cluster, enter the following command:

   ```bash
   $ govc tags.create -c <zone_tag_category> <zone_tag>
   ```

4. Attach region tags to each vCenter datacenter object by entering the following command:

   ```bash
   $ govc tags.attach -c <region_tag_category> <region_tag_1> /<datacenter_1>
   ```

5. Attach the zone tags to each vCenter datacenter object by entering the following command:

   ```bash
   $ govc tags.attach -c <zone_tag_category> <zone_tag_1> /<datacenter_1>/host/vcs-mdcnc-workload-1
   ```
6. Change to the directory that contains the installation program and initialize the cluster deployment according to your chosen installation requirements.

Sample install-config.yaml file with multiple datacenters defined in a vSphere center

---
compute:
  ---
  vsphere:
    zones:
      - "<machine_pool_zone_1>
      - "<machine_pool_zone_2>
  ---
controlPlane:
  ---
  vsphere:
    zones:
      - "<machine_pool_zone_1>
      - "<machine_pool_zone_2>
  ---
platform:
  vsphere:
    vcenters:
      ---
    datacenters:
      - <datacenter1_name>
      - <datacenter2_name>
    failureDomains:
      - name: <machine_pool_zone_1>
        region: <region_tag_1>
        zone: <zone_tag_1>
        server: <fully_qualified_domain_name>
        topology:
          datacenter: <datacenter1>
          computeCluster: "/<datacenter1>/host/<cluster1>"
          networks:
            - <VM_Network1_name>
            datastore: "/<datacenter1>/datastore/<datastore1>"
            resourcePool: "/<datacenter1>/host/<cluster1>/Resources/<resourcePool1>"
            folder: "/<datacenter1>/vm/<folder1>"
      - name: <machine_pool_zone_2>
        region: <region_tag_2>
        zone: <zone_tag_2>
        server: <fully_qualified_domain_name>
        topology:

          networks:
            - <VM_Network2_name>
            datastore: "/<datacenter2>/datastore/<datastore2>"
            resourcePool: "/<datacenter2>/host/<cluster2>/Resources/<resourcePool2>"
            folder: "/<datacenter2>/vm/<folder2>"
---

22.6.12. Network configuration phases
There are two phases prior to OpenShift Container Platform installation where you can customize the network configuration.

Phase 1

You can customize the following network-related fields in the install-config.yaml file before you create the manifest files:

- networking.networkType
- networking.clusterNetwork
- networking.serviceNetwork
- networking.machineNetwork

For more information on these fields, refer to Installation configuration parameters.

**NOTE**

Set the networking.machineNetwork to match the CIDR that the preferred NIC resides in.

**IMPORTANT**

The CIDR range 172.17.0.0/16 is reserved by libVirt. You cannot use this range or any range that overlaps with this range for any networks in your cluster.

Phase 2

After creating the manifest files by running openshift-install create manifests, you can define a customized Cluster Network Operator manifest with only the fields you want to modify. You can use the manifest to specify advanced network configuration.

You cannot override the values specified in phase 1 in the install-config.yaml file during phase 2. However, you can further customize the network plugin during phase 2.

22.6.13. Specifying advanced network configuration

You can use advanced network configuration for your network plugin to integrate your cluster into your existing network environment. You can specify advanced network configuration only before you install the cluster.

**IMPORTANT**

Customizing your network configuration by modifying the OpenShift Container Platform manifest files created by the installation program is not supported. Applying a manifest file that you create, as in the following procedure, is supported.

**Prerequisites**

- You have created the install-config.yaml file and completed any modifications to it.

**Procedure**
1. Change to the directory that contains the installation program and create the manifests:

   ```bash
   $ ./openshift-install create manifests --dir <installation_directory>
   ```

   `<installation_directory>` specifies the name of the directory that contains the `install-config.yaml` file for your cluster.

2. Create a stub manifest file for the advanced network configuration that is named `cluster-network-03-config.yml` in the `<installation_directory>/manifests/` directory:

   ```yaml
   apiVersion: operator.openshift.io/v1
   kind: Network
   metadata:
     name: cluster
   spec:
     defaultNetwork:
       openshiftSDNConfig:
         vxlanPort: 4800
   ```

3. Specify the advanced network configuration for your cluster in the `cluster-network-03-config.yml` file, such as in the following examples:

   **Specify a different VXLAN port for the OpenShift SDN network provider**

   ```yaml
   apiVersion: operator.openshift.io/v1
   kind: Network
   metadata:
     name: cluster
   spec:
     defaultNetwork:
       openshiftSDNConfig:
         vxlanPort: 4800
   ```

   **Enable IPsec for the OVN-Kubernetes network provider**

   ```yaml
   apiVersion: operator.openshift.io/v1
   kind: Network
   metadata:
     name: cluster
   spec:
     defaultNetwork:
       ovnKubernetesConfig:
         ipsecConfig: {}
   ```

4. Optional: Back up the `manifests/cluster-network-03-config.yml` file. The installation program consumes the `manifests/` directory when you create the Ignition config files.

5. Remove the Kubernetes manifest files that define the control plane machines and compute machineSets:

   ```bash
   $ rm -f openshift/99_openshift-cluster-api_master-machines-* .yaml openshift/99_openshift-cluster-api_worker-machineset-* .yaml
   ```

   Because you create and manage these resources yourself, you do not have to initialize them.
• You can preserve the MachineSet files to create compute machines by using the machine API, but you must update references to them to match your environment.

The configuration for the cluster network is specified as part of the Cluster Network Operator (CNO) configuration and stored in a custom resource (CR) object that is named `cluster`. The CR specifies the fields for the `Network` API in the `operator.openshift.io` API group.

The CNO configuration inherits the following fields during cluster installation from the `Network` API in the `Network.config.openshift.io` API group and these fields cannot be changed:

- `clusterNetwork` - IP address pools from which pod IP addresses are allocated.
- `serviceNetwork` - IP address pool for services.
- `defaultNetwork.type` - Cluster network plugin, such as OpenShift SDN or OVN-Kubernetes.

You can specify the cluster network plugin configuration for your cluster by setting the fields for the `defaultNetwork` object in the CNO object named `cluster`.

The fields for the Cluster Network Operator (CNO) are described in the following table:

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>metadata.name</td>
<td>string</td>
<td>The name of the CNO object. This name is always <code>cluster</code>.</td>
</tr>
<tr>
<td>spec.clusterNetwork</td>
<td>array</td>
<td>A list specifying the blocks of IP addresses from which pod IP addresses are allocated and the subnet prefix length assigned to each individual node in the cluster. For example:</td>
</tr>
</tbody>
</table>
|                    |          | spec:
|                    |          |  - clusterNetwork:
|                    |          |    - cidr: 10.128.0.0/19
|                    |          |    hostPrefix: 23
|                    |          |    - cidr: 10.128.32.0/19
|                    |          |    hostPrefix: 23
|                    |          | You can customize this field only in the `install-config.yaml` file before you create the manifests. The value is read-only in the manifest file. |
A block of IP addresses for services. The OpenShift SDN and OVN-Kubernetes network plugins support only a single IP address block for the service network. For example:

```
spec:
  serviceName:
    - 172.30.0.0/14
```

You can customize this field only in the `install-config.yaml` file before you create the manifests. The value is read-only in the manifest file.

You can customize this field only in the `install-config.yaml` file before you create the manifests. The value is read-only in the manifest file.

### spec.defaultNetwork object configuration

The values for the `defaultNetwork` object are defined in the following table:

#### Table 22.51. `defaultNetwork` object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>string</td>
<td>Either <strong>OpenShiftSDN</strong> or <strong>OVN-Kubernetes</strong>. The Red Hat OpenShift Networking network plugin is selected during installation. This value cannot be changed after cluster installation.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>NOTE</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>OpenShift Container Platform uses the OVN-Kubernetes network plugin by default.</td>
</tr>
<tr>
<td>openshiftSDNConfig</td>
<td>object</td>
<td>This object is only valid for the OpenShift SDN network plugin.</td>
</tr>
<tr>
<td>ovnKubernetesConfig</td>
<td>object</td>
<td>This object is only valid for the OVN-Kubernetes network plugin.</td>
</tr>
</tbody>
</table>

### Configuration for the OpenShift SDN network plugin

The following table describes the configuration fields for the OpenShift SDN network plugin:
### Table 22.52. openshiftSDNConfig object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mode</td>
<td>string</td>
<td>Configures the network isolation mode for OpenShift SDN. The default value is <code>NetworkPolicy</code>. The values <code>Multitenant</code> and <code>Subnet</code> are available for backwards compatibility with OpenShift Container Platform 3.x but are not recommended. This value cannot be changed after cluster installation.</td>
</tr>
<tr>
<td>mtu</td>
<td>integer</td>
<td>The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU. If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes. If your cluster requires different MTU values for different nodes, you must set this value to 50 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1450. This value cannot be changed after cluster installation.</td>
</tr>
<tr>
<td>vxlanPort</td>
<td>integer</td>
<td>The port to use for all VXLAN packets. The default value is 4789. This value cannot be changed after cluster installation. If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number. On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port 9000 and port 9999.</td>
</tr>
</tbody>
</table>

### Example OpenShift SDN configuration

```yaml
defaultNetwork:
  type: OpenShiftSDN
  openshiftSDNConfig:
    mode: NetworkPolicy
    mtu: 1450
    vxlanPort: 4789
```

### Configuration for the OVN-Kubernetes network plugin

The following table describes the configuration fields for the OVN-Kubernetes network plugin:
### Table 22.53. ovnKubernetesConfig object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mtu</td>
<td>integer</td>
<td>The maximum transmission unit (MTU) for the Geneve (Generic Network Virtualization Encapsulation) overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU. If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes. If your cluster requires different MTU values for different nodes, you must set this value to 100 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1400.</td>
</tr>
<tr>
<td>genevePort</td>
<td>integer</td>
<td>The port to use for all Geneve packets. The default value is 6081. This value cannot be changed after cluster installation.</td>
</tr>
<tr>
<td>ipsecConfig</td>
<td>object</td>
<td>Specify an empty object to enable IPsec encryption.</td>
</tr>
<tr>
<td>policyAuditConfig</td>
<td>object</td>
<td>Specify a configuration object for customizing network policy audit logging. If unset, the defaults audit log settings are used.</td>
</tr>
<tr>
<td>gatewayConfig</td>
<td>object</td>
<td>Optional: Specify a configuration object for customizing how egress traffic is sent to the node gateway.</td>
</tr>
</tbody>
</table>

**NOTE**

While migrating egress traffic, you can expect some disruption to workloads and service traffic until the Cluster Network Operator (CNO) successfully rolls out the changes.
If your existing network infrastructure overlaps with the **100.64.0.0/16** IPv4 subnet, you can specify a different IP address range for internal use by OVN-Kubernetes. You must ensure that the IP address range does not overlap with any other subnet used by your OpenShift Container Platform installation. The IP address range must be larger than the maximum number of nodes that can be added to the cluster. For example, if the `clusterNetwork.cidr` value is **10.128.0.0/14** and the `clusterNetwork.hostPrefix` value is **/23**, then the maximum number of nodes is $2^{(23-14)}=512$.

This field cannot be changed after installation.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>v4InternalSubnet</td>
<td>If your existing network infrastructure overlaps with the <strong>100.64.0.0/16</strong> IPv4 subnet, you can specify a different IP address range for internal use by OVN-Kubernetes. You must ensure that the IP address range does not overlap with any other subnet used by your OpenShift Container Platform installation. The IP address range must be larger than the maximum number of nodes that can be added to the cluster. For example, if the <code>clusterNetwork.cidr</code> value is <strong>10.128.0.0/14</strong> and the <code>clusterNetwork.hostPrefix</code> value is <strong>/23</strong>, then the maximum number of nodes is $2^{(23-14)}=512$. This field cannot be changed after installation.</td>
<td>The default value is <strong>100.64.0.0/16</strong>.</td>
</tr>
</tbody>
</table>
If your existing network infrastructure overlaps with the \texttt{fd98::/48} IPv6 subnet, you can specify a different IP address range for internal use by OVN-Kubernetes. You must ensure that the IP address range does not overlap with any other subnet used by your OpenShift Container Platform installation. The IP address range must be larger than the maximum number of nodes that can be added to the cluster.

This field cannot be changed after installation.

The default value is \texttt{fd98::/48}.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{v6InternalSubnet}</td>
<td></td>
<td>If your existing network infrastructure overlaps with the \texttt{fd98::/48} IPv6 subnet, you can specify a different IP address range for internal use by OVN-Kubernetes. You must ensure that the IP address range does not overlap with any other subnet used by your OpenShift Container Platform installation. The IP address range must be larger than the maximum number of nodes that can be added to the cluster. This field cannot be changed after installation.</td>
</tr>
</tbody>
</table>

The default value is \texttt{fd98::/48}.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{rateLimit}</td>
<td>integer</td>
<td>The maximum number of messages to generate every second per node. The default value is 20 messages per second.</td>
</tr>
<tr>
<td>\texttt{maxFileSize}</td>
<td>integer</td>
<td>The maximum size for the audit log in bytes. The default value is 50000000 or 50 MB.</td>
</tr>
</tbody>
</table>
One of the following additional audit log targets:

- **libc**
  - The libc **syslog()** function of the journald process on the host.

- **udp:<host>:<port>**
  - A syslog server. Replace `<host>:<port>` with the host and port of the syslog server.

- **unix:<file>**
  - A Unix Domain Socket file specified by `<file>`.

- **null**
  - Do not send the audit logs to any additional target.

The syslog facility, such as **kern**, as defined by RFC5424. The default value is **local0**.

<table>
<thead>
<tr>

**Table 22.55. gatewayConfig object**

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>routingViaHost</strong></td>
<td>boolean</td>
<td>Set this field to <strong>true</strong> to send egress traffic from pods to the host networking stack. For highly-specialized installations and applications that rely on manually configured routes in the kernel routing table, you might want to route egress traffic to the host networking stack. By default, egress traffic is processed in OVN to exit the cluster and is not affected by specialized routes in the kernel routing table. The default value is <strong>false</strong>.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>This field has an interaction with the Open vSwitch hardware offloading feature. If you set this field to <strong>true</strong>, you do not receive the performance benefits of the offloading because egress traffic is processed by the host networking stack.</td>
</tr>
<tr>
<td><strong>ipForwarding</strong></td>
<td>object</td>
<td>You can control IP forwarding for all traffic on OVN-Kubernetes managed interfaces by using the <strong>ipForwarding</strong> specification in the <strong>Network</strong> resource. Specify <strong>Restricted</strong> to only allow IP forwarding for Kubernetes related traffic. Specify <strong>Global</strong> to allow forwarding of all IP traffic. For new installations, the default is <strong>Restricted</strong>. For updates to OpenShift Container Platform 4.14, the default is <strong>Global</strong>.</td>
</tr>
</tbody>
</table>

**Example OVN-Kubernetes configuration with IPSec enabled**

```yaml
defaultNetwork:
  type: OVNKubernetes
ovnKubernetesConfig:
```
kubeProxyConfig object configuration

The values for the `kubeProxyConfig` object are defined in the following table:

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>iptablesSyncPeriod</code></td>
<td>string</td>
<td>The refresh period for <code>iptables</code> rules. The default value is <strong>30s</strong>. Valid suffixes include <strong>s</strong>, <strong>m</strong>, and <strong>h</strong> and are described in the Go time package documentation.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>NOTE</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Because of performance improvements introduced in OpenShift Container Platform 4.3 and greater, adjusting the <code>iptablesSyncPeriod</code> parameter is no longer necessary.</td>
</tr>
<tr>
<td><code>proxyArguments.iptables-min-sync-period</code></td>
<td>array</td>
<td>The minimum duration before refreshing <code>iptables</code> rules. This field ensures that the refresh does not happen too frequently. Valid suffixes include <strong>s</strong>, <strong>m</strong>, and <strong>h</strong> and are described in the Go time package. The default value is:</td>
</tr>
</tbody>
</table>

```
kubeProxyConfig:
  proxyArguments:
    iptables-min-sync-period: -0s
```

22.6.15. Creating the Ignition config files

Because you must manually start the cluster machines, you must generate the Ignition config files that the cluster needs to make its machines.
**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

**Prerequisites**

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

- Obtain the Ignition config files:

  ```bash
  $ ./openshift-install create ignition-configs --dir <installation_directory>
  
  For `<installation_directory>`, specify the directory name to store the files that the installation program creates.
  
  **IMPORTANT**

  If you created an `install-config.yaml` file, specify the directory that contains it. Otherwise, specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

  The following files are generated in the directory:

  - `auth`  
  - `kubeadmin-password`  
  - `kubeconfig`  
  - `bootstrap.ign`  
  - `master.ign`  
  - `metadata.json`  
  - `worker.ign`

**22.6.16. Extracting the infrastructure name**
The Ignition config files contain a unique cluster identifier that you can use to uniquely identify your cluster in VMware vSphere. If you plan to use the cluster identifier as the name of your virtual machine folder, you must extract it.

**Prerequisites**

- You obtained the OpenShift Container Platform installation program and the pull secret for your cluster.
- You generated the Ignition config files for your cluster.
- You installed the **jq** package.

**Procedure**

To extract and view the infrastructure name from the Ignition config file metadata, run the following command:

```
$ jq -r .infraID <installation_directory>/metadata.json
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

**Example output**

```
openshift-vw9j6
```

The output of this command is your cluster name and a random string.

**22.6.17. Installing RHCOS and starting the OpenShift Container Platform bootstrap process**

To install OpenShift Container Platform on user-provisioned infrastructure on VMware vSphere, you must install Red Hat Enterprise Linux CoreOS (RHCOS) on vSphere hosts. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS machines have rebooted.

**Prerequisites**

- You have obtained the Ignition config files for your cluster.
- You have access to an HTTP server that you can access from your computer and that the machines that you create can access.
- You have created a **vSphere cluster**.

**Procedure**
1. Upload the bootstrap Ignition config file, which is named `<installation_directory>/bootstrap.ign`, that the installation program created to your HTTP server. Note the URL of this file.

2. Save the following secondary Ignition config file for your bootstrap node to your computer as `<installation_directory>/merge-bootstrap.ign`:

   ```json
   {
   "ignition": {
   "config": {
   "merge": [{
   "source": "<bootstrap_ignition_config_url>",
   "verification": {} }
   ],
   "timeouts": {},
   "version": "3.2.0"
   },
   "networkd": {},
   "passwd": {},
   "storage": {},
   "systemd": {} }
   }
   
   1 Specify the URL of the bootstrap Ignition config file that you hosted.
   
   When you create the virtual machine (VM) for the bootstrap machine, you use this Ignition config file.

3. Locate the following Ignition config files that the installation program created:

   - `<installation_directory>/master.ign`
   - `<installation_directory>/worker.ign`
   - `<installation_directory>/merge-bootstrap.ign`

4. Convert the Ignition config files to Base64 encoding. Later in this procedure, you must add these files to the extra configuration parameter `guestinfo.ignition.config.data` in your VM. For example, if you use a Linux operating system, you can use the `base64` command to encode the files.

   ```bash
   $ base64 -w0 <installation_directory>/master.ign > <installation_directory>/master.64
   
   $ base64 -w0 <installation_directory>/worker.ign > <installation_directory>/worker.64
   
   $ base64 -w0 <installation_directory>/merge-bootstrap.ign > <installation_directory>/merge-bootstrap.64
   ```
IMPORTANT
If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

5. Obtain the RHCOS OVA image. Images are available from the RHCOS image mirror page.

IMPORTANT
The RHCOS images might not change with every release of OpenShift Container Platform. You must download an image with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image version that matches your OpenShift Container Platform version if it is available.

The filename contains the OpenShift Container Platform version number in the format `rhcos-vmware.<architecture>.ova`.

6. In the vSphere Client, create a folder in your datacenter to store your VMs.
   a. Click the VMs and Templates view.
   b. Right-click the name of your datacenter.
   c. Click New Folder → New VM and Template Folder.
   d. In the window that is displayed, enter the folder name. If you did not specify an existing folder in the `install-config.yaml` file, then create a folder with the same name as the infrastructure ID. You use this folder name so vCenter dynamically provisions storage in the appropriate location for its Workspace configuration.

7. In the vSphere Client, create a template for the OVA image and then clone the template as needed.

NOTE
In the following steps, you create a template and then clone the template for all of your cluster machines. You then provide the location for the Ignition config file for that cloned machine type when you provision the VMs.

   a. From the Hosts and Clusters tab, right-click your cluster name and select Deploy OVF Template.
   b. On the Select an OVF tab, specify the name of the RHCOS OVA file that you downloaded.
   c. On the Select a name and folder tab, set a Virtual machine name for your template, such as Template-RHCOS. Click the name of your vSphere cluster and select the folder you created in the previous step.
   d. On the Select a compute resource tab, click the name of your vSphere cluster.
   e. On the Select storage tab, configure the storage options for your VM.
      - Select Thin Provision or Thick Provision, based on your storage preferences.
Select the datastore that you specified in your `install-config.yaml` file.

If you want to encrypt your virtual machines, select `Encrypt this virtual machine`. See the section titled “Requirements for encrypting virtual machines” for more information.

f. On the **Select network** tab, specify the network that you configured for the cluster, if available.

g. When creating the OVF template, do not specify values on the **Customize template** tab or configure the template any further.

**IMPORTANT**

Do not start the original VM template. The VM template must remain off and must be cloned for new RHCOs machines. Starting the VM template configures the VM template as a VM on the platform, which prevents it from being used as a template that compute machine sets can apply configurations to.

8. Optional: Update the configured virtual hardware version in the VM template, if necessary. Follow [Upgrading a virtual machine to the latest hardware version](#) in the VMware documentation for more information.

**IMPORTANT**

It is recommended that you update the hardware version of the VM template to version 15 before creating VMs from it, if necessary. Using hardware version 13 for your cluster nodes running on vSphere is now deprecated. If your imported template defaults to hardware version 13, you must ensure that your ESXi host is on 6.7U3 or later before upgrading the VM template to hardware version 15. If your vSphere version is less than 6.7U3, you can skip this upgrade step; however, a future version of OpenShift Container Platform is scheduled to remove support for hardware version 13 and vSphere versions less than 6.7U3.

9. After the template deploys, deploy a VM for a machine in the cluster.

a. Right-click the template name and click **Clone → Clone to Virtual Machine**

b. On the **Select a name and folder** tab, specify a name for the VM. You might include the machine type in the name, such as `control-plane-0` or `compute-1`.

**NOTE**

Ensure that all virtual machine names across a vSphere installation are unique.

c. On the **Select a name and folder** tab, select the name of the folder that you created for the cluster.

d. On the **Select a compute resource** tab, select the name of a host in your datacenter.

e. On the **Select clone options** tab, select **Customize this virtual machine’s hardware**

f. On the **Customize hardware** tab, click **Advanced Parameters**.
IMPORTANT

The following configuration suggestions are for example purposes only. As a cluster administrator, you must configure resources according to the resource demands placed on your cluster. To best manage cluster resources, consider creating a resource pool from the cluster’s root resource pool.

- Optional: Override default DHCP networking in vSphere. To enable static IP networking:
  - Set your static IP configuration:

  **Example command**

  ```
  $ export IPCFG="ip=<ip>::<gateway>::<netmask>::<hostname>::<iface>::none
  nameserver=srv1 [nameserver=srv2 [nameserver=srv3 [...]]]"
  ```

  **Example command**

  ```
  $ export IPCFG="ip=192.168.100.101::192.168.100.254:255.255.255.0::none
  nameserver=8.8.8.8"
  ```

  - Set the `guestinfo.afterburn.initrd.network-kargs` property before you boot a VM from an OVA in vSphere:

    **Example command**

    ```
    $ govc vm.change -vm "<vm_name>" -e "guestinfo.afterburn.initrd.network-kargs=${IPCFG}"
    ```

- Add the following configuration parameter names and values by specifying data in the Attribute and Values fields. Ensure that you select the Add button for each parameter that you create.

  - `guestinfo.ignition.config.data`: Locate the base-64 encoded files that you created previously in this procedure, and paste the contents of the base64-encoded Ignition config file for this machine type.

  - `guestinfo.ignition.config.data.encoding`: Specify base64.

  - `disk.EnableUUID`: Specify TRUE.

  - `stealclock.enable`: If this parameter was not defined, add it and specify TRUE.

  - Create a child resource pool from the cluster’s root resource pool. Perform resource allocation in this child resource pool.

  g. In the Virtual Hardware panel of the Customize hardware tab, modify the specified values as required. Ensure that the amount of RAM, CPU, and disk storage meets the minimum requirements for the machine type.

  h. Complete the remaining configuration steps. On clicking the Finish button, you have completed the cloning operation.

  i. From the Virtual Machines tab, right-click on your VM and then select Power → Power On.
j. Check the console output to verify that Ignition ran.

Example command

```
Ignition: ran on 2022/03/14 14:48:33 UTC (this boot)
Ignition: user-provided config was applied
```

Next steps

- Create the rest of the machines for your cluster by following the preceding steps for each machine.

**IMPORTANT**

You must create the bootstrap and control plane machines at this time. Because some pods are deployed on compute machines by default, also create at least two compute machines before you install the cluster.

### 22.6.18. Adding more compute machines to a cluster in vSphere

You can add more compute machines to a user-provisioned OpenShift Container Platform cluster on VMware vSphere.

After your vSphere template deploys in your OpenShift Container Platform cluster, you can deploy a virtual machine (VM) for a machine in that cluster.

**Prerequisites**

- Obtain the base64-encoded Ignition file for your compute machines.
- You have access to the vSphere template that you created for your cluster.

**Procedure**

1. Right-click the template’s name and click **Clone → Clone to Virtual Machine**

2. On the **Select a name and folder** tab, specify a name for the VM. You might include the machine type in the name, such as **compute-1**.

   **NOTE**

   Ensure that all virtual machine names across a vSphere installation are unique.

3. On the **Select a name and folder** tab, select the name of the folder that you created for the cluster.

4. On the **Select a compute resource** tab, select the name of a host in your datacenter.

5. On the **Select storage** tab, select storage for your configuration and disk files.

6. On the **Select clone options** tab, select **Customize this virtual machine’s hardware**

7. On the **Customize hardware** tab, click **Advanced Parameters**.
Add the following configuration parameter names and values by specifying data in the Attribute and Values fields. Ensure that you select the Add button for each parameter that you create.

- guestinfo.ignition.config.data: Paste the contents of the base64-encoded compute Ignition config file for this machine type.
- guestinfo.ignition.config.data.encoding: Specify base64.
- disk.EnableUUID: Specify TRUE.

8. In the Virtual Hardware panel of the Customize hardware tab, modify the specified values as required. Ensure that the amount of RAM, CPU, and disk storage meets the minimum requirements for the machine type. If many networks exist, select Add New Device > Network Adapter, and then enter your network information in the fields provided by the New Network menu item.

9. Complete the remaining configuration steps. On clicking the Finish button, you have completed the cloning operation.

10. From the Virtual Machines tab, right-click on your VM and then select Power → Power On.

Next steps

- Continue to create more compute machines for your cluster.

22.6.19. Disk partitioning

In most cases, data partitions are originally created by installing RHCOS, rather than by installing another operating system. In such cases, the OpenShift Container Platform installer should be allowed to configure your disk partitions.

However, there are two cases where you might want to intervene to override the default partitioning when installing an OpenShift Container Platform node:

- Create separate partitions: For greenfield installations on an empty disk, you might want to add separate storage to a partition. This is officially supported for making /var or a subdirectory of /var, such as /var/lib/etcd, a separate partition, but not both.

  IMPORTANT
  For disk sizes larger than 100GB, and especially disk sizes larger than 1TB, create a separate /var partition. See "Creating a separate /var partition" and this Red Hat Knowledgebase article for more information.

  IMPORTANT
  Kubernetes supports only two file system partitions. If you add more than one partition to the original configuration, Kubernetes cannot monitor all of them.

- Retain existing partitions: For a brownfield installation where you are reinstalling OpenShift Container Platform on an existing node and want to retain data partitions installed from your previous operating system, there are both boot arguments and options to coreos-installer that allow you to retain existing data partitions.
Creating a separate /var partition

In general, disk partitioning for OpenShift Container Platform should be left to the installer. However, there are cases where you might want to create separate partitions in a part of the filesystem that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the /var partition or a subdirectory of /var. For example:

- **/var/lib/containers**: Holds container-related content that can grow as more images and containers are added to a system.
- **/var/lib/etcd**: Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.
- **/var**: Holds data that you might want to keep separate for purposes such as auditing.

**IMPORTANT**

For disk sizes larger than 100GB, and especially larger than 1TB, create a separate /var partition.

Storing the contents of a /var directory separately makes it easier to grow storage for those areas as needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

Because /var must be in place before a fresh installation of Red Hat Enterprise Linux CoreOS (RHCOS), the following procedure sets up the separate /var partition by creating a machine config manifest that is inserted during the openshift-install preparation phases of an OpenShift Container Platform installation.

**Procedure**

1. Create a directory to hold the OpenShift Container Platform installation files:

   ```bash
   $ mkdir $HOME/clusterconfig
   ```

2. Run openshift-install to create a set of files in the **manifest** and **openshift** subdirectories. Answer the system questions as you are prompted:

   ```bash
   $ openshift-install create manifests --dir $HOME/clusterconfig
   ? SSH Public Key ...
   $ ls $HOME/clusterconfig/openshift/
   99_kubeadmin-password-secret.yaml
   99_openshift-cluster-api_master-machines-0.yaml
   99_openshift-cluster-api_master-machines-1.yaml
   99_openshift-cluster-api_master-machines-2.yaml
   ...
   ```

3. Create a Butane config that configures the additional partition. For example, name the file $HOME/clusterconfig/98-var-partition.bu, change the disk device name to the name of the storage device on the worker systems, and set the storage size as appropriate. This example places the /var directory on a separate partition:
variant: openshift
version: 4.14.0
metadata:
  labels:
    machineconfiguration.openshift.io/role: worker
name: 98-var-partition
storage:
disks:
  - device: /dev/disk/by-id/<device_name> 1
    partitions:
      - label: var
        start_mib: <partition_start_offset> 2
        size_mib: <partition_size> 3
  filesystems:
    - device: /dev/disk/by-partlabel/var
      path: /var
      format: xfs
      mount_options: [defaults, prjquota] 4
      with_mount_unit: true

1. The storage device name of the disk that you want to partition.

2. When adding a data partition to the boot disk, a minimum value of 25000 mebibytes is recommended. The root file system is automatically resized to fill all available space up to the specified offset. If no value is specified, or if the specified value is smaller than the recommended minimum, the resulting root file system will be too small, and future reinstalls of RHCOS might overwrite the beginning of the data partition.

3. The size of the data partition in mebibytes.

4. The prjquota mount option must be enabled for filesystems used for container storage.

**NOTE**

When creating a separate /var partition, you cannot use different instance types for worker nodes, if the different instance types do not have the same device name.

4. Create a manifest from the Butane config and save it to the `clusterconfig/openshift` directory. For example, run the following command:

   ```
   $ butane $HOME/clusterconfig/98-var-partition.bu -o $HOME/clusterconfig/openshift/98-var-partition.yaml
   ```

5. Run `openshift-install` again to create Ignition configs from a set of files in the `manifest` and `openshift` subdirectories:

   ```
   $ openshift-install create ignition-configs --dir $HOME/clusterconfig
   $ ls $HOME/clusterconfig/
auth bootstrap.ign master.ign metadata.json worker.ign
   ```

Now you can use the Ignition config files as input to the vSphere installation procedures to install Red Hat Enterprise Linux CoreOS (RHCOS) systems.
22.6.20. Updating the bootloader using bootupd

To update the bootloader by using bootupd, you must either install bootupd on RHCOS machines manually or provide a machine config with the enabled systemd unit. Unlike grubby or other bootloader tools, bootupd does not manage kernel space configuration such as passing kernel arguments.

After you have installed bootupd, you can manage it remotely from the OpenShift Container Platform cluster.

NOTE

It is recommended that you use bootupd only on bare metal or virtualized hypervisor installations, such as for protection against the BootHole vulnerability.

Manual install method

You can manually install bootupd by using the bootctl command-line tool.

1. Inspect the system status:

```bash
# bootupctl status
```

**Example output for x86_64**

```
Component EFI
Installed: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
Update: At latest version
```

**Example output for aarch64**

```
Component EFI
Installed: grub2-efi-aa64-1:2.02-99.el8_4.1.aarch64,shim-aa64-15.4-2.el8_1.aarch64
Update: At latest version
```

2. RHCOS images created without bootupd installed on them require an explicit adoption phase. If the system status is Adoptable, perform the adoption:

```bash
# bootupctl adopt-and-update
```

**Example output**

```
Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
```

3. If an update is available, apply the update so that the changes take effect on the next reboot:

```bash
# bootupctl update
```

**Example output**

```
Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
```
Machine config method

Another way to enable **bootupd** is by providing a machine config.

- Provide a machine config file with the enabled **systemd** unit, as shown in the following example:

  **Example output**

  ```
  variant: rhcos
  version: 1.1.0
  systemd:
    units:
      - name: custom-bootupd-auto.service
        enabled: true
        contents: |
          [Unit]
          Description=Bootupd automatic update
          [Service]
          ExecStart=/usr/bin/bootupctl update
          RemainAfterExit=yes
          [Install]
          WantedBy=multi-user.target
  ```

  **22.6.21. Waiting for the bootstrap process to complete**

  The OpenShift Container Platform bootstrap process begins after the cluster nodes first boot into the persistent RHCOS environment that has been installed to disk. The configuration information provided through the Ignition config files is used to initialize the bootstrap process and install OpenShift Container Platform on the machines. You must wait for the bootstrap process to complete.

  **Prerequisites**

  - You have created the Ignition config files for your cluster.
  - You have configured suitable network, DNS and load balancing infrastructure.
  - You have obtained the installation program and generated the Ignition config files for your cluster.
  - You installed RHCOS on your cluster machines and provided the Ignition config files that the OpenShift Container Platform installation program generated.
  - Your machines have direct internet access or have an HTTP or HTTPS proxy available.

  **Procedure**

  1. Monitor the bootstrap process:

     ```bash
     $ ./openshift-install --dir <installation_directory> wait-for bootstrap-complete \  
        --log-level=info
     ```

     **1** For `<installation_directory>`, specify the path to the directory that you stored the installation files in.
To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

Example output

INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
INFO API v1.27.3 up
INFO Waiting up to 30m0s for bootstrapping to complete...
INFO It is now safe to remove the bootstrap resources

The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After the bootstrap process is complete, remove the bootstrap machine from the load balancer.

**IMPORTANT**

You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the bootstrap machine itself.

### 22.6.22. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig  
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   ```

   **Example output**

   ```bash
   system:admin
   ```

### 22.6.23. Approving the certificate signing requests for your machines
When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

Prerequisites

- You added machines to your cluster.

Procedure

1. Confirm that the cluster recognizes the machines:

```
$ oc get nodes
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>64m</td>
<td>v1.27.3</td>
</tr>
</tbody>
</table>

The output lists all of the machines that you created.

**NOTE**

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```
$ oc get csr
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-8b2br</td>
<td>15m</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-8vnps</td>
<td>15m</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Pending</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:
NOTE

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the machine-approver if the Kubelet requests a new certificate with identical parameters.

NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the oc exec, oc rsh, and oc logs commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the node-bootstrapper service account in the system:node or system:admin groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

  $ oc adm certificate approve <csr_name>  
  
  <csr_name> is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

  $ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve

  
  NOTE

  Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

  $ oc get csr

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-c57lv</td>
<td>5m26s</td>
<td>system:node:ip-10-0-95-157.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
</tbody>
</table>
5. If the remaining CSRs are not approved, and are in the Pending status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

  ```bash
  $ oc adm certificate approve <csr_name>
  ```

  `<csr_name>` is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

  ```bash
  $ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs oc adm certificate approve
  ```

6. After all client and server CSRs have been approved, the machines have the Ready status. Verify this by running the following command:

  ```bash
  $ oc get nodes
  ```

Example output

```
NAME      STATUS    ROLES   AGE  VERSION
master-0  Ready     master  73m  v1.27.3
master-1  Ready     master  73m  v1.27.3
master-2  Ready     master  74m  v1.27.3
worker-0  Ready     worker  11m  v1.27.3
worker-1  Ready     worker  11m  v1.27.3
```

**NOTE**

It can take a few minutes after approval of the server CSRs for the machines to transition to the Ready status.

Additional information

- For more information on CSRs, see Certificate Signing Requests.

22.6.23.1. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

**Prerequisites**

- Your control plane has initialized.

**Procedure**

1. Watch the cluster components come online:

  ```bash
  $ watch -n5 oc get clusteroperators
  ```
Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
<th>SINCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>authentication</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>19m</td>
</tr>
<tr>
<td>baremetal</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>37m</td>
</tr>
<tr>
<td>cloud-credential</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>

2. Configure the Operators that are not available.

### 22.6.23.2. Image registry removed during installation

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as Removed. This allows openshift-installer to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the managementState from Removed to Managed.

### 22.6.23.3. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.
Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the Recreate rollout strategy during upgrades.

### 22.6.23.3.1. Configuring block registry storage for VMware vSphere

To allow the image registry to use block storage types such as vSphere Virtual Machine Disk (VMDK) during upgrades as a cluster administrator, you can use the Recreate rollout strategy.

**IMPORTANT**

Block storage volumes are supported but not recommended for use with image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

**Procedure**

1. To set the image registry storage as a block storage type, patch the registry so that it uses the Recreate rollout strategy and runs with only 1 replica:

   ```bash
   $ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec":
   {"rolloutStrategy":"Recreate","replicas":1}}'
   ```

2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.

   a. Create a `pvc.yaml` file with the following contents to define a VMware vSphere `PersistentVolumeClaim` object:

   ```yaml
   kind: PersistentVolumeClaim
   apiVersion: v1
   metadata:
     name: image-registry-storage
     namespace: openshift-image-registry
   spec:
     accessModes:
     - ReadWriteOnce
     resources:
       requests:
         storage: 100Gi
   ```

   1. A unique name that represents the `PersistentVolumeClaim` object.
   2. The namespace for the `PersistentVolumeClaim` object, which is `openshift-image-registry`.
   3. The access mode of the persistent volume claim. With `ReadWriteOnce`, the volume can be mounted with read and write permissions by a single node.
   4. The size of the persistent volume claim.
b. Create the `PersistentVolumeClaim` object from the file:

```
$ oc create -f pvc.yaml -n openshift-image-registry
```

3. Edit the registry configuration so that it references the correct PVC:

```
$ oc edit config.imageregistry.operator.openshift.io -o yaml
```

**Example output**

```
storage:
pvc:
  claim: 1
```

By creating a custom PVC, you can leave the `claim` field blank for the default automatic creation of an `image-registry-storage` PVC.

For instructions about configuring registry storage so that it references the correct PVC, see Configuring the registry for vSphere.

### 22.6.24. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

**Prerequisites**

- Your control plane has initialized.
- You have completed the initial Operator configuration.

**Procedure**

1. Confirm that all the cluster components are online with the following command:

```
$ watch -n5 oc get clusteroperators
```

**Example output**

```
<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
</tr>
</thead>
<tbody>
<tr>
<td>authentication</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>baremetal</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>cloud-credential</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>cluster-autoscaler</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>config-operator</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>console</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>csi-snapshot-controller</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>dns</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>

</tr>
<tr>
<td>etcd</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>image-registry</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
<tr>
<td>ingress</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
</tbody>
</table>
```
Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

$ ./openshift-install --dir <installation_directory> wait-for install-complete

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

**Example output**

INFO Waiting up to 30m0s for the cluster to initialize...

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.
2. Confirm that the Kubernetes API server is communicating with the pods.
   a. To view a list of all pods, use the following command:

   ```
   $ oc get pods --all-namespaces
   ```

   **Example output**

<table>
<thead>
<tr>
<th>NAMESPACE</th>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>openshift-apiserver-operator</td>
<td>openshift-apiserver-operator-85cb746d55-zqhs8</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td></td>
<td>Running 9m</td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apiserver-67b9g</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td></td>
<td>Running 3m</td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apiserver-ljcmx</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td></td>
<td>Running 1m</td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apiserver-z25h4</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td></td>
<td>Running 2m</td>
<td></td>
<td></td>
</tr>
<tr>
<td>openshift-authentication-operator</td>
<td>authentication-operator-69d5d8bf84-vh2n8</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td></td>
<td>Running 0, 5m</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>...</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

   b. View the logs for a pod that is listed in the output of the previous command by using the following command:

   ```
   $ oc logs <pod_name> -n <namespace> 1
   ```

   Specify the pod name and namespace, as shown in the output of the previous command.

   If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation.
   See "Enabling multipathing with kernel arguments on RHCOS" in the Post-installation machine configuration tasks documentation for more information.

You can add extra compute machines after the cluster installation is completed by following Adding compute machines to vSphere.

### 22.6.25. Configuring vSphere DRS anti-affinity rules for control plane nodes

vSphere Distributed Resource Scheduler (DRS) anti-affinity rules can be configured to support higher availability of OpenShift Container Platform Control Plane nodes. Anti-affinity rules ensure that the vSphere Virtual Machines for the OpenShift Container Platform Control Plane nodes are not scheduled to the same vSphere Host.
IMPORTANT

- The following information applies to compute DRS only and does not apply to storage DRS.

- The `govc` command is an open-source command available from VMware; it is not available from Red Hat. The `govc` command is not supported by the Red Hat support.

- Instructions for downloading and installing `govc` are found on the VMware documentation website.

Create an anti-affinity rule by running the following command:

**Example command**

```bash
$ govc cluster.rule.create \
   -name openshift4-control-plane-group \
   -dc MyDatacenter -cluster MyCluster \n   -enable \
   -anti-affinity master-0 master-1 master-2
```

After creating the rule, your control plane nodes are automatically migrated by vSphere so they are not running on the same hosts. This might take some time while vSphere reconciles the new rule. Successful command completion is shown in the following procedure.

**NOTE**

The migration occurs automatically and might cause brief OpenShift API outage or latency until the migration finishes.

The vSphere DRS anti-affinity rules need to be updated manually in the event of a control plane VM name change or migration to a new vSphere Cluster.

**Procedure**

1. Remove any existing DRS anti-affinity rule by running the following command:

   ```bash
   $ govc cluster.rule.remove \
      -name openshift4-control-plane-group \
      -dc MyDatacenter -cluster MyCluster
   ```

   **Example Output**

   ```bash
   [13-10-22 09:33:24] Reconfigure /MyDatacenter/host/MyCluster...OK
   ```

2. Create the rule again with updated names by running the following command:

   ```bash
   $ govc cluster.rule.create \
      -name openshift4-control-plane-group \
      -dc MyDatacenter -cluster MyOtherCluster \n      -enable \
      -anti-affinity master-0 master-1 master-2
   ```
22.6.26. Backing up VMware vSphere volumes

OpenShift Container Platform provisions new volumes as independent persistent disks to freely attach and detach the volume on any node in the cluster. As a consequence, it is not possible to back up volumes that use snapshots, or to restore volumes from snapshots. See Snapshot Limitations for more information.

Procedure

To create a backup of persistent volumes:

1. Stop the application that is using the persistent volume.
2. Clone the persistent volume.
3. Restart the application.
4. Create a backup of the cloned volume.
5. Delete the cloned volume.

22.6.27. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager Hybrid Cloud Console.

After you confirm that your OpenShift Cluster Manager Hybrid Cloud Console inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources
- See About remote health monitoring for more information about the Telemetry service

22.6.28. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- Set up your registry and configure registry storage.
- Optional: View the events from the vSphere Problem Detector Operator to determine if the cluster has permission or storage configuration issues.
- Optional: if you created encrypted virtual machines, create an encrypted storage class.

22.7. INSTALLING A CLUSTER ON VSPHERE IN A RESTRICTED NETWORK

In OpenShift Container Platform 4.14, you can install a cluster on VMware vSphere infrastructure in a restricted network by creating an internal mirror of the installation release content.
NOTE
OpenShift Container Platform supports deploying a cluster to a single VMware vCenter only. Deploying a cluster with machines/machine sets on multiple vCenters is not supported.

22.7.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You created a registry on your mirror host and obtained the imageContentSources data for your version of OpenShift Container Platform.

IMPORTANT
Because the installation media is on the mirror host, you can use that computer to complete all installation steps.

- You provisioned persistent storage for your cluster. To deploy a private image registry, your storage must provide the ReadWriteMany access mode.
- The OpenShift Container Platform installer requires access to port 443 on the vCenter and ESXi hosts. You verified that port 443 is accessible.
- If you use a firewall, you confirmed with the administrator that port 443 is accessible. Control plane nodes must be able to reach vCenter and ESXi hosts on port 443 for the installation to succeed.
- If you use a firewall and plan to use the Telemetry service, you configured the firewall to allow the sites that your cluster requires access to.

NOTE
If you are configuring a proxy, be sure to also review this site list.

22.7.2. About installations in restricted networks

In OpenShift Container Platform 4.14, you can perform an installation that does not require an active connection to the internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service’s Route 53 DNS and IAM services, require internet access. Depending on your network, you might require less internet access for an installation on bare metal hardware, Nutanix, or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift image registry and contains the installation media. You can create this registry on a mirror host, which can access both the internet and your closed network, or by using other methods that meet your restrictions.
22.7.2.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The ClusterVersion status includes an Unable to retrieve available updates error.
- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

22.7.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to obtain the images that are necessary to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager Hybrid Cloud Console to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

22.7.4. VMware vSphere infrastructure requirements

You must install the OpenShift Container Platform cluster on a VMware vSphere version 7.0 Update 2 or later instance that meets the requirements for the components that you use.

NOTE

OpenShift Container Platform version 4.14 supports VMware vSphere version 8.0.

You can host the VMware vSphere infrastructure on-premise or on a VMware Cloud Verified provider that meets the requirements outlined in the following tables:

Table 22.57. Version requirements for vSphere virtual environments

<table>
<thead>
<tr>
<th>Virtual environment product</th>
<th>Required version</th>
</tr>
</thead>
<tbody>
<tr>
<td>VMware virtual hardware</td>
<td>15 or later</td>
</tr>
<tr>
<td>vSphere ESXi hosts</td>
<td>7.0 Update 2 or later</td>
</tr>
<tr>
<td>vCenter host</td>
<td>7.0 Update 2 or later</td>
</tr>
</tbody>
</table>

IMPORTANT

You must ensure that the time on your ESXi hosts is synchronized before you install OpenShift Container Platform. See Edit Time Configuration for a Host in the VMware documentation.
### Table 22.58. Minimum supported vSphere version for VMware components

<table>
<thead>
<tr>
<th>Component</th>

<td>vSphere 7.0 Update 2 is required for OpenShift Container Platform. For more information about the compatibility of NSX and OpenShift Container Platform, see the Release Notes section of VMware’s NSX container plugin documentation.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

To ensure the best performance conditions for your cluster workloads that operate on Oracle® Cloud Infrastructure and on the Oracle® Cloud VMware Solution (OCVS) service, ensure volume performance units (VPUs) for your block volume are sized for your workloads.

The following list provides some guidance in selecting the VPUs needed for specific performance needs:

- **Test or proof of concept environment**: 100 GB, and 20 to 30 VPUs.
- **Base-production environment**: 500 GB, and 60 VPUs.
- **Heavy-use production environment**: More than 500 GB, and 100 or more VPUs.

Consider allocating additional VPUs to give enough capacity for updates and scaling activities. See Block Volume Performance Levels in the Oracle documentation.

### 22.7.5. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate.
Review the following details about the required network ports.

### Table 22.59. Ports used for all-machine to all-machine communications

<table>
<thead>
<tr>
<th>Protocol</th>

</tbody>
</table>

### 22.7.6. VMware vSphere CSI Driver Operator requirements

To install the vSphere CSI Driver Operator, the following requirements must be met:
VMware vSphere version 7.0 Update 2 or later
vCenter 7.0 Update 2 or later
Virtual machines of hardware version 15 or later
No third-party vSphere CSI driver already installed in the cluster

If a third-party vSphere CSI driver is present in the cluster, OpenShift Container Platform does not overwrite it. The presence of a third-party vSphere CSI driver prevents OpenShift Container Platform from updating to OpenShift Container Platform 4.13 or later.

NOTE
The VMware vSphere CSI Driver Operator is supported only on clusters deployed with `platform: vsphere` in the installation manifest.

Additional resources
- To remove a third-party vSphere CSI driver, see Removing a third-party vSphere CSI Driver.
- To update the hardware version for your vSphere nodes, see Updating hardware on nodes running in vSphere.

22.7.7. vCenter requirements

Before you install an OpenShift Container Platform cluster on your vCenter that uses infrastructure that the installer provisions, you must prepare your environment.

Required vCenter account privileges
To install an OpenShift Container Platform cluster in a vCenter, the installation program requires access to an account with privileges to read and create the required resources. Using an account that has global administrative privileges is the simplest way to access all of the necessary permissions.

If you cannot use an account with global administrative privileges, you must create roles to grant the privileges necessary for OpenShift Container Platform cluster installation. While most of the privileges are always required, some are required only if you plan for the installation program to provision a folder to contain the OpenShift Container Platform cluster on your vCenter instance, which is the default behavior. You must create or amend vSphere roles for the specified objects to grant the required privileges.

An additional role is required if the installation program is to create a vSphere virtual machine folder.

Example 22.22. Roles and privileges required for installation in vSphere API

<table>
<thead>
<tr>

**Required privileges in vCenter GUI:**

Additionally, the user requires some **ReadOnly** permissions, and some of the roles require permission to propagate the permissions to child objects. These settings vary depending on whether or not you install the cluster into an existing folder.

### Example 22.24. Required permissions and propagation settings

<table>

</table>
For more information about creating an account with only the required privileges, see vSphere Permissions and User Management Tasks in the vSphere documentation.

**Using OpenShift Container Platform with vMotion**
If you intend on using vMotion in your vSphere environment, consider the following before installing an OpenShift Container Platform cluster.

- OpenShift Container Platform generally supports compute-only vMotion, where generally implies that you meet all VMware best practices for vMotion. To help ensure the uptime of your compute and control plane nodes, ensure that you follow the VMware best practices for vMotion, and use VMware anti-affinity rules to improve the availability of OpenShift Container Platform during maintenance or hardware issues.

  For more information about vMotion and anti-affinity rules, see the VMware vSphere documentation for vMotion networking requirements and VM anti-affinity rules.

- Using Storage vMotion can cause issues and is not supported. If you are using vSphere volumes in your pods, migrating a VM across datastores, either manually or through Storage vMotion, causes invalid references within OpenShift Container Platform persistent volume (PV) objects that can result in data loss.

- OpenShift Container Platform does not support selective migration of VMDKs across datastores, using datastore clusters for VM provisioning or for dynamic or static provisioning of PVs, or using a datastore that is part of a datastore cluster for dynamic or static provisioning of PVs.

**IMPORTANT**
You can specify the path of any datastore that exists in a datastore cluster. By default, Storage Distributed Resource Scheduler (SDRS), which uses Storage vMotion, is automatically enabled for a datastore cluster. Red Hat does not support Storage vMotion, so you must disable Storage DRS to avoid data loss issues for your OpenShift Container Platform cluster.

If you must specify VMs across multiple datastores, use a datastore object to specify a failure domain in your cluster’s install-config.yaml configuration file. For more information, see “VMware vSphere region and zone enablement”.

**Cluster resources**
When you deploy an OpenShift Container Platform cluster that uses installer-provisioned infrastructure, the installation program must be able to create several resources in your vCenter instance.

A standard OpenShift Container Platform installation creates the following vCenter resources:

- 1 Folder
Virtual machines:
- 1 template
- 1 temporary bootstrap node
- 3 control plane nodes
- 3 compute machines

Although these resources use 856 GB of storage, the bootstrap node is destroyed during the cluster installation process. A minimum of 800 GB of storage is required to use a standard cluster.

If you deploy more compute machines, the OpenShift Container Platform cluster will use more storage.

Cluster limits
Available resources vary between clusters. The number of possible clusters within a vCenter is limited primarily by available storage space and any limitations on the number of required resources. Be sure to consider both limitations to the vCenter resources that the cluster creates and the resources that you require to deploy a cluster, such as IP addresses and networks.

Networking requirements
Use Dynamic Host Configuration Protocol (DHCP) for the network and ensure that the DHCP server is configured to provide persistent IP addresses to the cluster machines.

NOTE
You do not need to use the DHCP for the network if you want to provision nodes with static IP addresses.

Configure the default gateway to use the DHCP server. All nodes must be in the same VLAN. You cannot scale the cluster using a second VLAN as a Day 2 operation.

You must use the Dynamic Host Configuration Protocol (DHCP) for the network and ensure that the DHCP server is configured to provide persistent IP addresses to the cluster machines. In the DHCP lease, you must configure the DHCP to use the default gateway. All nodes must be in the same VLAN. You cannot scale the cluster using a second VLAN as a Day 2 operation.

The VM in your restricted network must have access to vCenter so that it can provision and manage nodes, persistent volume claims (PVCs), and other resources. Additionally, you must create the following networking resources before you install the OpenShift Container Platform cluster:

NOTE
It is recommended that each OpenShift Container Platform node in the cluster must have access to a Network Time Protocol (NTP) server that is discoverable via DHCP. Installation is possible without an NTP server. However, asynchronous server clocks will cause errors, which NTP server prevents.

Required IP Addresses
For a network that uses DHCP, an installer-provisioned vSphere installation requires two static IP addresses:
The **API** address is used to access the cluster API.

The **Ingress** address is used for cluster ingress traffic.

You must provide these IP addresses to the installation program when you install the OpenShift Container Platform cluster.

**DNS records**

You must create DNS records for two static IP addresses in the appropriate DNS server for the vCenter instance that hosts your OpenShift Container Platform cluster. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the cluster base domain that you specify when you install the cluster. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>`.

**Table 22.62. Required DNS records**

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>API VIP</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>This DNS A/AAAA or CNAME record must point to the load balancer for the control plane machines. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Ingress VIP</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A wildcard DNS A/AAAA or CNAME record that points to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**Static IP addresses for vSphere nodes**

You can provision bootstrap, control plane, and compute nodes to be configured with static IP addresses in environments where Dynamic Host Configuration Protocol (DHCP) does not exist. To configure this environment, you must provide values to the `platform.vsphere.hosts.role` parameter in the `install-config.yaml` file.

**IMPORTANT**

Static IP addresses for vSphere nodes is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see Technology Preview Features Support Scope.
By default, the installation program is configured to use the DHCP for the network, but this network has limited configurable capabilities.

After you define one or more machine pools in your `install-config.yaml` file, you can define network definitions for nodes on your network. Ensure that the number of network definitions matches the number of machine pools that you configured for your cluster.

The following example shows a network configuration for a node with the role `compute`:

```
---
platform:
  vsphere:
    hosts:
      - role: compute
        networkDevice:
          ipAddrs:
            - 192.168.204.10/24
          gateway: 192.168.204.1
          nameservers:
            - 192.168.204.1
---
```

1. Valid network definition values include `bootstrap`, `control-plane`, and `compute`. You must list at least one `bootstrap` network definition in your `install-config.yaml` configuration file.

2. Lists IPv4, IPv6, or both IP addresses that the installation program passes to the network interface. The machine API controller assigns all configured IP addresses to the default network interface.

3. The default gateway for the network interface.

4. Lists up to 3 DNS nameservers.

**IMPORTANT**

To enable the Technology Preview feature of static IP addresses for vSphere nodes for your cluster, you must include `featureSet:TechPreviewNoUpgrade` as the initial entry in the `install-config.yaml` file.

After you deployed your cluster to run nodes with static IP addresses, you can scale a machine to use one of these static IP addresses. Additionally, you can use a machine set to configure a machine to use one of the configured static IP addresses.

**Additional resources**

- Scaling machines to use static IP addresses
- Using a machine set to scale machines with configured static IP addresses

**22.7.8. Generating a key pair for cluster node SSH access**

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added
to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The ./openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>
   ```

   Specify the path and file name, such as ~/.ssh/id_ed25519, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   ```
   $ cat <path>/<file_name>.pub
   ```

   For example, run the following to view the ~/.ssh/id_ed25519.pub public key:

   ```
   $ cat ~/.ssh/id_ed25519.pub
   ```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the ./openshift-install gather command.
NOTE
On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.

a. If the ssh-agent process is not already running for your local user, start it as a background task:

   $ eval "$(ssh-agent -s)"

Example output

   Agent pid 31874

NOTE
If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the ssh-agent:

   $ ssh-add <path>/<file_name>  

Specify the path and file name for your SSH private key, such as ~/.ssh/id_ed25519

Example output

   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

22.7.9. Adding vCenter root CA certificates to your system trust

Because the installation program requires access to your vCenter’s API, you must add your vCenter’s trusted root CA certificates to your system trust before you install an OpenShift Container Platform cluster.

Procedure

1. From the vCenter home page, download the vCenter’s root CA certificates. Click Download trusted root CA certificates in the vSphere Web Services SDK section. The <vCenter>/certs/download.zip file downloads.

2. Extract the compressed file that contains the vCenter root CA certificates. The contents of the compressed file resemble the following file structure:

   certs
     └── lin
3. Add the files for your operating system to the system trust. For example, on a Fedora operating system, run the following command:

```bash
# cp certs/lin/* /etc/pki/ca-trust/source/anchors
```

4. Update your system trust. For example, on a Fedora operating system, run the following command:

```bash
# update-ca-trust extract
```

### 22.7.10. Creating the RHCOS image for restricted network installations

Download the Red Hat Enterprise Linux CoreOS (RHCOS) image to install OpenShift Container Platform on a restricted network VMware vSphere environment.

**Prerequisites**

- Obtain the OpenShift Container Platform installation program. For a restricted network installation, the program is on your mirror registry host.

**Procedure**

1. Log in to the Red Hat Customer Portal’s [Product Downloads page](#).

**IMPORTANT**

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available.
3. Download the Red Hat Enterprise Linux CoreOS (RHCOS) - vSphere image.

4. Upload the image you downloaded to a location that is accessible from the bastion server.

The image is now available for a restricted installation. Note the image name or location for use in OpenShift Container Platform deployment.

### 22.7.11. VMware vSphere region and zone enablement

You can deploy an OpenShift Container Platform cluster to multiple vSphere datacenters that run in a single VMware vCenter. Each datacenter can run multiple clusters. This configuration reduces the risk of a hardware failure or network outage that can cause your cluster to fail.

**IMPORTANT**

The VMware vSphere region and zone enablement feature requires the vSphere Container Storage Interface (CSI) driver as the default storage driver in the cluster. As a result, the feature only available on a newly installed cluster.

A cluster that was upgraded from a previous release defaults to using the in-tree vSphere driver, so you must enable CSI automatic migration for the cluster. You can then configure multiple regions and zones for the upgraded cluster.

The default installation configuration deploys a cluster to a single vSphere datacenter. If you want to deploy a cluster to multiple vSphere datacenters, you must create an installation configuration file that enables the region and zone feature.

The default install-config.yaml file includes vcenters and failureDomains fields, where you can specify multiple vSphere datacenters and clusters for your OpenShift Container Platform cluster. You can leave these fields blank if you want to install an OpenShift Container Platform cluster in a vSphere environment that consists of single datacenter.

The following list describes terms associated with defining zones and regions for your cluster:

- **Failure domain**: Establishes the relationships between a region and zone. You define a failure domain by using vCenter objects, such as a datastore object. A failure domain defines the vCenter location for OpenShift Container Platform cluster nodes.

- **Region**: Specifies a vCenter datacenter. You define a region by using a tag from the openshift-region tag category.

- **Zone**: Specifies a vCenter cluster. You define a zone by using a tag from the openshift-zone tag category.

**NOTE**

If you plan on specifying more than one failure domain in your install-config.yaml file, you must create tag categories, zone tags, and region tags in advance of creating the configuration file.

You must create a vCenter tag for each vCenter datacenter, which represents a region. Additionally, you must create a vCenter tag for each cluster than runs in a datacenter, which represents a zone. After you create the tags, you must attach each tag to their respective datacenters and clusters.
The following table outlines an example of the relationship among regions, zones, and tags for a configuration with multiple vSphere datacenters running in a single VMware vCenter.

<table>
<thead>
<tr>
<th>Datacenter (region)</th>
<th>Cluster (zone)</th>
<th>Tags</th>
</tr>
</thead>
<tbody>
<tr>
<td>us-east</td>
<td>us-east-1</td>
<td>us-east-1a</td>
</tr>
<tr>

<td>us-west-1b</td>
</tr>
<tr>
<td></td>
<td>us-west-2</td>
<td>us-west-2a</td>
</tr>
<tr>
<td></td>
<td></td>
<td>us-west-2b</td>
</tr>
</tbody>
</table>

Additional resources

- Additional VMware vSphere configuration parameters
- Deprecated VMware vSphere configuration parameters
- vSphere automatic migration
- VMware vSphere CSI Driver Operator

22.7.12. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on VMware vSphere.

Prerequisites

- You have the OpenShift Container Platform installation program and the pull secret for your cluster. For a restricted network installation, these files are on your mirror host.
- You have the `imageContentSources` values that were generated during mirror registry creation.
- You have obtained the contents of the certificate for your mirror registry.
- You have retrieved a Red Hat Enterprise Linux CoreOS (RHCOS) image and uploaded it to an accessible location.

Procedure

1. Create the `install-config.yaml` file.
a. Change to the directory that contains the installation program and run the following command:

```bash
$ ./openshift-install create install-config --dir <installation_directory>
```

For **<installation_directory>**, specify the directory name to store the files that the installation program creates.

When specifying the directory:

- Verify that the directory has the `execute` permission. This permission is required to run Terraform binaries under the installation directory.
- Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

**NOTE**

Always delete the `~/.powervs` directory to avoid reusing a stale configuration. Run the following command:

```bash
$ rm -rf ~/.powervs
```

b. At the prompts, provide the configuration details for your cloud:

i. Optional: Select an SSH key to use to access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

ii. Select `vsphere` as the platform to target.

iii. Specify the name of your vCenter instance.

iv. Specify the user name and password for the vCenter account that has the required permissions to create the cluster.

   The installation program connects to your vCenter instance.

v. Select the data center in your vCenter instance to connect to.
NOTE

After you create the installation configuration file, you can modify the file to create a multiple vSphere datacenters environment. This means that you can deploy an OpenShift Container Platform cluster to multiple vSphere datacenters that run in a single VMware vCenter. For more information about creating this environment, see the section named VMware vSphere region and zone enablement.

vi. Select the default vCenter datastore to use.

WARNING

You can specify the path of any datastore that exists in a datastore cluster. By default, Storage Distributed Resource Scheduler (SDRS), which uses Storage vMotion, is automatically enabled for a datastore cluster. Red Hat does not support Storage vMotion, so you must disable Storage DRS to avoid data loss issues for your OpenShift Container Platform cluster.

You cannot specify more than one datastore path. If you must specify VMs across multiple datastores, use a datastore object to specify a failure domain in your cluster’s install-config.yaml configuration file. For more information, see “VMware vSphere region and zone enablement”.

vii. Select the vCenter cluster to install the OpenShift Container Platform cluster in. The installation program uses the root resource pool of the vSphere cluster as the default resource pool.

viii. Select the network in the vCenter instance that contains the virtual IP addresses and DNS records that you configured.

ix. Enter the virtual IP address that you configured for control plane API access.

x. Enter the virtual IP address that you configured for cluster ingress.

xi. Enter the base domain. This base domain must be the same one that you used in the DNS records that you configured.

xii. Enter a descriptive name for your cluster.

The cluster name you enter must match the cluster name you specified when configuring the DNS records.

2. In the install-config.yaml file, set the value of platform.vsphere.clusterOSImage to the image location or name. For example:

```
platform:
  vsphere:
    clusterOSImage: http://mirror.example.com/images/rhcos-43.8.1.20191231630.0-
```
3. Edit the `install-config.yaml` file to give the additional information that is required for an installation in a restricted network.

   a. Update the `pullSecret` value to contain the authentication information for your registry:

   ```yaml
   pullSecret: 
   {"auths": {"<mirror_host_name>:5000": {"auth": ";<credentials>", "email": "you@example.com"}}}"
   
   For `<mirror_host_name>`, specify the registry domain name that you specified in the certificate for your mirror registry, and for `<credentials>`, specify the base64-encoded user name and password for your mirror registry.
   
   b. Add the `additionalTrustBundle` parameter and value.

   ```yaml
   additionalTrustBundle: |
   -----BEGIN CERTIFICATE-----
   ZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZ
   -----END CERTIFICATE-----
   
   The value must be the contents of the certificate file that you used for your mirror registry. The certificate file can be an existing, trusted certificate authority, or the self-signed certificate that you generated for the mirror registry.
   
   c. Add the image content resources, which resemble the following YAML excerpt:

   ```yaml
   imageContentSources:
   - mirrors:
     - `<mirror_host_name>:5000/<repo_name>/release
       source: quay.io/openshift-release-dev/ocp-release
     - `<mirror_host_name>:5000/<repo_name>/release
       source: registry.redhat.io/ocp/release
   
   For these values, use the `imageContentSources` that you recorded during mirror registry creation.
   
   d. Optional: Set the publishing strategy to `Internal`:

   ```yaml
   publish: Internal
   
   By setting this option, you create an internal Ingress Controller and a private load balancer.

   **IMPORTANT**

   Azure Firewall does not work seamlessly with Azure Public Load balancers. Thus, when using Azure Firewall for restricting internet access, the `publish` field in `install-config.yaml` should be set to `Internal`. 
4. Make any other modifications to the install-config.yaml file that you require. You can find more information about the available parameters in the Installation configuration parameters section.

5. Back up the install-config.yaml file so that you can use it to install multiple clusters.

**IMPORTANT**

The install-config.yaml file is consumed during the installation process. If you want to reuse the file, you must back it up now.

Additional resources

- Installation configuration parameters

22.7.12.1. Sample install-config.yaml file for an installer-provisioned VMware vSphere cluster

You can customize the install-config.yaml file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute:
  - architecture: amd64
    name: worker_node
    platform: {}
    replicas: 3
    controlPlane:
      architecture: amd64
      name: parent_node
      platform: {}
      replicas: 3
    metadata:
      creationTimestamp: null
      name: test
      platform:
        vsphere:
          apiVIPs:
            - 10.0.0.1
          failureDomains:
            - name: failure_domain_name
              region: default_region_name
              server: fully_qualified_domain_name
            topology:
              computeCluster: /<datacenter>/host/<cluster>
              datacenter: <datacenter>
              datastore: /<datacenter>/datastore/<datastore>
          networks:
            - <VM_Network_name>
            resourcePool: /<datacenter>/host/<cluster>/Resources/<resourcePool>
            folder: /<datacenter_name>/vm/<folder_name>/<subfolder_name>
          zone: default_zone_name
          ingressVIPs:
```

CHAPTER 22. INSTALLING ON VSPHERE
The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, `-`, and the first line of the controlPlane section must not. Only one control plane pool is used.

Establishes the relationships between a region and zone. You define a failure domain by using vCenter objects, such as a datastore object. A failure domain defines the vCenter location for OpenShift Container Platform cluster nodes.

The path to the vSphere datastore that holds virtual machine files, templates, and ISO images.

**IMPORTANT**

You can specify the path of any datastore that exists in a datastore cluster. By default, Storage vMotion is automatically enabled for a datastore cluster. Red Hat does not support Storage vMotion, so you must disable Storage vMotion to avoid data loss issues for your OpenShift Container Platform cluster.

If you must specify VMs across multiple datastores, use a datastore object to specify a failure domain in your cluster’s `install-config.yaml` configuration file. For more information, see "VMware vSphere region and zone enablement".
Optional: Provides an existing resource pool for machine creation. If you do not specify a value, the installation program uses the root resource pool of the vSphere cluster.

The vSphere disk provisioning method.

The location of the Red Hat Enterprise Linux CoreOS (RHCOS) image that is accessible from the bastion server.

For `<local_registry>`, specify the registry domain name, and optionally the port, that your mirror registry uses to serve content. For example `registry.example.com` or `registry.example.com:5000`. For `<credentials>`, specify the base64-encoded user name and password for your mirror registry.

Provide the contents of the certificate file that you used for your mirror registry.

Provide the `imageContentSources` section from the output of the command to mirror the repository.

**NOTE**

In OpenShift Container Platform 4.12 and later, the `apiVIP` and `ingressVIP` configuration settings are deprecated. Instead, use a list format to enter values in the `apiVIPS` and `ingressVIPs` configuration settings.

### 22.7.12.2. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**Prerequisites**

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

**Procedure**

1. Edit your `install-config.yaml` file and add the proxy settings. For example:
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port>
  httpsProxy: https://<username>:<pswd>@<ip>:<port>
noProxy: example.com
additionalTrustBundle:
  -----BEGIN CERTIFICATE-----
  <MY_TRUSTED_CA_CERT>
  -----END CERTIFICATE-----
additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle>

1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.

2. A proxy URL to use for creating HTTPS connections outside the cluster.

3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations. You must include vCenter’s IP address and the IP range that you use for its machines.

4. If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the trustedCA field of the Proxy object. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

5. Optional: The policy to determine the configuration of the Proxy object to reference the user-ca-bundle config map in the trustedCA field. The allowed values are Proxyonly and Always. Use Proxyonly to reference the user-ca-bundle config map only when http/https proxy is configured. Use Always to always reference the user-ca-bundle config map. The default value is Proxyonly.

NOTE
The installation program does not support the proxy readinessEndpoints field.

NOTE
If the installer times out, restart and then complete the deployment by using the wait-for command of the installer. For example:

```bash
$ ./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.
NOTE

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

22.7.12.3. Configuring regions and zones for a VMware vCenter

You can modify the default installation configuration file, so that you can deploy an OpenShift Container Platform cluster to multiple vSphere datacenters that run in a single VMware vCenter.

The default `install-config.yaml` file configuration from the previous release of OpenShift Container Platform is deprecated. You can continue to use the deprecated default configuration, but the `openshift-installer` will prompt you with a warning message that indicates the use of deprecated fields in the configuration file.

**IMPORTANT**

The example uses the `govc` command. The `govc` command is an open source command available from VMware; it is not available from Red Hat. The Red Hat support team does not maintain the `govc` command. Instructions for downloading and installing `govc` are found on the VMware documentation website.

Prerequisites

- You have an existing `install-config.yaml` installation configuration file.

**IMPORTANT**

You must specify at least one failure domain for your OpenShift Container Platform cluster, so that you can provision datacenter objects for your VMware vCenter server. Consider specifying multiple failure domains if you need to provision virtual machine nodes in different datacenters, clusters, datastores, and other components.

Procedure

1. Enter the following `govc` command-line tool commands to create the **openshift-region** and **openshift-zone** vCenter tag categories:

   **IMPORTANT**

   If you specify different names for the **openshift-region** and **openshift-zone** vCenter tag categories, the installation of the OpenShift Container Platform cluster fails.

   ```bash
   $ govc tags.category.create -d "OpenShift region" openshift-region
   $ govc tags.category.create -d "OpenShift zone" openshift-zone
   ```

2. To create a region tag for each region vSphere datacenter where you want to deploy your cluster, enter the following command in your terminal:

   ```bash
   $ govc tags.create -c <region_tag_category> <region_tag>
   ```
3. To create a zone tag for each vSphere cluster where you want to deploy your cluster, enter the following command:

```bash
$ govc tags.create -c <zone_tag_category> <zone_tag>
```

4. Attach region tags to each vCenter datacenter object by entering the following command:

```bash
$ govc tags.attach -c <region_tag_category> <region_tag_1> /<datacenter_1>
```

5. Attach the zone tags to each vCenter datacenter object by entering the following command:

```bash
$ govc tags.attach -c <zone_tag_category> <zone_tag_1> /<datacenter_1>/host/vcs-mdnc-workload-1
```

6. Change to the directory that contains the installation program and initialize the cluster deployment according to your chosen installation requirements.

**Sample install-config.yaml file with multiple datacenters defined in a vSphere center**

```yaml
---
compute:
  vsphere:
    zones:
      - "<machine_pool_zone_1>"
      - "<machine_pool_zone_2>"

controlPlane:
  vsphere:
    zones:
      - "<machine_pool_zone_1>"
      - "<machine_pool_zone_2>"

platform:
  vsphere:
    vcenters:
      datacenters:
        - <datacenter1_name>
        - <datacenter2_name>
    failureDomains:
      - name: <machine_pool_zone_1>
        region: <region_tag_1>
        zone: <zone_tag_1>
        server: <fully_qualified_domain_name>
        topology:
          datacenter: <datacenter1>
          computeCluster: "/<datacenter1>/host/<cluster1>"
          networks:
            - <VM_Network1_name>
          datastore: "/<datacenter1>/datastore/<datastore1>"
          resourcePool: "/<datacenter1>/host/<cluster1>/Resources/<resourcePool1>"
          folder: "/<datacenter1>/vm/<folder1>"
```
22.7.13. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

**Prerequisites**

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.
- Optional: Before you create the cluster, configure an external load balancer in place of the default load balancer.

**IMPORTANT**

You do not need to specify API and Ingress static addresses for your installation program. If you choose this configuration, you must take additional actions to define network targets that accept an IP address from each referenced vSphere subnet. See the section “Configuring an external load balancer”.

**Procedure**

- Change to the directory that contains the installation program and initialize the cluster deployment:

  ```bash
  $ ./openshift-install create cluster --dir <installation_directory> \  
  --log-level=info
  ```

  1. For `<installation_directory>`, specify the location of your customized `./install-config.yaml` file.

  2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

```yaml
- name: <machine_pool_zone_2>
  region: <region_tag_2>
  zone: <zone_tag_2>
  server: <fully_qualified_domain_name>
  topology:
    datacenter: <datacenter2>
    computeCluster: "/<datacenter2>/host/<cluster2>"
  networks:
  - <VM_Network2_name>
    datastore: "/<datacenter2>/datastore/<datastore2>"
    resourcePool: "/<datacenter2>/host/<cluster2>/Resources/<resourcePool2>"
    folder: "/<datacenter2>/vm/<folder2>"
```
Verification
When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the **kubeadmin** user.

- Credential information also outputs to `<installation_directory>/openshift_install.log`.

**IMPORTANT**
Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

Example output

```plaintext
... INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

22.7.14. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of **oc**.

**Installing the OpenShift CLI on Linux**

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.
Procedure

2. Select the architecture from the Product Variant drop-down list.

3. Select the appropriate version from the Version drop-down list.

4. Click Download Now next to the OpenShift v4.14 Linux Client entry and save the file.

5. Unpack the archive:

   $ tar xvf <file>

6. Place the oc binary in a directory that is on your PATH.
   To check your PATH, execute the following command:

   $ echo $PATH

Verification

- After you install the OpenShift CLI, it is available using the oc command:

  $ oc <command>

Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

Procedure

2. Select the appropriate version from the Version drop-down list.

3. Click Download Now next to the OpenShift v4.14 Windows Client entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the oc binary to a directory that is on your PATH.
   To check your PATH, open the command prompt and execute the following command:

   C:\> path

Verification

- After you install the OpenShift CLI, it is available using the oc command:

  C:\> oc <command>

Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.
Procedure

2. Select the appropriate version from the Version drop-down list.

3. Click Download Now next to the OpenShift v4.14 macOS Client entry and save the file.

   NOTE
   For macOS arm64, choose the OpenShift v4.14 macOS arm64 Client entry.

4. Unpack and unzip the archive.

5. Move the oc binary to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:
   
   $ echo $PATH

Verification

- After you install the OpenShift CLI, it is available using the oc command:

  $ oc <command>

22.7.15. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster kubeconfig file. The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.

- You installed the oc CLI.

Procedure

1. Export the kubeadmin credentials:

   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig

   For <installation_directory>, specify the path to the directory that you stored the installation files in.

2. Verify you can run oc commands successfully using the exported configuration:

   $ oc whoami
Example output

system:admin

22.7.16. Disabling the default OperatorHub catalog sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

Procedure

- Disable the sources for the default catalogs by adding `disableAllDefaultSources: true` to the `OperatorHub` object:

  ```bash
  $ oc patch OperatorHub cluster --type json \n  -p '[{"op": "add", "path": "/spec/disableAllDefaultSources", "value": true}]'
  ```

TIP

Alternatively, you can use the web console to manage catalog sources. From the Administration → Cluster Settings → Configuration → OperatorHub page, click the Sources tab, where you can create, update, delete, disable, and enable individual sources.

22.7.17. Creating registry storage

After you install the cluster, you must create storage for the Registry Operator.

22.7.17.1. Image registry removed during installation

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as Removed. This allows openshift-installer to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the managementState from Removed to Managed.

22.7.17.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the Recreate rollout strategy during upgrades.

22.7.17.2.1. Configuring registry storage for VMware vSphere

As a cluster administrator, following installation you must configure your registry to use storage.
Prerequisites

- Cluster administrator permissions.
- A cluster on VMware vSphere.
- Persistent storage provisioned for your cluster, such as Red Hat OpenShift Data Foundation.

**IMPORTANT**

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. **ReadWriteOnce** access also requires that the registry uses the **Recreate** rollout strategy. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have "100Gi" capacity.

**IMPORTANT**

Testing shows issues with using the NFS server on RHEL as storage backend for core services. This includes the OpenShift Container Registry and Quay, Prometheus for monitoring storage, and Elasticsearch for logging storage. Therefore, using RHEL NFS to back PVs used by core services is not recommended. Other NFS implementations on the marketplace might not have these issues. Contact the individual NFS implementation vendor for more information on any testing that was possibly completed against these OpenShift Container Platform core components.

Procedure

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

   **NOTE**

   When you use shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

   ```
   $ oc get pod -n openshift-image-registry -l docker-registry=default
   ```

   **Example output**

   No ressources found in openshift-image-registry namespace

   **NOTE**

   If you do have a registry pod in your output, you do not need to continue with this procedure.
3. Check the registry configuration:

```
$ oc edit configs.imageregistry.operator.openshift.io
```

**Example output**

```
storage:
pvc:
  claim: 1
```

Leave the `claim` field blank to allow the automatic creation of an `image-registry-storage` persistent volume claim (PVC). The PVC is generated based on the default storage class. However, be aware that the default storage class might provide ReadWriteOnce (RWO) volumes, such as a RADOS Block Device (RBD), which can cause issues when you replicate to more than one replica.

4. Check the `clusteroperator` status:

```
$ oc get clusteroperator image-registry
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
</tr>
</thead>
<tbody>
<tr>
<td>image-registry</td>
<td>4.7</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
</tbody>
</table>

### 22.7.18. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager Hybrid Cloud Console.

After you confirm that your OpenShift Cluster Manager Hybrid Cloud Console inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use `subscription watch` to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- See [About remote health monitoring](#) for more information about the Telemetry service

### 22.7.19. Configuring an external load balancer

You can configure an OpenShift Container Platform cluster to use an external load balancer in place of the default load balancer.
IMPORTANT

Configuring an external load balancer depends on your vendor’s load balancer.

The information and examples in this section are for guideline purposes only. Consult the vendor documentation for more specific information about the vendor’s load balancer.

Red Hat supports the following services for an external load balancer:

- OpenShift API
- Ingress Controller

You can choose to configure one or both of these services for an external load balancer. Configuring only the Ingress Controller service is a common configuration option.

The following configuration options are supported for external load balancers:

- Use a node selector to map the Ingress Controller to a specific set of nodes. You must assign a static IP address to each node in this set, or configure each node to receive the same IP address from the Dynamic Host Configuration Protocol (DHCP). Infrastructure nodes commonly receive this type of configuration.

- Target all IP addresses on a subnet. This configuration can reduce maintenance overhead, because you can create and destroy nodes within those networks without reconfiguring the load balancer targets. If you deploy your ingress pods by using a machine set on a smaller network, such as a /27 or /28, you can simplify your load balancer targets.

TIP

You can list all IP addresses that exist in a network by checking the machine config pool’s resources.

Considerations

- For a front-end IP address, you can use the same IP address for the front-end IP address, the Ingress Controller’s load balancer, and API load balancer. Check the vendor’s documentation for this capability.

- For a back-end IP address, ensure that an IP address for an OpenShift Container Platform control plane node does not change during the lifetime of the external load balancer. You can achieve this by completing one of the following actions:
  - Assign a static IP address to each control plane node.
  - Configure each node to receive the same IP address from the DHCP every time the node requests a DHCP lease. Depending on the vendor, the DHCP lease might be in the form of an IP reservation or a static DHCP assignment.
  - Manually define each node that runs the Ingress Controller in the external load balancer for the Ingress Controller back-end service. For example, if the Ingress Controller moves to an undefined node, a connection outage can occur.

OpenShift API prerequisites

- You defined a front-end IP address.
• TCP ports 6443 and 22623 are exposed on the front-end IP address of your load balancer. Check the following items:
  o Port 6443 provides access to the OpenShift API service.
  o Port 22623 can provide ignition startup configurations to nodes.
• The front-end IP address and port 6443 are reachable by all users of your system with a location external to your OpenShift Container Platform cluster.
• The front-end IP address and port 22623 are reachable only by OpenShift Container Platform nodes.
• The load balancer backend can communicate with OpenShift Container Platform control plane nodes on port 6443 and 22623.

**Ingress Controller prerequisites**

• You defined a front-end IP address.
• TCP ports 443 and 80 are exposed on the front-end IP address of your load balancer.
• The front-end IP address, port 80 and port 443 are reachable by all users of your system with a location external to your OpenShift Container Platform cluster.
• The front-end IP address, port 80 and port 443 are reachable to all nodes that operate in your OpenShift Container Platform cluster.
• The load balancer backend can communicate with OpenShift Container Platform nodes that run the Ingress Controller on ports 80, 443, and 1936.

**Prerequisite for health check URL specifications**

You can configure most load balancers by setting health check URLs that determine if a service is available or unavailable. OpenShift Container Platform provides these health checks for the OpenShift API, Machine Configuration API, and Ingress Controller backend services.

The following examples demonstrate health check specifications for the previously listed backend services:

**Example of a Kubernetes API health check specification**

```
Path: HTTPS:6443/readyz
Healthy threshold: 2
Unhealthy threshold: 2
Timeout: 10
Interval: 10
```

**Example of a Machine Config API health check specification**

```
Path: HTTPS:22623/healthz
Healthy threshold: 2
Unhealthy threshold: 2
Timeout: 10
Interval: 10
```
Example of an Ingress Controller health check specification

Path: HTTP:1936/healthz/ready
Healthy threshold: 2
Unhealthy threshold: 2
Timeout: 5
Interval: 10

Procedure

1. Configure the HAProxy Ingress Controller, so that you can enable access to the cluster from your load balancer on ports 6443, 443, and 80:

Example HAProxy configuration

```
#...
listen my-cluster-api-6443
  bind 192.168.1.100:6443
  mode tcp
  balance roundrobin
  option httpchk
  http-check connect
  http-check send meth GET uri /readyz
  http-check expect status 200
    server my-cluster-master-2 192.168.1.101:6443 check inter 10s rise 2 fall 2
    server my-cluster-master-0 192.168.1.102:6443 check inter 10s rise 2 fall 2
    server my-cluster-master-1 192.168.1.103:6443 check inter 10s rise 2 fall 2

listen my-cluster-machine-config-api-22623
  bind 192.168.1.1000.0.0.0:22623
  mode tcp
  balance roundrobin
  option httpchk
  http-check connect
  http-check send meth GET uri /healthz
  http-check expect status 200
    server my-cluster-master-2 192.0168.21.2101:22623 check inter 10s rise 2 fall 2
    server my-cluster-master-0 192.168.2.3:22623 check inter 10s rise 2 fall 2
    server my-cluster-master-1 192.168.1.1030.2.1:22623 check inter 10s rise 2 fall 2

listen my-cluster-apps-443
  bind 192.168.1.100:443
  mode tcp
  balance roundrobin
  option httpchk
  http-check connect
  http-check send meth GET uri /healthz/ready
  http-check expect status 200
    server my-cluster-worker-0 192.168.1.111:443 check port 1936 inter 10s rise 2 fall 2
    server my-cluster-worker-1 192.168.1.112:443 check port 1936 inter 10s rise 2 fall 2
    server my-cluster-worker-2 192.168.1.113:443 check port 1936 inter 10s rise 2 fall 2

listen my-cluster-apps-80
  bind 192.168.1.100:80
  mode tcp
```
2. Use the `curl` CLI command to verify that the external load balancer and its resources are operational:

a. Verify that the cluster machine configuration API is accessible to the Kubernetes API server resource, by running the following command and observing the response:

```
$ curl https://<loadbalancer_ip_address>:6443/version --insecure
```

If the configuration is correct, you receive a JSON object in response:

```
{
  "major": "1",
  "minor": "11+",
  "gitVersion": "v1.11.0+ad103ed",
  "gitCommit": "ad103ed",
  "gitTreeState": "clean",
  "buildDate": "2019-01-09T06:44:10Z",
  "goVersion": "go1.10.3",
  "compiler": "gc",
  "platform": "linux/amd64"
}
```

b. Verify that the cluster machine configuration API is accessible to the Machine config server resource, by running the following command and observing the output:

```
$ curl -v https://<loadbalancer_ip_address>:22623/healthz --insecure
```

If the configuration is correct, the output from the command shows the following response:

```
HTTP/1.1 200 OK
Content-Length: 0
```

c. Verify that the controller is accessible to the Ingress Controller resource on port 80, by running the following command and observing the output:

```
$ curl -I -L -H "Host: console-openshift-console.apps.<cluster_name>.<base_domain>" http://<load_balancer_front_end_IP_address>
```

If the configuration is correct, the output from the command shows the following response:

```
HTTP/1.1 302 Found
content-length: 0
location: https://console-openshift-console.apps.ocp4.private.opequon.net/
cache-control: no-cache
```
d. Verify that the controller is accessible to the Ingress Controller resource on port 443, by running the following command and observing the output:

```
```

If the configuration is correct, the output from the command shows the following response:

```
HTTP/1.1 200 OK
referrer-policy: strict-origin-when-cross-origin
set-cookie: csrf-token=UlYWOyQ62LWjw2h003xY5KLh1a0Py2hhctw0WmV2YEdhJjFyQwWcGBsja261dG
LgaYO0nxzVErhiXt6QepA7g==; Path=; Secure; SameSite=Lax
x-content-type-options: nosniff
x-dns-prefetch-control: off
x-frame-options: DENY
x-xss-protection: 1; mode=block
date: Wed, 04 Oct 2023 16:29:38 GMT
content-type: text/html; charset=utf-8
set-cookie: 1e2670d92730b515ce3a1bb65da45062=1bf5e9573c9a2760c964ed1659cc1673; path=/; HttpOnly; Secure; SameSite=None
cache-control: private
```

3. Configure the DNS records for your cluster to target the front-end IP addresses of the external load balancer. You must update records to your DNS server for the cluster API and applications over the load balancer.

**Examples of modified DNS records**

- `<load_balancer_ip_address>` A `api.<cluster_name>.<base_domain>`
  A record pointing to Load Balancer Front End

- `<load_balancer_ip_address>` A `apps.<cluster_name>.<base_domain>`
  A record pointing to Load Balancer Front End

**IMPORTANT**

DNS propagation might take some time for each DNS record to become available. Ensure that each DNS record propagates before validating each record.

4. Use the `curl` CLI command to verify that the external load balancer and DNS record configuration are operational:

a. Verify that you can access the cluster API, by running the following command and observing the output:

```
$ curl https://api.<cluster_name>.<base_domain>:6443/version --insecure
```

If the configuration is correct, you receive a JSON object in response:
b. Verify that you can access the cluster machine configuration, by running the following command and observing the output:

```bash
$ curl -v https://api.<cluster_name>.<base_domain>:22623/healthz --insecure
```

If the configuration is correct, the output from the command shows the following response:

```
HTTP/1.1 200 OK
Content-Length: 0
```

c. Verify that you can access each cluster application on port, by running the following command and observing the output:

```bash
$ curl http://console-openshift-console.apps.<cluster_name>.<base_domain> -I -L --insecure
```

If the configuration is correct, the output from the command shows the following response:

```
HTTP/1.1 302 Found
content-length: 0
location: https://console-openshift-console.apps.<cluster_name>.<base_domain>/
cache-control: no-cacheHTTP/1.1 200 OK
collector-transport-context: 20fd96d722
content-type: text/html; charset=utf-8
set-cookie: csrf-token=9HoZgszDNzjKq/JuLJMeoKXlihVVw2YgZc09c3TBOBU4Ni6kDXaH1LdicNhN1UsQWzon4Dor9GWGfpTaEQ==; Path=/; Secure
x-content-type-options: nosniff
x-dns-prefetch-control: off
x-frame-options: DENY
x-xss-protection: 1; mode=block
date: Tue, 17 Nov 2020 08:42:10 GMT
content-type: text/html; charset=utf-8
set-cookie: 1e2670d92730b515ce3a1bb65da45062=9b714eb87e93cf34853e87a92d6894be; path=/; HttpOnly; Secure; SameSite=None
```

d. Verify that you can access each cluster application on port 443, by running the following command and observing the output:

```bash
$ curl https://console-openshift-console.apps.<cluster_name>.<base_domain> -I -L --insecure
```
If the configuration is correct, the output from the command shows the following response:

HTTP/1.1 200 OK
referrer-policy: strict-origin-when-cross-origin
set-cookie: csrf-token=UlYWOyQ62LWjw2h003xtYSKlh1a0Py2hhctw0WmV2YEdhJjFyQwWcGBsja261dG

cache-control: private

22.7.20. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- If necessary, see Registering your disconnected cluster
- Set up your registry and configure registry storage.

22.8. INSTALLING A CLUSTER ON VSPHERE IN A RESTRICTED NETWORK WITH USER-PROVISIONED INFRASTRUCTURE

In OpenShift Container Platform version 4.14, you can install a cluster on VMware vSphere infrastructure that you provision in a restricted network.

**NOTE**

OpenShift Container Platform supports deploying a cluster to a single VMware vCenter only. Deploying a cluster with machines/machine sets on multiple vCenters is not supported.

**IMPORTANT**

The steps for performing a user-provisioned infrastructure installation are provided as an example only. Installing a cluster with infrastructure you provide requires knowledge of the vSphere platform and the installation process of OpenShift Container Platform. Use the user-provisioned infrastructure installation instructions as a guide; you are free to create the required resources through other methods.

22.8.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
You read the documentation on selecting a cluster installation method and preparing it for users.

You created a registry on your mirror host and obtained the `imageContentSources` data for your version of OpenShift Container Platform.

**IMPORTANT**

Because the installation media is on the mirror host, you can use that computer to complete all installation steps.

You provisioned persistent storage for your cluster. To deploy a private image registry, your storage must provide `ReadWriteMany` access modes.

Completing the installation requires that you upload the Red Hat Enterprise Linux CoreOS (RHCOS) OVA on vSphere hosts. The machine from which you complete this process requires access to port 443 on the vCenter and ESXi hosts. You verified that port 443 is accessible.

If you use a firewall, you confirmed with the administrator that port 443 is accessible. Control plane nodes must be able to reach vCenter and ESXi hosts on port 443 for the installation to succeed.

If you use a firewall and plan to use the Telemetry service, you configured the firewall to allow the sites that your cluster requires access to.

**NOTE**

Be sure to also review this site list if you are configuring a proxy.

### 22.8.2. About installations in restricted networks

In OpenShift Container Platform 4.14, you can perform an installation that does not require an active connection to the internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service’s Route 53 DNS and IAM services, require internet access. Depending on your network, you might require less internet access for an installation on bare metal hardware, Nutanix, or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift image registry and contains the installation media. You can create this registry on a mirror host, which can access both the internet and your closed network, or by using other methods that meet your restrictions.

**IMPORTANT**

Because of the complexity of the configuration for user-provisioned installations, consider completing a standard user-provisioned infrastructure installation before you attempt a restricted network installation using user-provisioned infrastructure. Completing this test installation might make it easier to isolate and troubleshoot any issues that might arise during your installation in a restricted network.
22.8.2.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The **ClusterVersion** status includes an **Unable to retrieve available updates** error.
- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

22.8.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to obtain the images that are necessary to install your cluster.

You must have internet access to:

- Access **OpenShift Cluster Manager Hybrid Cloud Console** to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access **Quay.io** to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

22.8.4. VMware vSphere infrastructure requirements

You must install the OpenShift Container Platform cluster on a VMware vSphere version 7.0 Update 2 or later instance that meets the requirements for the components that you use.

**NOTE**

OpenShift Container Platform version 4.14 supports VMware vSphere version 8.0.

You can host the VMware vSphere infrastructure on-premise or on a VMware Cloud Verified provider that meets the requirements outlined in the following tables:

**Table 22.63. Version requirements for vSphere virtual environments**

<table>
<thead>
<tr>
<th>Virtual environment product</th>
<th>Required version</th>
</tr>
</thead>
<tbody>
<tr>
<td>VMware virtual hardware</td>
<td>15 or later</td>
</tr>
<tr>
<td>vSphere ESXi hosts</td>
<td>7.0 Update 2 or later</td>
</tr>
<tr>
<td>vCenter host</td>
<td>7.0 Update 2 or later</td>
</tr>
</tbody>
</table>

**IMPORTANT**

You must ensure that the time on your ESXi hosts is synchronized before you install OpenShift Container Platform. See **Edit Time Configuration for a Host** in the VMware documentation.
### Table 22.64. Minimum supported vSphere version for VMware components

<table>
<thead>
<tr>
<th>Component</th>
<th>Minimum supported versions</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hypervisor</td>
<td>vSphere 7.0 Update 2 and later with virtual hardware version 15</td>
<td>This version is the minimum version that Red Hat Enterprise Linux CoreOS (RHCOS) supports. For more information about supported hardware on the latest version of Red Hat Enterprise Linux (RHEL) that is compatible with RHCOS, see Hardware on the Red Hat Customer Portal.</td>
</tr>
<tr>
<td>Storage with in-tree drivers</td>
<td>vSphere 7.0 Update 2 and later</td>
<td>This plugin creates vSphere storage by using the in-tree storage drivers for vSphere included in OpenShift Container Platform.</td>
</tr>
<tr>
<td>Optional: Networking (NSX-T)</td>
<td>vSphere 7.0 Update 2 and later</td>
<td>vSphere 7.0 Update 2 is required for OpenShift Container Platform. For more information about the compatibility of NSX and OpenShift Container Platform, see the Release Notes section of VMware’s NSX container plugin documentation.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

To ensure the best performance conditions for your cluster workloads that operate on Oracle® Cloud Infrastructure and on the Oracle® Cloud VMware Solution (OCVS) service, ensure volume performance units (VPUs) for your block volume are sized for your workloads.

The following list provides some guidance in selecting the VPUs needed for specific performance needs:

- Test or proof of concept environment: 100 GB, and 20 to 30 VPUs.
- Base-production environment: 500 GB, and 60 VPUs.
- Heavy-use production environment: More than 500 GB, and 100 or more VPUs.

Consider allocating additional VPUs to give enough capacity for updates and scaling activities. See Block Volume Performance Levels in the Oracle documentation.

#### 22.8.5. VMware vSphere CSI Driver Operator requirements

To install the vSphere CSI Driver Operator, the following requirements must be met:

- VMware vSphere version 7.0 Update 2 or later
• vCenter 7.0 Update 2 or later
• Virtual machines of hardware version 15 or later
• No third-party vSphere CSI driver already installed in the cluster

If a third-party vSphere CSI driver is present in the cluster, OpenShift Container Platform does not overwrite it. The presence of a third-party vSphere CSI driver prevents OpenShift Container Platform from updating to OpenShift Container Platform 4.13 or later.

**NOTE**

The VMware vSphere CSI Driver Operator is supported only on clusters deployed with `platform: vsphere` in the installation manifest.

**Additional resources**

• To remove a third-party vSphere CSI driver, see [Removing a third-party vSphere CSI Driver](#).

• To update the hardware version for your vSphere nodes, see [Updating hardware on nodes running in vSphere](#).

### 22.8.6. Requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines. This section describes the requirements for deploying OpenShift Container Platform on user-provisioned infrastructure.

#### 22.8.6.1. vCenter requirements

Before you install an OpenShift Container Platform cluster on your vCenter that uses infrastructure that you provided, you must prepare your environment.

**Required vCenter account privileges**

To install an OpenShift Container Platform cluster in a vCenter, your vSphere account must include privileges for reading and creating the required resources. Using an account that has global administrative privileges is the simplest way to access all of the necessary permissions.

**Example 22.25. Roles and privileges required for installation in vSphere API**

<table>
<thead>
<tr>
<th>vSphere object for role</th>
<th>When required</th>
<th>Required privileges in vSphere API</th>
</tr>
</thead>
</table>

For more information about creating an account with only the required privileges, see vSphere Permissions and User Management Tasks in the vSphere documentation.

Using OpenShift Container Platform with vMotion
If you intend on using vMotion in your vSphere environment, consider the following before installing an OpenShift Container Platform cluster.

- OpenShift Container Platform generally supports compute-only vMotion, where generally implies that you meet all VMware best practices for vMotion. To help ensure the uptime of your compute and control plane nodes, ensure that you follow the VMware best practices for vMotion, and use VMware anti-affinity rules to improve the availability of OpenShift Container Platform during maintenance or hardware issues.

For more information about vMotion and anti-affinity rules, see the VMware vSphere documentation for vMotion networking requirements and VM anti-affinity rules.

- Using Storage vMotion can cause issues and is not supported. If you are using vSphere volumes in your pods, migrating a VM across datastores, either manually or through Storage vMotion, causes invalid references within OpenShift Container Platform persistent volume (PV) objects that can result in data loss.

- OpenShift Container Platform does not support selective migration of VMDKs across datastores, using datastore clusters for VM provisioning or for dynamic or static provisioning of PVs, or using a datastore that is part of a datastore cluster for dynamic or static provisioning of PVs.

**IMPORTANT**

You can specify the path of any datastore that exists in a datastore cluster. By default, Storage Distributed Resource Scheduler (SDRS), which uses Storage vMotion, is automatically enabled for a datastore cluster. Red Hat does not support Storage vMotion, so you must disable Storage DRS to avoid data loss issues for your OpenShift Container Platform cluster.

If you must specify VMs across multiple datastores, use a datastore object to specify a failure domain in your cluster’s `install-config.yaml` configuration file. For more information, see “VMware vSphere region and zone enablement”.

Cluster resources
When you deploy an OpenShift Container Platform cluster that uses infrastructure that you provided, you must create the following resources in your vCenter instance:

- 1 Folder
- 1 Tag category
Virtual machines:
- 1 template
- 1 temporary bootstrap node
- 3 control plane nodes
- 3 compute machines

Although these resources use 856 GB of storage, the bootstrap node is destroyed during the cluster installation process. A minimum of 800 GB of storage is required to use a standard cluster.

If you deploy more compute machines, the OpenShift Container Platform cluster will use more storage.

**Cluster limits**
Available resources vary between clusters. The number of possible clusters within a vCenter is limited primarily by available storage space and any limitations on the number of required resources. Be sure to consider both limitations to the vCenter resources that the cluster creates and the resources that you require to deploy a cluster, such as IP addresses and networks.

**Networking requirements**
Use Dynamic Host Configuration Protocol (DHCP) for the network and ensure that the DHCP server is configured to provide persistent IP addresses to the cluster machines.

NOTE
You do not need to use the DHCP for the network if you want to provision nodes with static IP addresses.

Configure the default gateway to use the DHCP server. All nodes must be in the same VLAN. You cannot scale the cluster using a second VLAN as a Day 2 operation.

You must use the Dynamic Host Configuration Protocol (DHCP) for the network and ensure that the DHCP server is configured to provide persistent IP addresses to the cluster machines. In the DHCP lease, you must configure the DHCP to use the default gateway. All nodes must be in the same VLAN. You cannot scale the cluster using a second VLAN as a Day 2 operation.

Additionally, you must create the following networking resources before you install the OpenShift Container Platform cluster:

NOTE
It is recommended that each OpenShift Container Platform node in the cluster must have access to a Network Time Protocol (NTP) server that is discoverable via DHCP. Installation is possible without an NTP server. However, asynchronous server clocks will cause errors, which NTP server prevents.

**Required IP Addresses**
**DNS records**
You must create DNS records for two static IP addresses in the appropriate DNS server for the vCenter instance that hosts your OpenShift Container Platform cluster. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the cluster base domain that you specify when you install the
cluster. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>`.

Table 22.65. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>API VIP</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>This DNS A/AAAA or CNAME record must point to the load balancer for the control plane machines. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Ingress VIP</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A wildcard DNS A/AAAA or CNAME record that points to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. This record must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>

Additional resources

- Creating a compute machine set on vSphere

22.8.6.2. Required machines for cluster installation

The smallest OpenShift Container Platform clusters require the following hosts:

Table 22.66. Minimum required hosts

<table>
<thead>
<tr>
<th>Hosts</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>One temporary bootstrap machine</td>
<td>The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.</td>
</tr>
<tr>
<td>Three control plane machines</td>
<td>The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.</td>
</tr>
<tr>
<td>At least two compute machines, which are also known as worker machines.</td>
<td>The workloads requested by OpenShift Container Platform users run on the compute machines.</td>
</tr>
</tbody>
</table>
To maintain high availability of your cluster, use separate physical hosts for these cluster machines.

The bootstrap and control plane machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system. However, the compute machines can choose between Red Hat Enterprise Linux CoreOS (RHCOS), Red Hat Enterprise Linux (RHEL) 8.6 and later.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 9.2 and inherits all of its hardware certifications and requirements. See Red Hat Enterprise Linux technology capabilities and limits.

### 22.8.6.3. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

**Table 22.67. Minimum resource requirements**

<table>
<thead>
<tr>
<th>Machine</th>
<th>Operating System</th>
<th>vCPU</th>
<th>Virtual RAM</th>
<th>Storage</th>
<th>Input/Output Per Second (IOPS)[1]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS, RHEL 8.6 and later [2]</td>
<td>2</td>
<td>8 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
</tbody>
</table>

1. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.

2. As with all user-provisioned installations, if you choose to use RHEL compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and has been removed in OpenShift Container Platform 4.10 and later.

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

**Additional resources**

- Optimizing storage

### 22.8.6.4. Requirements for encrypting virtual machines

You can encrypt your virtual machines prior to installing OpenShift Container Platform 4.14 by meeting the following requirements.
You have configured a Standard key provider in vSphere. For more information, see Adding a
KMS to vCenter Server.

IMPORTANT
The Native key provider in vCenter is not supported. For more information, see vSphere Native Key Provider Overview.

- You have enabled host encryption mode on all of the ESXi hosts that are hosting the cluster. For more information, see Enabling host encryption mode.

- You have a vSphere account which has all cryptographic privileges enabled. For more information, see Cryptographic Operations Privileges.

When you deploy the OVF template in the section titled "Installing RHCOS and starting the OpenShift Container Platform bootstrap process", select the option to "Encrypt this virtual machine" when you are selecting storage for the OVF template. After completing cluster installation, create a storage class that uses the encryption storage policy you used to encrypt the virtual machines.

Additional resources
- Creating an encrypted storage class

22.8.6.5. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The kube-controller-manager only approves the kubelet client CSRs. The machine-approver cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

22.8.6.6. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in initramfs during boot to fetch their Ignition config files.

During the initial boot, the machines require an IP address configuration that is set either through a DHCP server or statically by providing the required boot options. After a network connection is established, the machines download their Ignition config files from an HTTP or HTTPS server. The Ignition config files are then used to set the exact state of each machine. The Machine Config Operator completes more changes to the machines, such as the application of new certificates or keys, after installation.

It is recommended to use a DHCP server for long-term management of the cluster machines. Ensure that the DHCP server is configured to provide persistent IP addresses, DNS server information, and hostnames to the cluster machines.
NOTE

If a DHCP service is not available for your user-provisioned infrastructure, you can instead provide the IP networking configuration and the address of the DNS server to the nodes at RHCOS install time. These can be passed as boot arguments if you are installing from an ISO image. See the Installing RHCOS and starting the OpenShift Container Platform bootstrap process section for more information about static IP provisioning and advanced networking options.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

22.8.6.6.1. Setting the cluster node hostnames through DHCP

On Red Hat Enterprise Linux CoreOS (RHCOS) machines, the hostname is set through NetworkManager. By default, the machines obtain their hostname through DHCP. If the hostname is not provided by DHCP, set statically through kernel arguments, or another method, it is obtained through a reverse DNS lookup. Reverse DNS lookup occurs after the network has been initialized on a node and can take time to resolve. Other system services can start prior to this and detect the hostname as localhost or similar. You can avoid this by using DHCP to provide the hostname for each cluster node.

Additionally, setting the hostnames through DHCP can bypass any manual DNS record name configuration errors in environments that have a DNS split-horizon implementation.

22.8.6.6.2. Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Port</th>
<th>Description</th>
</tr>

Ethernet adaptor hardware address requirements
When provisioning VMs for the cluster, the ethernet interfaces configured for each VM must use a MAC address from the VMware Organizationally Unique Identifier (OUI) allocation ranges:

- 00:05:69:00:00:00 to 00:05:69:FF:FF
- 00:0c:29:00:00:00 to 00:0c:29:FF:FF
- 00:1c:14:00:00:00 to 00:1c:14:FF:FF
- 00:50:56:00:00:00 to 00:50:56:3F:FF

If a MAC address outside the VMware OUI is used, the cluster installation will not succeed.

NTP configuration for user-provisioned infrastructure
OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a
disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for Configuring chrony time service.

If a DHCP server provides NTP server information, the chrony time service on the Red Hat Enterprise Linux CoreOS (RHCOS) machines read the information and can sync the clock with the NTP servers.

Additional resources

- Configuring chrony time service

22.8.6.7. User-provisioned DNS requirements

In OpenShift Container Platform deployments, DNS name resolution is required for the following components:

- The Kubernetes API
- The OpenShift Container Platform application wildcard
- The bootstrap, control plane, and compute machines

Reverse DNS resolution is also required for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the hostnames for all the nodes, unless the hostnames are provided by DHCP. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

NOTE

It is recommended to use a DHCP server to provide the hostnames to each cluster node. See the DHCP recommendations for user-provisioned infrastructure section for more information.

The following DNS records are required for a user-provisioned OpenShift Container Platform cluster and they must be in place before installation. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>.

Table 22.71. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes API</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the API load balancer. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Component</td>
<td>Record</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>---------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>api-int.&lt;cluster_name&gt;..&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to internally identify the API load balancer. These records must be resolvable from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Routes</td>
<td>*.apps.&lt;cluster_name&gt;..&lt;base_domain&gt;.</td>
<td>A wildcard DNS A/AAAA or CNAME record that refers to the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster. For example, console-openshift-console.apps.&lt;cluster_name&gt;..&lt;base_domain&gt; is used as a wildcard route to the OpenShift Container Platform console.</td>
</tr>
<tr>
<td>Bootstrap machine</td>
<td>bootstrap.&lt;cluster_name&gt;..&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Control plane</td>
<td>&lt;master&gt;&lt;n&gt;.&lt;cluster_name&gt;..&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Compute machines</td>
<td>&lt;worker&gt;&lt;n&gt;.&lt;cluster_name&gt;..&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**NOTE**

In OpenShift Container Platform 4.4 and later, you do not need to specify etcd host and SRV records in your DNS configuration.

**TIP**

You can use the `dig` command to verify name and reverse name resolution. See the section on Validating DNS resolution for user-provisioned infrastructure for detailed validation steps.
22.8.6.7.1. Example DNS configuration for user-provisioned clusters

This section provides A and PTR record configuration samples that meet the DNS requirements for deploying OpenShift Container Platform on user-provisioned infrastructure. The samples are not meant to provide advice for choosing one DNS solution over another.

In the examples, the cluster name is `ocp4` and the base domain is `example.com`.

Example DNS A record configuration for a user-provisioned cluster

The following example is a BIND zone file that shows sample A records for name resolution in a user-provisioned cluster.

```plaintext
$TTL 1W
@ IN SOA ns1.example.com. root (2019070700 ; serial 3H ; refresh (3 hours) 30M ; retry (30 minutes) 2W ; expiry (2 weeks) 1W ) ; minimum (1 week)

99.1.168.192.in-addr.arpa. IN PTR master2.ocp4.example.com. 6
;
11.1.168.192.in-addr.arpa. IN PTR worker0.ocp4.example.com. 7
7.1.168.192.in-addr.arpa. IN PTR worker1.ocp4.example.com. 8
;
;EOF
```

1 Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer.
2 Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer and is used for internal cluster communications.
3 Provides reverse DNS resolution for the bootstrap machine.
4 5 6 Provides reverse DNS resolution for the control plane machines.
Provides reverse DNS resolution for the compute machines.

NOTE

A PTR record is not required for the OpenShift Container Platform application wildcard.

22.8.6.8. Load balancing requirements for user-provisioned infrastructure

Before you install OpenShift Container Platform, you must provision the API and application Ingress load balancing infrastructure. In production scenarios, you can deploy the API and application Ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

NOTE

If you want to deploy the API and application Ingress load balancers with a Red Hat Enterprise Linux (RHEL) instance, you must purchase the RHEL subscription separately.

The load balancing infrastructure must meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.
   - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

   **IMPORTANT**

   Do not configure session persistence for an API load balancer. Configuring session persistence for a Kubernetes API server might cause performance issues from excess application traffic for your OpenShift Container Platform cluster and the Kubernetes API that runs inside the cluster.

Configure the following ports on both the front and back of the load balancers:

**Table 22.72. API load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the /readyz endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
</tbody>
</table>
22623
Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.

**NOTE**

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the `/readyz` endpoint to the removal of the API server instance from the pool. Within the time frame after `/readyz` returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application Ingress load balancer**: Provides an ingress point for application traffic flowing in from outside the cluster. A working configuration for the Ingress router is required for an OpenShift Container Platform cluster.

Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

**TIP**

If the true IP address of the client can be seen by the application Ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

Configure the following ports on both the front and back of the load balancers:

**Table 22.73. Application Ingress load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>
If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application Ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

22.8.6.8.1. Example load balancer configuration for user-provisioned clusters

This section provides an example API and application Ingress load balancer configuration that meets the load balancing requirements for user-provisioned clusters. The sample is an `/etc/haproxy/haproxy.cfg` configuration for an HAProxy load balancer. The example is not meant to provide advice for choosing one load balancing solution over another.

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

**NOTE**

If you are using HAProxy as a load balancer and SELinux is set to enforcing, you must ensure that the HAProxy service can bind to the configured TCP port by running `setsebool -P haproxy_connect_any=1`.

Example 22.30. Sample API and application Ingress load balancer configuration

```
global
log 127.0.0.1 local2
pidfile /var/run/haproxy.pid
maxconn 4000
daemon
defaults
mode http
log global
dontlognull
option http-server-close
option redispatch
retries 3
timeout http-request 10s
timeout queue 1m
timeout connect 10s
timeout client 1m
timeout server 1m
timeout http-keep-alive 10s
timeout check 10s
maxconn 3000
listen api-server-6443 1
bind *:6443
mode tcp
server bootstrap bootstrap.ocp4.example.com:6443 check inter 1s backup
 2
server master0 master0.ocp4.example.com:6443 check inter 1s
server master1 master1.ocp4.example.com:6443 check inter 1s
server master2 master2.ocp4.example.com:6443 check inter 1s
listen machine-config-server-22623 3
```
Port 6443 handles the Kubernetes API traffic and points to the control plane machines.  

The bootstrap entries must be in place before the OpenShift Container Platform cluster installation and they must be removed after the bootstrap process is complete.

Port 22623 handles the machine config server traffic and points to the control plane machines.

Port 443 handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

Port 80 handles the HTTP traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

NOTE

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application Ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

TIP

If you are using HAProxy as a load balancer, you can check that the haproxy process is listening on ports 6443, 22623, 443, and 80 by running netstat -nltupe on the HAProxy node.

22.8.7. Preparing the user-provisioned infrastructure

Before you install OpenShift Container Platform on user-provisioned infrastructure, you must prepare the underlying infrastructure.

This section provides details about the high-level steps required to set up your cluster infrastructure in preparation for an OpenShift Container Platform installation. This includes configuring IP networking and network connectivity for your cluster nodes, enabling the required ports through your firewall, and
setting up the required DNS and load balancing infrastructure.

After preparation, your cluster infrastructure must meet the requirements outlined in the Requirements for a cluster with user-provisioned infrastructure section.

Prerequisites

- You have reviewed the OpenShift Container Platform 4.x Tested Integrations page.
- You have reviewed the infrastructure requirements detailed in the Requirements for a cluster with user-provisioned infrastructure section.

Procedure

1. If you are using DHCP to provide the IP networking configuration to your cluster nodes, configure your DHCP service.
   
   a. Add persistent IP addresses for the nodes to your DHCP server configuration. In your configuration, match the MAC address of the relevant network interface to the intended IP address for each node.
   
   b. When you use DHCP to configure IP addressing for the cluster machines, the machines also obtain the DNS server information through DHCP. Define the persistent DNS server address that is used by the cluster nodes through your DHCP server configuration.

   **NOTE**

   If you are not using a DHCP service, you must provide the IP networking configuration and the address of the DNS server to the nodes at RHCOS install time. These can be passed as boot arguments if you are installing from an ISO image. See the Installing RHCOS and starting the OpenShift Container Platform bootstrap process section for more information about static IP provisioning and advanced networking options.

   c. Define the hostnames of your cluster nodes in your DHCP server configuration. See the Setting the cluster node hostnames through DHCP section for details about hostname considerations.

   **NOTE**

   If you are not using a DHCP service, the cluster nodes obtain their hostname through a reverse DNS lookup.

2. Ensure that your network infrastructure provides the required network connectivity between the cluster components. See the Networking requirements for user-provisioned infrastructure section for details about the requirements.

3. Configure your firewall to enable the ports required for the OpenShift Container Platform cluster components to communicate. See Networking requirements for user-provisioned infrastructure section for details about the ports that are required.
IMPORTANT

By default, port 1936 is accessible for an OpenShift Container Platform cluster, because each control plane node needs access to this port.

Avoid using the Ingress load balancer to expose this port, because doing so might result in the exposure of sensitive information, such as statistics and metrics, related to Ingress Controllers.

4. Setup the required DNS infrastructure for your cluster.
   a. Configure DNS name resolution for the Kubernetes API, the application wildcard, the bootstrap machine, the control plane machines, and the compute machines.
   b. Configure reverse DNS resolution for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.
      See the User-provisioned DNS requirements section for more information about the OpenShift Container Platform DNS requirements.

5. Validate your DNS configuration.
   a. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses in the responses correspond to the correct components.
   b. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names in the responses correspond to the correct components.
      See the Validating DNS resolution for user-provisioned infrastructure section for detailed DNS validation steps.

6. Provision the required API and application ingress load balancing infrastructure. See the Load balancing requirements for user-provisioned infrastructure section for more information about the requirements.

NOTE

Some load balancing solutions require the DNS name resolution for the cluster nodes to be in place before the load balancing is initialized.

22.8.8. Validating DNS resolution for user-provisioned infrastructure

You can validate your DNS configuration before installing OpenShift Container Platform on user-provisioned infrastructure.

IMPORTANT

The validation steps detailed in this section must succeed before you install your cluster.

Prerequisites

- You have configured the required DNS records for your user-provisioned infrastructure.

Procedure
1. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses contained in the responses correspond to the correct components.

   a. Perform a lookup against the Kubernetes API record name. Check that the result points to the IP address of the API load balancer:

   ```
   $ dig +noall +answer @<nameserver_ip> api.<cluster_name>.<base_domain>
   ```

   1. Replace `<nameserver_ip>` with the IP address of the nameserver, `<cluster_name>` with your cluster name, and `<base_domain>` with your base domain name.

   **Example output**

   ```
   api.ocp4.example.com. 604800 IN A 192.168.1.5
   ```

   b. Perform a lookup against the Kubernetes internal API record name. Check that the result points to the IP address of the API load balancer:

   ```
   $ dig +noall +answer @<nameserver_ip> api-int.<cluster_name>.<base_domain>
   ```

   **Example output**

   ```
   api-int.ocp4.example.com. 604800 IN A 192.168.1.5
   ```

   c. Test an example `*.apps.<cluster_name>.<base_domain>` DNS wildcard lookup. All of the application wildcard lookups must resolve to the IP address of the application ingress load balancer:

   ```
   $ dig +noall +answer @<nameserver_ip> random.apps.<cluster_name>.<base_domain>
   ```

   **Example output**

   ```
   random.apps.ocp4.example.com. 604800 IN A 192.168.1.5
   ```

   **NOTE**

   In the example outputs, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

   You can replace `random` with another wildcard value. For example, you can query the route to the OpenShift Container Platform console:

   ```
   $ dig +noall +answer @<nameserver_ip> console-openshift-console.apps.<cluster_name>.<base_domain>
   ```

   **Example output**
d. Run a lookup against the bootstrap DNS record name. Check that the result points to the IP address of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> bootstrap.<cluster_name>.<base_domain>
```

**Example output**

```
bootstrap.ocp4.example.com. 604800 IN A 192.168.1.96
```

e. Use this method to perform lookups against the DNS record names for the control plane and compute nodes. Check that the results correspond to the IP addresses of each node.

2. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names contained in the responses correspond to the correct components.

a. Perform a reverse lookup against the IP address of the API load balancer. Check that the response includes the record names for the Kubernetes API and the Kubernetes internal API:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.5
```

**Example output**

```
5.1.168.192.in-addr.arpa. 604800 IN PTR api-int.ocp4.example.com.
```

1. Provides the record name for the Kubernetes internal API.
2. Provides the record name for the Kubernetes API.

**NOTE**

A PTR record is not required for the OpenShift Container Platform application wildcard. No validation step is needed for reverse DNS resolution against the IP address of the application ingress load balancer.

b. Perform a reverse lookup against the IP address of the bootstrap node. Check that the result points to the DNS record name of the bootstrap node:

```
$ dig +noall +answer @<nameserver_ip> -x 192.168.1.96
```

**Example output**

```
```

c. Use this method to perform reverse lookups against the IP addresses for the control plane and compute nodes. Check that the results correspond to the DNS record names of each node.
22.8.9. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The ./openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N "" -f /path/<file_name>
   ``

   Specify the path and file name, such as ~/.ssh/id_ed25519, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   ```bash
   $ cat /path/<file_name>.pub
   ```

   For example, run the following to view the ~/.ssh/id_ed25519.pub public key:

   ```bash
   $ cat ~/.ssh/id_ed25519.pub
   ```
3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the ./openshift-install gather command.

**NOTE**

On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.

a. If the ssh-agent process is not already running for your local user, start it as a background task:

   $ eval "$(ssh-agent -s)"

**Example output**

   Agent pid 31874

**NOTE**

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the ssh-agent:

   $ ssh-add <path>/<file_name> ¹

   ¹ Specify the path and file name for your SSH private key, such as ~/.ssh/id_ed25519

**Example output**

   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program. If you install a cluster on infrastructure that you provision, you must provide the key to the installation program.

**22.8.10. VMware vSphere region and zone enablement**

You can deploy an OpenShift Container Platform cluster to multiple vSphere datacenters that run in a single VMware vCenter. Each datacenter can run multiple clusters. This configuration reduces the risk of a hardware failure or network outage that can cause your cluster to fail.
IMPORTANT

The VMware vSphere region and zone enablement feature requires the vSphere Container Storage Interface (CSI) driver as the default storage driver in the cluster. As a result, the feature only available on a newly installed cluster.

A cluster that was upgraded from a previous release defaults to using the in-tree vSphere driver, so you must enable CSI automatic migration for the cluster. You can then configure multiple regions and zones for the upgraded cluster.

The default installation configuration deploys a cluster to a single vSphere datacenter. If you want to deploy a cluster to multiple vSphere datacenters, you must create an installation configuration file that enables the region and zone feature.

The default install-config.yaml file includes vcenters and failureDomains fields, where you can specify multiple vSphere datacenters and clusters for your OpenShift Container Platform cluster. You can leave these fields blank if you want to install an OpenShift Container Platform cluster in a vSphere environment that consists of single datacenter.

The following list describes terms associated with defining zones and regions for your cluster:

- Failure domain: Establishes the relationships between a region and zone. You define a failure domain by using vCenter objects, such as a datastore object. A failure domain defines the vCenter location for OpenShift Container Platform cluster nodes.

- Region: Specifies a vCenter datacenter. You define a region by using a tag from the openshift-region tag category.

- Zone: Specifies a vCenter cluster. You define a zone by using a tag from the openshift-zone tag category.

NOTE

If you plan on specifying more than one failure domain in your install-config.yaml file, you must create tag categories, zone tags, and region tags in advance of creating the configuration file.

You must create a vCenter tag for each vCenter datacenter, which represents a region. Additionally, you must create a vCenter tag for each cluster than runs in a datacenter, which represents a zone. After you create the tags, you must attach each tag to their respective datacenters and clusters.

The following table outlines an example of the relationship among regions, zones, and tags for a configuration with multiple vSphere datacenters running in a single VMware vCenter.

<table>
<thead>
<tr>
<th>Datacenter (region)</th>
<th>Cluster (zone)</th>
<th>Tags</th>
</tr>
</thead>
<tbody>
<tr>
<td>us-east</td>
<td>us-east-1</td>
<td>us-east-1a</td>
</tr>
<tr>
<td></td>
<td></td>
<td>us-east-1b</td>
</tr>
<tr>
<td>us-east</td>
<td>us-east-2</td>
<td>us-east-2a</td>
</tr>
<tr>
<td></td>
<td></td>
<td>us-east-2b</td>
</tr>
</tbody>
</table>
## Additional resources

- Additional VMware vSphere configuration parameters
- Deprecated VMware vSphere configuration parameters
- vSphere automatic migration
- VMware vSphere CSI Driver Operator

### 22.8.11. Manually creating the installation configuration file

For user-provisioned installations of OpenShift Container Platform, you manually generate your installation configuration file.

**IMPORTANT**

The Cluster Cloud Controller Manager Operator performs a connectivity check on a provided hostname or IP address. Ensure that you specify a hostname or an IP address to a reachable vCenter server. If you provide metadata to a non-existent vCenter server, installation of the cluster fails at the bootstrap stage.

### Prerequisites

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.
- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.
- Obtain the `imageContentSources` section from the output of the command to mirror the repository.
- Obtain the contents of the certificate for your mirror registry.

### Procedure

1. Create an installation directory to store your required installation assets in:

   ```
   $ mkdir <installation_directory>
   ```
IMPORTANT

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample `install-config.yaml` file template that is provided and save it in the `<installation_directory>`.

NOTE

You must name this configuration file `install-config.yaml`.

- Unless you use a registry that RHCOS trusts by default, such as `docker.io`, you must provide the contents of the certificate for your mirror repository in the `additionalTrustBundle` section. In most cases, you must provide the certificate for your mirror.

- You must include the `imageContentSources` section from the output of the command to mirror the repository.

IMPORTANT

- The `ImageContentSourcePolicy` file is generated as an output of `oc mirror` after the mirroring process is finished.

- The `oc mirror` command generates an `ImageContentSourcePolicy` file which contains the YAML needed to define `ImageContentSourcePolicy`. Copy the text from this file and paste it into your `install-config.yaml` file.

- You must run the `oc mirror` command twice. The first time you run the `oc mirror` command, you get a full `ImageContentSourcePolicy` file. The second time you run the `oc mirror` command, you only get the difference between the first and second run. Because of this behavior, you must always keep a backup of these files in case you need to merge them into one complete `ImageContentSourcePolicy` file. Keeping a backup of these two output files ensures that you have a complete `ImageContentSourcePolicy` file.

NOTE

For some platform types, you can alternatively run `/openshift-install create install-config --dir <installation_directory>` to generate an `install-config.yaml` file. You can provide details about your cluster configuration at the prompts.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

IMPORTANT

The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.
Additional resources

- Installation configuration parameters

22.8.11.1. Sample install-config.yaml file for VMware vSphere

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
additionalTrustBundlePolicy: Proxyonly
apiVersion: v1
baseDomain: example.com
compute:
  - architecture: amd64
    name: <worker_node>
    platform: {}
    replicas: 0
controlPlane:
  architecture: amd64
  name: <parent_node>
  platform: {}
  replicas: 3
metadata:
  creationTimestamp: null
  name: test
networking:
  networking:
---
platform:
  vsphere:
    failureDomains:
      - name: <failure_domain_name>
      region: <default_region_name>
      server: <fully_qualified_domain_name>
      topology:
        computeCluster: "/<datacenter>/host/<cluster>
        datacenter: <datacenter>
        datastore: "/<datacenter>/datastore/<datastore>"
      networks:
        - <VM_Network_name>
        resourcePool: "/<datacenter>/host/<cluster>/Resources/<resourcePools>"
        folder: "/<datacenter_name>/vm/<folder_name>/<subfolder_name>
      zone: <default_zone_name>
vcenters:
  - datacenters:
    - <datacenter>
    password: <password>
    port: 443
    server: <fully_qualified_domain_name>
    user: administrator@vsphere.local
    diskType: thin
fips: false
pullSecret: '{"auths": {"<local_registry>": {"auth": "<credentials>", "email": "you@example.com"}}}'
sshKey: 'ssh-ed25519 AAAA...'
The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, -, and the first line of the controlPlane section must not. Both sections define a single machine pool, so only one control plane is used. OpenShift Container Platform does not support defining multiple compute pools.

You must set the value of the replicas parameter to 0. This parameter controls the number of workers that the cluster creates and manages for you, which are functions that the cluster does not perform when you use user-provisioned infrastructure. You must manually deploy worker machines for the cluster to use before you finish installing OpenShift Container Platform.

The number of control plane machines that you add to the cluster. Because the cluster uses this values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

The cluster name that you specified in your DNS records.

Establishes the relationships between a region and zone. You define a failure domain by using vCenter objects, such as a datastore object. A failure domain defines the vCenter location for OpenShift Container Platform cluster nodes.

The vSphere datacenter.

The path to the vSphere datastore that holds virtual machine files, templates, and ISO images.

**IMPORTANT**

You can specify the path of any datastore that exists in a datastore cluster. By default, Storage vMotion is automatically enabled for a datastore cluster. Red Hat does not support Storage vMotion, so you must disable Storage vMotion to avoid data loss issues for your OpenShift Container Platform cluster.

If you must specify VMs across multiple datastores, use a datastore object to specify a failure domain in your cluster’s install-config.yaml configuration file. For more information, see "VMware vSphere region and zone enablement".

Optional: For installer-provisioned infrastructure, the absolute path of an existing resource pool where the installation program creates the virtual machines, for example, /<datacenter_name>/host/<cluster_name>/Resources/<resource_pool_name>/<optional_nested_resource_pool_name>. If you do not specify a value, resources are installed in the root of the cluster /example_datacenter/host/example_cluster/Resources.
Optional: For installer-provisioned infrastructure, the absolute path of an existing folder where the installation program creates the virtual machines, for example,

The password associated with the vSphere user.

The fully-qualified hostname or IP address of the vCenter server.

**IMPORTANT**

The Cluster Cloud Controller Manager Operator performs a connectivity check on a provided hostname or IP address. Ensure that you specify a hostname or an IP address to a reachable vCenter server. If you provide metadata to a non-existent vCenter server, installation of the cluster fails at the bootstrap stage.

The vSphere disk provisioning method.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see Installing the system in FIPS mode. When running Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures.

For `<local_registry>`, specify the registry domain name, and optionally the port, that your mirror registry uses to serve content. For example `registry.example.com` or `registry.example.com:5000`. For `<credentials>`, specify the base64-encoded user name and password for your mirror registry.

The public portion of the default SSH key for the core user in Red Hat Enterprise Linux CoreOS (RHCOS).

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

Provide the contents of the certificate file that you used for your mirror registry.

Provide the `imageContentSources` section from the output of the command to mirror the repository.

22.8.11.2. Configuring the cluster-wide proxy during installation
Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

Prerequisites

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

NOTE

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
     httpProxy: http://<username>:<pswd>@<ip>:<port>
     httpsProxy: https://<username>:<pswd>@<ip>:<port>
     noProxy: example.com
   additionalTrustBundle: |
     -----BEGIN CERTIFICATE-----
     <MY_TRUSTED_CA_CERT>
     -----END CERTIFICATE-----
   additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle>
   ```

   - **1** A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.
   - **2** A proxy URL to use for creating HTTPS connections outside the cluster.
   - **3** A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, `.y.com` matches `x.y.com`, but not `y.com`. Use * to bypass the proxy for all destinations. You must include vCenter’s IP address and the IP range that you use for its machines.
   - **4** If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges these contents with the Red Hat
Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the trustedCA field of the Proxy object. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

Optional: The policy to determine the configuration of the Proxy object to reference the user-ca-bundle config map in the trustedCA field. The allowed values are Proxyonly and Always. Use Proxyonly to reference the user-ca-bundle config map only when http/https proxy is configured. Use Always to always reference the user-ca-bundle config map. The default value is Proxyonly.

NOTE

The installation program does not support the proxy readinessEndpoints field.

NOTE

If the installer times out, restart and then complete the deployment by using the wait-for command of the installer. For example:

```
$ ./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

NOTE

Only the Proxy object named cluster is supported, and no additional proxies can be created.

22.8.11.3. Configuring regions and zones for a VMware vCenter

You can modify the default installation configuration file, so that you can deploy an OpenShift Container Platform cluster to multiple vSphere datacenters that run in a single VMware vCenter.

The default install-config.yaml file configuration from the previous release of OpenShift Container Platform is deprecated. You can continue to use the deprecated default configuration, but the openshift-installer will prompt you with a warning message that indicates the use of deprecated fields in the configuration file.

IMPORTANT

The example uses the govc command. The govc command is an open source command available from VMware; it is not available from Red Hat. The Red Hat support team does not maintain the govc command. Instructions for downloading and installing govc are found on the VMware documentation website.

Prerequisites

- You have an existing install-config.yaml installation configuration file.
IMPORTANT

You must specify at least one failure domain for your OpenShift Container Platform cluster, so that you can provision datacenter objects for your VMware vCenter server. Consider specifying multiple failure domains if you need to provision virtual machine nodes in different datacenters, clusters, datastores, and other components.

Procedure

1. Enter the following `govc` command-line tool commands to create the `openshift-region` and `openshift-zone` vCenter tag categories:

```
$ govc tags.category.create -d "OpenShift region" openshift-region
$ govc tags.category.create -d "OpenShift zone" openshift-zone
```

IMPORTANT

If you specify different names for the `openshift-region` and `openshift-zone` vCenter tag categories, the installation of the OpenShift Container Platform cluster fails.

2. To create a region tag for each region vSphere datacenter where you want to deploy your cluster, enter the following command in your terminal:

```
$ govc tags.create -c <region_tag_category> <region_tag>
```

3. To create a zone tag for each vSphere cluster where you want to deploy your cluster, enter the following command:

```
$ govc tags.create -c <zone_tag_category> <zone_tag>
```

4. Attach region tags to each vCenter datacenter object by entering the following command:

```
$ govc tags.attach -c <region_tag_category> <region_tag_1> /<datacenter_1>
```

5. Attach the zone tags to each vCenter datacenter object by entering the following command:

```
$ govc tags.attach -c <zone_tag_category> <zone_tag_1> /<datacenter_1>/host/vcs-mdcnc-workload-1
```

6. Change to the directory that contains the installation program and initialize the cluster deployment according to your chosen installation requirements.

Sample `install-config.yaml` file with multiple datacenters defined in a vSphere center

```yaml
---
compute:
  ---
vsphere:
  zones:
```
22.8.12. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.
IMPORTANT

- The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

Prerequisites

- You obtained the OpenShift Container Platform installation program. For a restricted network installation, these files are on your mirror host.

- You created the `install-config.yaml` installation configuration file.

Procedure

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

   $ ./openshift-install create manifests --dir <installation_directory>  

   For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.

2. Remove the Kubernetes manifest files that define the control plane machines, compute machine sets, and control plane machine sets:

   Because you create and manage these resources yourself, you do not have to initialize them.

   - You can preserve the compute machine set files to create compute machines by using the machine API, but you must update references to them to match your environment.

3. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yaml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:

   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yaml` file.

   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.

   c. Save and exit the file.
4. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

```
$ ./openshift-install create ignition-configs --dir <installation_directory> 1
```

1. For `<installation_directory>`, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The `kubeadmin-password` and `kubeconfig` files are created in the `./<installation_directory>/auth` directory:

```
├── auth
│   ├── kubeadmin-password
│   └── kubeconfig
├── bootstrap.ign
├── master.ign
├── metadata.json
└── worker.ign
```

22.8.13. Configuring chrony time service

You must set the time server and related settings used by the chrony time service (`chronyd`) by modifying the contents of the `chrony.conf` file and passing those contents to your nodes as a machine config.

**Procedure**

1. Create a Butane config including the contents of the `chrony.conf` file. For example, to configure chrony on worker nodes, create a `99-worker-chrony.bu` file.

```
variant: openshift
version: 4.14.0
metadata:
    name: 99-worker-chrony 1
    labels:
        machineconfiguration.openshift.io/role: worker 2
storage:
    files:
    - path: /etc/chrony.conf
      mode: 0644 3
      overwrite: true
      contents:
        inline:
          pool 0.rhel.pool.ntp.org iburst 4
          driftfile /var/lib/chrony/drift
```

**NOTE**

See "Creating machine configs with Butane" for information about Butane.
On control plane nodes, substitute master for worker in both of these locations.

Specify an octal value mode for the mode field in the machine config file. After creating the file and applying the changes, the mode is converted to a decimal value. You can check the YAML file with the command `oc get mc <mc-name> -o yaml`.

Specify any valid, reachable time source, such as the one provided by your DHCP server.

2. Use Butane to generate a `MachineConfig` object file, `99-worker-chrony.yaml`, containing the configuration to be delivered to the nodes:

   ```bash
   $ butane 99-worker-chrony.bu -o 99-worker-chrony.yaml
   ```

3. Apply the configurations in one of two ways:

   - If the cluster is not running yet, after you generate manifest files, add the `MachineConfig` object file to the `<installation_directory>/openshift` directory, and then continue to create the cluster.
   - If the cluster is already running, apply the file:

     ```bash
     $ oc apply -f ./99-worker-chrony.yaml
     ```

22.8.14. Extracting the infrastructure name

The Ignition config files contain a unique cluster identifier that you can use to uniquely identify your cluster in VMware vSphere. If you plan to use the cluster identifier as the name of your virtual machine folder, you must extract it.

Prerequisites

- You obtained the OpenShift Container Platform installation program and the pull secret for your cluster.
- You generated the Ignition config files for your cluster.
- You installed the `jq` package.

Procedure

- To extract and view the infrastructure name from the Ignition config file metadata, run the following command:

  ```bash
  $ jq -r .infraID <installation_directory>/metadata.json
  ```

  - For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

Example output
22.8.15. Installing RHCOS and starting the OpenShift Container Platform bootstrap process

To install OpenShift Container Platform on user-provisioned infrastructure on VMware vSphere, you must install Red Hat Enterprise Linux CoreOS (RHCOS) on vSphere hosts. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS machines have rebooted.

Prerequisites

- You have obtained the Ignition config files for your cluster.
- You have access to an HTTP server that you can access from your computer and that the machines that you create can access.
- You have created a vSphere cluster.

Procedure

1. Upload the bootstrap Ignition config file, which is named `<installation_directory>/bootstrap.ign`, that the installation program created to your HTTP server. Note the URL of this file.

2. Save the following secondary Ignition config file for your bootstrap node to your computer as `<installation_directory>/merge-bootstrap.ign`:

   ```json
   {
     "ignition": {
       "config": {
         "merge": [
           {
             "source": "<bootstrap_ignition_config_url>",  
             "verification": {}  
           }
         ]
       },
       "timeouts": {},
       "version": "3.2.0"
     },
     "networkd": {},
     "passwd": {},
     "storage": {},
     "systemd": {}
   }
   ```

   Specify the URL of the bootstrap Ignition config file that you hosted.
When you create the virtual machine (VM) for the bootstrap machine, you use this Ignition config file.

3. Locate the following Ignition config files that the installation program created:

   - `<installation_directory>/master.ign`
   - `<installation_directory>/worker.ign`
   - `<installation_directory>/merge-bootstrap.ign`

4. Convert the Ignition config files to Base64 encoding. Later in this procedure, you must add these files to the extra configuration parameter `guestinfo.ignition.config.data` in your VM. For example, if you use a Linux operating system, you can use the `base64` command to encode the files.

   ```
   $ base64 -w0 <installation_directory>/master.ign > <installation_directory>/master.64
   $ base64 -w0 <installation_directory>/worker.ign > <installation_directory>/worker.64
   $ base64 -w0 <installation_directory>/merge-bootstrap.ign > <installation_directory>/merge-bootstrap.64
   ```

   **IMPORTANT**
   
   If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

5. Obtain the RHCOS OVA image. Images are available from the RHCOS image mirror page.

   **IMPORTANT**
   
   The RHCOS images might not change with every release of OpenShift Container Platform. You must download an image with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image version that matches your OpenShift Container Platform version if it is available.

   The filename contains the OpenShift Container Platform version number in the format `rhcos-vmware.<architecture>.ova`.

6. In the vSphere Client, create a folder in your datacenter to store your VMs.

   a. Click the **VMs and Templates** view.

   b. Right-click the name of your datacenter.

   c. Click **New Folder** → **New VM and Template Folder**.

   d. In the window that is displayed, enter the folder name. If you did not specify an existing folder in the `install-config.yaml` file, then create a folder with the same name as the infrastructure ID. You use this folder name so vCenter dynamically provisions storage in the appropriate location for its Workspace configuration.
7. In the vSphere Client, create a template for the OVA image and then clone the template as needed.

**NOTE**
In the following steps, you create a template and then clone the template for all of your cluster machines. You then provide the location for the Ignition config file for that cloned machine type when you provision the VMs.

a. From the Hosts and Clusters tab, right-click your cluster name and select **Deploy OVF Template**.

b. On the Select an OVF tab, specify the name of the RHCOS OVA file that you downloaded.

c. On the Select a name and folder tab, set a **Virtual machine name** for your template, such as **Template-RHCOS**. Click the name of your vSphere cluster and select the folder you created in the previous step.

d. On the Select a compute resource tab, click the name of your vSphere cluster.

e. On the Select storage tab, configure the storage options for your VM.
   - Select **Thin Provision** or **Thick Provision**, based on your storage preferences.
   - Select the datastore that you specified in your **install-config.yaml** file.
   - If you want to encrypt your virtual machines, select **Encrypt this virtual machine**. See the section titled “Requirements for encrypting virtual machines” for more information.

f. On the Select network tab, specify the network that you configured for the cluster, if available.

g. When creating the OVF template, do not specify values on the **Customize template** tab or configure the template any further.

**IMPORTANT**
Do not start the original VM template. The VM template must remain off and must be cloned for new RHCOS machines. Starting the VM template configures the VM template as a VM on the platform, which prevents it from being used as a template that compute machine sets can apply configurations to.

8. Optional: Update the configured virtual hardware version in the VM template, if necessary. Follow **Upgrading a virtual machine to the latest hardware version** in the VMware documentation for more information.
IMPORTANT

It is recommended that you update the hardware version of the VM template to version 15 before creating VMs from it, if necessary. Using hardware version 13 for your cluster nodes running on vSphere is now deprecated. If your imported template defaults to hardware version 13, you must ensure that your ESXi host is on 6.7U3 or later before upgrading the VM template to hardware version 15. If your vSphere version is less than 6.7U3, you can skip this upgrade step; however, a future version of OpenShift Container Platform is scheduled to remove support for hardware version 13 and vSphere versions less than 6.7U3.

9. After the template deploys, deploy a VM for a machine in the cluster.

   a. Right-click the template name and click **Clone → Clone to Virtual Machine**

   b. On the **Select a name and folder** tab, specify a name for the VM. You might include the machine type in the name, such as **control-plane-0** or **compute-1**.

   **NOTE**

   Ensure that all virtual machine names across a vSphere installation are unique.

   c. On the **Select a name and folder** tab, select the name of the folder that you created for the cluster.

   d. On the **Select a compute resource** tab, select the name of a host in your datacenter.

   e. On the **Select clone options** tab, select **Customize this virtual machine’s hardware**

   f. On the **Customize hardware** tab, click **Advanced Parameters**.

IMPORTANT

The following configuration suggestions are for example purposes only. As a cluster administrator, you must configure resources according to the resource demands placed on your cluster. To best manage cluster resources, consider creating a resource pool from the cluster’s root resource pool.

- Optional: Override default DHCP networking in vSphere. To enable static IP networking:
  
  - Set your static IP configuration:

  **Example command**

  ```bash
  $ export IPCFG="ip=<ip>::<gateway>::<netmask>::<hostname>::<iface>::none
  nameserver=srv1 [nameserver=srv2 [nameserver=srv3 [...]]]
  
  Example command

  $ export IPCFG="ip=192.168.100.101::192.168.100.254::255.255.255.0::none
  nameserver=8.8.8.8"
  ```
Set the `guestinfo.afterburn.initrd.network-kargs` property before you boot a VM from an OVA in vSphere:

**Example command**

```
$ govc vm.change -vm "<vm_name>" -e "guestinfo.afterburn.initrd.network-kargs=${IPCFG}"
```

- Add the following configuration parameter names and values by specifying data in the **Attribute** and **Values** fields. Ensure that you select the **Add** button for each parameter that you create.
  - `guestinfo.ignition.config.data`: Locate the base-64 encoded files that you created previously in this procedure, and paste the contents of the base64-encoded Ignition config file for this machine type.
  - `guestinfo.ignition.config.data.encoding`: Specify `base64`.
  - `disk.EnableUUID`: Specify `TRUE`.
  - `stealclock.enable`: If this parameter was not defined, add it and specify `TRUE`.
  - Create a child resource pool from the cluster’s root resource pool. Perform resource allocation in this child resource pool.

- In the **Virtual Hardware** panel of the **Customize hardware** tab, modify the specified values as required. Ensure that the amount of RAM, CPU, and disk storage meets the minimum requirements for the machine type.

- Complete the remaining cloning operation. On clicking the **Finish** button, you have completed the cloning operation.

- From the **Virtual Machines** tab, right-click on your VM and then select **Power → Power On**.

- Check the console output to verify that Ignition ran.

**Example command**

```
Ignition: ran on 2022/03/14 14:48:33 UTC (this boot)
Ignition: user-provided config was applied
```

**Next steps**

- Create the rest of the machines for your cluster by following the preceding steps for each machine.

**IMPORTANT**

You must create the bootstrap and control plane machines at this time. Because some pods are deployed on compute machines by default, also create at least two compute machines before you install the cluster.

**22.8.16. Adding more compute machines to a cluster in vSphere**
You can add more compute machines to a user-provisioned OpenShift Container Platform cluster on VMware vSphere.

After your vSphere template deploys in your OpenShift Container Platform cluster, you can deploy a virtual machine (VM) for a machine in that cluster.

Prerequisites

- Obtain the base64-encoded Ignition file for your compute machines.
- You have access to the vSphere template that you created for your cluster.

Procedure

1. Right-click the template’s name and click **Clone → Clone to Virtual Machine**

2. On the **Select a name and folder** tab, specify a name for the VM. You might include the machine type in the name, such as **compute-1**.

   **NOTE**

   Ensure that all virtual machine names across a vSphere installation are unique.

3. On the **Select a name and folder** tab, select the name of the folder that you created for the cluster.

4. On the **Select a compute resource** tab, select the name of a host in your datacenter.

5. On the **Select storage** tab, select storage for your configuration and disk files.

6. On the **Select clone options** tab, select **Customize this virtual machine’s hardware**

7. On the **Customize hardware** tab, click **Advanced Parameters**.

   - Add the following configuration parameter names and values by specifying data in the **Attribute** and **Values** fields. Ensure that you select the **Add** button for each parameter that you create.

     - **guestinfo.ignition.config.data**: Paste the contents of the base64-encoded compute Ignition config file for this machine type.
     - **guestinfo.ignition.config.data.encoding**: Specify **base64**.
     - **disk.EnableUUID**: Specify **TRUE**.

8. In the **Virtual Hardware** panel of the **Customize hardware** tab, modify the specified values as required. Ensure that the amount of RAM, CPU, and disk storage meets the minimum requirements for the machine type. If many networks exist, select **Add New Device > Network Adapter**, and then enter your network information in the fields provided by the **New Network** menu item.

9. Complete the remaining configuration steps. On clicking the **Finish** button, you have completed the cloning operation.

10. From the **Virtual Machines** tab, right-click on your VM and then select **Power → Power On**.
Next steps

- Continue to create more compute machines for your cluster.

22.8.17. Disk partitioning

In most cases, data partitions are originally created by installing RHCOS, rather than by installing another operating system. In such cases, the OpenShift Container Platform installer should be allowed to configure your disk partitions.

However, there are two cases where you might want to intervene to override the default partitioning when installing an OpenShift Container Platform node:

- Create separate partitions: For greenfield installations on an empty disk, you might want to add separate storage to a partition. This is officially supported for making /var or a subdirectory of /var, such as /var/lib/etcd, a separate partition, but not both.

  **IMPORTANT**

  For disk sizes larger than 100GB, and especially disk sizes larger than 1TB, create a separate /var partition. See "Creating a separate /var partition" and this Red Hat Knowledgebase article for more information.

- Retain existing partitions: For a brownfield installation where you are reinstalling OpenShift Container Platform on an existing node and want to retain data partitions installed from your previous operating system, there are both boot arguments and options to coreos-installer that allow you to retain existing data partitions.

**Creating a separate /var partition**

In general, disk partitioning for OpenShift Container Platform should be left to the installer. However, there are cases where you might want to create separate partitions in a part of the filesystem that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the /var partition or a subdirectory of /var. For example:

- /var/lib/containers: Holds container-related content that can grow as more images and containers are added to a system.

- /var/lib/etcd: Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.

- /var: Holds data that you might want to keep separate for purposes such as auditing.

  **IMPORTANT**

  For disk sizes larger than 100GB, and especially larger than 1TB, create a separate /var partition.
Storing the contents of a /var directory separately makes it easier to grow storage for those areas as needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

Because /var must be in place before a fresh installation of Red Hat Enterprise Linux CoreOS (RHCOS), the following procedure sets up the separate /var partition by creating a machine config manifest that is inserted during the openshift-install preparation phases of an OpenShift Container Platform installation.

**Procedure**

1. Create a directory to hold the OpenShift Container Platform installation files:

   ```bash
   $ mkdir $HOME/clusterconfig
   ```

2. Run openshift-install to create a set of files in the manifest and openshift subdirectories. Answer the system questions as you are prompted:

   ```bash
   $ openshift-install create manifests --dir $HOME/clusterconfig
   ? SSH Public Key ...
   $ ls $HOME/clusterconfig/openshift/
   99_kubeadmin-password-secret.yaml
   99_openshift-cluster-api_master-machines-0.yaml
   99_openshift-cluster-api_master-machines-1.yaml
   99_openshift-cluster-api_master-machines-2.yaml
   ...
   ```

3. Create a Butane config that configures the additional partition. For example, name the file $HOME/clusterconfig/98-var-partition.bu, change the disk device name to the name of the storage device on the worker systems, and set the storage size as appropriate. This example places the /var directory on a separate partition:

   ```yaml
   variant: openshift
   version: 4.14.0
   metadata:
     labels:
       machineconfiguration.openshift.io/role: worker
     name: 98-var-partition
   storage:
     disks:
       - device: /dev/disk/by-id/<device_name>
         partitions:
           - label: var
             start_mib: <partition_start_offset>
             size_mib: <partition_size>
         filesystems:
           - device: /dev/disk/by-partlabel/var
             path: /var
             format: xfs
             mount_options: [defaults, prjquota]
             with_mount_unit: true
   ```

   1. The storage device name of the disk that you want to partition.
When adding a data partition to the boot disk, a minimum value of 25000 mebibytes is recommended. The root file system is automatically resized to fill all available space up to the size of the data partition in mebibytes.

The `prjquota` mount option must be enabled for filesystems used for container storage.

NOTE

When creating a separate `/var` partition, you cannot use different instance types for worker nodes, if the different instance types do not have the same device name.

4. Create a manifest from the Butane config and save it to the `clusterconfig/openshift` directory. For example, run the following command:

```
$ butane $HOME/clusterconfig/98-var-partition.bu -o $HOME/clusterconfig/openshift/98-var-partition.yaml
```

5. Run `openshift-install` again to create Ignition configs from a set of files in the `manifest` and `openshift` subdirectories:

```
$ openshift-install create ignition-configs --dir $HOME/clusterconfig
$ ls $HOME/clusterconfig/auth bootstrap.ign master.ign metadata.json worker.ign
```

Now you can use the Ignition config files as input to the vSphere installation procedures to install Red Hat Enterprise Linux CoreOS (RHCOS) systems.

### 22.8.18. Updating the bootloader using `bootupd`

To update the bootloader by using `bootupd`, you must either install `bootupd` on RHCOS machines manually or provide a machine config with the enabled `systemd` unit. Unlike `grubby` or other bootloader tools, `bootupd` does not manage kernel space configuration such as passing kernel arguments.

After you have installed `bootupd`, you can manage it remotely from the OpenShift Container Platform cluster.

NOTE

It is recommended that you use `bootupd` only on bare metal or virtualized hypervisor installations, such as for protection against the BootHole vulnerability.

#### Manual install method

You can manually install `bootupd` by using the `bootctl` command-line tool.

1. Inspect the system status:

```
# bootupctl status
```

Example output for x86_64
2. RHCOS images created without `bootupd` installed on them require an explicit adoption phase. If the system status is `Adoptable`, perform the adoption:

   ```bash
   # bootupctl adopt-and-update
   ```

   **Example output**

   ```
   Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
   ```

3. If an update is available, apply the update so that the changes take effect on the next reboot:

   ```bash
   # bootupctl update
   ```

   **Example output**

   ```
   Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
   ```

**Machine config method**

Another way to enable `bootupd` is by providing a machine config.

- Provide a machine config file with the enabled `systemd` unit, as shown in the following example:

   **Example output**

   ```
   variant: rhcos
   version: 1.1.0
   systemd:
     units:
       - name: custom-bootupd-auto.service
         enabled: true
         contents:
           [Unit]
           Description=Bootupd automatic update

           [Service]
           ExecStart=/usr/bin/bootupctl update
           RemainAfterExit=yes

           [Install]
           WantedBy=multi-user.target
   ```
22.8.19. Waiting for the bootstrap process to complete

The OpenShift Container Platform bootstrap process begins after the cluster nodes first boot into the persistent RHCOS environment that has been installed to disk. The configuration information provided through the Ignition config files is used to initialize the bootstrap process and install OpenShift Container Platform on the machines. You must wait for the bootstrap process to complete.

Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have obtained the installation program and generated the Ignition config files for your cluster.
- You installed RHCOS on your cluster machines and provided the Ignition config files that the OpenShift Container Platform installation program generated.

Procedure

1. Monitor the bootstrap process:

   ```bash
   $ ./openshift-install --dir <installation_directory> wait-for bootstrap-complete \\
   --log-level=info
   ```

   1 For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   2 To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

   Example output

   ```
   INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
   INFO API v1.27.3 up
   INFO Waiting up to 30m0s for bootstrapping to complete...
   INFO It is now safe to remove the bootstrap resources
   ```

   The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After the bootstrap process is complete, remove the bootstrap machine from the load balancer.

   **IMPORTANT**

   You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the bootstrap machine itself.

22.8.20. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container
Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

Procedure

1. Export the `kubeadmin` credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   ```

   **Example output**

   ```
   system:admin
   ```

22.8.21. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

Prerequisites

- You added machines to your cluster.

Procedure

1. Confirm that the cluster recognizes the machines:

   ```bash
   $ oc get nodes
   ```

   **Example output**

   ```
   NAME      STATUS    ROLES   AGE  VERSION
   master-0  Ready     master  63m  v1.27.3
   master-1  Ready     master  63m  v1.27.3
   master-2  Ready     master  64m  v1.27.3
   ```

   The output lists all of the machines that you created.
NOTE

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```bash
$ oc get csr
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-8b2br</td>
<td>15m</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-8vnps</td>
<td>15m</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Pending</td>
</tr>
</tbody>
</table>

In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

**NOTE**

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the `machine-approver` if the Kubelet requests a new certificate with identical parameters.

**NOTE**

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the `oc exec`, `oc rsh`, and `oc logs` commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the `node-bootstrapper` service account in the `system:node` or `system:admin` groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

```bash
$ oc adm certificate approve <csr_name>
```
<csr_name> is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs --no-run-if-empty oc adm certificate approve
```

**NOTE**
Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-c57lv</td>
<td>5m26s</td>
<td>system:node:ip-10-0-95-157.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
</tbody>
</table>

5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> 1
```

**NOTE**
<csr_name> is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs oc adm certificate approve
```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.27.3</td>
</tr>
</tbody>
</table>
NOTE
It can take a few minutes after approval of the server CSRs for the machines to transition to the Ready status.

Additional information
- For more information on CSRs, see Certificate Signing Requests.

22.8.22. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

Prerequisites
- Your control plane has initialized.

Procedure

1. Watch the cluster components come online:

```bash
$ watch -n5 oc get clusteroperators
```

Example output

<table>
<thead>
<tr>
<th>NAME</th>

</table>
Configure the Operators that are not available.

22.8.22.1. Disabling the default OperatorHub catalog sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

Procedure

- Disable the sources for the default catalogs by adding `disableAllDefaultSources: true` to the OperatorHub object:

  ```
  $ oc patch OperatorHub cluster --type json
    -p '[{"op": "add", "path": "/spec/disableAllDefaultSources", "value": true}]'
  ```

  **TIP**
  Alternatively, you can use the web console to manage catalog sources. From the Administration → Cluster Settings → Configuration → OperatorHub page, click the Sources tab, where you can create, update, delete, disable, and enable individual sources.

22.8.22.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the Recreate rollout strategy during upgrades.

22.8.22.2.1. Configuring registry storage for VMware vSphere

As a cluster administrator, following installation you must configure your registry to use storage.

**Prerequisites**

- Cluster administrator permissions.
- A cluster on VMware vSphere.
• Persistent storage provisioned for your cluster, such as Red Hat OpenShift Data Foundation.

**IMPORTANT**

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. **ReadWriteOnce** access also requires that the registry uses the **Recreate** rollout strategy. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

• Must have "100Gi" capacity.

**IMPORTANT**

Testing shows issues with using the NFS server on RHEL as storage backend for core services. This includes the OpenShift Container Registry and Quay, Prometheus for monitoring storage, and Elasticsearch for logging storage. Therefore, using RHEL NFS to back PVs used by core services is not recommended.

Other NFS implementations on the marketplace might not have these issues. Contact the individual NFS implementation vendor for more information on any testing that was possibly completed against these OpenShift Container Platform core components.

**Procedure**

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

   **NOTE**

   When you use shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

   ```bash
   $ oc get pod -n openshift-image-registry -l docker-registry=default
   **Example output**
   No resourses found in openshift-image-registry namespace
   **NOTE**
   If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

   ```bash
   $ oc edit configs.imageregistry.operator.openshift.io
   **Example output**
   ```
Leave the claim field blank to allow the automatic creation of an image-registry-storage persistent volume claim (PVC). The PVC is generated based on the default storage class. However, be aware that the default storage class might provide ReadWriteOnce (RWO) volumes, such as a RADOS Block Device (RBD), which can cause issues when you replicate to more than one replica.

4. Check the clusteroperator status:

```
$ oc get clusteroperator image-registry
```

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
</tr>
</thead>
<tbody>
<tr>
<td>image-registry</td>
<td>4.7</td>
<td>True</td>
<td>False</td>
<td>False</td>
</tr>
</tbody>
</table>

22.8.22.2.2. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

Procedure

- To set the image registry storage to an empty directory:

```
$ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec": {"storage": {"emptyDir":{}}}}'
```

**WARNING**

Configure this option for only non-production clusters.

If you run this command before the Image Registry Operator initializes its components, the oc patch command fails with the following error:

```
Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
```

Wait a few minutes and run the command again.

22.8.22.2.3. Configuring block registry storage for VMware vSphere

To allow the image registry to use block storage types such as vSphere Virtual Machine Disk (VMDK) during upgrades as a cluster administrator, you can use the **Recreate** rollout strategy.
IMPORTANT

Block storage volumes are supported but not recommended for use with image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

Procedure

1. To set the image registry storage as a block storage type, patch the registry so that it uses the **Recreate** rollout strategy and runs with only 1 replica:

   ```bash
   $ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec":
   {"rolloutStrategy":"Recreate","replicas":1}}'
   ```

2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.

   a. Create a `pvc.yaml` file with the following contents to define a VMware vSphere **PersistentVolumeClaim** object:

      ```yaml
      kind: PersistentVolumeClaim
      apiVersion: v1
      metadata:
        name: image-registry-storage
        namespace: openshift-image-registry
      spec:
        accessModes:
        - ReadWriteOnce
        resources:
          requests:
            storage: 100Gi
      ```

      1. A unique name that represents the **PersistentVolumeClaim** object.
      2. The namespace for the **PersistentVolumeClaim** object, which is `openshift-image-registry`.
      3. The access mode of the persistent volume claim. With **ReadWriteOnce**, the volume can be mounted with read and write permissions by a single node.
      4. The size of the persistent volume claim.

   b. Create the **PersistentVolumeClaim** object from the file:

      ```bash
      $ oc create -f pvc.yaml -n openshift-image-registry
      $$ oc edit config.imageregistry.operator.openshift.io -o yaml
      ```

3. Edit the registry configuration so that it references the correct PVC:

   ```bash
   $ oc edit config.imageregistry.operator.openshift.io -o yaml
   ```
By creating a custom PVC, you can leave the **claim** field blank for the default automatic creation of an **image-registry-storage** PVC.

For instructions about configuring registry storage so that it references the correct PVC, see [Configuring the registry for vSphere](#).

### 22.8.23. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

**Prerequisites**

- Your control plane has initialized.
- You have completed the initial Operator configuration.

**Procedure**

1. Confirm that all the cluster components are online with the following command:

   ```bash
   $ watch -n5 oc get clusteroperators
   ```

**Example output**

<table>
<thead>
<tr>

<td>False</td>
<td>False</td>
<td>38m</td>
</tr>
</tbody>
</table>
Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```bash
$ ./openshift-install --dir <installation_directory> wait-for install-complete
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

### Example output

INFO Waiting up to 30m0s for the cluster to initialize...

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

2. Confirm that the Kubernetes API server is communicating with the pods.
   a. To view a list of all pods, use the following command:

   ```bash
   $ oc get pods --all-namespaces
   ```

   **Example output**

<table>
<thead>
<tr>
<th>NAMESPACE</th>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>openshift-apiserver-operator</td>
<td>openshift-apiserver-operator-85cb746d55-zqhs8</td>
<td>1/1</td>
<td></td>
</tr>
</tbody>
</table>
b. View the logs for a pod that is listed in the output of the previous command by using the following command:

```
$ oc logs <pod_name> -n <namespace>
```

Specify the pod name and namespace, as shown in the output of the previous command.

If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation. See "Enabling multipathing with kernel arguments on RHCOS" in the Post-installation machine configuration tasks documentation for more information.

4. Register your cluster on the Cluster registration page.

You can add extra compute machines after the cluster installation is completed by following Adding compute machines to vSphere.

### 22.8.24. Configuring vSphere DRS anti-affinity rules for control plane nodes

vSphere Distributed Resource Scheduler (DRS) anti-affinity rules can be configured to support higher availability of OpenShift Container Platform Control Plane nodes. Anti-affinity rules ensure that the vSphere Virtual Machines for the OpenShift Container Platform Control Plane nodes are not scheduled to the same vSphere Host.

**IMPORTANT**

- The following information applies to compute DRS only and does not apply to storage DRS.

- The `govc` command is an open-source command available from VMware; it is not available from Red Hat. The `govc` command is not supported by the Red Hat support.

- Instructions for downloading and installing `govc` are found on the VMware documentation website.

Create an anti-affinity rule by running the following command:

```
Example command
```
After creating the rule, your control plane nodes are automatically migrated by vSphere so they are not running on the same hosts. This might take some time while vSphere reconciles the new rule. Successful command completion is shown in the following procedure.

NOTE
The migration occurs automatically and might cause brief OpenShift API outage or latency until the migration finishes.

The vSphere DRS anti-affinity rules need to be updated manually in the event of a control plane VM name change or migration to a new vSphere Cluster.

Procedure

1. Remove any existing DRS anti-affinity rule by running the following command:

```
$ govc cluster.rule.remove \
  -name openshift4-control-plane-group \
  -dc MyDatacenter -cluster MyCluster
```

Example Output

```
[13-10-22 09:33:24] Reconfigure /MyDatacenter/host/MyCluster...OK
```

2. Create the rule again with updated names by running the following command:

```
$ govc cluster.rule.create \
  -name openshift4-control-plane-group \
  -dc MyDatacenter -cluster MyOtherCluster \
  -enable \n  -anti-affinity master-0 master-1 master-2
```

22.8.25. Backing up VMware vSphere volumes

OpenShift Container Platform provisions new volumes as independent persistent disks to freely attach and detach the volume on any node in the cluster. As a consequence, it is not possible to back up volumes that use snapshots, or to restore volumes from snapshots. See Snapshot Limitations for more information.

Procedure

To create a backup of persistent volumes:

1. Stop the application that is using the persistent volume.
2. Clone the persistent volume.
3. Restart the application.

4. Create a backup of the cloned volume.

5. Delete the cloned volume.

22.8.26. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager Hybrid Cloud Console.

After you confirm that your OpenShift Cluster Manager Hybrid Cloud Console inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources
- See About remote health monitoring for more information about the Telemetry service

22.8.27. Next steps
- Customize your cluster.
- If the mirror registry that you used to install your cluster has a trusted CA, add it to the cluster by configuring additional trust stores.
- If necessary, you can opt out of remote health reporting.
- Optional: View the events from the vSphere Problem Detector Operator to determine if the cluster has permission or storage configuration issues.
- Optional: if you created encrypted virtual machines, create an encrypted storage class.

22.9. INSTALLING A THREE-NODE CLUSTER ON VSPHERE

In OpenShift Container Platform version 4.14, you can install a three-node cluster on VMware vSphere. A three-node cluster consists of three control plane machines, which also act as compute machines. This type of cluster provides a smaller, more resource efficient cluster, for cluster administrators and developers to use for testing, development, and production.

You can install a three-node cluster using either installer-provisioned or user-provisioned infrastructure.

22.9.1. Configuring a three-node cluster

You configure a three-node cluster by setting the number of worker nodes to 0 in the install-config.yaml file before deploying the cluster. Setting the number of worker nodes to 0 ensures that the control plane machines are schedulable. This allows application workloads to be scheduled to run from the control plane nodes.
NOTE
Because application workloads run from control plane nodes, additional subscriptions are required, as the control plane nodes are considered to be compute nodes.

Prerequisites
- You have an existing `install-config.yaml` file.

Procedure
1. Set the number of compute replicas to 0 in your `install-config.yaml` file, as shown in the following `compute` stanza:

   Example install-config.yaml file for a three-node cluster
   ```yaml
   apiVersion: v1
   baseDomain: example.com
   compute:
     - name: worker
       platform: {}
       replicas: 0
     # ...
   ```

2. If you are deploying a cluster with user-provisioned infrastructure:
   - Configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes. In a three-node cluster, the Ingress Controller pods run on the control plane nodes. For more information, see the "Load balancing requirements for user-provisioned infrastructure".
   
   - After you create the Kubernetes manifest files, make sure that the `spec.mastersSchedulable` parameter is set to `true` in `cluster-scheduler-02-config.yml` file. You can locate this file in `<installation_directory>/manifests`. For more information, see "Creating the Kubernetes manifest and Ignition config files" in "Installing a cluster on vSphere with user-provisioned infrastructure".
   
   - Do not create additional worker nodes.

Example cluster-scheduler-02-config.yml file for a three-node cluster
   ```yaml
   apiVersion: config.openshift.io/v1
   kind: Scheduler
   metadata:
     creationTimestamp: null
     name: cluster
   spec:
     mastersSchedulable: true
   policy:
     name: ""
   status: {}  
   ```

22.9.2. Next steps
22.10. CONFIGURING THE VSPHERE CONNECTION SETTINGS AFTER AN INSTALLATION

After installing an OpenShift Container Platform cluster on vSphere with the platform integration feature enabled, you might need to update the vSphere connection settings manually, depending on the installation method.

For installations using the Assisted Installer, you must update the connection settings. This is because the Assisted Installer adds default connection settings to the vSphere connection configuration wizard as placeholders during the installation.

For installer-provisioned or user-provisioned infrastructure installations, you should have entered valid connection settings during the installation. You can use the vSphere connection configuration wizard at any time to validate or modify the connection settings, but this is not mandatory for completing the installation.

22.10.1. Configuring the vSphere connection settings

Modify the following vSphere configuration settings as required:

- vCenter address
- vCenter cluster
- vCenter username
- vCenter password
- vCenter address
- vSphere data center
- vSphere datastore
- Virtual machine folder

Prerequisites

- The Assisted Installer has finished installing the cluster successfully.
- The cluster is connected to https://console.redhat.com.

Procedure

1. In the Administrator perspective, navigate to Home → Overview.

2. Under Status, click vSphere connection to open the vSphere connection configuration wizard.
3. In the **vCenter** field, enter the network address of the vSphere vCenter server. This can be either a domain name or an IP address. It appears in the vSphere web client URL; for example `https://[your_vCenter_address]/ui`.

4. In the **vCenter cluster** field, enter the name of the vSphere vCenter cluster where OpenShift Container Platform is installed.

   **IMPORTANT**
   This step is mandatory if you installed OpenShift Container Platform 4.13 or later.

5. In the **Username** field, enter your vSphere vCenter username.

6. In the **Password** field, enter your vSphere vCenter password.

   **WARNING**
   The system stores the username and password in the `vsphere-creds` secret in the `kube-system` namespace of the cluster. An incorrect vCenter username or password makes the cluster nodes unschedulable.

7. In the **Datacenter** field, enter the name of the vSphere data center that contains the virtual machines used to host the cluster; for example, *SDDC-Datacenter*.

8. In the **Default data store** field, enter the path and name of the vSphere data store that stores the persistent data volumes; for example, `/SDDC-Datacenter/datastore/datastorename`.

   **WARNING**
   Updating the vSphere data center or default data store after the configuration has been saved detaches any active vSphere PersistentVolumes.

9. In the **Virtual Machine Folder** field, enter the data center folder that contains the virtual machine of the cluster; for example, `/SDDC-Datacenter/vm/ci-ln-hjg4vg2-c61657-t2gzr`. For the OpenShift Container Platform installation to succeed, all virtual machines comprising the cluster must be located in a single data center folder.

10. Click **Save Configuration**. This updates the `cloud-provider-config` ConfigMap resource in the `openshift-config` namespace, and starts the configuration process.

11. Reopen the **vSphere connection configuration** wizard and expand the **Monitored operators** panel. Check that the status of the operators is either **Progressing** or **Healthy**.

### 22.10.2. Verifying the configuration
The connection configuration process updates operator statuses and control plane nodes. It takes approximately an hour to complete. During the configuration process, the nodes will reboot. Previously bound **PersistentVolumeClaims** objects might become disconnected.

**Prerequisites**

- You have saved the configuration settings in the **vSphere connection configuration** wizard.

**Procedure**

1. Check that the configuration process completed successfully:
   
   a. In the OpenShift Container Platform Administrator perspective, navigate to **Home → Overview**.
   
   b. Under **Status** click **Operators**. Wait for all operator statuses to change from **Progressing** to **All succeeded**. A **Failed** status indicates that the configuration failed.
   
   c. Under **Status**, click **Control Plane**. Wait for the response rate of all Control Pane components to return to 100%. A **Failed** control plane component indicates that the configuration failed.

   A failure indicates that at least one of the connection settings is incorrect. Change the settings in the **vSphere connection configuration** wizard and save the configuration again.

2. Check that you are able to bind **PersistentVolumeClaims** objects by performing the following steps:
   
   a. Create a **StorageClass** object using the following YAML:

   ```yaml
   kind: StorageClass
   apiVersion: storage.k8s.io/v1
   metadata:
     name: vsphere-sc
   provisioner: kubernetes.io/vsphere-volume
   parameters:
     datastore: YOURVCENTERDATASTORE
     diskformat: thin
     reclaimPolicy: Delete
   volumeBindingMode: Immediate
   ```

   b. Create a **PersistentVolumeClaims** object using the following YAML:

   ```yaml
   kind: PersistentVolumeClaim
   apiVersion: v1
   metadata:
     name: test-pvc
   namespace: openshift-config
   annotations:
     volume.beta.kubernetes.io/storage-provisioner: kubernetes.io/vsphere-volume
   finalizers:
     - kubernetes.io/pvc-protection
   spec:
     accessModes:
     - ReadWriteOnce
     resources:
   ```
If you are unable to create a PersistentVolumeClaims object, you can troubleshoot by navigating to Storage → PersistentVolumeClaims in the Administrator perspective of the OpenShift Container Platform web console.

For instructions on creating storage objects, see Dynamic provisioning.

22.11. UNINSTALLING A CLUSTER ON VSPHERE THAT USES INSTALLER-PROVISIONED INFRASTRUCTURE

You can remove a cluster that you deployed in your VMware vSphere instance by using installer-provisioned infrastructure.

NOTE

When you run the openshift-install destroy cluster command to uninstall OpenShift Container Platform, vSphere volumes are not automatically deleted. The cluster administrator must manually find the vSphere volumes and delete them.

22.11.1. Removing a cluster that uses installer-provisioned infrastructure

You can remove a cluster that uses installer-provisioned infrastructure from your cloud.

NOTE

After uninstallation, check your cloud provider for any resources not removed properly, especially with User Provisioned Infrastructure (UPI) clusters. There might be resources that the installer did not create or that the installer is unable to access.

Prerequisites

- You have a copy of the installation program that you used to deploy the cluster.
- You have the files that the installation program generated when you created your cluster.

Procedure

1. From the directory that contains the installation program on the computer that you used to install the cluster, run the following command:

$$ ./openshift-install destroy cluster \
--dir <installation_directory> --log-level info 1 2$$

1 For <installation_directory>, specify the path to the directory that you stored the installation files in.

2 To view different details, specify warn, debug, or error instead of info.
NOTE
You must specify the directory that contains the cluster definition files for your cluster. The installation program requires the `metadata.json` file in this directory to delete the cluster.

2. Optional: Delete the `<installation_directory>` directory and the OpenShift Container Platform installation program.

22.12. USING THE VSPHERE PROBLEM DETECTOR OPERATOR

22.12.1. About the vSphere Problem Detector Operator

The vSphere Problem Detector Operator checks clusters that are deployed on vSphere for common installation and misconfiguration issues that are related to storage.

The Operator runs in the `openshift-cluster-storage-operator` namespace and is started by the Cluster Storage Operator when the Cluster Storage Operator detects that the cluster is deployed on vSphere. The vSphere Problem Detector Operator communicates with the vSphere vCenter Server to determine the virtual machines in the cluster, the default datastore, and other information about the vSphere vCenter Server configuration. The Operator uses the credentials from the Cloud Credential Operator to connect to vSphere.

The Operator runs the checks according to the following schedule:

- The checks run every 8 hours.
- If any check fails, the Operator runs the checks again in intervals of 1 minute, 2 minutes, 4, 8, and so on. The Operator doubles the interval up to a maximum interval of 8 hours.
- When all checks pass, the schedule returns to an 8 hour interval.

The Operator increases the frequency of the checks after a failure so that the Operator can report success quickly after the failure condition is remedied. You can run the Operator manually for immediate troubleshooting information.

22.12.2. Running the vSphere Problem Detector Operator checks

You can override the schedule for running the vSphere Problem Detector Operator checks and run the checks immediately.

The vSphere Problem Detector Operator automatically runs the checks every 8 hours. However, when the Operator starts, it runs the checks immediately. The Operator is started by the Cluster Storage Operator when the Cluster Storage Operator starts and determines that the cluster is running on vSphere. To run the checks immediately, you can scale the vSphere Problem Detector Operator to 0 and back to 1 so that it restarts the vSphere Problem Detector Operator.

Prerequisites

- Access to the cluster as a user with the `cluster-admin` role.

Procedure

1. Scale the Operator to 0:
If the deployment does not scale to zero immediately, you can run the following command to wait for the pods to exit:

```bash
$ oc wait pods -l name=vsphere-problem-detector-operator \
   --for=delete --timeout=5m -n openshift-cluster-storage-operator
```

2. Scale the Operator back to 1:

```bash
$ oc scale deployment/vsphere-problem-detector-operator --replicas=1 \
   -n openshift-cluster-storage-operator
```

3. Delete the old leader lock to speed up the new leader election for the Cluster Storage Operator:

```bash
$ oc delete -n openshift-cluster-storage-operator \
   cm vsphere-problem-detector-lock
```

**Verification**

- View the events or logs that are generated by the vSphere Problem Detector Operator. Confirm that the events or logs have recent timestamps.

### 22.12.3. Viewing the events from the vSphere Problem Detector Operator

After the vSphere Problem Detector Operator runs and performs the configuration checks, it creates events that can be viewed from the command line or from the OpenShift Container Platform web console.

**Procedure**

- To view the events by using the command line, run the following command:

```bash
$ oc get event -n openshift-cluster-storage-operator \
   --sort-by={.metadata.creationTimestamp}
```

**Example output**

```
16m Normal Started pod/vsphere-problem-detector-operator-xxxxx Started container vsphere-problem-detector
16m Normal Created pod/vsphere-problem-detector-operator-xxxxx Created container vsphere-problem-detector
16m Normal LeaderElection configmap/vsphere-problem-detector-lock vsphere-problem-detector-operator-xxxxx became leader
```

- To view the events by using the OpenShift Container Platform web console, navigate to **Home → Events** and select **openshift-cluster-storage-operator** from the **Project** menu.

### 22.12.4. Viewing the logs from the vSphere Problem Detector Operator
After the vSphere Problem Detector Operator runs and performs the configuration checks, it creates log records that can be viewed from the command line or from the OpenShift Container Platform web console.

**Procedure**

- To view the logs by using the command line, run the following command:

  ```
  $ oc logs deployment/vsphere-problem-detector-operator \
  -n openshift-cluster-storage-operator
  ```

**Example output**

```
I0108 08:32:28.445696       1 operator.go:209] ClusterInfo passed
I0108 08:32:28.451029       1 datastore.go:57] CheckStorageClasses checked 1 storage classes, 0 problems found
I0108 08:32:28.451047       1 operator.go:209] CheckStorageClasses passed
I0108 08:32:28.452160       1 operator.go:209] CheckDefaultDatastore passed
I0108 08:32:28.480648       1 operator.go:271] CheckNodeDiskUUID:<host_name> passed
I0108 08:32:28.480685       1 operator.go:271] CheckNodeProviderID:<host_name> passed
```

- To view the Operator logs with the OpenShift Container Platform web console, perform the following steps:

  a. Navigate to *Workloads* → *Pods*.

  b. Select *openshift-cluster-storage-operator* from the *Projects* menu.

  c. Click the link for the *vsphere-problem-detector-operator* pod.

  d. Click the *Logs* tab on the *Pod details* page to view the logs.

### 22.12.5. Configuration checks run by the vSphere Problem Detector Operator

The following tables identify the configuration checks that the vSphere Problem Detector Operator runs. Some checks verify the configuration of the cluster. Other checks verify the configuration of each node in the cluster.

**Table 22.74. Cluster configuration checks**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>CheckDefaultDatastore</strong></td>
<td>Verifies that the default datastore name in the vSphere configuration is short enough for use with dynamic provisioning.</td>
</tr>
</tbody>
</table>

If this check fails, you can expect the following:

- **systemd** logs errors to the journal such as *Failed to set up mount unit: Invalid argument.*

- **systemd** does not unmount volumes if the virtual machine is shut down or rebooted without draining all the pods from the node.

If this check fails, reconfigure vSphere with a shorter name for the default datastore.
CheckFolderPermissions

Verifies the permission to list volumes in the default datastore. This permission is required to create volumes. The Operator verifies the permission by listing the / and /kubevols directories. The root directory must exist. It is acceptable if the /kubevols directory does not exist when the check runs. The /kubevols directory is created when the datastore is used with dynamic provisioning if the directory does not already exist.

If this check fails, review the required permissions for the vCenter account that was specified during the OpenShift Container Platform installation.

CheckStorageClasses

Verifies the following:

- The fully qualified path to each persistent volume that is provisioned by this storage class is less than 255 characters.
- If a storage class uses a storage policy, the storage class must use one policy only and that policy must be defined.

CheckTaskPermissions

Verifies the permission to list recent tasks and datastores.

ClusterInfo

Collects the cluster version and UUID from vSphere vCenter.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CheckFolderPermissions</td>
<td>Verifies the permission to list volumes in the default datastore. This permission is required to create volumes. The Operator verifies the permission by listing the / and /kubevols directories. The root directory must exist. It is acceptable if the /kubevols directory does not exist when the check runs. The /kubevols directory is created when the datastore is used with dynamic provisioning if the directory does not already exist. If this check fails, review the required permissions for the vCenter account that was specified during the OpenShift Container Platform installation.</td>
</tr>
<tr>
<td>CheckStorageClasses</td>
<td>Verifies the following:</td>
</tr>
<tr>
<td></td>
<td>- The fully qualified path to each persistent volume that is provisioned by this storage class is less than 255 characters.</td>
</tr>
<tr>
<td></td>
<td>- If a storage class uses a storage policy, the storage class must use one policy only and that policy must be defined.</td>
</tr>
<tr>
<td>CheckTaskPermissions</td>
<td>Verifies the permission to list recent tasks and datastores.</td>
</tr>
<tr>
<td>ClusterInfo</td>
<td>Collects the cluster version and UUID from vSphere vCenter.</td>
</tr>
</tbody>
</table>

### Table 22.75. Node configuration checks

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CheckNodeDiskUUID</td>
<td>Verifies that all the vSphere virtual machines are configured with disk.enableUUID=TRUE.</td>
</tr>
<tr>
<td></td>
<td>If this check fails, see the How to check 'disk.EnableUUID' parameter from VM in vSphere Red Hat Knowledgebase solution.</td>
</tr>
<tr>
<td>CheckNodeProviderID</td>
<td>Verifies that all nodes are configured with the ProviderID from vSphere vCenter. This check fails when the output from the following command does not include a provider ID for each node.</td>
</tr>
<tr>
<td></td>
<td>$ oc get nodes -o custom-columns=NAME:.metadata.name,PROVIDER_ID:.spec.providerID,UUID:.status.nodeInfo.systemUUID</td>
</tr>
<tr>
<td></td>
<td>If this check fails, refer to the vSphere product documentation for information about setting the provider ID for each node in the cluster.</td>
</tr>
<tr>
<td>CollectNodeESXiVersion</td>
<td>Reports the version of the ESXi hosts that run nodes.</td>
</tr>
</tbody>
</table>
22.12.6. About the storage class configuration check

The names for persistent volumes that use vSphere storage are related to the datastore name and cluster ID.

When a persistent volume is created, **systemd** creates a mount unit for the persistent volume. The **systemd** process has a 255 character limit for the length of the fully qualified path to the VDMK file that is used for the persistent volume.

The fully qualified path is based on the naming conventions for **systemd** and vSphere. The naming conventions use the following pattern:

```
/var/lib/kubelet/plugins/kubernetes.io/vsphere-volume/mounts/[<datastore>] 00000000-0000-0000-0000-000000000000/<cluster_id>-dynamic-pvc-00000000-0000-0000-0000-000000000000.vmdk
```

- The naming conventions require 205 characters of the 255 character limit.
- The datastore name and the cluster ID are determined from the deployment.
- The datastore name and cluster ID are substituted into the preceding pattern. Then the path is processed with the **systemd-escape** command to escape special characters. For example, a hyphen character uses four characters after it is escaped. The escaped value is `\x2d`.
- After processing with **systemd-escape** to ensure that **systemd** can access the fully qualified path to the VDMK file, the length of the path must be less than 255 characters.

22.12.7. Metrics for the vSphere Problem Detector Operator

The vSphere Problem Detector Operator exposes the following metrics for use by the OpenShift Container Platform monitoring stack.

**Table 22.76. Metrics exposed by the vSphere Problem Detector Operator**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>vsphere_cluster_check_total</strong></td>
<td>Cumulative number of cluster-level checks that the vSphere Problem Detector Operator performed. This count includes both successes and failures.</td>
</tr>
<tr>
<td><strong>vsphere_cluster_check_errors</strong></td>
<td>Number of failed cluster-level checks that the vSphere Problem Detector Operator performed. For example, a value of 1 indicates that one cluster-level check failed.</td>
</tr>
<tr>
<td><strong>vsphere_esxi_version_total</strong></td>
<td>Number of ESXi hosts with a specific version. Be aware that if a host runs more than one node, the host is counted only once.</td>
</tr>
<tr>
<td><strong>vsphere_node_check_total</strong></td>
<td>Cumulative number of node-level checks that the vSphere Problem Detector Operator performed. This count includes both successes and failures.</td>
</tr>
</tbody>
</table>
### vsphere_node_check_errors

Number of failed node-level checks that the vSphere Problem Detector Operator performed. For example, a value of 1 indicates that one node-level check failed.

### vsphere_node_hw_version_total

Number of vSphere nodes with a specific hardware version.

### vsphere_vcenter_info

Information about the vSphere vCenter Server.

#### 22.12.8. Additional resources

- Monitoring overview

#### 22.13. INSTALLATION CONFIGURATION PARAMETERS FOR VSPHERE

Before you deploy an OpenShift Container Platform cluster on vSphere, you provide parameters to customize your cluster and the platform that hosts it. When you create the `install-config.yaml` file, you provide values for the required parameters through the command line. You can then modify the `install-config.yaml` file to customize your cluster further.

#### 22.13.1. Available installation configuration parameters for vSphere

The following tables specify the required, optional, and vSphere-specific installation configuration parameters that you can set as part of the installation process.

#### NOTE

After installation, you cannot modify these parameters in the `install-config.yaml` file.

#### 22.13.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion:</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is v1. The installation program may also support older API versions.</td>
<td>String</td>
</tr>
</tbody>
</table>
### baseDomain:
The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the `baseDomain` and `metadata.name` parameter values that uses the `<metadata.name>`. `<baseDomain>` format.

A fully-qualified domain or subdomain name, such as example.com.

### metadata:
Kubernetes resource `ObjectMeta`, from which only the `name` parameter is consumed.

### metadata: name:
The name of the cluster. DNS records for the cluster are all subdomains of `{{.metadata.name}}. {{.baseDomain}}`.

String of lowercase letters and hyphens (-), such as dev.

### platform:
The configuration for the specific platform upon which to perform the installation: alibabacloud, aws, baremetal, azure, gcp, ibmcloud, nutanix, openstack, powervs, vsphere, or {}. For additional information about `platform`. `<platform>` parameters, consult the table for your specific platform that follows.

Object
### 22.13.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

- If you use the Red Hat OpenShift Networking OVN-Kubernetes network plugin, both IPv4 and IPv6 address families are supported.

- If you use the Red Hat OpenShift Networking OpenShift SDN network plugin, only the IPv4 address family is supported.

**NOTE**

On VMware vSphere, dual-stack networking can specify either IPv4 or IPv6 as the primary address family.

If you configure your cluster to use both IP address families, review the following requirements:

- Both IP families must use the same network interface for the default gateway.

- Both IP families must have the default gateway.

- You must specify IPv4 and IPv6 addresses in the same order for all network configuration parameters. For example, in the following configuration IPv4 addresses are listed before IPv6 addresses.

```yaml
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
      hostPrefix: 23
    - cidr: fd00:10:128::/56
      hostPrefix: 64
  serviceNetwork:
    - 172.30.0.0/16
    - fd00:172:16::/112
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>pullSecret:</td>
<td>Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.</td>
<td>{</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;auths&quot;:{</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;cloud.openshift.com&quot;:{</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;auth&quot;:&quot;b3Blb=&quot;,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;email&quot;:&quot;<a href="mailto:you@example.com">you@example.com</a>&quot;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>},</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;quay.io&quot;:{</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;auth&quot;:&quot;b3Blb=&quot;,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;email&quot;:&quot;<a href="mailto:you@example.com">you@example.com</a>&quot;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>}</td>
</tr>
<tr>
<td></td>
<td></td>
<td>}</td>
</tr>
</tbody>
</table>
NOTE
Globalnet is not supported with Red Hat OpenShift Data Foundation disaster recovery solutions. For regional disaster recovery scenarios, ensure that you use a nonoverlapping range of private IP addresses for the cluster and service networks in each cluster.

Table 22.78. Network parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking:</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>NOTE</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>You cannot modify parameters specified by the networking object after installation.</td>
</tr>
<tr>
<td>networking:</td>
<td></td>
<td><strong>NOTE</strong></td>
</tr>
<tr>
<td>networkType:</td>
<td>The Red Hat OpenShift Networking network plugin to install.</td>
<td>Either OpenShiftSDN or OVNKubernetes. OpenShiftSDN is a CNI plugin for all-Linux networks. OVNKubernetes is a CNI plugin for Linux networks and hybrid networks that contain both Linux and Windows servers. The default value is OVNKubernetes.</td>
</tr>
<tr>
<td>networking:</td>
<td></td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td>clusterNetwork:</td>
<td>The IP address blocks for pods.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td></td>
<td>The default value is 10.128.0.0/14 with a host prefix of /23.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td></td>
<td>If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td></td>
</tr>
<tr>
<td>networking:</td>
<td></td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td>clusterNetwork:</td>
<td>Required if you use networking.clusterNetwork. An IP address block.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td>cид:</td>
<td>An IPv4 network.</td>
<td></td>
</tr>
<tr>
<td>networking:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>clusterNetwork:</td>
<td>The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given cид. A hostPrefix value of 23 provides 510 (2^32 - 23 - 2) pod IP addresses.</td>
<td></td>
</tr>
<tr>
<td>hostPrefix:</td>
<td></td>
<td>A subnet prefix.</td>
</tr>
<tr>
<td></td>
<td>The default value is 23.</td>
<td></td>
</tr>
</tbody>
</table>
### networking: serviceNetwork:

The IP address block for services. The default value is **172.30.0.0/16**.

The OpenShift SDN and OVN-Kubernetes network plugins support only a single IP address block for the service network.

- networking: serviceNetwork:
  - 172.30.0.0/16

### networking: machineNetwork:

The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap.

- networking: machineNetwork:
  - cidr: 10.0.0.0/16

### networking: machineNetwork: cidr:

Required if you use `networking.machineNetwork`. An IP address block. The default value is **10.0.0.0/16** for all platforms other than libvirt and IBM Power® Virtual Server. For libvirt, the default value is **192.168.126.0/24**. For IBM Power® Virtual Server, the default value is **192.168.0.0/24**.

- networking: machineNetwork: cidr:
  - 10.0.0.0/16

**NOTE**

Set the `networking.machineNetwork` to match the CIDR that the preferred NIC resides in.

### 22.13.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

**Table 22.79. Optional parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle:</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>capabilities:</td>
<td>Controls the installation of optional core cluster components. You can reduce the footprint of your OpenShift Container Platform cluster by disabling optional components. For more information, see the &quot;Cluster capabilities&quot; page in Installing.</td>
<td>String array</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>------------------------------------------------------------------------------</td>
<td>-----------------------------</td>
</tr>
<tr>
<td>capabilities:</td>
<td>Selects an initial set of optional capabilities to enable. Valid values are</td>
<td>String</td>
</tr>
<tr>
<td>baselineCapabilitySet:</td>
<td>None, v4.11, v4.12 and vCurrent. The default value is vCurrent.</td>
<td></td>
</tr>
<tr>
<td>capabilities:</td>
<td>Extends the set of optional capabilities beyond what you specify in baselineCapabilitySet. You may specify multiple capabilities in this parameter.</td>
<td>String array</td>
</tr>
<tr>
<td>additionalEnabledCapabilities:</td>
<td>Enables workload partitioning, which isolates OpenShift Container Platform services, cluster management workloads, and infrastructure pods to run on a reserved set of CPUs. Workload partitioning can only be enabled during installation and cannot be disabled after installation. While this field enables workload partitioning, it does not configure workloads to use specific CPUs. For more information, see the Workload partitioning page in the Scalability and Performance section.</td>
<td>None or AllNodes. None is the default value.</td>
</tr>
<tr>
<td>cpuPartitioningMode:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>compute:</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of MachinePool objects.</td>
</tr>
<tr>
<td>compute: architecture:</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, clusters with varied architectures are not supported. All pools must specify the same architecture. Valid values are amd64 (the default).</td>
<td>String</td>
</tr>
<tr>
<td>compute: name:</td>
<td>Required if you use compute. The name of the machine pool.</td>
<td>worker</td>
</tr>
<tr>
<td>compute: platform:</td>
<td>Required if you use compute. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the controlPlane.platform parameter value.</td>
<td>alibabacloud, aws, azure, gcp, ibmcloud, nutanix, openstack, powervs, vsphere, or {}</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------------------------------------------------------------------------</td>

<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual or an empty string (“”). [1]</td>
</tr>
</tbody>
</table>
### fips:

Enable or disable FIPS mode. The default is `false` (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see [Installing the system in FIPS mode](#). When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures.

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.

1. Not all CCO modes are supported for all cloud providers. For more information about CCO modes, see the "Managing cloud provider credentials" entry in the Authentication and authorization content.

### 22.13.1.4. Additional VMware vSphere configuration parameters

Additional VMware vSphere configuration parameters are described in the following table:

**Table 22.80. Additional VMware vSphere cluster parameters**
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>platform:</strong> vsphere: apiVIPs:</td>
<td>Virtual IP (VIP) addresses that you configured for control plane API access. <strong>Note:</strong> This parameter applies only to installer-provisioned infrastructure.</td>
<td>Multiple IP addresses</td>
</tr>
<tr>
<td><strong>platform:</strong> vsphere: diskType:</td>
<td>Optional. The disk provisioning method. This value defaults to the vSphere default storage policy if not set.</td>
<td>Valid values are <strong>thin</strong>, <strong>thick</strong>, or <strong>eagerZeroedThick</strong>.</td>
</tr>
<tr>
<td><strong>platform:</strong> vsphere: failureDomains:</td>
<td>Establishes the relationships between a region and zone. You define a failure domain by using vCenter objects, such as a <strong>datastore</strong> object. A failure domain defines the vCenter location for OpenShift Container Platform cluster nodes.</td>
<td>String</td>
</tr>
<tr>
<td><strong>platform:</strong> vsphere: failureDomains: topology: networks:</td>
<td>Lists any network in the vCenter instance that contains the virtual IP addresses and DNS records that you configured.</td>
<td>String</td>
</tr>
<tr>
<td><strong>platform:</strong> vsphere: failureDomains: region:</td>
<td>If you define multiple failure domains for your cluster, you must attach the tag to each vCenter datacenter. To define a region, use a tag from the <strong>openshift-region</strong> tag category. For a single vSphere datacenter environment, you do not need to attach a tag, but you must enter an alphanumeric value, such as <strong>datacenter</strong>, for the parameter.</td>
<td>String</td>
</tr>
<tr>
<td><strong>platform:</strong> vsphere: failureDomains: zone:</td>
<td>If you define multiple failure domains for your cluster, you must attach the tag to each vCenter cluster. To define a zone, use a tag from the <strong>openshift-zone</strong> tag category. For a single vSphere datacenter environment, you do not need to attach a tag, but you must enter an alphanumeric value, such as <strong>cluster</strong>, for the parameter.</td>
<td>String</td>
</tr>
<tr>
<td><strong>platform:</strong> vsphere: failureDomains: template:</td>
<td>Specify the absolute path to a pre-existing Red Hat Enterprise Linux CoreOS (RHCOS) image template or virtual machine. The installation program can use the image template or virtual machine to quickly install RHCOS on vSphere hosts. Consider using this parameter as an alternative to uploading an RHCOS image on vSphere hosts. The parameter is available for use only on installer-provisioned infrastructure.</td>
<td>String</td>
</tr>
</tbody>
</table>
platform: vsphere:
ingressVIPs: Virtual IP (VIP) addresses that you configured for cluster Ingress.

Note: This parameter applies only to installer-provisioned infrastructure.

platform: vsphere:
Describes your account on the cloud platform that hosts your cluster. You can use the parameter to customize the platform. When providing additional configuration settings for compute and control plane machines in the machine pool, the parameter is optional. You can only specify one vCenter server for your OpenShift Container Platform cluster.

platform: vsphere:
vcenters:
Lists any fully-qualified hostname or IP address of a vCenter server.

platform: vsphere:
vcenters:
datacenters:
Lists and defines the datacenters where OpenShift Container Platform virtual machines (VMs) operate. The list of datacenters must match the list of datacenters specified in the failureDomains field.

### 22.13.1.5. Deprecated VMware vSphere configuration parameters

In OpenShift Container Platform 4.13, the following vSphere configuration parameters are deprecated. You can continue to use these parameters, but the installation program does not automatically specify these parameters in the install-config.yaml file.

The following table lists each deprecated vSphere configuration parameter:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>platform: vsphere: apiVIP:</td>
<td>The virtual IP (VIP) address that you configured for control plane API access. Note: In OpenShift Container Platform 4.12 and later, the apiVIP configuration setting is deprecated. Instead, use a List format to enter a value in the apiVIPs configuration setting.</td>
<td>An IP address, for example 128.0.0.1.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------</td>
</tr>
<tr>
<td>platform: vsphere:</td>

<td>Virtual IP (VIP) addresses that you configured for cluster Ingress.</td>
<td>An IP address, for example 128.0.0.1.</td>
</tr>
<tr>
<td>ingressVIP:</td>
<td>Note: In OpenShift Container Platform 4.12 and later, the ingressVIP configuration setting is deprecated. Instead, use a List format to enter a value in the ingressVIPs configuration setting.</td>
<td></td>
</tr>
<tr>
<td>platform: vsphere:</td>
<td>The network in the vCenter instance that contains the virtual IP addresses and DNS records that you configured.</td>
<td>String</td>
</tr>
<tr>
<td>network:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>platform: vsphere:</td>
<td>The password for the vCenter user name.</td>
<td>String</td>
</tr>
<tr>
<td>password:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>platform: vsphere:</td>
<td>Optional. The absolute path of an existing resource pool where the installation program creates the virtual machines. If you do not specify a value, the installation program installs the resources in the root of the cluster under /&lt;datacenter_name&gt;/host/&lt;cluster_name&gt;/Resources.</td>
<td>String, for example, /&lt;datacenter_name&gt;/host/&lt;cluster_name&gt;/Resources/&lt;resource_pool_name&gt;/&lt;optional_nested_resource_pool_name&gt;.</td>
</tr>
<tr>
<td>resourcePool:</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
The user name to use to connect to the vCenter instance with. This user must have at least the roles and privileges that are required for static or dynamic persistent volume provisioning in vSphere.

The fully-qualified hostname or IP address of a vCenter server.

**22.13.1.6. Optional VMware vSphere machine pool configuration parameters**

Optional VMware vSphere machine pool configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>platform: vsphere: username:</td>
<td>The user name to use to connect to the vCenter instance with. This user must have at least the roles and privileges that are required for static or dynamic persistent volume provisioning in vSphere.</td>
<td>String</td>
</tr>
<tr>
<td>platform: vsphere: vCenter:</td>
<td>The fully-qualified hostname or IP address of a vCenter server.</td>
<td>String</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>platform: vsphere: clusterOSImage:</td>
<td>The location from which the installation program downloads the Red Hat Enterprise Linux CoreOS (RHCOS) image. Before setting a path value for this parameter, ensure that the default RHCOS boot image in the OpenShift Container Platform release matches the RHCOS image template or virtual machine version; otherwise, cluster installation might fail.</td>
<td>An HTTP or HTTPS URL, optionally with a SHA-256 checksum. For example, <a href="https://mirror.openshift.com/images/rhcos-">https://mirror.openshift.com/images/rhcos-</a>&lt;version&gt;-vmware.&lt;architecture&gt;.ova.</td>
</tr>
<tr>
<td>platform: vsphere: osDisk: diskSizeGB:</td>
<td>The size of the disk in gigabytes.</td>
<td>Integer</td>
</tr>
<tr>
<td>platform: vsphere: cpus:</td>
<td>The total number of virtual processor cores to assign a virtual machine. The value of platform.vsphere.cpus must be a multiple of platform.vsphere.coresPerSocket value.</td>
<td>Integer</td>
</tr>
</tbody>
</table>
### Parameter List

<tr>
<td></td>
<td>The size of a virtual machine’s memory in megabytes.</td>
<td></td>
</tr>
</tbody>
</table>
23.1. INSTALLING A CLUSTER ON ANY PLATFORM

In OpenShift Container Platform version 4.14, you can install a cluster on any infrastructure that you provision, including virtualization and cloud environments.

**IMPORTANT**

Review the information in the guidelines for deploying OpenShift Container Platform on non-tested platforms before you attempt to install an OpenShift Container Platform cluster in virtualized or cloud environments.

23.1.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- If you use a firewall, you configured it to allow the sites that your cluster requires access to.

**NOTE**

Be sure to also review this site list if you are configuring a proxy.

23.1.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager Hybrid Cloud Console to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

23.1.3. Requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.
This section describes the requirements for deploying OpenShift Container Platform on user-provisioned infrastructure.

### 23.1.3.1. Required machines for cluster installation

The smallest OpenShift Container Platform clusters require the following hosts:

#### Table 23.1. Minimum required hosts

<table>
<thead>
<tr>
<th>Hosts</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>One temporary bootstrap machine</td>
<td>The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.</td>
</tr>
<tr>
<td>Three control plane machines</td>
<td>The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.</td>
</tr>
<tr>
<td>At least two compute machines, which are also known as worker machines.</td>
<td>The workloads requested by OpenShift Container Platform users run on the compute machines.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

To maintain high availability of your cluster, use separate physical hosts for these cluster machines.

The bootstrap and control plane machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system. However, the compute machines can choose between Red Hat Enterprise Linux CoreOS (RHCOS), Red Hat Enterprise Linux (RHEL) 8.6 and later.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 9.2 and inherits all of its hardware certifications and requirements. See [Red Hat Enterprise Linux technology capabilities and limits](#).

### 23.1.3.2. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

#### Table 23.2. Minimum resource requirements

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
</tbody>
</table>
1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or hyperthreading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: (threads per core × cores) × sockets = vCPUs.

2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.

3. As with all user-provisioned installations, if you choose to use RHEL compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and has been removed in OpenShift Container Platform 4.10 and later.

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

### 23.1.3.3. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The `kube-controller-manager` only approves the kubelet client CSRs. The `machine-approver` cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

### 23.1.3.4. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require networking to be configured in `initramfs` during boot to fetch their Ignition config files.

During the initial boot, the machines require an IP address configuration that is set either through a DHCP server or statically by providing the required boot options. After a network connection is established, the machines download their Ignition config files from an HTTP or HTTPS server. The Ignition config files are then used to set the exact state of each machine. The Machine Config Operator completes more changes to the machines, such as the application of new certificates or keys, after installation.

It is recommended to use a DHCP server for long-term management of the cluster machines. Ensure that the DHCP server is configured to provide persistent IP addresses, DNS server information, and hostnames to the cluster machines.
NOTE

If a DHCP service is not available for your user-provisioned infrastructure, you can instead provide the IP networking configuration and the address of the DNS server to the nodes at RHCOS install time. These can be passed as boot arguments if you are installing from an ISO image. See the *Installing RHCOS and starting the OpenShift Container Platform bootstrap process* section for more information about static IP provisioning and advanced networking options.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

### 23.1.3.4.1 Setting the cluster node hostnames through DHCP

On Red Hat Enterprise Linux CoreOS (RHCOS) machines, the hostname is set through NetworkManager. By default, the machines obtain their hostname through DHCP. If the hostname is not provided by DHCP, set statically through kernel arguments, or another method, it is obtained through a reverse DNS lookup. Reverse DNS lookup occurs after the network has been initialized on a node and can take time to resolve. Other system services can start prior to this and detect the hostname as *localhost* or similar. You can avoid this by using DHCP to provide the hostname for each cluster node.

Additionally, setting the hostnames through DHCP can bypass any manual DNS record name configuration errors in environments that have a DNS split-horizon implementation.

### 23.1.3.4.2 Network connectivity requirements

You must configure the network connectivity between machines to allow OpenShift Container Platform cluster components to communicate. Each machine must be able to resolve the hostnames of all other machines in the cluster.

This section provides details about the ports that are required.

**IMPORTANT**

In connected OpenShift Container Platform environments, all nodes are required to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

### Table 23.3. Ports used for all-machine to all-machine communications

<table>
<thead>
<tr>

<td>TCP</td>
<td>6443</td>
<td>Kubernetes API</td>
</tr>
</tbody>
</table>

**Table 23.4. Ports used for all-machine to control plane communications**

**Table 23.5. Ports used for control plane machine to control plane machine communications**

**NTP configuration for user-provisioned infrastructure**

OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for Configuring chrony time service.

If a DHCP server provides NTP server information, the chrony time service on the Red Hat Enterprise Linux CoreOS (RHCOS) machines read the information and can sync the clock with the NTP servers.

**Additional resources**

- Configuring chrony time service

**23.1.3.5. User-provisioned DNS requirements**
In OpenShift Container Platform deployments, DNS name resolution is required for the following components:

- The Kubernetes API
- The OpenShift Container Platform application wildcard
- The bootstrap, control plane, and compute machines

Reverse DNS resolution is also required for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.

DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the hostnames for all the nodes, unless the hostnames are provided by DHCP. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

NOTE
It is recommended to use a DHCP server to provide the hostnames to each cluster node. See the DHCP recommendations for user-provisioned infrastructure section for more information.

The following DNS records are required for a user-provisioned OpenShift Container Platform cluster and they must be in place before installation. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>`.

### Table 23.6. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes API</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the API load balancer. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td></td>
<td>api-int.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to internally identify the API load balancer. These records must be resolvable from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

The API server must be able to resolve the worker nodes by the hostnames that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.
<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Routes</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A wildcard DNS A/AAAA or CNAME record that refers to the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster. For example, <code>console-openshift-console.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;</code> is used as a wildcard route to the OpenShift Container Platform console.</td>
</tr>
<tr>
<td>Bootstrap machine</td>
<td>bootstrap.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>A DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Control plane machines</td>
<td>&lt;master&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Compute machines</td>
<td>&lt;worker&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;.</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**NOTE**

In OpenShift Container Platform 4.4 and later, you do not need to specify etcd host and SRV records in your DNS configuration.

**TIP**

You can use the `dig` command to verify name and reverse name resolution. See the section on *Validating DNS resolution for user-provisioned infrastructure* for detailed validation steps.

### 23.1.3.5.1. Example DNS configuration for user-provisioned clusters

This section provides A and PTR record configuration samples that meet the DNS requirements for deploying OpenShift Container Platform on user-provisioned infrastructure. The samples are not meant to provide advice for choosing one DNS solution over another.

In the examples, the cluster name is *ocp4* and the base domain is *example.com*.

#### Example DNS A record configuration for a user-provisioned cluster

The following example is a BIND zone file that shows sample A records for name resolution in a user-provisioned cluster.
Example 23.1. Sample DNS zone database

1 Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer.

2 Provides name resolution for the Kubernetes API. The record refers to the IP address of the API load balancer and is used for internal cluster communications.

3 Provides name resolution for the wildcard routes. The record refers to the IP address of the application ingress load balancer. The application ingress load balancer targets the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

NOTE

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.
Provides name resolution for the bootstrap machine.

Provides name resolution for the control plane machines.

Provides name resolution for the compute machines.

Example DNS PTR record configuration for a user-provisioned cluster

The following example BIND zone file shows sample PTR records for reverse name resolution in a user-provisioned cluster.

Example 23.2. Sample DNS zone database for reverse records

```
$TTL 1W
@ IN SOA ns1.example.com. root (2019070700 ; serial
3H ; refresh (3 hours)30M ; retry (30 minutes)
2W ; expiry (2 weeks)1W ) ; minimum (1 week)
IN NS ns1.example.com.

5.1.168.192.in-addr.arpa. IN PTR api.ocp4.example.com. 1
5.1.168.192.in-addr.arpa. IN PTR api-int.ocp4.example.com. 2

96.1.168.192.in-addr.arpa. IN PTR bootstrap.ocp4.example.com. 3

97.1.168.192.in-addr.arpa. IN PTR master0.ocp4.example.com. 4
98.1.168.192.in-addr.arpa. IN PTR master1.ocp4.example.com. 5
99.1.168.192.in-addr.arpa. IN PTR master2.ocp4.example.com. 6

11.1.168.192.in-addr.arpa. IN PTR worker0.ocp4.example.com. 7
7.1.168.192.in-addr.arpa. IN PTR worker1.ocp4.example.com. 8

;EOF
```

1 Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer.

2 Provides reverse DNS resolution for the Kubernetes API. The PTR record refers to the record name of the API load balancer and is used for internal cluster communications.

3 Provides reverse DNS resolution for the bootstrap machine.

4, 5, 6 Provides reverse DNS resolution for the control plane machines.

7, 8 Provides reverse DNS resolution for the compute machines.
NOTE
A PTR record is not required for the OpenShift Container Platform application wildcard.

23.1.3.6. Load balancing requirements for user-provisioned infrastructure

Before you install OpenShift Container Platform, you must provision the API and application Ingress load balancing infrastructure. In production scenarios, you can deploy the API and application Ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

NOTE
If you want to deploy the API and application Ingress load balancers with a Red Hat Enterprise Linux (RHEL) instance, you must purchase the RHEL subscription separately.

The load balancing infrastructure must meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:

   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.
   
   - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

   **IMPORTANT**

   Do not configure session persistence for an API load balancer. Configuring session persistence for a Kubernetes API server might cause performance issues from excess application traffic for your OpenShift Container Platform cluster and the Kubernetes API that runs inside the cluster.

Configure the following ports on both the front and back of the load balancers:

**Table 23.7. API load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the /readyz endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>
NOTE

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the /readyz endpoint to the removal of the API server instance from the pool. Within the time frame after /readyz returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. Application Ingress load balancer

Provides an ingress point for application traffic flowing in from outside the cluster. A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

TIP

If the true IP address of the client can be seen by the application Ingress load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

Configure the following ports on both the front and back of the load balancers:

Table 23.8. Application Ingress load balancer

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress Controller pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>

NOTE

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application Ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

23.1.3.6.1. Example load balancer configuration for user-provisioned clusters

This section provides an example API and application Ingress load balancer configuration that meets the load balancing requirements for user-provisioned clusters. The sample is an /etc/haproxy/haproxy.cfg configuration for an HAProxy load balancer. The example is not meant to provide advice for choosing
one load balancing solution over another.

In the example, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

**NOTE**

If you are using HAProxy as a load balancer and SELinux is set to `enforcing`, you must ensure that the HAProxy service can bind to the configured TCP port by running `setsebool -P haproxy_connect_any=1`.

---

Example 23.3. Sample API and application Ingress load balancer configuration

```plaintext
global
  log       127.0.0.1 local2
  pidfile   /var/run/haproxy.pid
  maxconn   4000
daemon
defaults
  mode              http
  log                global
  option             dontlognull
  option http-server-close
  option             redispatch
  retries            3
  timeout http-request 10s
  timeout queue      1m
  timeout connect    10s
  timeout client     1m
  timeout server     1m
  timeout http-keep-alive 10s
  timeout check      10s
  maxconn            3000
listen api-server-6443
  bind *:6443
  mode tcp
  server bootstrap bootstrap.ocp4.example.com:6443 check inter 1s backup
  server master0 master0.ocp4.example.com:6443 check inter 1s
  server master1 master1.ocp4.example.com:6443 check inter 1s
  server master2 master2.ocp4.example.com:6443 check inter 1s
listen machine-config-server-22623
  bind *:22623
  mode tcp
  server bootstrap bootstrap.ocp4.example.com:22623 check inter 1s backup
  server master0 master0.ocp4.example.com:22623 check inter 1s
  server master1 master1.ocp4.example.com:22623 check inter 1s
  server master2 master2.ocp4.example.com:22623 check inter 1s
listen ingress-router-443
  bind *:443
  mode tcp
  balance source
  server worker0 worker0.ocp4.example.com:443 check inter 1s
  server worker1 worker1.o cp4.example.com:443 check inter 1s
```
Port 6443 handles the Kubernetes API traffic and points to the control plane machines.

The bootstrap entries must be in place before the OpenShift Container Platform cluster installation and they must be removed after the bootstrap process is complete.

Port 22623 handles the machine config server traffic and points to the control plane machines.

Port 443 handles the HTTPS traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

Port 80 handles the HTTP traffic and points to the machines that run the Ingress Controller pods. The Ingress Controller pods run on the compute machines by default.

**NOTE**

If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application Ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes.

**TIP**

If you are using HAProxy as a load balancer, you can check that the `haproxy` process is listening on ports 6443, 22623, 443, and 80 by running `netstat -nltupe` on the HAProxy node.

### 23.1.4. Preparing the user-provisioned infrastructure

Before you install OpenShift Container Platform on user-provisioned infrastructure, you must prepare the underlying infrastructure.

This section provides details about the high-level steps required to set up your cluster infrastructure in preparation for an OpenShift Container Platform installation. This includes configuring IP networking and network connectivity for your cluster nodes, enabling the required ports through your firewall, and setting up the required DNS and load balancing infrastructure.

After preparation, your cluster infrastructure must meet the requirements outlined in the *Requirements for a cluster with user-provisioned infrastructure* section.

**Prerequisites**

- You have reviewed the [OpenShift Container Platform 4.x Tested Integrations](#) page.
- You have reviewed the infrastructure requirements detailed in the *Requirements for a cluster with user-provisioned infrastructure* section.
Procedure

1. If you are using DHCP to provide the IP networking configuration to your cluster nodes, configure your DHCP service.
   a. Add persistent IP addresses for the nodes to your DHCP server configuration. In your configuration, match the MAC address of the relevant network interface to the intended IP address for each node.
   b. When you use DHCP to configure IP addressing for the cluster machines, the machines also obtain the DNS server information through DHCP. Define the persistent DNS server address that is used by the cluster nodes through your DHCP server configuration.

   **NOTE**
   If you are not using a DHCP service, you must provide the IP networking configuration and the address of the DNS server to the nodes at RHCOS install time. These can be passed as boot arguments if you are installing from an ISO image. See the Installing RHCOS and starting the OpenShift Container Platform bootstrap process section for more information about static IP provisioning and advanced networking options.

c. Define the hostnames of your cluster nodes in your DHCP server configuration. See the Setting the cluster node hostnames through DHCP section for details about hostname considerations.

   **NOTE**
   If you are not using a DHCP service, the cluster nodes obtain their hostname through a reverse DNS lookup.

2. Ensure that your network infrastructure provides the required network connectivity between the cluster components. See the Networking requirements for user-provisioned infrastructure section for details about the requirements.

3. Configure your firewall to enable the ports required for the OpenShift Container Platform cluster components to communicate. See Networking requirements for user-provisioned infrastructure section for details about the ports that are required.

   **IMPORTANT**
   By default, port **1936** is accessible for an OpenShift Container Platform cluster, because each control plane node needs access to this port.

   Avoid using the Ingress load balancer to expose this port, because doing so might result in the exposure of sensitive information, such as statistics and metrics, related to Ingress Controllers.

4. Setup the required DNS infrastructure for your cluster.
   a. Configure DNS name resolution for the Kubernetes API, the application wildcard, the bootstrap machine, the control plane machines, and the compute machines.
   b. Configure reverse DNS resolution for the Kubernetes API, the bootstrap machine, the control plane machines, and the compute machines.
See the *User-provisioned DNS requirements* section for more information about the OpenShift Container Platform DNS requirements.

5. Validate your DNS configuration.

   a. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses in the responses correspond to the correct components.

   b. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names in the responses correspond to the correct components.

      See the *Validating DNS resolution for user-provisioned infrastructure* section for detailed DNS validation steps.

6. Provision the required API and application ingress load balancing infrastructure. See the *Load balancing requirements for user-provisioned infrastructure* section for more information about the requirements.

**NOTE**

Some load balancing solutions require the DNS name resolution for the cluster nodes to be in place before the load balancing is initialized.

### 23.1.5. Validating DNS resolution for user-provisioned infrastructure

You can validate your DNS configuration before installing OpenShift Container Platform on user-provisioned infrastructure.

**IMPORTANT**

The validation steps detailed in this section must succeed before you install your cluster.

**Prerequisites**

- You have configured the required DNS records for your user-provisioned infrastructure.

**Procedure**

1. From your installation node, run DNS lookups against the record names of the Kubernetes API, the wildcard routes, and the cluster nodes. Validate that the IP addresses contained in the responses correspond to the correct components.

   a. Perform a lookup against the Kubernetes API record name. Check that the result points to the IP address of the API load balancer:

   ```
   $ dig +noall +answer @<nameserver_ip> api.<cluster_name>.<base_domain>
   ```

   Replace `<nameserver_ip>` with the IP address of the nameserver, `<cluster_name>` with your cluster name, and `<base_domain>` with your base domain name.

**Example output**

```bash
api.ocp4.example.com. 604800 IN A 192.168.1.5
```
b. Perform a lookup against the Kubernetes internal API record name. Check that the result points to the IP address of the API load balancer:

```bash
$ dig +noall +answer @<nameserver_ip> api-int.<cluster_name>.<base_domain>
```

Example output

```
api-int.ocp4.example.com. 604800 IN A 192.168.1.5
```

c. Test an example `*.apps.<cluster_name>.<base_domain>` DNS wildcard lookup. All of the application wildcard lookups must resolve to the IP address of the application ingress load balancer:

```bash
$ dig +noall +answer @<nameserver_ip> random.apps.<cluster_name>.<base_domain>
```

Example output

```
random.apps.ocp4.example.com. 604800 IN A 192.168.1.5
```

NOTE

In the example outputs, the same load balancer is used for the Kubernetes API and application ingress traffic. In production scenarios, you can deploy the API and application ingress load balancers separately so that you can scale the load balancer infrastructure for each in isolation.

You can replace `random` with another wildcard value. For example, you can query the route to the OpenShift Container Platform console:

```bash
$ dig +noall +answer @<nameserver_ip> console-openshift-console.apps.<cluster_name>.<base_domain>
```

Example output

```
console-openshift-console.apps.ocp4.example.com. 604800 IN A 192.168.1.5
```

d. Run a lookup against the bootstrap DNS record name. Check that the result points to the IP address of the bootstrap node:

```bash
$ dig +noall +answer @<nameserver_ip> bootstrap.<cluster_name>.<base_domain>
```

Example output

```
bootstrap.ocp4.example.com. 604800 IN A 192.168.1.96
```

e. Use this method to perform lookups against the DNS record names for the control plane and compute nodes. Check that the results correspond to the IP addresses of each node.
2. From your installation node, run reverse DNS lookups against the IP addresses of the load balancer and the cluster nodes. Validate that the record names contained in the responses correspond to the correct components.

   a. Perform a reverse lookup against the IP address of the API load balancer. Check that the response includes the record names for the Kubernetes API and the Kubernetes internal API:

   ```
   $ dig +noall +answer @<nameserver_ip> -x 192.168.1.5
   
   Example output
   ```

   ```
   5.1.168.192.in-addr.arpa. 604800 IN PTR api-int.ocp4.example.com. 1
   5.1.168.192.in-addr.arpa. 604800 IN PTR api.ocp4.example.com. 2
   ```

   1 Provides the record name for the Kubernetes internal API.

   2 Provides the record name for the Kubernetes API.

   **NOTE**

   A PTR record is not required for the OpenShift Container Platform application wildcard. No validation step is needed for reverse DNS resolution against the IP address of the application ingress load balancer.

   b. Perform a reverse lookup against the IP address of the bootstrap node. Check that the result points to the DNS record name of the bootstrap node:

   ```
   $ dig +noall +answer @<nameserver_ip> -x 192.168.1.96
   
   Example output
   ```

   ```
   ```

c. Use this method to perform reverse lookups against the IP addresses for the control plane and compute nodes. Check that the results correspond to the DNS record names of each node.

23.1.6. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the `core` user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH into the RHCOS nodes as the user `core`. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.
If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ ssh-keygen -t ed25519 -N '' -f <path>/<file_name>
   ```

   Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the `x86_64`, `ppc64le`, and `s390x` architectures, do not create a key that uses the `ed25519` algorithm. Instead, create a key that uses the `rsa` or `ecdsa` algorithm.

2. View the public SSH key:

   ```
   $ cat <path>/<file_name>.pub
   ```

   For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

   ```
   $ cat ~/.ssh/id_ed25519.pub
   ```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

   **NOTE**

   On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.
a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

```bash
$ eval "$(ssh-agent -s)"
```

**Example output**

```
Agent pid 31874
```

**NOTE**

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

```bash
$ ssh-add <path>/<file_name>
```

Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

**Example output**

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program. If you install a cluster on infrastructure that you provision, you must provide the key to the installation program.

### 23.1.7. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

**Prerequisites**

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

**Procedure**

1. Access the **Infrastructure Provider** page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.
IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

23.1.8. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

IMPORTANT

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of oc.

Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure

2. Select the architecture from the Product Variant drop-down list.

3. Select the appropriate version from the Version drop-down list.

4. Click Download Now next to the OpenShift v4.14 Linux Client entry and save the file.

5. Unpack the archive:

```
$ tar xvf <file>
```

6. Place the oc binary in a directory that is on your PATH.
To check your `PATH`, execute the following command:

```
$ echo $PATH
```

**Verification**

- After you install the OpenShift CLI, it is available using the `oc` command:

```
$ oc <command>
```

**Installing the OpenShift CLI on Windows**

You can install the OpenShift CLI (`oc`) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version from the Version drop-down list.
3. Click Download Now next to the OpenShift v4.14 Windows Client entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the `oc` binary to a directory that is on your `PATH`. To check your `PATH`, open the command prompt and execute the following command:

```
C:\> path
```

**Verification**

- After you install the OpenShift CLI, it is available using the `oc` command:

```
C:\> oc <command>
```

**Installing the OpenShift CLI on macOS**

You can install the OpenShift CLI (`oc`) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version from the Version drop-down list.
3. Click Download Now next to the OpenShift v4.14 macOS Client entry and save the file.
4. Unpack and unzip the archive.

**NOTE**

For macOS arm64, choose the OpenShift v4.14 macOS arm64 Client entry.
5. Move the `oc` binary to a directory on your PATH. To check your PATH, open a terminal and execute the following command:

```bash
$ echo $PATH
```

**Verification**

- After you install the OpenShift CLI, it is available using the `oc` command:

```bash
$ oc <command>
```

### 23.1.9. Manually creating the installation configuration file

**Prerequisites**

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.

- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Create an installation directory to store your required installation assets in:

   ```bash
   $ mkdir <installation_directory>
   ```

   **IMPORTANT**

   You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample `install-config.yaml` file template that is provided and save it in the `<installation_directory>`.

   **NOTE**

   You must name this configuration file `install-config.yaml`.

   **NOTE**

   For some platform types, you can alternatively run `./openshift-install create install-config --dir <installation_directory>` to generate an `install-config.yaml` file. You can provide details about your cluster configuration at the prompts.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.
23.1.9.1. Sample install-config.yaml file for other platforms

You can customize the install-config.yaml file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: example.com
compute:
  - hyperthreading: Enabled
    name: worker
    replicas: 0
controlPlane:
  hyperthreading: Enabled
  name: master
  replicas: 3
metadata:
  name: test
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
  hostPrefix: 23
  networkType: OVNKubernetes
  serviceNetwork:
    - 172.30.0.0/16
platform:
  none: {}
fips: false
pullSecret: '{"auths": ...}''
sshKey: 'ssh-ed25519 AAAA...'
```

1. The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

2. The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, -, and the first line of the controlPlane section must not. Only one control plane pool is used.

3. Specifies whether to enable or disable simultaneous multithreading (SMT), or hyperthreading. By default, SMT is enabled to increase the performance of the cores in your machines. You can disable it by setting the parameter value to Disabled. If you disable SMT, you must disable it in all cluster machines; this includes both control plane and compute machines.

4. The compute section must begin with a hyphen, -.

5. The controlPlane section must not begin with a hyphen, -.

6. IMPORTANT

NOTE

Simultaneous multithreading (SMT) is enabled by default. If SMT is not enabled in your BIOS settings, the hyperthreading parameter has no effect.
IMPORTANT

If you disable hyperthreading, whether in the BIOS or in the install-config.yaml file, ensure that your capacity planning accounts for the dramatically decreased machine performance.

You must set this value to 0 when you install OpenShift Container Platform on user-provisioned infrastructure. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. In user-provisioned installations, you must manually deploy the compute machines before you finish installing the cluster.

NOTE

If you are installing a three-node cluster, do not deploy any compute machines when you install the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

The number of control plane machines that you add to the cluster. Because the cluster uses these values as the number of etcd endpoints in the cluster, the value must match the number of control plane machines that you deploy.

The cluster name that you specified in your DNS records.

A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to access the pods from an external network, you must configure load balancers and routers to manage the traffic.

NOTE

Class E CIDR range is reserved for a future use. To use the Class E CIDR range, you must ensure your networking environment accepts the IP addresses within the Class E CIDR range.

The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23, then each node is assigned a /23 subnet out of the given cidr, which allows for 510 \(2^{32 - 23} - 2\) pod IP addresses. If you are required to provide access to nodes from an external network, configure load balancers and routers to manage the traffic.

The cluster network plugin to install. The supported values are OVNKubernetes and OpenShiftSDN. The default value is OVNKubernetes.

The IP address pool to use for service IP addresses. You can enter only one IP address pool. This block must not overlap with existing physical networks. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.

You must set the platform to none. You cannot provide additional platform configuration variables for your platform.
Clusters that are installed with the platform type **none** are unable to use some features, such as managing compute machines with the Machine API. This limitation applies even if the compute machines that are attached to the cluster are installed on a platform that would normally support the feature. This parameter cannot be changed after installation.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see [Installing the system in FIPS mode](#). When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures.

The pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

The SSH public key for the **core** user in Red Hat Enterprise Linux CoreOS (RHCOS).

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

### 23.1.9.2. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**Prerequisites**

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.
NOTE

The Proxy object status.noProxy field is populated with the values of the networking.machineNetwork[].cidr, networking.clusterNetwork[].cidr, and networking.serviceNetwork[] fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object status.noProxy field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your install-config.yaml file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port>  
  httpsProxy: https://<username>:<pswd>@<ip>:<port>  
  noProxy: example.com
additionalTrustBundle: |
  -----BEGIN CERTIFICATE-----
  <MY_TRUSTED_CA_CERT>
  -----END CERTIFICATE-----
additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle>
```

1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.

2. A proxy URL to use for creating HTTPS connections outside the cluster.

3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.

4. If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the trustedCA field of the Proxy object. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

5. Optional: The policy to determine the configuration of the Proxy object to reference the user-ca-bundle config map in the trustedCA field. The allowed values are Proxyonly and Always. Use Proxyonly to reference the user-ca-bundle config map only when http/https proxy is configured. Use Always to always reference the user-ca-bundle config map. The default value is Proxyonly.

NOTE

The installation program does not support the proxy readinessEndpoints field.
NOTE

If the installer times out, restart and then complete the deployment by using the `wait-for` command of the installer. For example:

```
$ ./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

NOTE

Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

23.1.9.3. Configuring a three-node cluster

Optionally, you can deploy zero compute machines in a bare metal cluster that consists of three control plane machines only. This provides smaller, more resource efficient clusters for cluster administrators and developers to use for testing, development, and production.

In three-node OpenShift Container Platform environments, the three control plane machines are schedulable, which means that your application workloads are scheduled to run on them.

Prerequisites

- You have an existing `install-config.yaml` file.

Procedure

- Ensure that the number of compute replicas is set to 0 in your `install-config.yaml` file, as shown in the following `compute` stanza:

```
compute:
- name: worker
  platform: {}
  replicas: 0
```

NOTE

You must set the value of the `replicas` parameter for the compute machines to 0 when you install OpenShift Container Platform on user-provisioned infrastructure, regardless of the number of compute machines you are deploying. In installer-provisioned installations, the parameter controls the number of compute machines that the cluster creates and manages for you. This does not apply to user-provisioned installations, where the compute machines are deployed manually.

For three-node cluster installations, follow these next steps:
If you are deploying a three-node cluster with zero compute nodes, the Ingress Controller pods run on the control plane nodes. In three-node cluster deployments, you must configure your application ingress load balancer to route HTTP and HTTPS traffic to the control plane nodes. See the Load balancing requirements for user-provisioned infrastructure section for more information.

When you create the Kubernetes manifest files in the following procedure, ensure that the mastersSchedulable parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file is set to true. This enables your application workloads to run on the control plane nodes.

Do not deploy any compute nodes when you create the Red Hat Enterprise Linux CoreOS (RHCOS) machines.

## 23.1.10. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

### IMPORTANT

- The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

### Prerequisites

- You obtained the OpenShift Container Platform installation program.

- You created the `install-config.yaml` installation configuration file.

### Procedure

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

   ```shell
   $ ./openshift-install create manifests --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.
WARNING

If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.

IMPORTANT

When you configure control plane nodes from the default unschedulable to schedulable, additional subscriptions are required. This is because control plane nodes then become compute nodes.

2. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:

   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.

   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.

   c. Save and exit the file.

3. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

   ```
   $ ./openshift-install create ignition-configs --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the same installation directory.

   Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The `kubeadmin-password` and `kubeconfig` files are created in the `./<installation_directory>/auth` directory:

   ```
   ├── auth
   │   └── kubeadmin-password
   │       └── kubeconfig
   │           └── bootstrap.ign
   │           └── master.ign
   │                   └── metadata.json
   │                       └── worker.ign
   ```

23.1.11. Installing RHCOS and starting the OpenShift Container Platform bootstrap process

To install OpenShift Container Platform on bare metal infrastructure that you provision, you must install Red Hat Enterprise Linux CoreOS (RHCOS) on the machines. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation
To install RHCOS on the machines, follow either the steps to use an ISO image or network PXE booting.

**NOTE**

The compute node deployment steps included in this installation document are RHCOS-specific. If you choose instead to deploy RHEL-based compute nodes, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Only RHEL 8 compute machines are supported.

You can configure RHCOS during ISO and PXE installations by using the following methods:

- **Kernel arguments**: You can use kernel arguments to provide installation-specific information. For example, you can specify the locations of the RHCOS installation files that you uploaded to your HTTP server and the location of the Ignition config file for the type of node you are installing. For a PXE installation, you can use the `APPEND` parameter to pass the arguments to the kernel of the live installer. For an ISO installation, you can interrupt the live installation boot process to add the kernel arguments. In both installation cases, you can use special `coreos.inst.` arguments to direct the live installer, as well as standard installation boot arguments for turning standard kernel services on or off.

- **Ignition configs**: OpenShift Container Platform Ignition config files (*.*ign) are specific to the type of node you are installing. You pass the location of a bootstrap, control plane, or compute node Ignition config file during the RHCOS installation so that it takes effect on first boot. In special cases, you can create a separate, limited Ignition config to pass to the live system. That Ignition config could do a certain set of tasks, such as reporting success to a provisioning system after completing installation. This special Ignition config is consumed by the `coreos-installer` to be applied on first boot of the installed system. Do not provide the standard control plane and compute node Ignition configs to the live ISO directly.

- **coreos-installer**: You can boot the live ISO installer to a shell prompt, which allows you to prepare the permanent system in a variety of ways before first boot. In particular, you can run the `coreos-installer` command to identify various artifacts to include, work with disk partitions, and set up networking. In some cases, you can configure features on the live system and copy them to the installed system.

Whether to use an ISO or PXE install depends on your situation. A PXE install requires an available DHCP service and more preparation, but can make the installation process more automated. An ISO install is a more manual process and can be inconvenient if you are setting up more than a few machines.

**NOTE**

As of OpenShift Container Platform 4.6, the RHCOS ISO and other installation artifacts provide support for installation on disks with 4K sectors.

### 23.11.1. Installing RHCOS by using an ISO image

You can use an ISO image to install RHCOS on the machines.

**Prerequisites**
You have created the Ignition config files for your cluster.

You have configured suitable network, DNS and load balancing infrastructure.

You have an HTTP server that can be accessed from your computer, and from the machines that you create.

You have reviewed the Advanced RHCOS installation configuration section for different ways to configure features, such as networking and disk partitioning.

Procedure

1. Obtain the SHA512 digest for each of your Ignition config files. For example, you can use the following on a system running Linux to get the SHA512 digest for your `bootstrap.ign` Ignition config file:

   ```bash
   $ sha512sum <installation_directory>/bootstrap.ign
   
   The digests are provided to the coreos-installer in a later step to validate the authenticity of the Ignition config files on the cluster nodes.
   ```

2. Upload the bootstrap, control plane, and compute node Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

   **IMPORTANT**

   You can add or change configuration settings in your Ignition configs before saving them to your HTTP server. If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

3. From the installation host, validate that the Ignition config files are available on the URLs. The following example gets the Ignition config file for the bootstrap node:

   ```bash
   $ curl -k http://<HTTP_server>/bootstrap.ign
   
   Example output
   
   Replace `bootstrap.ign` with `master.ign` or `worker.ign` in the command to validate that the Ignition config files for the control plane and compute nodes are also available.

4. Although it is possible to obtain the RHCOS images that are required for your preferred method of installing operating system instances from the RHCOS image mirror page, the recommended way to obtain the correct version of your RHCOS images are from the output of `openshift-install` command:

   ```bash
   $ openshift-install coreos print-stream-json | grep \."iso[^\.]"\
   
   Example output
   ```
IMPORTANT

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available. Use only ISO images for this procedure. RHCOS qcow2 images are not supported for this installation type.

ISO file names resemble the following example:

```
rhcos-<version>-live.<architecture>.iso
```

5. Use the ISO to start the RHCOS installation. Use one of the following installation options:
   - Burn the ISO image to a disk and boot it directly.
   - Use ISO redirection by using a lights-out management (LOM) interface.

6. Boot the RHCOS ISO image without specifying any options or interrupting the live boot sequence. Wait for the installer to boot into a shell prompt in the RHCOS live environment.

NOTE

It is possible to interrupt the RHCOS installation boot process to add kernel arguments. However, for this ISO procedure you should use the `coreos-installer` command as outlined in the following steps, instead of adding kernel arguments.

7. Run the `coreos-installer` command and specify the options that meet your installation requirements. At a minimum, you must specify the URL that points to the Ignition config file for the node type, and the device that you are installing to:

```
$ sudo coreos-installer install --ignition-url=http://<HTTP_server>/<node_type>.ign <device> --ignition-hash=sha512-<digest>
```

1. You must run the `coreos-installer` command by using `sudo`, because the `core` user does not have the required root privileges to perform the installation.

2. The `--ignition-hash` option is required when the Ignition config file is obtained through an HTTP URL to validate the authenticity of the Ignition config file on the cluster node. `<digest>` is the Ignition config file SHA512 digest obtained in a preceding step.
NOTE

If you want to provide your Ignition config files through an HTTPS server that uses TLS, you can add the internal certificate authority (CA) to the system trust store before running `coreos-installer`.

The following example initializes a bootstrap node installation to the `/dev/sda` device. The Ignition config file for the bootstrap node is obtained from an HTTP web server with the IP address 192.168.1.2:

```bash
$ sudo coreos-installer install --ignition-url=http://192.168.1.2:80/installation_directory/bootstrap.ign /dev/sda --ignition-hash=sha512-a5a2d43879223273c9b60af66b44202a1d1248fc01cf156c46d4a79f552b6bad47bc8cc78ddf0116e80c59d2ea9e32ba53bc807afbc581aa059311def2c3e3b
```

8. Monitor the progress of the RHCOS installation on the console of the machine.

IMPORTANT

Be sure that the installation is successful on each node before commencing with the OpenShift Container Platform installation. Observing the installation process can also help to determine the cause of RHCOS installation issues that might arise.

9. After RHCOS installs, you must reboot the system. During the system reboot, it applies the Ignition config file that you specified.

10. Check the console output to verify that Ignition ran.

Example command

Ignition: ran on 2022/03/14 14:48:33 UTC (this boot)
Ignition: user-provided config was applied

11. Continue to create the other machines for your cluster.

IMPORTANT

You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, also create at least two compute machines before you install OpenShift Container Platform.

If the required network, DNS, and load balancer infrastructure are in place, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS nodes have rebooted.
NOTE

RHCOS nodes do not include a default password for the core user. You can access the nodes by running ssh core@<node>.<cluster_name>.<base_domain> as a user with access to the SSH private key that is paired to the public key that you specified in your install_config.yaml file. OpenShift Container Platform 4 cluster nodes running RHCOS are immutable and rely on Operators to apply cluster changes. Accessing cluster nodes by using SSH is not recommended. However, when investigating installation issues, if the OpenShift Container Platform API is not available, or the kubelet is not properly functioning on a target node, SSH access might be required for debugging or disaster recovery.

23.1.11.2. Installing RHCOS by using PXE or iPXE booting

You can use PXE or iPXE booting to install RHCOS on the machines.

Prerequisites

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
- You have configured suitable PXE or iPXE infrastructure.
- You have an HTTP server that can be accessed from your computer, and from the machines that you create.
- You have reviewed the Advanced RHCOS installation configuration section for different ways to configure features, such as networking and disk partitioning.

Procedure

1. Upload the bootstrap, control plane, and compute node Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

   IMPORTANT

   You can add or change configuration settings in your Ignition configs before saving them to your HTTP server. If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

2. From the installation host, validate that the Ignition config files are available on the URLs. The following example gets the Ignition config file for the bootstrap node:

   $ curl -k http://<HTTP_server>/bootstrap.ign

   Example output

   % Total    % Received % Xferd  Average Speed   Time    Time     Time  Current
   Dload  Upload   Total   Spent    Left  Speed
   0     0    0     0    0     0      0      0 --:--:-- --:--:-- --:--:--     0{"ignition":
   
   0("version":"3.2.0"),"passwd":{"users":[{"name":"core","sshAuthorizedKeys":[]}"ssh-rsa...
Replace `bootstrap.ign` with `master.ign` or `worker.ign` in the command to validate that the Ignition config files for the control plane and compute nodes are also available.

3. Although it is possible to obtain the RHCOS `kernel`, `initramfs` and `rootfs` files that are required for your preferred method of installing operating system instances from the RHCOS image mirror page, the recommended way to obtain the correct version of your RHCOS files are from the output of `openshift-install` command:

```
$ openshift-install coreos print-stream-json | grep -Eo "https.*\w+\(\.(img)\)"
```

Example output

```
"<url>/art/storage/releases/rhcos-4.14-aarch64/<release>/aarch64/rhcos-<release>-live-kernel-aarch64"  
"<url>/art/storage/releases/rhcos-4.14-aarch64/<release>/aarch64/rhcos-<release>-live-initramfs.aarch64.img"  
"<url>/art/storage/releases/rhcos-4.14-aarch64/<release>/aarch64/rhcos-<release>-live-rootfs.aarch64.img"  
"<url>/art/storage/releases/rhcos-4.14-ppc64le/49.84.202110081256-0/ppc64le/rhcos-<release>-live-kernel-ppc64le"  
"<url>/art/storage/releases/rhcos-4.14-ppc64le/<release>/ppc64le/rhcos-<release>-live-initramfs.ppc64le.img"  
"<url>/art/storage/releases/rhcos-4.14-ppc64le/<release>/ppc64le/rhcos-<release>-live-rootfs.ppc64le.img"  
"<url>/art/storage/releases/rhcos-4.14-s390x/<release>/s390x/rhcos-<release>-live-kernel-s390x"  
"<url>/art/storage/releases/rhcos-4.14-s390x/<release>/s390x/rhcos-<release>-live-initramfs.s390x.img"  
"<url>/art/storage/releases/rhcos-4.14-s390x/<release>/s390x/rhcos-<release>-live-rootfs.s390x.img"  
"<url>/art/storage/releases/rhcos-4.14/<release>/x86_64/rhcos-<release>-live-kernel-x86_64"  
"<url>/art/storage/releases/rhcos-4.14/<release>/x86_64/rhcos-<release>-live-initramfs.x86_64.img"  
"<url>/art/storage/releases/rhcos-4.14/<release>/x86_64/rhcos-<release>-live-rootfs.x86_64.img"
```

**IMPORTANT**

The RHCOS artifacts might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate `kernel`, `initramfs`, and `rootfs` artifacts described below for this procedure. RHCOS QCOW2 images are not supported for this installation type.

The file names contain the OpenShift Container Platform version number. They resemble the following examples:

- **kernel**: `rhcos-<version>-live-kernel-<architecture>`
- **initramfs**: `rhcos-<version>-live-initramfs.<architecture>.img`
- **rootfs**: `rhcos-<version>-live-rootfs.<architecture>.img`

4. Upload the **rootfs**, **kernel**, and **initramfs** files to your HTTP server.

**IMPORTANT**

If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

5. Configure the network boot infrastructure so that the machines boot from their local disks after RHCOS is installed on them.

6. Configure PXE or iPXE installation for the RHCOS images and begin the installation.

   Modify one of the following example menu entries for your environment and verify that the image and Ignition files are properly accessible:

   - For **PXE** (*x86_64*):

     ```
     DEFAULT pxeboot
     TIMEOUT 20
     PROMPT 0
     LABEL pxeboot
     KERNEL http://<HTTP_server>/rhcos-<version>-live-kernel-<architecture>
     <architecture>.img coreos.live.rootfs_url=http://<HTTP_server>/rhcos-<version>-live-
     rootfs.<architecture>.img coreos.inst.install_dev=/dev/sda
     coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign
     ```

     **1** Specify the location of the live **kernel** file that you uploaded to your HTTP server. The URL must be HTTP, TFTP, or FTP; HTTPS and NFS are not supported.

     **2** If you use multiple NICs, specify a single interface in the **ip** option. For example, to use DHCP on a NIC that is named `eno1`, set `ip=eno1:dhcp`.

     **3** Specify the locations of the RHCOS files that you uploaded to your HTTP server. The **initrd** parameter value is the location of the **initramfs** file, the **coreos.live.rootfs_url** parameter value is the location of the **rootfs** file, and the **coreos.inst.ignition_url** parameter value is the location of the bootstrap Ignition config file. You can also add more kernel arguments to the **APPEND** line to configure networking or other boot options.

   **NOTE**

   This configuration does not enable serial console access on machines with a graphical console. To configure a different console, add one or more `console=` arguments to the **APPEND** line. For example, add `console=tty0` `console=ttyS0` to set the first PC serial port as the primary console and the graphical console as a secondary console. For more information, see How does one set up a serial terminal and/or console in Red Hat Enterprise Linux? and "Enabling the serial console for PXE and ISO installation" in the "Advanced RHCOS installation configuration" section.

   - For **iPXE** (*x86_64* + *aarch64*):

     ```
     ```
Specify the locations of the RHCOS files that you uploaded to your HTTP server. The \texttt{kernel} parameter value is the location of the \texttt{kernel} file, the \texttt{initrd=main} argument is needed for booting on UEFI systems, the \texttt{coreos.live.rootfs_url} parameter value is the location of the \texttt{rootfs} file, and the \texttt{coreos.inst.ignition_url} parameter value is the location of the bootstrap Ignition config file.

If you use multiple NICs, specify a single interface in the \texttt{ip} option. For example, to use DHCP on a NIC that is named \texttt{eno1}, set \texttt{ip=eno1:dhcp}.

Specify the location of the \texttt{initramfs} file that you uploaded to your HTTP server.

\textbf{NOTE}

This configuration does not enable serial console access on machines with a graphical console. To configure a different console, add one or more \texttt{console=} arguments to the \texttt{kernel} line. For example, add \texttt{console=tty0 console=ttyS0} to set the first PC serial port as the primary console and the graphical console as a secondary console. For more information, see \textit{How does one set up a serial terminal and/or console in Red Hat Enterprise Linux?} and "Enabling the serial console for PXE and ISO installation" in the "Advanced RHCOS installation configuration" section.

\textbf{NOTE}

To network boot the CoreOS \texttt{kernel} on \texttt{aarch64} architecture, you need to use a version of iPXE build with the \texttt{IMAGE_GZIP} option enabled. See \texttt{IMAGE_GZIP} option in iPXE.

For PXE (with UEFI and Grub as second stage) on aarch64:

\begin{verbatim}
menuentry 'Install CoreOS' {
  linux rhcos-<version>-live-kernel-<architecture>
  <architecture>.img
  coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign
  initrd rhcos-<version>-live-initramfs.<architecture>.img
}
\end{verbatim}

1. Specify the locations of the RHCOS files that you uploaded to your HTTP/TFTP server. The \texttt{kernel} parameter value is the location of the \texttt{kernel} file on your TFTP server. The \texttt{coreos.live.rootfs_url} parameter value is the location of the \texttt{rootfs} file, and the \texttt{coreos.inst.ignition_url} parameter value is the location of the bootstrap Ignition config file on your HTTP Server.

2. If you use multiple NICs, specify a single interface in the \texttt{ip} option. For example, to use
3 Specify the location of the `initramfs` file that you uploaded to your TFTP server.

7. Monitor the progress of the RHCOS installation on the console of the machine.

**IMPORTANT**

Be sure that the installation is successful on each node before commencing with the OpenShift Container Platform installation. Observing the installation process can also help to determine the cause of RHCOS installation issues that might arise.

8. After RHCOS installs, the system reboots. During reboot, the system applies the Ignition config file that you specified.

9. Check the console output to verify that Ignition ran.

**Example command**

```
Ignition: ran on 2022/03/14 14:48:33 UTC (this boot)
Ignition: user-provided config was applied
```

10. Continue to create the machines for your cluster.

**IMPORTANT**

You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, also create at least two compute machines before you install the cluster.

If the required network, DNS, and load balancer infrastructure are in place, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS nodes have rebooted.

**NOTE**

RHCOS nodes do not include a default password for the `core` user. You can access the nodes by running `ssh core@<node>.<cluster_name>`. `<base_domain>` as a user with access to the SSH private key that is paired to the public key that you specified in your `install_config.yaml` file. OpenShift Container Platform 4 cluster nodes running RHCOS are immutable and rely on Operators to apply cluster changes. Accessing cluster nodes by using SSH is not recommended. However, when investigating installation issues, if the OpenShift Container Platform API is not available, or the kubelet is not properly functioning on a target node, SSH access might be required for debugging or disaster recovery.

### 23.1.11.3. Advanced RHCOS installation configuration

A key benefit for manually provisioning the Red Hat Enterprise Linux CoreOS (RHCOS) nodes for OpenShift Container Platform is to be able to do configuration that is not available through default OpenShift Container Platform installation methods. This section describes some of the configurations that you can do using techniques that include:
• Passing kernel arguments to the live installer
• Running `coreos-installer` manually from the live system
• Customizing a live ISO or PXE boot image

The advanced configuration topics for manual Red Hat Enterprise Linux CoreOS (RHCOS) installations detailed in this section relate to disk partitioning, networking, and using Ignition configs in different ways.

23.11.3.1. Using advanced networking options for PXE and ISO installations

Networking for OpenShift Container Platform nodes uses DHCP by default to gather all necessary configuration settings. To set up static IP addresses or configure special settings, such as bonding, you can do one of the following:

• Pass special kernel parameters when you boot the live installer.
• Use a machine config to copy networking files to the installed system.
• Configure networking from a live installer shell prompt, then copy those settings to the installed system so that they take effect when the installed system first boots.

To configure a PXE or iPXE installation, use one of the following options:

• See the "Advanced RHCOS installation reference" tables.
• Use a machine config to copy networking files to the installed system.

To configure an ISO installation, use the following procedure.

Procedure

1. Boot the ISO installer.

2. From the live system shell prompt, configure networking for the live system using available RHEL tools, such as `nmcli` or `nmtui`.

3. Run the `coreos-installer` command to install the system, adding the `--copy-network` option to copy networking configuration. For example:

```bash
$ sudo coreos-installer install --copy-network \
  --ignition-url=http://host/worker.ign /dev/disk/by-id/scsi-<serial_number>
```

**IMPORTANT**

The `--copy-network` option only copies networking configuration found under `/etc/NetworkManager/system-connections`. In particular, it does not copy the system hostname.

4. Reboot into the installed system.

Additional resources

• See Getting started with `nmcli` and Getting started with `nmtui` in the RHEL 8 documentation for more information about the `nmcli` and `nmtui` tools.
23.1.11.3.2. Disk partitioning

The disk partitions are created on OpenShift Container Platform cluster nodes during the Red Hat Enterprise Linux CoreOS (RHCOS) installation. Each RHCOS node of a particular architecture uses the same partition layout, unless the default partitioning configuration is overridden. During the RHCOS installation, the size of the root file system is increased to use the remaining available space on the target device.

There are two cases where you might want to override the default partitioning when installing RHCOS on an OpenShift Container Platform cluster node:

- **Creating separate partitions:** For greenfield installations on an empty disk, you might want to add separate storage to a partition. This is officially supported for mounting `/var` or a subdirectory of `/var`, such as `/var/lib/etcd`, on a separate partition, but not both.

  IMPORTANT

  For disk sizes larger than 100GB, and especially disk sizes larger than 1TB, create a separate `/var` partition. See “Creating a separate `/var` partition” and this Red Hat Knowledgebase article for more information.

  IMPORTANT

  Kubernetes supports only two file system partitions. If you add more than one partition to the original configuration, Kubernetes cannot monitor all of them.

- **Retaining existing partitions:** For a brownfield installation where you are reinstalling OpenShift Container Platform on an existing node and want to retain data partitions installed from your previous operating system, there are both boot arguments and options to `coreos-installer` that allow you to retain existing data partitions.

  WARNING

  The use of custom partitions could result in those partitions not being monitored by OpenShift Container Platform or alerted on. If you are overriding the default partitioning, see Understanding OpenShift File System Monitoring (eviction conditions) for more information about how OpenShift Container Platform monitors your host file systems.

23.1.11.3.2.1. Creating a separate `/var` partition

In general, you should use the default disk partitioning that is created during the RHCOS installation. However, there are cases where you might want to create a separate partition for a directory that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the `/var` directory or a subdirectory of `/var`. For example:

- **/var/lib/containers:** Holds container-related content that can grow as more images and containers are added to a system.
- `/var/lib/etcd`: Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.

- `/var`: Holds data that you might want to keep separate for purposes such as auditing.

**IMPORTANT**

For disk sizes larger than 100GB, and especially larger than 1TB, create a separate `/var` partition.

Storing the contents of a `/var` directory separately makes it easier to grow storage for those areas as needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

The use of a separate partition for the `/var` directory or a subdirectory of `/var` also prevents data growth in the partitioned directory from filling up the root file system.

The following procedure sets up a separate `/var` partition by adding a machine config manifest that is wrapped into the Ignition config file for a node type during the preparation phase of an installation.

**Procedure**

1. On your installation host, change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

   ```bash
   $ openshift-install create manifests --dir <installation_directory>
   ```

2. Create a Butane config that configures the additional partition. For example, name the file `~/.clusterconfig/98-var-partition.bu`, change the disk device name to the name of the storage device on the worker systems, and set the storage size as appropriate. This example places the `/var` directory on a separate partition:

```
variant: openshift
version: 4.14.0
metadata:
  labels:
    machineconfiguration.openshift.io/role: worker
  name: 98-var-partition
storage:
disks:
  - device: /dev/disk/by-id/<device_name> ¹
    partitions:
      - label: var
        start_mib: <partition_start_offset> ²
        size_mib: <partition_size> ³
    filesystems:
      - device: /dev/disk/by-partlabel/var
        path: /var
        format: xfs
        mount_options: [defaults, prjquota] ⁴
        with_mount_unit: true
```

¹ The storage device name of the disk that you want to partition.
When adding a data partition to the boot disk, a minimum offset value of 25000 mebibytes is recommended. The root file system is automatically resized to fill all available space up to the size of the data partition in mebibytes.

The `prjquota` mount option must be enabled for filesystems used for container storage.

**NOTE**

When creating a separate `/var` partition, you cannot use different instance types for compute nodes, if the different instance types do not have the same device name.

3. Create a manifest from the Butane config and save it to the `clusterconfig/openshift` directory. For example, run the following command:

   ```bash
   $ butane $HOME/clusterconfig/98-var-partition.bu -o $HOME/clusterconfig/openshift/98-var-partition.yaml
   ``

4. Create the Ignition config files:

   ```bash
   $ openshift-install create ignition-configs --dir <installation_directory>
   ```

   **For `<installation_directory>`, specify the same installation directory.**

   Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory:

   ```mermaid
   flowchart LR
   auth
   | kubeadmin-password |
   | kubeconfig |
   | bootstrap.ign |
   | master.ign |
   | metadata.json |
   | worker.ign |
   ```

   The files in the `<installation_directory>/manifest` and `<installation_directory>/openshift` directories are wrapped into the Ignition config files, including the file that contains the `98-var-partition` custom `MachineConfig` object.

**Next steps**

- You can apply the custom disk partitioning by referencing the Ignition config files during the RHCOS installations.

**23.1.11.3.2.2. Retaining existing partitions**

For an ISO installation, you can add options to the `coreos-installer` command that cause the installer to maintain one or more existing partitions. For a PXE installation, you can add `coreos.inst.*` options to the `APPEND` parameter to preserve partitions.
Saved partitions might be data partitions from an existing OpenShift Container Platform system. You can identify the disk partitions you want to keep either by partition label or by number.

**NOTE**

If you save existing partitions, and those partitions do not leave enough space for RHCOS, the installation will fail without damaging the saved partitions.

**Retaining existing partitions during an ISO installation**

This example preserves any partition in which the partition label begins with `data` (`data*`):

```bash
# coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign \
   --save-partlabel 'data*' /dev/disk/by-id/scsi-<serial_number>
```

The following example illustrates running the `coreos-installer` in a way that preserves the sixth (6) partition on the disk:

```bash
# coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign \
   --save-partindex 6 /dev/disk/by-id/scsi-<serial_number>
```

This example preserves partitions 5 and higher:

```bash
# coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign \
   --save-partindex 5- /dev/disk/by-id/scsi-<serial_number>
```

In the previous examples where partition saving is used, `coreos-installer` recreates the partition immediately.

**Retaining existing partitions during a PXE installation**

This **APPEND** option preserves any partition in which the partition label begins with `data` (`'data*':`

```bash
coreos.inst.save_partlabel=data*
```

This **APPEND** option preserves partitions 5 and higher:

```bash
coreos.inst.save_partindex=5-
```

This **APPEND** option preserves partition 6:

```bash
coreos.inst.save_partindex=6
```

**23.1.11.3.3. Identifying Ignition configs**

When doing an RHCOS manual installation, there are two types of Ignition configs that you can provide, with different reasons for providing each one:

- **Permanent install Ignition config**: Every manual RHCOS installation needs to pass one of the Ignition config files generated by `openshift-installer`, such as `bootstrap.ign`, `master.ign` and `worker.ign`, to carry out the installation.
IMPORTANT

It is not recommended to modify these Ignition config files directly. You can update the manifest files that are wrapped into the Ignition config files, as outlined in examples in the preceding sections.

For PXE installations, you pass the Ignition configs on the APPEND line using the `coreos.inst.ignition_url` option. For ISO installations, after the ISO boots to the shell prompt, you identify the Ignition config on the `coreos-installer` command line with the `--ignition-url` option. In both cases, only HTTP and HTTPS protocols are supported.

- **Live install Ignition config**: This type can be created by using the `coreos-installer customize` subcommand and its various options. With this method, the Ignition config passes to the live install medium, runs immediately upon booting, and performs setup tasks before or after the RHCOS system installs to disk. This method should only be used for performing tasks that must be done once and not applied again later, such as with advanced partitioning that cannot be done using a machine config.
  
  For PXE or ISO boots, you can create the Ignition config and APPEND the `ignition.config.url` option to identify the location of the Ignition config. You also need to append `ignition.firstboot` `ignition.platform.id=metal` or the `ignition.config.url` option will be ignored.

23.1.11.3.4. Advanced RHCOS installation reference

This section illustrates the networking configuration and other advanced options that allow you to modify the Red Hat Enterprise Linux CoreOS (RHCOS) manual installation process. The following tables describe the kernel arguments and command-line options you can use with the RHCOS live installer and the `coreos-installer` command.

23.1.11.3.4.1. Networking and bonding options for ISO installations

If you install RHCOS from an ISO image, you can add kernel arguments manually when you boot the image to configure networking for a node. If no networking arguments are specified, DHCP is activated in the initramfs when RHCOS detects that networking is required to fetch the Ignition config file.

IMPORTANT

When adding networking arguments manually, you must also add the `rd.neednet=1` kernel argument to bring the network up in the initramfs.

The following information provides examples for configuring networking and bonding on your RHCOS nodes for ISO installations. The examples describe how to use the `ip=`, `nameserver=`, and `bond=` kernel arguments.

NOTE

Ordering is important when adding the kernel arguments: `ip=`, `nameserver=`, and then `bond=`.

The networking options are passed to the `dracut` tool during system boot. For more information about the networking options supported by `dracut`, see the `dracut.cmdline` manual page.

The following examples are the networking options for ISO installation.

Configuring DHCP or static IP addresses
To configure an IP address, either use DHCP (ip=dhcp) or set an individual static IP address (ip=<host_ip>). If setting a static IP, you must then identify the DNS server IP address (nameserver=<dns_ip>) on each node. The following example sets:

- The node's IP address to 10.10.10.2
- The gateway address to 10.10.10.254
- The netmask to 255.255.255.0
- The hostname to core0.example.com
- The DNS server address to 4.4.4.41
- The auto-configuration value to none. No auto-configuration is required when IP networking is configured statically.

```plaintext
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none
nameserver=4.4.4.41
```

**NOTE**

When you use DHCP to configure IP addressing for the RHCOS machines, the machines also obtain the DNS server information through DHCP. For DHCP-based deployments, you can define the DNS server address that is used by the RHCOS nodes through your DHCP server configuration.

Configuring an IP address without a static hostname

You can configure an IP address without assigning a static hostname. If a static hostname is not set by the user, it will be picked up and automatically set by a reverse DNS lookup. To configure an IP address without a static hostname refer to the following example:

- The node's IP address to 10.10.10.2
- The gateway address to 10.10.10.254
- The netmask to 255.255.255.0
- The DNS server address to 4.4.4.41
- The auto-configuration value to none. No auto-configuration is required when IP networking is configured statically.

```plaintext
ip=10.10.10.2::10.10.10.254:255.255.255.0:enp1s0:none
nameserver=4.4.4.41
```

Specifying multiple network interfaces

You can specify multiple network interfaces by setting multiple ip= entries.

```plaintext
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none
ip=10.10.10.3::10.10.10.254:255.255.255.0:core0.example.com:enp2s0:none
```

Configuring default gateway and route

Optional: You can configure routes to additional networks by setting an rd.route= value.
NOTE

When you configure one or multiple networks, one default gateway is required. If the additional network gateway is different from the primary network gateway, the default gateway must be the primary network gateway.

- Run the following command to configure the default gateway:
  
  \[
  \text{ip}=:10.10.10.254:::
  \]

- Enter the following command to configure the route for the additional network:
  
  \[
  \text{rd.route}=20.20.20.0/24:20.20.20.254:enp2s0
  \]

Disabling DHCP on a single interface
You can disable DHCP on a single interface, such as when there are two or more network interfaces and only one interface is being used. In the example, the \text{enp1s0} interface has a static networking configuration and DHCP is disabled for \text{enp2s0}, which is not used:

\[
\begin{align*}
\text{ip}=10.10.10.2::10.10.254:255.255.255.0:core0.example.com:enp1s0:none \\
\text{ip}=:::core0.example.com:enp2s0:none
\end{align*}
\]

Combining DHCP and static IP configurations
You can combine DHCP and static IP configurations on systems with multiple network interfaces, for example:

\[
\begin{align*}
\text{ip}=\text{enp1s0}:\text{dhcp} \\
\text{ip}=10.10.10.2::10.10.254:255.255.255.0:core0.example.com:enp2s0:none
\end{align*}
\]

Configuring VLANs on individual interfaces
Optional: You can configure VLANs on individual interfaces by using the \text{vlan=} parameter.

- To configure a VLAN on a network interface and use a static IP address, run the following command:
  
  \[
  \begin{align*}
  \text{ip}=10.10.10.2::10.10.254:255.255.255.0:core0.example.com:enp2s0.100:0none \\
  \text{vlan}=enp2s0.100:enp2s0
  \end{align*}
  \]

- To configure a VLAN on a network interface and to use DHCP, run the following command:
  
  \[
  \begin{align*}
  \text{ip}=enp2s0.100:dhcp \\
  \text{vlan}=enp2s0.100:enp2s0
  \end{align*}
  \]

Providing multiple DNS servers
You can provide multiple DNS servers by adding a \text{nameserver=} entry for each server, for example:

\[
\begin{align*}
\text{nameserver}=1.1.1.1 \\
\text{nameserver}=8.8.8.8
\end{align*}
\]

Bonding multiple network interfaces to a single interface
Optional: You can bond multiple network interfaces to a single interface by using the \text{bond=} option. Refer to the following examples:
The syntax for configuring a bonded interface is: \[ bond=<name>[:<network_interfaces>][:options] \]

- \(<name>\) is the bonding device name (bond0), \(<network_interfaces>\) represents a comma-separated list of physical (ethernet) interfaces (em1,em2), and \(options\) is a comma-separated list of bonding options. Enter `modinfo bonding` to see available options.

- When you create a bonded interface using `bond=`, you must specify how the IP address is assigned and other information for the bonded interface.
  - To configure the bonded interface to use DHCP, set the bond’s IP address to `dhcp`. For example:
    ```
    bond=bond0:em1,em2:mode=active-backup
    ip=bond0:dhcp
    ```
  - To configure the bonded interface to use a static IP address, enter the specific IP address you want and related information. For example:
    ```
    bond=bond0:em1,em2:mode=active-backup
    ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:bond0:none
    ```

Bonding multiple SR-IOV network interfaces to a dual port NIC interface

**IMPORTANT**

Support for Day 1 operations associated with enabling NIC partitioning for SR-IOV devices is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see [Technology Preview Features Support Scope](#).

Optional: You can bond multiple SR-IOV network interfaces to a dual port NIC interface by using the `bond=` option.

On each node, you must perform the following tasks:

1. Create the SR-IOV virtual functions (VFs) following the guidance in Managing SR-IOV devices. Follow the procedure in the "Attaching SR-IOV networking devices to virtual machines" section.

2. Create the bond, attach the desired VFs to the bond and set the bond link state up following the guidance in Configuring network bonding. Follow any of the described procedures to create the bond.

The following examples illustrate the syntax you must use:

- The syntax for configuring a bonded interface is `bond=<name>[:<network_interfaces>][:options]`.
  - `<name>` is the bonding device name (bond0), `<network_interfaces>` represents the virtual functions (VFs) by their known name in the kernel and shown in the output of the `ip link` command (eno1f0, eno2f0), and `options` is a comma-separated list of bonding options. Enter `modinfo bonding` to see available options.
• When you create a bonded interface using `bond=`, you must specify how the IP address is assigned and other information for the bonded interface.

  • To configure the bonded interface to use DHCP, set the bond’s IP address to `dhcp`. For example:

    ```
    bond=bond0:eno1f0,eno2f0:mode=active-backup
    ip=bond0:dhcp
    ```

  • To configure the bonded interface to use a static IP address, enter the specific IP address you want and related information. For example:

    ```
    bond=bond0:eno1f0,eno2f0:mode=active-backup
    ip=10.10.2::10.10.254:255.255.255.0:core0.example.com:bond0:none
    ```

Using network teaming

Optional: You can use a network teaming as an alternative to bonding by using the `team=` parameter:

• The syntax for configuring a team interface is: `team=name[:network_interfaces]`

  `name` is the team device name (team0) and `network_interfaces` represents a comma-separated list of physical (ethernet) interfaces (em1, em2).

NOTE

Teaming is planned to be deprecated when RHCOS switches to an upcoming version of RHEL. For more information, see this Red Hat Knowledgebase Article.

Use the following example to configure a network team:

```
team=team0:em1,em2
ip=team0:dhcp
```

</tr>
<tr>
<td>--dest-karg-append &lt;arg&gt;</td>
<td>Add a kernel argument to each boot of the destination system.</td>
</tr>
<tr>
<td>--dest-karg-delete &lt;arg&gt;</td>
<td>Delete a kernel argument from each boot of the destination system.</td>
</tr>
<tr>
<td>--network-keyfile &lt;path&gt;</td>
<td>Configure networking by using the specified NetworkManager keyfile for live and destination systems.</td>
</tr>
</tbody>
</table>
---

**--ignition-ca <path>**
Specify an additional TLS certificate authority to be trusted by Ignition.

**--pre-install <path>**
Run the specified script before installation.

**--post-install <path>**
Run the specified script after installation.

**--installer-config <path>**
Apply the specified installer configuration file.

**--live-ignition <path>**
Merge the specified Ignition config file into a new configuration fragment for the live environment.

**--live-karg-append <arg>**
Add a kernel argument to each boot of the live environment.

**--live-karg-delete <arg>**
Delete a kernel argument from each boot of the live environment.

**--live-karg-replace <k=o=n>**
Replace a kernel argument in each boot of the live environment, in the form `key=old=new`.

**-f, --force**
Overwrite an existing Ignition config.

**-o, --output <path>**
Write the ISO to a new output file.

**-h, --help**
Print help information.

---

**coreos-installer PXE subcommands**

<table>
<thead>
<tr>
<th>Subcommand</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>coreos-installer pxe customize &lt;options&gt; &lt;path&gt;</td>
<td>Customize a RHCOS live PXE boot config.</td>
</tr>
<tr>
<td>coreos-installer pxe ignition wrap &lt;options&gt;</td>
<td>Wrap an Ignition config in an image.</td>
</tr>
<tr>
<td>coreos-installer pxe ignition unwrap &lt;options&gt; &lt;image_name&gt;</td>
<td>Show the wrapped Ignition config in an image.</td>
</tr>

</table>

---

**coreos-installer PXE customize subcommand options**

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Note that not all of these options are accepted by all subcommands.

---
## coreos.inst boot options for ISO or PXE installations

You can automatically invoke `coreos-installer` options at boot time by passing `coreos.inst` boot arguments to the RHCOS live installer. These are provided in addition to the standard boot arguments.

- For ISO installations, the `coreos.inst` options can be added by interrupting the automatic boot at the bootloader menu. You can interrupt the automatic boot by pressing **TAB** while the **RHEL CoreOS (Live)** menu option is highlighted.

- For PXE or iPXE installations, the `coreos.inst` options must be added to the **APPEND** line before the RHCOS live installer is booted.

The following table shows the RHCOS live installer `coreos.inst` boot options for ISO and PXE installations.

### Table 23.10. coreos.inst boot options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--dest-ignition &lt;path&gt;</code></td>
<td>Merge the specified Ignition config file into a new configuration fragment for the destination system.</td>
</tr>
<tr>
<td><code>--dest-console &lt;spec&gt;</code></td>
<td>Specify the kernel and bootloader console for the destination system.</td>
</tr>
<tr>
<td><code>--dest-device &lt;path&gt;</code></td>
<td>Install and overwrite the specified destination device.</td>
</tr>
<tr>
<td><code>--network-keyfile &lt;path&gt;</code></td>
<td>Configure networking by using the specified NetworkManager keyfile for live and destination systems.</td>
</tr>
<tr>
<td><code>--ignition-ca &lt;path&gt;</code></td>
<td>Specify an additional TLS certificate authority to be trusted by Ignition.</td>
</tr>
<tr>
<td><code>--pre-install &lt;path&gt;</code></td>
<td>Run the specified script before installation.</td>
</tr>
<tr>

<td>Write the initramfs to a new output file.</td>
</tr>
<tr>
<td><code>-h, --help</code></td>
<td>Print help information.</td>
</tr>
</tbody>
</table>

**NOTE**

This option is required for PXE environments.
<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>coreos.inst.install_dev</td>
<td>Required. The block device on the system to install to. It is recommended to use the full path, such as /dev/sda, although sda is allowed.</td>
</tr>
<tr>
<td>coreos.inst.ignition_url</td>
<td>Optional: The URL of the Ignition config to embed into the installed system. If no URL is specified, no Ignition config is embedded. Only HTTP and HTTPS protocols are supported.</td>
</tr>
<tr>
<td>coreos.inst.save_partlabel</td>
<td>Optional: Comma-separated labels of partitions to preserve during the install. Glob-style wildcards are permitted. The specified partitions do not need to exist.</td>
</tr>
<tr>
<td>coreos.inst.save_partindex</td>
<td>Optional: Comma-separated indexes of partitions to preserve during the install. Ranges m-n are permitted, and either m or n can be omitted. The specified partitions do not need to exist.</td>
</tr>
<tr>
<td>coreos.inst.insecure</td>
<td>Optional: Permits the OS image that is specified by coreos.inst.image_url to be unsigned.</td>
</tr>
<tr>
<td>coreos.inst.image_url</td>
<td>Optional: Download and install the specified RHCOS image.</td>
</tr>
<tr>
<td></td>
<td>• This argument should not be used in production environments and is intended for debugging purposes only.</td>
</tr>
<tr>
<td></td>
<td>• While this argument can be used to install a version of RHCOS that does not match the live media, it is recommended that you instead use the media that matches the version you want to install.</td>
</tr>
<tr>
<td></td>
<td>• If you are using coreos.inst.image_url, you must also use coreos.inst.insecure. This is because the bare-metal media are not GPG-signed for OpenShift Container Platform.</td>
</tr>
<tr>
<td></td>
<td>• Only HTTP and HTTPS protocols are supported.</td>
</tr>
<tr>
<td>coreos.inst.skip_reboot</td>
<td>Optional: The system will not reboot after installing. After the install finishes, you will receive a prompt that allows you to inspect what is happening during installation. This argument should not be used in production environments and is intended for debugging purposes only.</td>
</tr>
</tbody>
</table>
### Argument Description

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>coreos.inst.platform_id</td>
<td>Optional: The Ignition platform ID of the platform the RHCOS image is being installed on. Default is metal. This option determines whether or not to request an Ignition config from the cloud provider, such as VMware. For example: <code>coreos.inst.platform_id=vmware</code>.</td>
</tr>
<tr>
<td>ignition.config.url</td>
<td>Optional: The URL of the Ignition config for the live boot. For example, this can be used to customize how <code>coreos-installer</code> is invoked, or to run code before or after the installation. This is different from <code>coreos.inst.ignition_url</code>, which is the Ignition config for the installed system.</td>
</tr>
</tbody>
</table>

#### 23.11.4. Updating the bootloader using bootupd

To update the bootloader by using bootupd, you must either install bootupd on RHCOS machines manually or provide a machine config with the enabled systemd unit. Unlike grubby or other bootloader tools, bootupd does not manage kernel space configuration such as passing kernel arguments.

After you have installed bootupd, you can manage it remotely from the OpenShift Container Platform cluster.

**NOTE**

It is recommended that you use bootupd only on bare metal or virtualized hypervisor installations, such as for protection against the BootHole vulnerability.

##### Manual install method

You can manually install bootupd by using the bootctl command-line tool.

1. Inspect the system status:

   ```bash
   # bootupctl status
   ```

   **Example output for x86_64**

   ```
   Component EFI
   Installed: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
   Update: At latest version
   ```

   **Example output for aarch64**

   ```
   Component EFI
   Installed: grub2-efi-aa64-1:2.02-99.el8_4.1.aarch64,shim-aa64-15-4-2.el8_1.aarch64
   Update: At latest version
   ```

2. RHCOS images created without bootupd installed on them require an explicit adoption phase.
If the system status is **Adoptable**, perform the adoption:

```
# bootupctl adopt-and-update
```

**Example output**

```
Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
```

3. If an update is available, apply the update so that the changes take effect on the next reboot:

```
# bootupctl update
```

**Example output**

```
Updated: grub2-efi-x64-1:2.04-31.fc33.x86_64,shim-x64-15-8.x86_64
```

**Machine config method**

Another way to enable **bootupd** is by providing a machine config.

- Provide a machine config file with the enabled **systemd** unit, as shown in the following example:

**Example output**

```
variant: rhcos
version: 1.1.0
systemd:
  units:
    - name: custom-bootupd-auto.service
      enabled: true
      contents:
        [Unit]
        Description=Bootupd automatic update

        [Service]
        ExecStart=/usr/bin/bootupctl update
        RemainAfterExit=yes

        [Install]
        WantedBy=multi-user.target
```

### 23.1.12. Waiting for the bootstrap process to complete

The OpenShift Container Platform bootstrap process begins after the cluster nodes first boot into the persistent RHCOS environment that has been installed to disk. The configuration information provided through the Ignition config files is used to initialize the bootstrap process and install OpenShift Container Platform on the machines. You must wait for the bootstrap process to complete.

**Prerequisites**

- You have created the Ignition config files for your cluster.
- You have configured suitable network, DNS and load balancing infrastructure.
You have obtained the installation program and generated the Ignition config files for your cluster.

You installed RHCOS on your cluster machines and provided the Ignition config files that the OpenShift Container Platform installation program generated.

Your machines have direct internet access or have an HTTP or HTTPS proxy available.

**Procedure**

1. Monitor the bootstrap process:

   ```bash
   $ ./openshift-install --dir <installation_directory> wait-for bootstrap-complete \  
   --log-level=info
   ``

   1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

   **Example output**

   ```plaintext
   INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...  
   INFO API v1.27.3 up  
   INFO Waiting up to 30m0s for bootstrapping to complete...  
   INFO It is now safe to remove the bootstrap resources
   
   The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.
   
   2. After the bootstrap process is complete, remove the bootstrap machine from the load balancer.

   **IMPORTANT**

   You must remove the bootstrap machine from the load balancer at this point. You can also remove or reformat the bootstrap machine itself.

23.1.13. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:
For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

```
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig
```

```
$ oc whoami

Example output

system:admin
```

23.14. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

Prerequisites

- You added machines to your cluster.

Procedure

1. Confirm that the cluster recognizes the machines:

```
$ oc get nodes

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>64m</td>
<td>v1.27.3</td>
</tr>
</tbody>
</table>
```

The output lists all of the machines that you created.

NOTE

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the Pending or Approved status for each machine that you added to the cluster:

```
$ oc get csr

Example output
```
In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

**NOTE**

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

**NOTE**

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrapper** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

  ```
  $ oc adm certificate approve <csr_name> ①
  ```

  ① `<csr_name>` is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

  ```
  $ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs --no-run-if-empty oc adm certificate approve
  ```

**NOTE**

Some Operators might not become available until some CSRs are approved.
4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-c57lv</td>
<td>5m26s</td>
<td>system:node:ip-10-0-95-157.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
</tbody>
</table>

...  

5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name> 1
```

1. `<csr_name>` is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}} | xargs oc adm certificate approve
```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>worker-0</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>worker-1</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.27.3</td>
</tr>
</tbody>
</table>

**NOTE**

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

**Additional information**

- For more information on CSRs, see [Certificate Signing Requests](#).
23.1.15. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

Prerequisites

- Your control plane has initialized.

Procedure

1. Watch the cluster components come online:

   $ watch -n5 oc get clusteroperators

Example output

<table>
<thead>
<tr>
<th>NAME</th>

2. Configure the Operators that are not available.

23.1.15.1. Disabling the default OperatorHub catalog sources
Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

Procedure

- Disable the sources for the default catalogs by adding `disableAllDefaultSources: true` to the `OperatorHub` object:

  ```bash
  $ oc patch OperatorHub cluster --type json \
  -p '[["op": "add", "path": "/spec/disableAllDefaultSources", "value": true]]'
  ```

TIP

Alternatively, you can use the web console to manage catalog sources. From the Administration → Cluster Settings → Configuration → OperatorHub page, click the Sources tab, where you can create, update, delete, disable, and enable individual sources.

23.1.15.2. Image registry removed during installation

On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as Removed. This allows `openshift-installer` to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the `managementState` from Removed to Managed.

23.1.15.3. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the `Recreate` rollout strategy during upgrades.

23.1.15.3.1. Configuring registry storage for bare metal and other manual installations

As a cluster administrator, following installation you must configure your registry to use storage.

Prerequisites

- You have access to the cluster as a user with the `cluster-admin` role.
- You have a cluster that uses manually-provisioned Red Hat Enterprise Linux CoreOS (RHCOS) nodes, such as bare metal.
- You have provisioned persistent storage for your cluster, such as Red Hat OpenShift Data Foundation.
IMPORTANT

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. **ReadWriteOnce** access also requires that the registry uses the **Recreate** rollout strategy. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have 100Gi capacity.

Procedure

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.

   **NOTE**

   When you use shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

   ```
   $ oc get pod -n openshift-image-registry -l docker-registry=default
   
   Example output
   
   No resources found in openshift-image-registry namespace
   
   **NOTE**

   If you do have a registry pod in your output, you do not need to continue with this procedure.

3. Check the registry configuration:

   ```
   $ oc edit configs.imageregistry.operator.openshift.io
   
   Example output
   
   storage:
   pvc:
   claim:
   
   Leave the `claim` field blank to allow the automatic creation of an `image-registry-storage` PVC.

4. Check the `clusteroperator` status:

   ```
   $ oc get clusteroperator image-registry
   
   Example output
5. Ensure that your registry is set to managed to enable building and pushing of images.

- Run:

  $ oc edit configs.imageregistry/cluster

Then, change the line

  managementState: Removed

to

  managementState: Managed

### 23.1.15.3.2. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

**Procedure**

- To set the image registry storage to an empty directory:

  $ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec": {"storage": {"emptyDir":{}}}}'

**WARNING**

Configure this option for only non-production clusters.

If you run this command before the Image Registry Operator initializes its components, the **oc patch** command fails with the following error:

- Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found

Wait a few minutes and run the command again.

### 23.1.15.3.3. Configuring block registry storage

To allow the image registry to use block storage types during upgrades as a cluster administrator, you can use the **Recreate** rollout strategy.
IMPORTANT

Block storage volumes, or block persistent volumes, are supported but not recommended for use with the image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

If you choose to use a block storage volume with the image registry, you must use a filesystem persistent volume claim (PVC).

Procedure

1. To set the image registry storage as a block storage type, patch the registry so that it uses the Recreate rollout strategy and runs with only one (1) replica:

   ```
   $ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{}"spec":
   {"rolloutStrategy":"Recreate","replicas":1}]'
   ```

2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.

3. Edit the registry configuration so that it references the correct PVC.

23.1.16. Completing installation on user-provisioned infrastructure

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

Prerequisites

- Your control plane has initialized.
- You have completed the initial Operator configuration.

Procedure

1. Confirm that all the cluster components are online with the following command:

   ```
   $ watch -n5 oc get clusteroperators
   ```

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
<th>SINCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>authentication</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>19m</td>
</tr>
<tr>
<td>baremetal</td>
<td>4.14.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>37m</td>

<td>False</td>
<td>False</td>
<td>31m</td>
</tr>
</tbody>
</table>
Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```
$ ./openshift-install --dir <installation_directory> wait-for install-complete
```

1 For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

Example output

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.
2. Confirm that the Kubernetes API server is communicating with the pods.

   a. To view a list of all pods, use the following command:

   ```bash
   $ oc get pods --all-namespaces
   
   Example output
   
<table>
<thead>
<tr>
<th>NAMESPACE</th>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>

<td>authentication-operator-69d5d8bf84-vh2n8</td>
<td>1/1</td>
<td>Running</td>
</tr>
<tr>
<td></td>
<td>Running 0 5m</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
   ...                                      |                                                        |       |        |
   
   b. View the logs for a pod that is listed in the output of the previous command by using the following command:

   ```bash
   $ oc logs <pod_name> -n <namespace>
   
   Specify the pod name and namespace, as shown in the output of the previous command.
   
   If the pod logs display, the Kubernetes API server can communicate with the cluster machines.

3. For an installation with Fibre Channel Protocol (FCP), additional steps are required to enable multipathing. Do not enable multipathing during installation.

   See "Enabling multipathing with kernel arguments on RHCOS" in the Post-installation machine configuration tasks documentation for more information.

23.1.17. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager Hybrid Cloud Console.

After you confirm that your OpenShift Cluster Manager Hybrid Cloud Console inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service
23.1.18. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- Set up your registry and configure registry storage.
CHAPTER 24. INSTALLATION CONFIGURATION

24.1. CUSTOMIZING NODES

OpenShift Container Platform supports both cluster-wide and per-machine configuration via Ignition, which allows arbitrary partitioning and file content changes to the operating system. In general, if a configuration file is documented in Red Hat Enterprise Linux (RHEL), then modifying it via Ignition is supported.

There are two ways to deploy machine config changes:

- Creating machine configs that are included in manifest files to start up a cluster during `openshift-install`.
- Creating machine configs that are passed to running OpenShift Container Platform nodes via the Machine Config Operator.

Additionally, modifying the reference config, such as the Ignition config that is passed to `coreos-installer` when installing bare-metal nodes allows per-machine configuration. These changes are currently not visible to the Machine Config Operator.

The following sections describe features that you might want to configure on your nodes in this way.

24.1.1. Creating machine configs with Butane

Machine configs are used to configure control plane and worker machines by instructing machines how to create users and file systems, set up the network, install systemd units, and more.

Because modifying machine configs can be difficult, you can use Butane configs to create machine configs for you, thereby making node configuration much easier.

24.1.1.1. About Butane

Butane is a command-line utility that OpenShift Container Platform uses to provide convenient, shorthand syntax for writing machine configs, as well as for performing additional validation of machine configs. The format of the Butane config file that Butane accepts is defined in the OpenShift Butane config spec.

24.1.1.2. Installing Butane

You can install the Butane tool (`butane`) to create OpenShift Container Platform machine configs from a command-line interface. You can install `butane` on Linux, Windows, or macOS by downloading the corresponding binary file.

TIP

Butane releases are backwards-compatible with older releases and with the Fedora CoreOS Config Transpiler (FCCT).

Procedure

2. Get the **butane** binary:
   a. For the newest version of Butane, save the latest **butane** image to your current directory:
      ```bash
      $ curl https://mirror.openshift.com/pub/openshift-v4/clients/butane/latest/butane --output butane
      $$ curl https://mirror.openshift.com/pub/openshift-v4/clients/butane/latest/butane-aarch64 --output butane
      $ chmod +x butane
      ```
   b. Optional: For a specific type of architecture you are installing Butane on, such as aarch64 or ppc64le, indicate the appropriate URL. For example:
      ```bash
      $ curl https://mirror.openshift.com/pub/openshift-v4/clients/butane/latest/butane-aarch64 --output butane
      ```

3. Make the downloaded binary file executable:
   ```bash
   $ chmod +x butane
   ```

4. Move the **butane** binary file to a directory on your **PATH**.
   To check your **PATH**, open a terminal and execute the following command:
   ```bash
   $ echo $PATH
   ```

**Verification steps**
- You can now use the Butane tool by running the **butane** command:
  ```bash
  $ butane <butane_file>
  ```

### 24.1.1.3. Creating a MachineConfig object by using Butane

You can use Butane to produce a **MachineConfig** object so that you can configure worker or control plane nodes at installation time or via the Machine Config Operator.

**Prerequisites**
- You have installed the **butane** utility.

**Procedure**

1. Create a Butane config file. The following example creates a file named **99-worker-custom.bu** that configures the system console to show kernel debug messages and specifies custom settings for the chrony time service:
   ```yaml
   variant: openshift
   version: 4.14.0
   metadata:
     name: 99-worker-custom
     labels:
       machineconfiguration.openshift.io/role: worker
   openshift:
     kernel_arguments:
       - loglevel=7
   storage:
   ```
NOTE

The 99-worker-custom.bu file is set to create a machine config for worker nodes. To deploy on control plane nodes, change the role from worker to master. To do both, you could repeat the whole procedure using different file names for the two types of deployments.

2. Create a MachineConfig object by giving Butane the file that you created in the previous step:

```bash
$ butane 99-worker-custom.bu -o ./99-worker-custom.yaml
```

A MachineConfig object YAML file is created for you to finish configuring your machines.

3. Save the Butane config in case you need to update the MachineConfig object in the future.

4. If the cluster is not running yet, generate manifest files and add the MachineConfig object YAML file to the openshift directory. If the cluster is already running, apply the file as follows:

```bash
$ oc create -f 99-worker-custom.yaml
```

**Additional resources**

- Adding kernel modules to nodes
- Encrypting and mirroring disks during installation

**24.1.2. Adding day-1 kernel arguments**

Although it is often preferable to modify kernel arguments as a day-2 activity, you might want to add kernel arguments to all master or worker nodes during initial cluster installation. Here are some reasons you might want to add kernel arguments during cluster installation so they take effect before the systems first boot up:

- You want to disable a feature, such as SELinux, so it has no impact on the systems when they first come up.
WARNING
Disabling SELinux on RHCOS is not supported.

- You need to do some low-level network configuration before the systems start.

To add kernel arguments to master or worker nodes, you can create a `MachineConfig` object and inject that object into the set of manifest files used by Ignition during cluster setup.

For a listing of arguments you can pass to a RHEL 8 kernel at boot time, see Kernel.org kernel parameters. It is best to only add kernel arguments with this procedure if they are needed to complete the initial OpenShift Container Platform installation.

**Procedure**

1. Change to the directory that contains the installation program and generate the Kubernetes manifests for the cluster:

   ```
   $ ./openshift-install create manifests --dir <installation_directory>
   ```

2. Decide if you want to add kernel arguments to worker or control plane nodes.

3. In the `openshift` directory, create a file (for example, `99-openshift-machineconfig-master-kargs.yaml`) to define a `MachineConfig` object to add the kernel settings. This example adds a `loglevel=7` kernel argument to control plane nodes:

   ```
   $ cat << EOF > 99-openshift-machineconfig-master-kargs.yaml
   apiVersion: machineconfiguration.openshift.io/v1
   kind: MachineConfig
   metadata:
     labels:
       machineconfiguration.openshift.io/role: master
   name: 99-openshift-machineconfig-master-kargs
   spec:
     kernelArguments:
     - loglevel=7
   EOF
   
   You can change `master` to `worker` to add kernel arguments to worker nodes instead. Create a separate YAML file to add to both master and worker nodes.

   You can now continue on to create the cluster.

**24.1.3. Adding kernel modules to nodes**

For most common hardware, the Linux kernel includes the device driver modules needed to use that hardware when the computer starts up. For some hardware, however, modules are not available in Linux. Therefore, you must find a way to provide those modules to each host computer. This procedure describes how to do that for nodes in an OpenShift Container Platform cluster.
When a kernel module is first deployed by following these instructions, the module is made available for the current kernel. If a new kernel is installed, the kmods-via-containers software will rebuild and deploy the module so a compatible version of that module is available with the new kernel.

The way that this feature is able to keep the module up to date on each node is by:

- Adding a systemd service to each node that starts at boot time to detect if a new kernel has been installed and
- If a new kernel is detected, the service rebuilds the module and installs it to the kernel

For information on the software needed for this procedure, see the kmods-via-containers github site.

A few important issues to keep in mind:

- This procedure is Technology Preview.
- Software tools and examples are not yet available in official RPM form and can only be obtained for now from unofficial github.com sites noted in the procedure.
- Third-party kernel modules you might add through these procedures are not supported by Red Hat.
- In this procedure, the software needed to build your kernel modules is deployed in a RHEL 8 container. Keep in mind that modules are rebuilt automatically on each node when that node gets a new kernel. For that reason, each node needs access to a yum repository that contains the kernel and related packages needed to rebuild the module. That content is best provided with a valid RHEL subscription.

24.1.3.1. Building and testing the kernel module container

Before deploying kernel modules to your OpenShift Container Platform cluster, you can test the process on a separate RHEL system. Gather the kernel module’s source code, the KVC framework, and the kmod-via-containers software. Then build and test the module. To do that on a RHEL 8 system, do the following:

Procedure

1. Register a RHEL 8 system:
   
   ```
   # subscription-manager register
   ```

2. Attach a subscription to the RHEL 8 system:
   
   ```
   # subscription-manager attach --auto
   ```

3. Install software that is required to build the software and container:
   
   ```
   # yum install podman make git -y
   ```

4. Clone the kmod-via-containers repository:
   
   a. Create a folder for the repository:
      
      ```
      $ mkdir kmods; cd kmods
      ```
b. Clone the repository:

   $ git clone https://github.com/kmods-via-containers/kmods-via-containers

5. Install a KVC framework instance on your RHEL 8 build host to test the module. This adds a kmods-via-container systemd service and loads it:

   a. Change to the kmod-via-containers directory:

       $ cd kmods-via-containers/

   b. Install the KVC framework instance:

       $ sudo make install

   c. Reload the systemd manager configuration:

       $ sudo systemctl daemon-reload

6. Get the kernel module source code. The source code might be used to build a third-party module that you do not have control over, but is supplied by others. You will need content similar to the content shown in the kvc-simple-kmod example that can be cloned to your system as follows:

   $ cd .. ; git clone https://github.com/kmods-via-containers/kvc-simple-kmod

7. Edit the configuration file, simple-kmod.conf file, in this example, and change the name of the Dockerfile to Dockerfile.rhel:

   a. Change to the kvc-simple-kmod directory:

       $ cd kvc-simple-kmod

   b. Rename the Dockerfile:

       $ cat simple-kmod.conf

   Example Dockerfile

       KMOD_CONTAINER_BUILD_CONTEXT="https://github.com/kmods-via-containers/kvc-simple-kmod.git"
       KMOD_CONTAINER_BUILD_FILE=Dockerfile.rhel
       KMOD_SOFTWARE_VERSION=dd1a7d4
       KMOD_NAMES="simple-kmod simple-procfs-kmod"

8. Create an instance of kmods-via-containers@.service for your kernel module, simple-kmod in this example:

       $ sudo make install

9. Enable the kmods-via-containers@.service instance:
10. Enable and start the systemd service:

$ sudo systemctl enable kmods-via-containers@simple-kmod.service --now

a. Review the service status:

$ sudo systemctl status kmods-via-containers@simple-kmod.service

Example output

* kmods-via-containers@simple-kmod.service - Kmods Via Containers - simple-kmod
Loaded: loaded (/etc/systemd/system/kmods-via-containers@.service; enabled; vendor preset: disabled)
Active: active (exited) since Sun 2020-01-12 23:49:49 EST; 5s ago...

11. To confirm that the kernel modules are loaded, use the `lsmod` command to list the modules:

$ lsmod | grep simple_

Example output

* simple_procfs_kmod     16384  0
* simple_kmod            16384  0

12. Optional. Use other methods to check that the `simple-kmod` example is working:

- Look for a "Hello world" message in the kernel ring buffer with `dmesg`:

  $ dmesg | grep 'Hello world'

  Example output

  [ 6420.761332] Hello world from simple_kmod.

- Check the value of `simple-procsfs-kmod` in `/proc`:

  $ sudo cat /proc/simple-procsfs-kmod

  Example output

  simple-procsfs-kmod number = 0

- Run the `spkut` command to get more information from the module:

  $ sudo spkut 44

  Example output

  OpenShift Container Platform 4.14 Installing
Going forward, when the system boots this service will check if a new kernel is running. If there is a new kernel, the service builds a new version of the kernel module and then loads it. If the module is already built, it will just load it.

24.1.3.2. Provisioning a kernel module to OpenShift Container Platform

Depending on whether or not you must have the kernel module in place when OpenShift Container Platform cluster first boots, you can set up the kernel modules to be deployed in one of two ways:

- **Provision kernel modules at cluster install time (day-1)** You can create the content as a MachineConfig object and provide it to openshift-install by including it with a set of manifest files.

- **Provision kernel modules via Machine Config Operator (day-2)** If you can wait until the cluster is up and running to add your kernel module, you can deploy the kernel module software via the Machine Config Operator (MCO).

In either case, each node needs to be able to get the kernel packages and related software packages at the time that a new kernel is detected. There are a few ways you can set up each node to be able to obtain that content.

- Provide RHEL entitlements to each node.

- Get RHEL entitlements from an existing RHEL host, from the /etc/pki/entitlement directory and copy them to the same location as the other files you provide when you build your Ignition config.

- Inside the Dockerfile, add pointers to a yum repository containing the kernel and other packages. This must include new kernel packages as they are needed to match newly installed kernels.

24.1.3.2.1. Provision kernel modules via a MachineConfig object

By packaging kernel module software with a MachineConfig object, you can deliver that software to worker or control plane nodes at installation time or via the Machine Config Operator.

**Procedure**

1. Register a RHEL 8 system:

   ```bash
   # subscription-manager register
   ```

2. Attach a subscription to the RHEL 8 system:

   ```bash
   # subscription-manager attach --auto
   ```

3. Install software needed to build the software:

   ```bash
   ```
4. Create a directory to host the kernel module and tooling:

```bash
$ mkdir kmods; cd kmods
```

5. Get the `kmods-via-containers` software:

   a. Clone the `kmods-via-containers` repository:

   ```bash
   $ git clone https://github.com/kmods-via-containers/kmods-via-containers
   ```

   b. Clone the `kvc-simple-kmod` repository:

   ```bash
   $ git clone https://github.com/kmods-via-containers/kvc-simple-kmod
   ```

6. Get your module software. In this example, `kvc-simple-kmod` is used.

7. Create a fakeroot directory and populate it with files that you want to deliver via Ignition, using the repositories cloned earlier:

   a. Create the directory:

   ```bash
   $ FAKEROOT=$(mktemp -d)
   ```

   b. Change to the `kmod-via-containers` directory:

   ```bash
   $ cd kmods-via-containers
   ```

   c. Install the KVC framework instance:

   ```bash
   $ make install DESTDIR=${FAKEROOT}/usr/local CONFDIR=${FAKEROOT}/etc/
   ```

   d. Change to the `kvc-simple-kmod` directory:

   ```bash
   $ cd ../kvc-simple-kmod
   ```

   e. Create the instance:

   ```bash
   $ make install DESTDIR=${FAKEROOT}/usr/local CONFDIR=${FAKEROOT}/etc/
   ```

8. Clone the fakeroot directory, replacing any symbolic links with copies of their targets, by running the following command:

```bash
$ cd ..&& rm -rf kmod-tree && cp -Lpr ${FAKEROOT} kmod-tree
```

9. Create a Butane config file, `99-simple-kmod.bu`, that embeds the kernel module tree and enables the systemd service.

**NOTE**

See "Creating machine configs with Butane" for information about Butane.
To deploy on control plane nodes, change `worker` to `master`. To deploy on both control plane and worker nodes, perform the remainder of these instructions once for each node type.

10. Use Butane to generate a machine config YAML file, `99-simple-kmod.yaml`, containing the files and configuration to be delivered:

   ```bash
   $ butane 99-simple-kmod.bu --files-dir . -o 99-simple-kmod.yaml
   ``

11. If the cluster is not up yet, generate manifest files and add this file to the `openshift` directory. If the cluster is already running, apply the file as follows:

   ```bash
   $ oc create -f 99-simple-kmod.yaml
   
   Your nodes will start the `kmods-via-containers@simple-kmod.service` service and the kernel modules will be loaded.

12. To confirm that the kernel modules are loaded, you can log in to a node (using `oc debug node/<openshift-node>`, then `chroot /host`). To list the modules, use the `lsmod` command:

   ```bash
   $ lsmod | grep simple_
   
   Example output
   
   simple_procfs_kmod     16384  0
   simple_kmod            16384  0
   
   24.1.4. Encrypting and mirroring disks during installation

   During an OpenShift Container Platform installation, you can enable boot disk encryption and mirroring on the cluster nodes.

   24.1.4.1. About disk encryption

   You can enable encryption for the boot disks on the control plane and compute nodes at installation time. OpenShift Container Platform supports the Trusted Platform Module (TPM) v2 and Tang encryption modes.
TPM v2

This is the preferred mode. TPM v2 stores passphrases in a secure cryptoprocessor on the server. You can use this mode to prevent decryption of the boot disk data on a cluster node if the disk is removed from the server.

Tang

Tang and Clevis are server and client components that enable network-bound disk encryption (NBDE). You can bind the boot disk data on your cluster nodes to one or more Tang servers. This prevents decryption of the data unless the nodes are on a secure network where the Tang servers are accessible. Clevis is an automated decryption framework used to implement decryption on the client side.

IMPORTANT

The use of the Tang encryption mode to encrypt your disks is only supported for bare metal and vSphere installations on user-provisioned infrastructure.

In earlier versions of Red Hat Enterprise Linux CoreOS (RHCOS), disk encryption was configured by specifying /etc/clevis.json in the Ignition config. That file is not supported in clusters created with OpenShift Container Platform 4.7 or later. Configure disk encryption by using the following procedure.

When the TPM v2 or Tang encryption modes are enabled, the RHCOS boot disks are encrypted using the LUKS2 format.

This feature:

- Is available for installer-provisioned infrastructure, user-provisioned infrastructure, and Assisted Installer deployments
- For Assisted installer deployments:
  - Each cluster can only have a single encryption method, Tang or TPM
  - Encryption can be enabled on some or all nodes
  - There is no Tang threshold; all servers must be valid and operational
  - Encryption applies to the installation disks only, not to the workload disks
- Is supported on Red Hat Enterprise Linux CoreOS (RHCOS) systems only
- Sets up disk encryption during the manifest installation phase, encrypting all data written to disk, from first boot forward
- Requires no user intervention for providing passphrases
- Uses AES-256-XTS encryption, or AES-256-CBC if FIPS mode is enabled

24.1.4.1.1. Configuring an encryption threshold

In OpenShift Container Platform, you can specify a requirement for more than one Tang server. You can also configure the TPM v2 and Tang encryption modes simultaneously. This enables boot disk data decryption only if the TPM secure cryptoprocessor is present and the Tang servers are accessible over a secure network.
You can use the **threshold** attribute in your Butane configuration to define the minimum number of TPM v2 and Tang encryption conditions required for decryption to occur.

The threshold is met when the stated value is reached through any combination of the declared conditions. In the case of offline provisioning, the offline server is accessed using an included advertisement, and only uses that supplied advertisement if the number of online servers do not meet the set threshold.

For example, the **threshold** value of **2** in the following configuration can be reached by accessing two Tang servers, with the offline server available as a backup, or by accessing the TPM secure cryptoprocessor and one of the Tang servers:

**Example Butane configuration for disk encryption**

```yaml
variant: openshift
version: 4.14.0
metadata:
  name: worker-storage
  labels:
    machineconfiguration.openshift.io/role: worker
boot_device:
  layout: x86_64
  luks:
    tpm2: true
    tang:
      - url: http://tang1.example.com:7500
        thumbprint: jwGN5tRFK-kF6piX89ssF3khXX
      - url: http://tang2.example.com:7500
        thumbprint: VCJsvZfjB5hSldw78rOrq7h2ZF
      - url: http://tang3.example.com:7500
        thumbprint: PLjNyRdGw03ziRoGjQYMahSZGu9
  advertisement: "{"payload": ","", "protected": ","", "signature": ",""
threshold: 2
openshift:
  fips: true
```

1. Set this field to the instruction set architecture of the cluster nodes. Some examples include, **x86_64**, **aarch64**, or **ppc64le**.
2. Include this field if you want to use a Trusted Platform Module (TPM) to encrypt the root file system.
3. Include this section if you want to use one or more Tang servers.
4. Optional: Include this field for offline provisioning. Ignition will provision the Tang server binding rather than fetching the advertisement from the server at runtime. This lets the server be unavailable at provisioning time.
5. Specify the minimum number of TPM v2 and Tang encryption conditions required for decryption to occur.
IMPORTANT

The default threshold value is 1. If you include multiple encryption conditions in your configuration but do not specify a threshold, decryption can occur if any of the conditions are met.

NOTE

If you require TPM v2 and Tang for decryption, the value of the threshold attribute must equal the total number of stated Tang servers plus one. If the threshold value is lower, it is possible to reach the threshold value by using a single encryption mode. For example, if you set tpm2 to true and specify two Tang servers, a threshold of 2 can be met by accessing the two Tang servers, even if the TPM secure cryptoprocessor is not available.

24.1.4.2. About disk mirroring

During OpenShift Container Platform installation on control plane and worker nodes, you can enable mirroring of the boot and other disks to two or more redundant storage devices. A node continues to function after storage device failure provided one device remains available.

Mirroring does not support replacement of a failed disk. Reprovision the node to restore the mirror to a pristine, non-degraded state.

NOTE

For user-provisioned infrastructure deployments, mirroring is available only on RHCOS systems. Support for mirroring is available on x86_64 nodes booted with BIOS or UEFI and on ppc64le nodes.

24.1.4.3. Configuring disk encryption and mirroring

You can enable and configure encryption and mirroring during an OpenShift Container Platform installation.

Prerequisites

- You have downloaded the OpenShift Container Platform installation program on your installation node.
- You installed Butane on your installation node.

NOTE

Butane is a command-line utility that OpenShift Container Platform uses to offer convenient, short-hand syntax for writing and validating machine configs. For more information, see “Creating machine configs with Butane”.

- You have access to a Red Hat Enterprise Linux (RHEL) 8 machine that can be used to generate a thumbprint of the Tang exchange key.

Procedure
1. If you want to use TPM v2 to encrypt your cluster, check to see if TPM v2 encryption needs to be enabled in the host firmware for each node. This is required on most Dell systems. Check the manual for your specific system.

2. If you want to use Tang to encrypt your cluster, follow these preparatory steps:
   a. Set up a Tang server or access an existing one. See Network-bound disk encryption for instructions.
   b. Install the `clevis` package on a RHEL 8 machine, if it is not already installed:
      ```
      $ sudo yum install clevis
      ```
   c. On the RHEL 8 machine, run the following command to generate a thumbprint of the exchange key. Replace `http://tang1.example.com:7500` with the URL of your Tang server:
      ```
      $ clevis-encrypt-tang '{"url":"http://tang1.example.com:7500"}' < /dev/null > /dev/null
      ```
      In this example, `tangd.socket` is listening on port `7500` on the Tang server.
   
   **NOTE**
   The `clevis-encrypt-tang` command generates a thumbprint of the exchange key. No data passes to the encryption command during this step; `/dev/null` exists here as an input instead of plain text. The encrypted output is also sent to `/dev/null`, because it is not required for this procedure.

   **Example output**
   ```
   The advertisement contains the following signing keys:
   PLjNyRdGw03zlRoGjQYMahSZGu9
   ```
   The thumbprint of the exchange key.

   When the **Do you wish to trust these keys? [ynYN]** prompt displays, type `Y`.
   
   d. Optional: For offline Tang provisioning:
      i. Obtain the advertisement from the server using the `curl` command. Replace `http://tang2.example.com:7500` with the URL of your Tang server:
         ```
         $ curl -f http://tang2.example.com:7500/adv > adv.jws && cat adv.jws
         ```
         **Expected output**
         ```
         {"payload": "eyJrZXlzIjogW3siYWxnIjogIkV", "protected": "eyJhbGciOiJFUzUxMiIsImN0eSI", "signature": "ADLgk7fZe3Yt4FyYsm0pHiau7Q"}
         ```
      ii. Provide the advertisement file to Clevis for encryption:
If the nodes are configured with static IP addressing, run `coreos-installer iso customize --dest-karg-append` or use the `coreos-installer --append-karg` option when installing RH COS nodes to set the IP address of the installed system. Append the `ip=` and other arguments needed for your network.

**IMPORTANT**

Some methods for configuring static IPs do not affect the initramfs after the first boot and will not work with Tang encryption. These include the `coreos-installer --copy-network` option, the `coreos-installer iso customize --network-keyfile` option, and the `coreos-installer pxe customize --network-keyfile` option, as well as adding `ip=` arguments to the kernel command line of the live ISO or PXE image during installation. Incorrect static IP configuration causes the second boot of the node to fail.

3. On your installation node, change to the directory that contains the installation program and generate the Kubernetes manifests for the cluster:

```
$ ./openshift-install create manifests --dir <installation_directory>
```

Replace `<installation_directory>` with the path to the directory that you want to store the installation files in.

4. Create a Butane config that configures disk encryption, mirroring, or both. For example, to configure storage for compute nodes, create a `$HOME/clusterconfig/worker-storage.bu` file.

### Butane config example for a boot device

```
variant: openshift
version: 4.14.0
metadata:
  name: worker-storage
  labels:
    machineconfiguration.openshift.io/role: worker
boot_device:
  layout: x86_64
  luks:
  tpm2: true
  tang:
    - url: http://tang1.example.com:7500
      thumbprint: PLjNyRdGw03zlRoGjQYMahSZGu9
    - url: http://tang2.example.com:7500
      thumbprint: VCJsvZFjBSiHSlMd78rOqr7h2ZF
      advertisement: "eyJrZXlzIjogW3siYWxnIjogIkV...
    threshold: 1
    mirror: 1
    devices: 12
```

$ clevis-encrypt-tang '{}"url":"http://tang2.example.com:7500","adv":"adv.jws"' < /dev/null > /dev/null
For control plane configurations, replace worker with master in both of these locations.

Set this field to the instruction set architecture of the cluster nodes. Some examples include, x86_64, aarch64, or ppc64le.

Include this section if you want to encrypt the root file system. For more details, see "About disk encryption".

Include this field if you want to use a Trusted Platform Module (TPM) to encrypt the root file system.

Include this section if you want to use one or more Tang servers.

Specify the URL of a Tang server. In this example, tangd.socket is listening on port 7500 on the Tang server.

Specify the exchange key thumbprint, which was generated in a preceding step.

Optional: Specify the advertisement for your offline Tang server in valid JSON format.

Specify the minimum number of TPM v2 and Tang encryption conditions that must be met for decryption to occur. The default value is 1. For more information about this topic, see "Configuring an encryption threshold".

Include this section if you want to mirror the boot disk. For more details, see "About disk mirroring".

List all disk devices that should be included in the boot disk mirror, including the disk that RHCOS will be installed onto.

Include this directive to enable FIPS mode on your cluster.

---

**IMPORTANT**

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see Installing the system in FIPS mode. If you are configuring nodes to use both disk encryption and mirroring, both features must be configured in the same Butane configuration file. If you are configuring disk encryption on a node with FIPS mode enabled, you must include the fips directive in the same Butane configuration file, even if FIPS mode is also enabled in a separate manifest.

5. Create a control plane or compute node manifest from the corresponding Butane configuration file and save it to the `<installation_directory>/openshift` directory. For example, to create a manifest for the compute nodes, run the following command:

```
$ butane $HOME/clusterconfig/worker-storage.bu -o <installation_directory>/openshift/99-worker-storage.yaml
```
Repeat this step for each node type that requires disk encryption or mirroring.

6. Save the Butane configuration file in case you need to update the manifests in the future.

7. Continue with the remainder of the OpenShift Container Platform installation.

TIP
You can monitor the console log on the RHCOS nodes during installation for error messages relating to disk encryption or mirroring.

IMPORTANT
If you configure additional data partitions, they will not be encrypted unless encryption is explicitly requested.

Verification
After installing OpenShift Container Platform, you can verify if boot disk encryption or mirroring is enabled on the cluster nodes.

1. From the installation host, access a cluster node by using a debug pod:
   a. Start a debug pod for the node, for example:

```
$ oc debug node/compute-1
```

   b. Set /host as the root directory within the debug shell. The debug pod mounts the root file system of the node in /host within the pod. By changing the root directory to /host, you can run binaries contained in the executable paths on the node:

```
# chroot /host
```

   NOTE
OpenShift Container Platform cluster nodes running Red Hat Enterprise Linux CoreOS (RHCOS) are immutable and rely on Operators to apply cluster changes. Accessing cluster nodes using SSH is not recommended. However, if the OpenShift Container Platform API is not available, or kubelet is not properly functioning on the target node, oc operations will be impacted. In such situations, it is possible to access nodes using ssh core@<node>.<cluster_name>.<base_domain> instead.

2. If you configured boot disk encryption, verify if it is enabled:
   a. From the debug shell, review the status of the root mapping on the node:

```
# cryptsetup status root
```

   Example output

```
/dev/mapper/root is active and is in use.
type:    LUKS2
```
ciphertext: aes-xts-plain64
keysize: 512 bits
key location: keyring
device: /dev/sda4
sector size: 512
offset: 32768 sectors
size: 15683456 sectors
mode: read/write

1. The encryption format. When the TPM v2 or Tang encryption modes are enabled, the
RHCOS boot disks are encrypted using the LUKS2 format.

2. The encryption algorithm used to encrypt the LUKS2 volume. The
aes-cbc-essiv:sha256 cipher is used if FIPS mode is enabled.

3. The device that contains the encrypted LUKS2 volume. If mirroring is enabled, the
value will represent a software mirror device, for example /dev/md126.

b. List the Clevis plugins that are bound to the encrypted device:

   # clevis luks list -d /dev/sda4

   Specify the device that is listed in the device field in the output of the preceding step.

   Example output

   1: sss "{"t":1,"pins":{"tang":["url":"http://tang.example.com:7500"]}}"

   In the example output, the Tang plugin is used by the Shamir’s Secret Sharing (SSS)
   Clevis plugin for the /dev/sda4 device.

3. If you configured mirroring, verify if it is enabled:

   a. From the debug shell, list the software RAID devices on the node:

      # cat /proc/mdstat

      Example output

      Personalities : [raid1]
      md126 : active raid1 sdb3[1] sda3[0] 393152 blocks super 1.0 [2/2] [UU]
      md127 : active raid1 sda4[0] sdb4[1] 51869632 blocks super 1.2 [2/2] [UU]
      unused devices: <none>

      The /dev/md126 software RAID mirror device uses the /dev/sda3 and /dev/sdb3 disk
devices on the cluster node.
b. Review the details of each of the software RAID devices listed in the output of the preceding command. The following example lists the details of the /dev/md126 device:

```
# mdadm --detail /dev/md126
```

**Example output**

```
/dev/md126:
    Version : 1.0
    Creation Time : Wed Jul  7 11:07:36 2021
    Raid Level : raid1 1
      Array Size : 393152 (383.94 MiB 402.59 MB)
      Used Dev Size : 393152 (383.94 MiB 402.59 MB)
      Raid Devices : 2
      Total Devices : 2
      Persistence : Superblock is persistent
      State : clean 2
      Active Devices : 2 3
      Working Devices : 2 4
      Failed Devices : 0 5
      Spare Devices : 0
    Consistency Policy : resync
      Name : any:md-boot 6
      UUID : ccfa3801:c520e0b5:2bee2755:69043055
      Events : 19
    Number   Major   Minor   RaidDevice State
        0     252        3        0      active sync   /dev/sda3 7
        1     252       19        1      active sync   /dev/sdb3 8
```

1. Specifies the RAID level of the device. `raid1` indicates RAID 1 disk mirroring.
2. Specifies the state of the RAID device.
3. States the number of underlying disk devices that are active and working.
4. States the number of underlying disk devices that are in a failed state.
5. The name of the software RAID device.
6. Provides information about the underlying disk devices used by the software RAID device.

```
# mdadm --detail /dev/md126
```

```
/dev/md126:
    Version : 1.0
    Creation Time : Wed Jul  7 11:07:36 2021

      Events : 19
    Number   Major   Minor   RaidDevice State
        0     252        3        0      active sync   /dev/sda3 7
        1     252       19        1      active sync   /dev/sdb3 8
```

1. Specifies the RAID level of the device. `raid1` indicates RAID 1 disk mirroring.
2. Specifies the state of the RAID device.
3. States the number of underlying disk devices that are active and working.
4. States the number of underlying disk devices that are in a failed state.
5. The name of the software RAID device.
6. Provides information about the underlying disk devices used by the software RAID device.
Example output

```
# mount | grep /dev/md

/dev/md126 on /boot type ext4 (rw,relatime,seclabel)
/dev/md127 on / type xfs
   (rw,relatime,seclabel,attr2,inode64,logbufs=8,logbsize=32k,prjquota)
/dev/md127 on /etc type xfs
   (rw,relatime,seclabel,attr2,inode64,logbufs=8,logbsize=32k,prjquota)
/dev/md127 on /usr type xfs
   (ro,relatime,seclabel,attr2,inode64,logbufs=8,logbsize=32k,prjquota)
/dev/md127 on /sysroot type xfs
   (ro,relatime,seclabel,attr2,inode64,logbufs=8,logbsize=32k,prjquota)
/dev/md127 on /var type xfs
   (rw,relatime,seclabel,attr2,inode64,logbufs=8,logbsize=32k,prjquota)
/dev/md127 on /var/lib/containers/storage/overlay type xfs
   (rw,relatime,seclabel,attr2,inode64,logbufs=8,logbsize=32k,prjquota)
/dev/md127 on /var/lib/kubelet/pods/e5054ed5-f882-4d14-b599-99c050d4e0c0/volume-subpaths/etc/tuned/1 type xfs
   (rw,relatime,seclabel,attr2,inode64,logbufs=8,logbsize=32k,prjquota)
/dev/md127 on /var/lib/kubelet/pods/e5054ed5-f882-4d14-b599-99c050d4e0c0/volume-subpaths/etc/tuned/2 type xfs
   (rw,relatime,seclabel,attr2,inode64,logbufs=8,logbsize=32k,prjquota)
/dev/md127 on /var/lib/kubelet/pods/e5054ed5-f882-4d14-b599-99c050d4e0c0/volume-subpaths/etc/tuned/3 type xfs
   (rw,relatime,seclabel,attr2,inode64,logbufs=8,logbsize=32k,prjquota)
/dev/md127 on /var/lib/kubelet/pods/e5054ed5-f882-4d14-b599-99c050d4e0c0/volume-subpaths/etc/tuned/4 type xfs
   (rw,relatime,seclabel,attr2,inode64,logbufs=8,logbsize=32k,prjquota)
/dev/md127 on /var/lib/kubelet/pods/e5054ed5-f882-4d14-b599-99c050d4e0c0/volume-subpaths/etc/tuned/5 type xfs
   (rw,relatime,seclabel,attr2,inode64,logbufs=8,logbsize=32k,prjquota)
```

In the example output, the `/boot` file system is mounted on the `/dev/md126` software RAID device and the root file system is mounted on `/dev/md127`.

4. Repeat the verification steps for each OpenShift Container Platform node type.

Additional resources

- For more information about the TPM v2 and Tang encryption modes, see Configuring automated unlocking of encrypted volumes using policy-based decryption.

24.1.4.4. Configuring a RAID-enabled data volume

You can enable software RAID partitioning to provide an external data volume. OpenShift Container Platform supports RAID 0, RAID 1, RAID 4, RAID 5, RAID 6, and RAID 10 for data protection and fault tolerance. See ”About disk mirroring” for more details.

Prerequisites

- You have downloaded the OpenShift Container Platform installation program on your installation node.
You have installed Butane on your installation node.

**NOTE**

Butane is a command-line utility that OpenShift Container Platform uses to provide convenient, short-hand syntax for writing machine configs, as well as for performing additional validation of machine configs. For more information, see the *Creating machine configs with Butane* section.

**Procedure**

1. Create a Butane config that configures a data volume by using software RAID.

   - To configure a data volume with RAID 1 on the same disks that are used for a mirrored boot disk, create a `$HOME/clusterconfig/raid1-storage.bu` file, for example:

   **RAID 1 on mirrored boot disk**

   ```yaml
   variant: openshift
   version: 4.14.0
   metadata:
     name: raid1-storage
     labels:
       machineconfiguration.openshift.io/role: worker
   boot_device:
     mirror:
       devices:
         - /dev/disk/by-id/scsi-3600508b400105e210000900000490000
         - /dev/disk/by-id/scsi-SSEAGATE_ST373453LW_3HW1RHM6
   storage:
     disks:
       - device: /dev/disk/by-id/scsi-3600508b400105e210000900000490000
         partitions:
           - label: root-1
             size_mib: 25000
           - label: var-1
           - device: /dev/disk/by-id/scsi-SSEAGATE_ST373453LW_3HW1RHM6
             partitions:
               - label: root-2
                 size_mib: 25000
               - label: var-2
       raid:
         - name: md-var
           level: raid1
           devices:
             - /dev/disk/by-partlabel/var-1
             - /dev/disk/by-partlabel/var-2
   filesystems:
     - device: /dev/md/md-var
       path: /var
       format: xfs
       wipe_filesystem: true
       with_mount_unit: true
   ```
When adding a data partition to the boot disk, a minimum value of 25000 mebibytes is recommended. If no value is specified, or if the specified value is smaller than the recommended minimum, the resulting root file system will be too small, and future reinstalls of RHCOS might overwrite the beginning of the data partition.

- To configure a data volume with RAID 1 on secondary disks, create a $HOME/clusterconfig/raid1-alt-storage.bu file, for example:

RAID 1 on secondary disks

```yaml
variant: openshift
version: 4.14.0
metadata:
    name: raid1-alt-storage
    labels:
        machineconfiguration.openshift.io/role: worker
storage:
    disks:
        - device: /dev/sdc
          wipe_table: true
          partitions:
            - label: data-1
            - device: /dev/sdd
              wipe_table: true
              partitions:
                - label: data-2
    raid:
        - name: md-var-lib-containers
          level: raid1
          devices:
            - /dev/disk/by-partlabel/data-1
            - /dev/disk/by-partlabel/data-2
          filesystems:
            - device: /dev/md/md-var-lib-containers
              path: /var/lib/containers
              format: xfs
              wipe_filesystem: true
              with_mount_unit: true
```

2. Create a RAID manifest from the Butane config you created in the previous step and save it to the `<installation_directory>/openshift` directory. For example, to create a manifest for the compute nodes, run the following command:

```
$ butane $HOME/clusterconfig/<butane_config>.bu -o <installation_directory>/openshift/<manifest_name>.yaml
```

   Replace `<butane_config>` and `<manifest_name>` with the file names from the previous step. For example, `raid1-alt-storage.bu` and `raid1-alt-storage.yaml` for secondary disks.

3. Save the Butane config in case you need to update the manifest in the future.

4. Continue with the remainder of the OpenShift Container Platform installation.
24.1.5. Configuring chrony time service

You can set the time server and related settings used by the chrony time service (chronyd) by modifying the contents of the chrony.conf file and passing those contents to your nodes as a machine config.

Procedure

1. Create a Butane config including the contents of the chrony.conf file. For example, to configure chrony on worker nodes, create a 99-worker-chrony.bu file.

   **NOTE**
   See “Creating machine configs with Butane” for information about Butane.

   ```yaml
   variant: openshift
   version: 4.14.0
   metadata:
     name: 99-worker-chrony
     labels:
       machineconfiguration.openshift.io/role: worker
   storage:
     files:
       - path: /etc/chrony.conf
         mode: 0644
         overwrite: true
         contents:
           inline:
             pool 0.rhel.pool.ntp.org iburst
             driftfile /var/lib/chrony/drift
             makestep 1.0 3
             rtt sync
             logdir /var/log/chrony
   ```

   **1** On control plane nodes, substitute master for worker in both of these locations.

   **2** Specify an octal value mode for the mode field in the machine config file. After creating the file and applying the changes, the mode is converted to a decimal value. You can check the YAML file with the command `oc get mc <mc-name> -o yaml`.

   **3** Specify any valid, reachable time source, such as the one provided by your DHCP server. Alternately, you can specify any of the following NTP servers: 1.rhel.pool.ntp.org, 2.rhel.pool.ntp.org, or 3.rhel.pool.ntp.org.

2. Use Butane to generate a MachineConfig object file, 99-worker-chrony.yaml, containing the configuration to be delivered to the nodes:

   ```bash
   $ butane 99-worker-chrony.bu -o 99-worker-chrony.yaml
   ```

3. Apply the configurations in one of two ways:
If the cluster is not running yet, after you generate manifest files, add the `MachineConfig` object file to the `<installation_directory>/openshift` directory, and then continue to create the cluster.

If the cluster is already running, apply the file:

```
$ oc apply -f ./99-worker-chrony.yaml
```

### 24.1.6. Additional resources

- For information on Butane, see Creating machine configs with Butane.
- For information on FIPS support, see Support for FIPS cryptography.

### 24.2. CONFIGURING YOUR FIREWALL

If you use a firewall, you must configure it so that OpenShift Container Platform can access the sites that it requires to function. You must always grant access to some sites, and you grant access to more if you use Red Hat Insights, the Telemetry service, a cloud to host your cluster, and certain build strategies.

#### 24.2.1. Configuring your firewall for OpenShift Container Platform

Before you install OpenShift Container Platform, you must configure your firewall to grant access to the sites that OpenShift Container Platform requires.

There are no special configuration considerations for services running on only controller nodes compared to worker nodes.

**NOTE**

If your environment has a dedicated load balancer in front of your OpenShift Container Platform cluster, review the allowlists between your firewall and load balancer to prevent unwanted network restrictions to your cluster.

**Procedure**

1. Allowlist the following registry URLs:

<table>
<thead>
<tr>
<th>URL</th>
<th>Port</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>registry.redhat.io</td>
<td>443</td>
<td>Provides core container images</td>
</tr>
<tr>
<td>access.redhat.com</td>
<td>443</td>
<td>Hosts all the container images that are stored on the Red Hat Ecosytem Catalog, including core container images.</td>
</tr>
<tr>
<td>quay.io</td>
<td>443</td>
<td>Provides core container images</td>
</tr>
<tr>
<td>cdn.quay.io</td>
<td>443</td>
<td>Provides core container images</td>
</tr>
<tr>
<td>cdn01.quay.io</td>
<td>443</td>
<td>Provides core container images</td>
</tr>
</tbody>
</table>
1. In a firewall environment, ensure that the **access.redhat.com** resource is on the allowlist. This resource hosts a signature store that a container client requires for verifying images when pulling them from **registry.access.redhat.com**.

You can use the wildcards *.quay.io and *.openshiftapps.com instead of cdn0[1-3].quay.io in your allowlist. When you add a site, such as quay.io, to your allowlist, do not add a wildcard entry, such as *.quay.io, to your denylist. In most cases, image registries use a content delivery network (CDN) to serve images. If a firewall blocks access, image downloads are denied when the initial download request redirects to a hostname such as cdn01.quay.io.

2. Allowlist any site that provides resources for a language or framework that your builds require.

3. If you do not disable Telemetry, you must grant access to the following URLs to access Red Hat Insights:

<table>
<thead>
<tr>
<th>URL</th>
<th>Port</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>cert-api.access.redhat.com</td>
<td>443</td>
<td>Required for Telemetry</td>
</tr>
<tr>
<td>api.access.redhat.com</td>
<td>443</td>
<td>Required for Telemetry</td>
</tr>
<tr>
<td>infogw.api.openshift.com</td>
<td>443</td>
<td>Required for Telemetry</td>
</tr>
<tr>
<td>console.redhat.com</td>
<td>443</td>
<td>Required for Telemetry and for insights-operator</td>
</tr>
</tbody>
</table>

4. If you use Alibaba Cloud, Amazon Web Services (AWS), Microsoft Azure, or Google Cloud Platform (GCP) to host your cluster, you must grant access to the URLs that provide the cloud provider API and DNS for that cloud:

<table>
<thead>
<tr>
<th>Cloud</th>
<th>URL</th>
<th>Port</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alibaba</td>
<td>*.aliyuncs.com</td>
<td>443</td>
<td>Required to access Alibaba Cloud services and resources. Review the Alibaba endpoints_config.go file to determine the exact endpoints to allow for the regions that you use.</td>
</tr>
<tr>
<td>Cloud</td>
<td>URL</td>
<td>Port</td>
<td>Function</td>
</tr>
<tr>
<td>-------</td>
<td>-----</td>
<td>------</td>
<td>----------</td>
</tr>
<tr>
<td>AWS</td>
<td>aws.amazon.com</td>
<td>443</td>
<td>Used to install and manage clusters in an AWS environment.</td>
</tr>
<tr>
<td></td>
<td>*.amazonaws.com</td>
<td>443</td>
<td>Required to access AWS services and resources. Review the AWS Service Endpoints in the AWS documentation to determine the exact endpoints to allow for the regions that you use.</td>
</tr>
<tr>
<td></td>
<td>ec2.amazonaws.com</td>
<td>443</td>
<td>Used to install and manage clusters in an AWS environment.</td>
</tr>
<tr>
<td></td>
<td>events.amazonaws.com</td>
<td>443</td>
<td>Used to install and manage clusters in an AWS environment.</td>
</tr>
<tr>
<td></td>
<td>iam.amazonaws.com</td>
<td>443</td>
<td>Used to install and manage clusters in an AWS environment.</td>
</tr>
<tr>
<td></td>
<td>route53.amazonaws.com</td>
<td>443</td>
<td>Used to install and manage clusters in an AWS environment.</td>
</tr>
<tr>
<td></td>
<td>s3.amazonaws.com</td>
<td>443</td>
<td>Used to install and manage clusters in an AWS environment.</td>
</tr>
<tr>
<td></td>
<td>s3.&lt;aws_region&gt;.amazonaws.com</td>
<td>443</td>
<td>Used to install and manage clusters in an AWS environment.</td>
</tr>
<tr>
<td></td>
<td>s3.dualstack.&lt;aws_region&gt;.amazonaws.com</td>
<td>443</td>
<td>Used to install and manage clusters in an AWS environment.</td>
</tr>
<tr>
<td></td>
<td>sts.amazonaws.com</td>
<td>443</td>
<td>Used to install and manage clusters in an AWS environment.</td>
</tr>
<tr>
<td></td>
<td>sts.&lt;aws_region&gt;.amazonaws.com</td>
<td>443</td>
<td>Used to install and manage clusters in an AWS environment.</td>
</tr>
<tr>
<td></td>
<td>tagging.us-east-1.amazonaws.com</td>
<td>443</td>
<td>Used to install and manage clusters in an AWS environment. This endpoint is always us-east-1, regardless of the region the cluster is deployed in.</td>
</tr>
<tr>
<td></td>
<td>ec2.&lt;aws_region&gt;.amazonaws.com</td>
<td>443</td>
<td>Used to install and manage clusters in an AWS environment.</td>
</tr>
<tr>
<td></td>
<td>elasticloadbalancing.&lt;aws_region&gt;.amazonaws.com</td>
<td>443</td>
<td>Used to install and manage clusters in an AWS environment.</td>
</tr>
<tr>
<td>Cloud</td>
<td>URL</td>
<td>Port</td>
<td>Function</td>
</tr>
<tr>
<td>---------</td>
<td>------------------------------------</td>
<td>------</td>
<td>--------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>servicequotas.&lt;aws_region&gt;.amazonaws.com</td>
<td>443</td>
<td>Required. Used to confirm quotas for deploying the service.</td>
</tr>
<tr>
<td></td>
<td>tagging.&lt;aws_region&gt;.amazonaws.com</td>
<td>443</td>
<td>Allows the assignment of metadata about AWS resources in the form of tags.</td>
</tr>
<tr>
<td></td>
<td>accounts.google.com</td>
<td>443</td>
<td>Required to access your GCP account.</td>
</tr>
<tr>
<td>GCP</td>
<td>*.googleapis.com</td>
<td>443</td>
<td>Required to access GCP services and resources. Review Cloud Endpoints in the GCP documentation to determine the endpoints to allow for your APIs.</td>
</tr>
<tr>
<td>Azure</td>
<td>management.azure.com</td>
<td>443</td>
<td>Required to access Azure services and resources. Review the Azure REST API reference in the Azure documentation to determine the endpoints to allow for your APIs.</td>
</tr>
<tr>
<td></td>
<td>*.blob.core.windows.net</td>
<td>443</td>
<td>Required to download Ignition files.</td>
</tr>
<tr>
<td></td>
<td>login.microsoftonline.com</td>
<td>443</td>
<td>Required to access Azure services and resources. Review the Azure REST API reference in the Azure documentation to determine the endpoints to allow for your APIs.</td>
</tr>
</tbody>
</table>

5. Allowlist the following URLs:

<table>
<thead>
<tr>
<th>URL</th>
<th>Port</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>mirror.openshift.com</td>
<td>443</td>
<td>Required to access mirrored installation content and images. This site is also a source of release image signatures, although the Cluster Version Operator needs only a single functioning source.</td>
</tr>
<tr>
<td>storage.googleapis.com/openshift-release</td>
<td>443</td>
<td>A source of release image signatures, although the Cluster Version Operator needs only a single functioning source.</td>
</tr>
<tr>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>443</td>
<td>Required to access the default cluster routes unless you set an ingress wildcard during installation.</td>
</tr>
<tr>
<td>URL</td>
<td>Port</td>
<td>Function</td>
</tr>
<tr>
<td>--------------------------------------</td>
<td>------</td>
<td>----------</td>
</tr>
<tr>
<td>quayio-production-s3.s3.amazonaws.com</td>
<td>443</td>
<td>Required to access Quay image content in AWS.</td>
</tr>
<tr>
<td>api.openshift.com</td>
<td>443</td>
<td>Required both for your cluster token and to check if updates are available for the cluster.</td>
</tr>
<tr>
<td>rhcos.mirror.openshift.com</td>
<td>443</td>
<td>Required to download Red Hat Enterprise Linux CoreOS (RHCOS) images.</td>
</tr>
<tr>
<td>console.redhat.com</td>
<td>443</td>
<td>Required for your cluster token.</td>
</tr>
<tr>
<td>sso.redhat.com</td>
<td>443</td>
<td>The <a href="https://console.redhat.com">https://console.redhat.com</a> site uses authentication from sso.redhat.com</td>
</tr>
</tbody>
</table>

Operators require route access to perform health checks. Specifically, the authentication and web console Operators connect to two routes to verify that the routes work. If you are the cluster administrator and do not want to allow ".apps.<cluster_name>.<base_domain>`, then allow these routes:

- `oauth-openshift.apps.<cluster_name>.<base_domain>`
- `console-openshift-console.apps.<cluster_name>.<base_domain>`, or the hostname that is specified in the `spec.route.hostname` field of the `consoles.operator/cluster` object if the field is not empty.

6. Allowlist the following URLs for optional third-party content:

<table>
<thead>
<tr>
<th>URL</th>
<th>Port</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>registry.connect.redhat.com</td>
<td>443</td>
<td>Required for all third-party images and certified operators.</td>
</tr>
<tr>
<td>rhc4tp-prod-z8cxf-image-registry-us-east-1-evenkylefocxqvofrk.s3.dualstack.us-east-1.amazonaws.com</td>
<td>443</td>
<td>Provides access to container images hosted on registry.connect.redhat.com</td>
</tr>
<tr>
<td>oso-rhc4tp-docker-registry.s3-us-west-2.amazonaws.com</td>
<td>443</td>
<td>Required for Sonatype Nexus, F5 Big IP operators.</td>
</tr>
</tbody>
</table>

7. If you use a default Red Hat Network Time Protocol (NTP) server allow the following URLs:

- 1.rhel.pool.ntp.org
- 2.rhel.pool.ntp.org
24.3. ENABLING LINUX CONTROL GROUP VERSION 1 (CGROUP V1)

As of OpenShift Container Platform 4.14, OpenShift Container Platform uses Linux control group version 2 (cgroup v2) in your cluster. If you are using cgroup v1 on OpenShift Container Platform 4.13 or earlier, migrating to OpenShift Container Platform 4.14 will not automatically update your cgroup configuration to version 2. A fresh installation of OpenShift Container Platform 4.14 will use cgroup v2 by default. However, you can enable Linux control group version 1 (cgroup v1) upon installation. Enabling cgroup v1 in OpenShift Container Platform disables all cgroup v2 controllers and hierarchies in your cluster.

cgroup v2 is the current version of the Linux cgroup API. cgroup v2 offers several improvements over cgroup v1, including a unified hierarchy, safer sub-tree delegation, new features such as Pressure Stall Information, and enhanced resource management and isolation.

You can switch between cgroup v1 and cgroup v2, as needed, by editing the node.config object. For more information, see "Configuring the Linux cgroup on your nodes" in the "Additional resources" of this section.

24.3.1. Enabling Linux cgroup v1 during installation

You can enable Linux control group version 1 (cgroup v1) when you install a cluster by creating installation manifests.

Procedure

1. Create or edit the node.config object to specify the v1 cgroup:

```yaml
apiVersion: config.openshift.io/v2
kind: Node
metadata:
  name: cluster
spec:
  cgroupMode: "v1"
```

2. Proceed with the installation as usual.

Additional resources

- OpenShift Container Platform installation overview
- Configuring the Linux cgroup on your nodes
CHAPTER 25. VALIDATING AN INSTALLATION

You can check the status of an OpenShift Container Platform cluster after an installation by following the procedures in this document.

25.1. REVIEWING THE INSTALLATION LOG

You can review a summary of an installation in the OpenShift Container Platform installation log. If an installation succeeds, the information required to access the cluster is included in the log.

Prerequisites
- You have access to the installation host.

Procedure
- Review the .openshift_install.log log file in the installation directory on your installation host:

  ```
  $ cat <install_dir>/openshift_install.log
  ```

Example output
Cluster credentials are included at the end of the log if the installation is successful, as outlined in the following example:

```
... time="2020-12-03T09:50:47Z" level=info msg="Install complete!"
time="2020-12-03T09:50:47Z" level=info msg="To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'"
time="2020-12-03T09:50:47Z" level=info msg="Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com"
time="2020-12-03T09:50:47Z" level=info msg="Login to the console with user: "\"kubeadmin\", and password: "\"password\""
...```

25.2. VIEWING THE IMAGE PULL SOURCE

For clusters with unrestricted network connectivity, you can view the source of your pulled images by using a command on a node, such as `crictl images`.

However, for disconnected installations, to view the source of pulled images, you must review the CRI-O logs to locate the `Trying to access` log entry, as shown in the following procedure. Other methods to view the image pull source, such as the `crictl images` command, show the non-mirrored image name, even though the image is pulled from the mirrored location.

Prerequisites
- You have access to the cluster as a user with the `cluster-admin` role.
Procedure

- Review the CRI-O logs for a master or worker node:

  ```
  $ oc adm node-logs <node_name> -u crio
  ```

Example output

The **Trying to access** log entry indicates where the image is being pulled from.

```
... Mar 17 02:52:50 ip-10-0-138-140.ec2.internal crio[1366]: time="2021-08-05 10:33:21.594930907Z" level=info msg="Pulling image: quay.io/openshift-release-dev/ocp-release:4.10.0-ppc64le" id=abcd713b-d0e1-4844-ac1c-474c5b60c07c name=/runtime.v1alpha2.ImageService/PullImage
Mar 17 02:52:50 ip-10-0-138-140.ec2.internal crio[1484]: time="2021-03-17 02:52:50.194341109Z" level=info msg="Trying to access "li0317gcp1.mirror-registry.qe.gcp.devcluster.openshift.com:5000/ocp/release@sha256:1926eae7cacb9c00f142ec98b00628970e974284b6ddaf9a6a086cb9af7a6c31"
Mar 17 02:52:50 ip-10-0-138-140.ec2.internal crio[1484]: time="2021-03-17 02:52:50.226788351Z" level=info msg="Trying to access "li0317gcp1.mirror-registry.qe.gcp.devcluster.openshift.com:5000/ocp/release@sha256:1926eae7cacb9c00f142ec98b00628970e974284b6ddaf9a6a086cb9af7a6c31"
```

The log might show the image pull source twice, as shown in the preceding example.

If your **ImageContentSourcePolicy** object lists multiple mirrors, OpenShift Container Platform attempts to pull the images in the order listed in the configuration, for example:

```
Trying to access "li0317gcp1.mirror-registry.qe.gcp.devcluster.openshift.com:5000/ocp/release@sha256:1926eae7cacb9c00f142ec98b00628970e974284b6ddaf9a6a086cb9af7a6c31"
Trying to access "li0317gcp2.mirror-registry.qe.gcp.devcluster.openshift.com:5000/ocp/release@sha256:1926eae7cacb9c00f142ec98b00628970e974284b6ddaf9a6a086cb9af7a6c31"
```

25.3. GETTING CLUSTER VERSION, STATUS, AND UPDATE DETAILS

You can view the cluster version and status by running the **oc get clusterversion** command. If the status shows that the installation is still progressing, you can review the status of the Operators for more information.

You can also list the current update channel and review the available cluster updates.

Prerequisites

- You have access to the cluster as a user with the **cluster-admin** role.
- You have installed the OpenShift CLI (**oc**).

Procedure

1. Obtain the cluster version and overall status:
   ```
   ```
$ oc get clusterversion

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>SINCE</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>version</td>
<td>4.6.4</td>
<td>True</td>
<td>False</td>
<td>6m25s</td>
<td>Cluster version is 4.6.4</td>
</tr>
</tbody>
</table>

The example output indicates that the cluster has been installed successfully.

2. If the cluster status indicates that the installation is still progressing, you can obtain more detailed progress information by checking the status of the Operators:

   $ oc get clusteroperators.config.openshift.io

3. View a detailed summary of cluster specifications, update availability, and update history:

   $ oc describe clusterversion

4. List the current update channel:

   $ oc get clusterversion -o jsonpath='{.items[0].spec}{"n"}'

   **Example output**

   ```
   {"channel":"stable-4.6","clusterID":"245539c1-72a3-41aa-9cec-72ed8cf25c5c"}
   ```

5. Review the available cluster updates:

   $ oc adm upgrade

   **Example output**

   Cluster version is 4.6.4

   Updates:

   VERSION IMAGE
   4.6.6   quay.io/openshift-release-dev/ocp-release@sha256:c7e8f18e8116356701bd23ae3a23fb9892dd5ea66c8300662ef30563d7104f349

   Additional resources

   - See [Querying Operator status after installation](#) for more information about querying Operator status if your installation is still progressing.
   - See [Troubleshooting Operator issues](#) for information about investigating issues with Operators.
   - See [Updating a cluster using the web console](#) for more information on updating your cluster.
   - See [Understanding update channels and releases](#) for an overview about update release channels.
25.4. CLUSTERS THAT USE SHORT-TERM CREDENTIALS: VERIFYING THE CREDENTIALS CONFIGURATION

You can verify that your cluster is using short-term security credentials for individual components.

Prerequisites

- You deployed an OpenShift Container Platform cluster using the Cloud Credential Operator utility (ccoctl) to implement short-term credentials.
- You installed the OpenShift CLI (oc).

Procedure

1. Log in as a user with cluster-admin privileges.

2. Verify that the cluster does not have root credentials by running the following command:

   ```bash
   $ oc get secrets -n kube-system <secret_name>
   ```

   where `<secret_name>` is the name of the root secret for your cloud provider.

<table>
<thead>
<tr>
<th>Platform</th>
<th>Secret name</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS</td>
<td>aws-creds</td>
</tr>
<tr>
<td>Azure</td>
<td>azure-credentials</td>
</tr>
<tr>
<td>GCP</td>
<td>gcp-credentials</td>
</tr>
</tbody>
</table>

   An error confirms that the root secret is not present on the cluster. The following example shows the expected output from an AWS cluster:

   **Example output**

   ```bash
   Error from server (NotFound): secrets "aws-creds" not found
   ```

3. Verify that the components are using short-term security credentials for individual components by running the following command:

   ```bash
   $ oc get authentication cluster \
   -o jsonpath \
   --template="{ .spec.serviceAccountIssuer }
   ```

   This command displays the value of the `.spec.serviceAccountIssuer` parameter in the cluster Authentication object. An output of a URL that is associated with your cloud provider indicates that the cluster is using manual mode with short-term credentials that are created and managed from outside of the cluster.
25.5. QUERYING THE STATUS OF THE CLUSTER NODES BY USING THE CLI

You can verify the status of the cluster nodes after an installation.

Prerequisites

- You have access to the cluster as a user with the `cluster-admin` role.
- You have installed the OpenShift CLI (`oc`).

Procedure

1. List the status of the cluster nodes. Verify that the output lists all of the expected control plane and compute nodes and that each node has a `Ready` status:

   ```
   $ oc get nodes
   NAME                          STATUS   ROLES    AGE   VERSION
   compute-1.example.com         Ready    worker   33m   v1.27.3
   control-plane-1.example.com   Ready    master   41m   v1.27.3
   control-plane-2.example.com   Ready    master   45m   v1.27.3
   compute-2.example.com         Ready    worker   38m   v1.27.3
   compute-3.example.com         Ready    worker   33m   v1.27.3
   control-plane-3.example.com   Ready    master   41m   v1.27.3
   ```

2. Review CPU and memory resource availability for each cluster node:

   ```
   $ oc adm top nodes
   NAME                          CPU(cores)   CPU%   MEMORY(bytes)   MEMORY%
   compute-1.example.com         128m         8%     1132Mi          16%
   control-plane-1.example.com   801m         22%    3471Mi          23%
   control-plane-2.example.com   1718m        49%    6085Mi          40%
   compute-2.example.com         935m         62%    5178Mi          75%
   compute-3.example.com         111m         7%     1131Mi          16%
   control-plane-3.example.com   942m         26%    4100Mi          27%
   ```

Additional resources

- See [Verifying node health](#) for more details about reviewing node health and investigating node issues.

25.6. REVIEWING THE CLUSTER STATUS FROM THE OPENSHIFT CONTAINER PLATFORM WEB CONSOLE

You can review the following information in the Overview page in the OpenShift Container Platform web console:
• The general status of your cluster
• The status of the control plane, cluster Operators, and storage
• CPU, memory, file system, network transfer, and pod availability
• The API address of the cluster, the cluster ID, and the name of the provider
• Cluster version information
• Cluster update status, including details of the current update channel and available updates
• A cluster inventory detailing node, pod, storage class, and persistent volume claim (PVC) information
• A list of ongoing cluster activities and recent events

Prerequisites

• You have access to the cluster as a user with the cluster-admin role.

Procedure

1. In the Administrator perspective, navigate to Home → Overview → Details → Cluster ID → OpenShift Cluster Manager to open your cluster’s Overview tab in the OpenShift Cluster Manager web console.

2. From the Overview tab on OpenShift Cluster Manager Hybrid Cloud Console, review the following information about your cluster:
   • vCPU and memory availability and resource usage
   • The cluster ID, status, type, region, and the provider name
   • Node counts by node type
   • Cluster version details, the creation date of the cluster, and the name of the cluster owner
   • The life cycle support status of the cluster
• Subscription information, including the service level agreement (SLA) status, the subscription unit type, the production status of the cluster, the subscription obligation, and the service level

**TIP**
To view the history for your cluster, click the **Cluster history** tab.

3. Navigate to the **Monitoring** page to review the following information:

• A list of any issues that have been detected

• A list of alerts that are firing

• The cluster Operator status and version

• The cluster’s resource usage

4. Optional: You can view information about your cluster that Red Hat Insights collects by navigating to the **Overview** menu. From this menu you can view the following information:

• Potential issues that your cluster might be exposed to, categorized by risk level

• Health-check status by category

**Additional resources**

• See [Using Insights to identify issues with your cluster](#) for more information about reviewing potential issues with your cluster.

### 25.8. CHECKING CLUSTER RESOURCE AVAILABILITY AND UTILIZATION

OpenShift Container Platform provides a comprehensive set of monitoring dashboards that help you understand the state of cluster components.

In the **Administrator** perspective, you can access dashboards for core OpenShift Container Platform components, including:

• etcd

• Kubernetes compute resources

• Kubernetes network resources

• Prometheus

• Dashboards relating to cluster and node performance
Prerequisites

- You have access to the cluster as a user with the `cluster-admin` role.

Procedure

1. In the Administrator perspective in the OpenShift Container Platform web console, navigate to **Observe → Dashboards**.

2. Choose a dashboard in the **Dashboard** list. Some dashboards, such as the **etcd** dashboard, produce additional sub-menus when selected.

3. Optional: Select a time range for the graphs in the **Time Range** list.
   - Select a pre-defined time period.
   - Set a custom time range by selecting **Custom time range** in the **Time Range** list.
     a. Input or select the **From** and **To** dates and times.
     b. Click **Save** to save the custom time range.

4. Optional: Select a **Refresh Interval**

5. Hover over each of the graphs within a dashboard to display detailed information about specific items.

Additional resources

- See **Monitoring overview** for more information about the OpenShift Container Platform monitoring stack.
25.9. LISTING ALERTS THAT ARE FIRING

Alerts provide notifications when a set of defined conditions are true in an OpenShift Container Platform cluster. You can review the alerts that are firing in your cluster by using the Alerting UI in the OpenShift Container Platform web console.

Prerequisites

- You have access to the cluster as a user with the `cluster-admin` role.

Procedure

1. In the Administrator perspective, navigate to the Observe → Alerting → Alerts page.
2. Review the alerts that are firing, including their Severity, State, and Source.
3. Select an alert to view more detailed information in the Alert Details page.

Additional resources

- See Managing alerts for further details about alerting in OpenShift Container Platform.

25.10. NEXT STEPS

- See Troubleshooting installations if you experience issues when installing your cluster.
- After installing OpenShift Container Platform, you can further expand and customize your cluster.
CHAPTER 26. TROUBLESHOOTING INSTALLATION ISSUES

To assist in troubleshooting a failed OpenShift Container Platform installation, you can gather logs from the bootstrap and control plane machines. You can also get debug information from the installation program. If you are unable to resolve the issue using the logs and debug information, see Determining where installation issues occur for component-specific troubleshooting.

NOTE

If your OpenShift Container Platform installation fails and the debug output or logs contain network timeouts or other connectivity errors, review the guidelines for configuring your firewall. Gathering logs from your firewall and load balancer can help you diagnose network-related errors.

26.1. PREREQUISITES

- You attempted to install an OpenShift Container Platform cluster and the installation failed.

26.2. GATHERING LOGS FROM A FAILED INSTALLATION

If you gave an SSH key to your installation program, you can gather data about your failed installation.

NOTE

You use a different command to gather logs about an unsuccessful installation than to gather logs from a running cluster. If you must gather logs from a running cluster, use the oc adm must-gather command.

Prerequisites

- Your OpenShift Container Platform installation failed before the bootstrap process finished. The bootstrap node is running and accessible through SSH.

- The ssh-agent process is active on your computer, and you provided the same SSH key to both the ssh-agent process and the installation program.

- If you tried to install a cluster on infrastructure that you provisioned, you must have the fully qualified domain names of the bootstrap and control plane nodes.

Procedure

1. Generate the commands that are required to obtain the installation logs from the bootstrap and control plane machines:

   - If you used installer-provisioned infrastructure, change to the directory that contains the installation program and run the following command:

   ```
   $ ./openshift-install gather bootstrap --dir <installation_directory>
   ```

   `installation_directory` is the directory you specified when you ran `./openshift-install create cluster`. This directory contains the OpenShift Container Platform definition files that the installation program creates.
For installer-provisioned infrastructure, the installation program stores information about the cluster, so you do not specify the hostnames or IP addresses.

- If you used infrastructure that you provisioned yourself, change to the directory that contains the installation program and run the following command:

```
$ ./openshift-install gather bootstrap --dir <installation_directory> \\
--bootstrap <bootstrap_address> \\
--master <master_1_address> \\
--master <master_2_address> \\
--master <master_3_address>
```

1. For **installation_directory**, specify the same directory you specified when you ran `./openshift-install create cluster`. This directory contains the OpenShift Container Platform definition files that the installation program creates.

2. `<bootstrap_address>` is the fully qualified domain name or IP address of the cluster's bootstrap machine.

3. 4. 5. For each control plane, or master, machine in your cluster, replace `<master_*_address>` with its fully qualified domain name or IP address.

**NOTE**

A default cluster contains three control plane machines. List all of your control plane machines as shown, no matter how many your cluster uses.

**Example output**

```
INFO Pulling debug logs from the bootstrap machine
INFO Bootstrap gather logs captured here "<installation_directory>/log-bundle-<timestamp>.tar.gz"
```

If you open a Red Hat support case about your installation failure, include the compressed logs in the case.

### 26.3. MANUALLY GATHERING LOGS WITH SSH ACCESS TO YOUR HOST(S)

Manually gather logs in situations where **must-gather** or automated collection methods do not work.

**IMPORTANT**

By default, SSH access to the OpenShift Container Platform nodes is disabled on the Red Hat OpenStack Platform (RHOSP) based installations.

**Prerequisites**

- You must have SSH access to your host(s).

**Procedure**
1. Collect the `bootkube.service` service logs from the bootstrap host using the `journalctl` command by running:

   ```
   $ journalctl -b -f -u bootkube.service
   ```

2. Collect the bootstrap host’s container logs using the `podman logs`. This is shown as a loop to get all of the container logs from the host:

   ```
   $ for pod in $(sudo podman ps -a -q); do sudo podman logs $pod; done
   ```

3. Alternatively, collect the host’s container logs using the `tail` command by running:

   ```
   # tail -f /var/lib/containers/storage/overlay-containers/*/userdata/ctr.log
   ```

4. Collect the `kubelet.service` and `crio.service` service logs from the master and worker hosts using the `journalctl` command by running:

   ```
   $ journalctl -b -f -u kubelet.service -u crio.service
   ```

5. Collect the master and worker host container logs using the `tail` command by running:

   ```
   $ sudo tail -f /var/log/containers/*
   ```

### 26.4. Manually Gathering Logs Without SSH Access to Your Host(s)

Manually gather logs in situations where `must-gather` or automated collection methods do not work.

If you do not have SSH access to your node, you can access the systems journal to investigate what is happening on your host.

**Prerequisites**

- Your OpenShift Container Platform installation must be complete.
- Your API service is still functional.
- You have system administrator privileges.

**Procedure**

1. Access `journald` unit logs under `/var/log` by running:

   ```
   $ oc adm node-logs --role=master -u kubelet
   ```

2. Access host file paths under `/var/log` by running:

   ```
   $ oc adm node-logs --role=master --path=openshift-apiserver
   ```

### 26.5. Getting Debug Information from the Installation Program

---

3648
You can use any of the following actions to get debug information from the installation program.

- Look at debug messages from a past installation in the hidden .openshift_install.log file. For example, enter:

  ```bash
  $ cat ~/installation_directory/.openshift_install.log
  ```

  For installation_directory, specify the same directory you specified when you ran ./openshift-install create cluster.

- Change to the directory that contains the installation program and re-run it with --log-level=debug:

  ```bash
  $ ./openshift-install create cluster --dir <installation_directory> --log-level debug
  ```

  For installation_directory, specify the same directory you specified when you ran ./openshift-install create cluster.

### 26.6. REINSTALLING THE OPENSHIFT CONTAINER PLATFORM CLUSTER

If you are unable to debug and resolve issues in the failed OpenShift Container Platform installation, consider installing a new OpenShift Container Platform cluster. Before starting the installation process again, you must complete thorough cleanup. For a user-provisioned infrastructure (UPI) installation, you must manually destroy the cluster and delete all associated resources. The following procedure is for an installer-provisioned infrastructure (IPI) installation.

**Procedure**

1. Destroy the cluster and remove all the resources associated with the cluster, including the hidden installer state files in the installation directory:

   ```bash
   $ ./openshift-install destroy cluster --dir <installation_directory>
   ```

   For installation_directory, specify the same directory you specified when you ran ./openshift-install create cluster. This directory contains the OpenShift Container Platform definition files that the installation program creates.

2. Before reinstalling the cluster, delete the installation directory:

   ```bash
   $ rm -rf <installation_directory>
   ```

3. Follow the procedure for installing a new OpenShift Container Platform cluster.

- Installing an OpenShift Container Platform cluster
CHAPTER 27. SUPPORT FOR FIPS CRYPTOGRAPHY

You can install an OpenShift Container Platform cluster in FIPS mode.

OpenShift Container Platform is designed for FIPS. When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures.

For more information about the NIST validation program, see Cryptographic Module Validation Program. For the latest NIST status for the individual versions of RHEL cryptographic libraries that have been submitted for validation, see Compliance Activities and Government Standards.

IMPORTANT

To enable FIPS mode for your cluster, you must run the installation program from a RHEL computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see Installing the system in FIPS mode.

For the Red Hat Enterprise Linux CoreOS (RHCOS) machines in your cluster, this change is applied when the machines are deployed based on the status of an option in the install-config.yaml file, which governs the cluster options that a user can change during cluster deployment. With Red Hat Enterprise Linux (RHEL) machines, you must enable FIPS mode when you install the operating system on the machines that you plan to use as worker machines.

Because FIPS must be enabled before the operating system that your cluster uses boots for the first time, you cannot enable FIPS after you deploy a cluster.

27.1. FIPS VALIDATION IN OPENSHIFT CONTAINER PLATFORM

OpenShift Container Platform uses certain FIPS validated or Modules In Process modules within RHEL and RHCOS for the operating system components that it uses. See RHEL8 core crypto components. For example, when users use SSH to connect to OpenShift Container Platform clusters and containers, those connections are properly encrypted.

OpenShift Container Platform components are written in Go and built with Red Hat’s golang compiler. When you enable FIPS mode for your cluster, all OpenShift Container Platform components that require cryptographic signing call RHEL and RHCOS cryptographic libraries.

Table 27.1. FIPS mode attributes and limitations in OpenShift Container Platform 4.14

<table>
<thead>
<tr>
<th>Attributes</th>
<th>Limitations</th>
</tr>
</thead>
<tbody>
<tr>
<td>FIPS support in RHEL 8 and RHCOS operating systems.</td>
<td>The FIPS implementation does not offer a single function that both computes hash functions and validates the keys that are based on that hash. This limitation will continue to be evaluated and improved in future OpenShift Container Platform releases.</td>
</tr>
<tr>
<td>FIPS support in CRI-O runtimes.</td>
<td></td>
</tr>
<tr>
<td>FIPS support in OpenShift Container Platform services.</td>
<td></td>
</tr>
</tbody>
</table>
27.2. FIPS SUPPORT IN COMPONENTS THAT THE CLUSTER USES

Although the OpenShift Container Platform cluster itself uses FIPS validated or Modules In Process modules, ensure that the systems that support your OpenShift Container Platform cluster use FIPS validated or Modules In Process modules for cryptography.

27.2.1. etcd

To ensure that the secrets that are stored in etcd use FIPS validated or Modules In Process encryption, boot the node in FIPS mode. After you install the cluster in FIPS mode, you can encrypt the etcd data by using the FIPS-approved aes cbc cryptographic algorithm.

27.2.2. Storage

For local storage, use RHEL-provided disk encryption or Container Native Storage that uses RHEL-provided disk encryption. By storing all data in volumes that use RHEL-provided disk encryption and enabling FIPS mode for your cluster, both data at rest and data in motion, or network data, are protected by FIPS validated or Modules In Process encryption. You can configure your cluster to encrypt the root filesystem of each node, as described in Customizing nodes.

27.2.3. Runtimes

To ensure that containers know that they are running on a host that is using FIPS validated or Modules In Process cryptography modules, use CRI-O to manage your runtimes.

27.3. INSTALLING A CLUSTER IN FIPS MODE

To install a cluster in FIPS mode, follow the instructions to install a customized cluster on your preferred infrastructure. Ensure that you set **fips: true** in the *install-config.yaml* file before you deploy your cluster.

**IMPORTANT**

To enable FIPS mode for your cluster, you must run the installation program from a RHEL computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see Installing the system in FIPS mode.

- Amazon Web Services
• Alibaba Cloud
• Microsoft Azure
• Bare metal
• Google Cloud Platform
• IBM Cloud®
• IBM Power®
• IBM Z® and IBM® LinuxONE
• IBM Z® and IBM® LinuxONE with RHEL KVM
• Red Hat OpenStack Platform (RHOSP)
• VMware vSphere

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.

To apply **AES CBC** encryption to your etcd data store, follow the Encrypting etcd data process after you install your cluster.

If you add RHEL nodes to your cluster, ensure that you enable FIPS mode on the machines before their initial boot. See Adding RHEL compute machines to an OpenShift Container Platform cluster and Enabling FIPS Mode in the RHEL 8 documentation.
