OpenShift Container Platform 4.14

Installing

Installing and configuring OpenShift Container Platform clusters
OpenShift Container Platform 4.14 Installing

Installing and configuring OpenShift Container Platform clusters
Abstract

This document provides information about installing OpenShift Container Platform and details about some configuration processes.
## Table of Contents

**CHAPTER 1. OPENSIFT CONTAINER PLATFORM INSTALLATION OVERVIEW** ........................................... 73
  1.1. ABOUT OPENSIFT CONTAINER PLATFORM INSTALLATION ........................................... 73
    1.1.1. About the installation program .............................................................................. 73
    1.1.2. About Red Hat Enterprise Linux CoreOS (RHCOS) .............................................. 74
    1.1.3. Glossary of common terms for OpenShift Container Platform installing ................. 74
    1.1.4. Installation process
      - The installation process with the Assisted Installer .................................................. 77
      - The installation process with Agent-based infrastructure ......................................... 77
      - The installation process with installer-provisioned infrastructure .............................. 77
      - The installation process with user-provisioned infrastructure ................................... 78
      - Installation process details ...................................................................................... 78
    1.1.5. Verifying node state after installation .................................................................... 80
    1.1.6. OpenShift Local overview ..................................................................................... 81
  1.2. SUPPORTED PLATFORMS FOR OPENSIFT CONTAINER PLATFORM CLUSTERS ........... 82

**CHAPTER 2. SELECTING A CLUSTER INSTALLATION METHOD AND PREPARING IT FOR USERS** ........... 84
  2.1. SELECTING A CLUSTER INSTALLATION TYPE ............................................................... 84
    2.1.1. Do you want to install and manage an OpenShift Container Platform cluster yourself? 84
    2.1.2. Have you used OpenShift Container Platform 3 and want to use OpenShift Container Platform 4? 85
    2.1.3. Do you want to use existing components in your cluster? ....................................... 85
    2.1.4. Do you need extra security for your cluster? ............................................................ 86
    2.2. PREPARING YOUR CLUSTER FOR USERS AFTER INSTALLATION .......................... 86
    2.3. PREPARING YOUR CLUSTER FOR WORKLOADS ......................................................... 86
    2.4. SUPPORTED INSTALLATION METHODS FOR DIFFERENT PLATFORMS ................. 87

**CHAPTER 3. CLUSTER CAPABILITIES** .......................................................................................... 93
  3.1. SELECTING CLUSTER CAPABILITIES .............................................................................. 93
  3.2. OPTIONAL CLUSTER CAPABILITIES IN OPENSIFT CONTAINER PLATFORM 4.14 .......... 95
    3.2.1. Bare-metal capability
      - Purpose ..................................................................................................................... 95
    3.2.2. Build capability
      - Purpose ..................................................................................................................... 96
    3.2.3. Cluster storage capability
      - Purpose ..................................................................................................................... 96
      - Notes ........................................................................................................................... 96
    3.2.4. Console capability
      - Purpose ..................................................................................................................... 96
    3.2.5. CSI snapshot controller capability
      - Purpose ..................................................................................................................... 96
    3.2.6. DeploymentConfig capability
      - Purpose ..................................................................................................................... 97
    3.2.7. Insights capability
      - Purpose ..................................................................................................................... 97
      - Notes ........................................................................................................................... 97
    3.2.8. Machine API capability
      - Purpose ..................................................................................................................... 97
    3.2.9. Marketplace capability
      - Purpose ..................................................................................................................... 98
    3.2.10. Node Tuning capability
      - Purpose ..................................................................................................................... 98
## 3.2.11. OpenShift samples capability

### Purpose

<table>
<thead>
<tr>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>98</td>
</tr>
</tbody>
</table>

## 3.2.12. Cluster Image Registry capability

### Purpose

<table>
<thead>
<tr>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>99</td>
</tr>
</tbody>
</table>

## 3.3. ADDITIONAL RESOURCES

<table>
<thead>
<tr>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>99</td>
</tr>
</tbody>
</table>

## CHAPTER 4. DISCONNECTED INSTALLATION MIRRORING

### 4.1. ABOUT DISCONNECTED INSTALLATION MIRRORING

<table>
<thead>
<tr>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>100</td>
</tr>
</tbody>
</table>

#### 4.1.1. Creating a mirror registry

<table>
<thead>
<tr>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>100</td>
</tr>
</tbody>
</table>

#### 4.1.2. Mirroring images for a disconnected installation

<table>
<thead>
<tr>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>100</td>
</tr>
</tbody>
</table>

### 4.2. CREATING A MIRROR REGISTRY WITH MIRROR REGISTRY FOR RED HAT OPENSSHIFT

#### 4.2.1. Prerequisites

<table>
<thead>
<tr>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>100</td>
</tr>
</tbody>
</table>

#### 4.2.2. Mirror registry for Red Hat OpenShift introduction

<table>
<thead>
<tr>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>101</td>
</tr>
</tbody>
</table>

#### 4.2.3. Mirroring on a local host with mirror registry for Red Hat OpenShift

<table>
<thead>
<tr>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>102</td>
</tr>
</tbody>
</table>

#### 4.2.4. Updating mirror registry for Red Hat OpenShift from a local host

<table>
<thead>
<tr>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>103</td>
</tr>
</tbody>
</table>

#### 4.2.5. Mirroring on a remote host with mirror registry for Red Hat OpenShift

<table>
<thead>
<tr>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>103</td>
</tr>
</tbody>
</table>

#### 4.2.6. Updating mirror registry for Red Hat OpenShift from a remote host

<table>
<thead>
<tr>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>105</td>
</tr>
</tbody>
</table>

#### 4.2.7. Replacing mirror registry for Red Hat OpenShift SSL/TLS certificates

<table>
<thead>
<tr>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>105</td>
</tr>
</tbody>
</table>

#### 4.2.8. Uninstalling the mirror registry for Red Hat OpenShift

<table>
<thead>
<tr>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>106</td>
</tr>
</tbody>
</table>

#### 4.2.9. Mirror registry for Red Hat OpenShift flags

<table>
<thead>
<tr>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>107</td>
</tr>
</tbody>
</table>

#### 4.2.10. Mirror registry for Red Hat OpenShift release notes

##### 4.2.10.1. Mirror registry for Red Hat OpenShift 1.3.10

<table>
<thead>
<tr>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>108</td>
</tr>
</tbody>
</table>

##### 4.2.10.2. Mirror registry for Red Hat OpenShift 1.3.9

<table>
<thead>
<tr>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>108</td>
</tr>
</tbody>
</table>

##### 4.2.10.3. Mirror registry for Red Hat OpenShift 1.3.8

<table>
<thead>
<tr>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>108</td>
</tr>
</tbody>
</table>

##### 4.2.10.4. Mirror registry for Red Hat OpenShift 1.3.7

<table>
<thead>
<tr>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>109</td>
</tr>
</tbody>
</table>

##### 4.2.10.5. Mirror registry for Red Hat OpenShift 1.3.6

<table>
<thead>
<tr>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>109</td>
</tr>
</tbody>
</table>

##### 4.2.10.6. Mirror registry for Red Hat OpenShift 1.3.5

<table>
<thead>
<tr>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>109</td>
</tr>
</tbody>
</table>

##### 4.2.10.7. Mirror registry for Red Hat OpenShift 1.3.4

<table>
<thead>
<tr>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>109</td>
</tr>
</tbody>
</table>

##### 4.2.10.8. Mirror registry for Red Hat OpenShift 1.3.3

<table>
<thead>
<tr>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>109</td>
</tr>
</tbody>
</table>

##### 4.2.10.9. Mirror registry for Red Hat OpenShift 1.3.2

<table>
<thead>
<tr>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>110</td>
</tr>
</tbody>
</table>

##### 4.2.10.10. Mirror registry for Red Hat OpenShift 1.3.1

<table>
<thead>
<tr>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>110</td>
</tr>
</tbody>
</table>

##### 4.2.10.11. Mirror registry for Red Hat OpenShift 1.3.0

<table>
<thead>
<tr>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>110</td>
</tr>
</tbody>
</table>

##### 4.2.10.11.1. New features

<table>
<thead>
<tr>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>110</td>
</tr>
</tbody>
</table>

##### 4.2.10.11.2. Bug fixes

<table>
<thead>
<tr>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>111</td>
</tr>
</tbody>
</table>

##### 4.2.10.12. Mirror registry for Red Hat OpenShift 1.2.9

<table>
<thead>
<tr>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>111</td>
</tr>
</tbody>
</table>

##### 4.2.10.13. Mirror registry for Red Hat OpenShift 1.2.8

<table>
<thead>
<tr>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>111</td>
</tr>
</tbody>
</table>

##### 4.2.10.14. Mirror registry for Red Hat OpenShift 1.2.7

<table>
<thead>
<tr>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>111</td>
</tr>
</tbody>
</table>

##### 4.2.10.14.1. Bug fixes

<table>
<thead>
<tr>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>111</td>

4.3. MIRRORING IMAGES FOR A DISCONNECTED INSTALLATION

4.3.1. Prerequisites

4.3.2. About the mirror registry

4.3.3. Preparing your mirror host

  4.3.3.1. Installing the OpenShift CLI by downloading the binary

  Installing the OpenShift CLI on Linux
  Installing the OpenShift CLI on Windows
  Installing the OpenShift CLI on macOS

4.3.4. Configuring credentials that allow images to be mirrored

4.3.5. Mirroring the OpenShift Container Platform image repository

  4.3.6.1. Cluster Samples Operator assistance for mirroring

4.3.6. The Cluster Samples Operator in a disconnected environment

4.3.7. Mirroring Operator catalogs for use with disconnected clusters

  4.3.7.1. Prerequisites

  4.3.7.2. Extracting and mirroring catalog contents

    4.3.7.2.1. Mirroring catalog contents to registries on the same network

    4.3.7.2.2. Mirroring catalog contents to airgapped registries

    4.3.7.3. Generated manifests

    4.3.7.4. Postinstallation requirements

4.3.8. Next steps

4.3.9. Additional resources

4.4. MIRRORING IMAGES FOR A DISCONNECTED INSTALLATION USING THE OC-MIRROR PLUGIN

4.4.1. About the oc-mirror plugin

4.4.2. oc-mirror compatibility and support

4.4.3. About the mirror registry

4.4.4. Prerequisites

4.4.5. Preparing your mirror hosts

  4.4.5.1. Installing the oc-mirror OpenShift CLI plugin

  4.4.5.2. Configuring credentials that allow images to be mirrored

4.4.6. Creating the image set configuration

4.4.7. Mirroring an image set to a mirror registry

  4.4.7.1. Mirroring an image set in a partially disconnected environment

    4.4.7.1.1. Mirroring from mirror to mirror

    4.4.7.2. Mirroring an image set in a fully disconnected environment

      4.4.7.2.1. Mirroring from mirror to disk

      4.4.7.2.2. Mirroring from disk to mirror

4.4.8. Configuring your cluster to use the resources generated by oc-mirror

4.4.9. Keeping your mirror registry content updated

  4.4.9.1. About updating your mirror registry content

      Adding new and updated images

      Pruning images

  4.4.9.2. Updating your mirror registry content

4.4.10. Performing a dry run

4.4.11. Including local OCI Operator catalogs

4.4.12. Image set configuration parameters

4.4.13. Image set configuration examples

  Use case: Including the shortest OpenShift Container Platform update path

  Use case: Including all versions of OpenShift Container Platform from a minimum to the latest version for multi-architecture releases

  Use case: Including Operator versions from a minimum to the latest

  Use case: Including the Nutanix CSI Operator

  Use case: Including the default Operator channel

  Use case: Including an entire catalog (all versions)
Use case: Including an entire catalog (channel heads only)
Use case: Including arbitrary images and helm charts
4.4.15. Additional resources

CHAPTER 5. INSTALLING ON ALIBABA .............................................. 163
5.1. PREPARING TO INSTALL ON ALIBABA CLOUD .................... 163
  5.1.1. Prerequisites ......................................................... 163
  5.1.2. Requirements for installing OpenShift Container Platform on Alibaba Cloud 163
  5.1.3. Registering and Configuring Alibaba Cloud Domain ....................... 163
  5.1.4. Supported Alibaba regions ............................................... 164
  5.1.5. Next steps ......................................................... 164
5.2. CREATING THE REQUIRED ALIBABA CLOUD RESOURCES ....... 164
  5.2.1. Creating the required RAM user ......................................... 164
  5.2.2. Configuring the Cloud Credential Operator utility ..................... 169
  5.2.3. Next steps ................................................................ 170
5.3. INSTALLING A CLUSTER QUICKLY ON ALIBABA CLOUD ........ 170
  5.3.1. Prerequisites ......................................................... 171
  5.3.2. Internet access for OpenShift Container Platform .................... 171
  5.3.3. Generating a key pair for cluster node SSH access ..................... 171
  5.3.4. Obtaining the installation program ........................................ 173
  5.3.5. Creating the installation configuration file ............................... 174
  5.3.6. Generating the required installation manifests .......................... 176
  5.3.7. Creating credentials for OpenShift Container Platform components with the ccoct1 tool .................................................. 176
  5.3.8. Deploying the cluster .................................................. 178
  5.3.9. Installing the OpenShift CLI by downloading the binary .............. 180
    Installing the OpenShift CLI on Linux ...................................... 180
    Installing the OpenShift CLI on Windows .................................. 181
    Installing the OpenShift CLI on macOS ..................................... 181
  5.3.10. Logging in to the cluster by using the CLI .............................. 182
  5.3.11. Logging in to the cluster by using the web console .................. 182
  5.3.12. Telemetry access for OpenShift Container Platform .................. 183
  5.3.13. Next steps ......................................................... 183
5.4. INSTALLING A CLUSTER ON ALIBABA CLOUD WITH CUSTOMIZATIONS ......................................................... 183
  5.4.1. Prerequisites ......................................................... 184
  5.4.2. Internet access for OpenShift Container Platform .................... 184
  5.4.3. Generating a key pair for cluster node SSH access ..................... 185
  5.4.4. Obtaining the installation program ........................................ 186
    5.4.4.1. Creating the installation configuration file ......................... 187
    5.4.4.2. Generating the required installation manifests .................... 189
    5.4.4.3. Creating credentials for OpenShift Container Platform components with the ccoct1 tool .................................................. 189
    5.4.4.4. Sample customized install-config.yaml file for Alibaba Cloud 192
    5.4.4.5. Configuring the cluster-wide proxy during installation .......... 193
  5.4.5. Deploying the cluster .................................................. 195
  5.4.6. Installing the OpenShift CLI by downloading the binary .............. 196
    Installing the OpenShift CLI on Linux ...................................... 196
    Installing the OpenShift CLI on Windows .................................. 197
    Installing the OpenShift CLI on macOS ..................................... 197
  5.4.7. Logging in to the cluster by using the CLI .............................. 198
  5.4.8. Logging in to the cluster by using the web console .................. 198
  5.4.9. Telemetry access for OpenShift Container Platform .................. 199
  5.4.10. Next steps ......................................................... 199
5.5. INSTALLING A CLUSTER ON ALIBABA CLOUD WITH NETWORK CUSTOMIZATIONS ......................................................... 200
5.5.1. Prerequisites
5.5.2. Internet access for OpenShift Container Platform
5.5.3. Generating a key pair for cluster node SSH access
5.5.4. Obtaining the installation program
5.5.5. Network configuration phases
  5.5.5.1. Creating the installation configuration file
  5.5.5.2. Generating the required installation manifests
  5.5.5.3. Sample customized install-config.yaml file for Alibaba Cloud
  5.5.5.4. Configuring the cluster-wide proxy during installation
5.5.6. Cluster Network Operator configuration
  5.5.6.1. Cluster Network Operator configuration object
  5.5.6.2. defaultNetwork object configuration
  5.5.6.3. Configuration for the OpenShift SDN network plugin
  5.5.6.4. Configuration for the OVN-Kubernetes network plugin
  5.5.6.5. kubeProxyConfig object configuration
5.5.7. Specifying advanced network configuration
5.5.8. Configuring hybrid networking with OVN-Kubernetes
5.5.9. Deploying the cluster
5.5.10. Installing the OpenShift CLI by downloading the binary
  5.5.10.1. Installing the OpenShift CLI on Linux
  5.5.10.2. Installing the OpenShift CLI on Windows
  5.5.10.3. Installing the OpenShift CLI on macOS
5.5.11. Logging in to the cluster by using the CLI
5.5.12. Logging in to the cluster by using the web console
5.5.13. Telemetry access for OpenShift Container Platform
5.5.14. Next steps

5.6. INSTALLING A CLUSTER ON ALIBABA CLOUD INTO AN EXISTING VPC
5.6.1. Prerequisites
5.6.2. Using a custom VPC
  5.6.2.1. Requirements for using your VPC
  5.6.2.2. VPC validation
  5.6.2.3. Division of permissions
  5.6.2.4. Isolation between clusters
5.6.3. Internet access for OpenShift Container Platform
5.6.4. Generating a key pair for cluster node SSH access
5.6.5. Obtaining the installation program
  5.6.5.1. Creating the installation configuration file
  5.6.5.2. Sample customized install-config.yaml file for Alibaba Cloud
  5.6.5.3. Generating the required installation manifests
  5.6.5.4. Configuring the Cloud Credential Operator utility
  5.6.5.5. Creating credentials for OpenShift Container Platform components with the ccoctl tool
5.6.6. Deploying the cluster
5.6.7. Installing the OpenShift CLI by downloading the binary
  5.6.7.1. Installing the OpenShift CLI on Linux
  5.6.7.2. Installing the OpenShift CLI on Windows
  5.6.7.3. Installing the OpenShift CLI on macOS
5.6.8. Logging in to the cluster by using the CLI
5.6.9. Logging in to the cluster by using the web console
5.6.10. Telemetry access for OpenShift Container Platform
5.6.11. Next steps

5.7. INSTALLATION CONFIGURATION PARAMETERS FOR ALIBABA CLOUD
5.7.1. Available installation configuration parameters for Alibaba Cloud
  5.7.1.1. Required configuration parameters
5.7.1.2. Network configuration parameters
5.7.1.3. Optional configuration parameters
5.7.1.4. Additional Alibaba Cloud configuration parameters

5.8. UNINSTALLING A CLUSTER ON ALIBABA CLOUD
5.8.1. Removing a cluster that uses installer-provisioned infrastructure

CHAPTER 6. INSTALLING ON AWS
6.1. PREPARING TO INSTALL ON AWS
6.1.1. Prerequisites
6.1.2. Requirements for installing OpenShift Container Platform on AWS
6.1.3. Choosing a method to install OpenShift Container Platform on AWS
6.1.3.1. Installing a cluster on a single node
6.1.3.2. Installing a cluster on installer-provisioned infrastructure
6.1.3.3. Installing a cluster on user-provisioned infrastructure
6.1.4. Next steps
6.2. CONFIGURING AN AWS ACCOUNT
6.2.1. Configuring Route 53
6.2.2. AWS account limits
6.2.3. Required AWS permissions for the IAM user
6.2.4. Creating an IAM user
6.2.5. IAM Policies and AWS authentication
6.2.5.1. Default permissions for IAM instance profiles
6.2.5.2. Specifying an existing IAM role
6.2.5.3. Using AWS IAM Analyzer to create policy templates
6.2.6. Supported AWS Marketplace regions
6.2.7. Supported AWS regions
6.2.7.1. AWS public regions
6.2.7.2. AWS GovCloud regions
6.2.7.3. AWS SC2S and C2S secret regions
6.2.7.4. AWS China regions
6.2.8. Next steps
6.3. INSTALLING A CLUSTER QUICKLY ON AWS
6.3.1. Prerequisites
6.3.2. Internet access for OpenShift Container Platform
6.3.3. Generating a key pair for cluster node SSH access
6.3.4. Obtaining the installation program
6.3.5. Deploying the cluster
6.3.6. Installing the OpenShift CLI by downloading the binary
   Installing the OpenShift CLI on Linux
   Installing the OpenShift CLI on Windows
   Installing the OpenShift CLI on macOS
6.3.7. Logging in to the cluster by using the CLI
6.3.8. Logging in to the cluster by using the web console
6.3.9. Telemetry access for OpenShift Container Platform
6.3.10. Next steps
6.4. INSTALLING A CLUSTER ON AWS WITH CUSTOMIZATIONS
6.4.1. Prerequisites
6.4.2. Internet access for OpenShift Container Platform
6.4.3. Generating a key pair for cluster node SSH access
6.4.4. Obtaining an AWS Marketplace image
6.4.5. Obtaining the installation program
6.4.6. Creating the installation configuration file

6.5.11. Configuring an Ingress Controller Network Load Balancer on a new AWS cluster
6.5.12. Configuring hybrid networking with OVN-Kubernetes
6.5.13. Deploying the cluster
6.5.14. Logging in to the cluster by using the CLI
6.5.15. Logging in to the cluster by using the web console
6.5.16. Telemetry access for OpenShift Container Platform
6.5.17. Next steps

6.6. INSTALLING A CLUSTER ON AWS IN A RESTRICTED NETWORK
6.6.1. Prerequisites
6.6.2. About installations in restricted networks
6.6.2.1. Additional limits
6.6.3. About using a custom VPC
6.6.3.1. Requirements for using your VPC
   Option 1: Create VPC endpoints
   Option 2: Create a proxy without VPC endpoints
   Option 3: Create a proxy with VPC endpoints
6.6.3.2. VPC validation
6.6.3.3. Division of permissions
6.6.3.4. Isolation between clusters
6.6.4. Internet access for OpenShift Container Platform
6.6.5. Generating a key pair for cluster node SSH access
6.6.6. Creating the installation configuration file
   6.6.6.1. Minimum resource requirements for cluster installation
   6.6.6.2. Sample customized install-config.yaml file for AWS
   6.6.6.3. Configuring the cluster-wide proxy during installation
6.6.7. Installing the OpenShift CLI by downloading the binary
   Installing the OpenShift CLI on Linux
   Installing the OpenShift CLI on Windows
   Installing the OpenShift CLI on macOS
6.6.8. Alternatives to storing administrator-level secrets in the kube-system project
   6.6.8.1. Manually creating long-term credentials
   6.6.8.2. Configuring an AWS cluster to use short-term credentials
      6.6.8.2.1. Configuring the Cloud Credential Operator utility
      6.6.8.2.2. Creating AWS resources with the Cloud Credential Operator utility
         6.6.8.2.2.1. Creating AWS resources with a single command
         6.6.8.2.2.2. Creating AWS resources individually
      6.6.8.2.3. Incorporating the Cloud Credential Operator utility manifests
6.6.9. Deploying the cluster
6.6.10. Logging in to the cluster by using the CLI
6.6.11. Disabling the default OperatorHub catalog sources
6.6.12. Telemetry access for OpenShift Container Platform
6.6.13. Next steps

6.7. INSTALLING A CLUSTER ON AWS INTO AN EXISTING VPC
6.7.1. Prerequisites
6.7.2. About using a custom VPC
   6.7.2.1. Requirements for using your VPC
      Option 1: Create VPC endpoints
      Option 2: Create a proxy without VPC endpoints
      Option 3: Create a proxy with VPC endpoints
   6.7.2.2. VPC validation
   6.7.2.3. Division of permissions
   6.7.2.4. Isolation between clusters
   6.7.2.5. AWS security groups
6.7.2.6. Modifying trust policy when installing into a shared VPC
6.7.3. Internet access for OpenShift Container Platform
6.7.4. Generating a key pair for cluster node SSH access
6.7.5. Obtaining the installation program
6.7.6. Creating the installation configuration file
   6.7.6.1. Minimum resource requirements for cluster installation
   6.7.6.2. Tested instance types for AWS
   6.7.6.3. Tested instance types for AWS on 64-bit ARM infrastructures
   6.7.6.4. Sample customized install-config.yaml file for AWS
   6.7.6.5. Configuring the cluster-wide proxy during installation
   6.7.6.6. Applying existing AWS security groups to the cluster
6.7.7. Installing the OpenShift CLI by downloading the binary
   Installing the OpenShift CLI on Linux
   Installing the OpenShift CLI on Windows
   Installing the OpenShift CLI on macOS
6.7.8. Alternatives to storing administrator-level secrets in the kube-system project
   6.7.8.1. Manually creating long-term credentials
   6.7.8.2. Configuring an AWS cluster to use short-term credentials
      6.7.8.2.1. Configuring the Cloud Credential Operator utility
      6.7.8.2.2. Creating AWS resources with the Cloud Credential Operator utility
         6.7.8.2.2.1. Creating AWS resources with a single command
         6.7.8.2.2.2. Creating AWS resources individually
      6.7.8.2.3. Incorporating the Cloud Credential Operator utility manifests
6.7.9. Deploying the cluster
6.7.10. Logging in to the cluster by using the CLI
6.7.11. Logging in to the cluster by using the web console
6.7.12. Telemetry access for OpenShift Container Platform
6.7.13. Next steps

6.8. INSTALLING A PRIVATE CLUSTER ON AWS
6.8.1. Prerequisites
6.8.2. Private clusters
   6.8.2.1. Private clusters in AWS
      6.8.2.1.1. Limitations
6.8.3. About using a custom VPC
   6.8.3.1. Requirements for using your VPC
      Option 1: Create VPC endpoints
      Option 2: Create a proxy without VPC endpoints
      Option 3: Create a proxy with VPC endpoints
   6.8.3.2. VPC validation
   6.8.3.3. Division of permissions
   6.8.3.4. Isolation between clusters
   6.8.3.5. AWS security groups
6.8.4. Internet access for OpenShift Container Platform
6.8.5. Generating a key pair for cluster node SSH access
6.8.6. Obtaining the installation program
6.8.7. Manually creating the installation configuration file
   6.8.7.1. Minimum resource requirements for cluster installation
   6.8.7.2. Tested instance types for AWS
   6.8.7.3. Tested instance types for AWS on 64-bit ARM infrastructures
   6.8.7.4. Sample customized install-config.yaml file for AWS
   6.8.7.5. Configuring the cluster-wide proxy during installation
   6.8.7.6. Applying existing AWS security groups to the cluster
6.8.8. Installing the OpenShift CLI by downloading the binary
6.9.12.2.2. Creating AWS resources individually
6.9.12.2.3. Incorporating the Cloud Credential Operator utility manifests
6.9.13. Deploying the cluster
6.9.14. Logging in to the cluster by using the CLI
6.9.15. Logging in to the cluster by using the web console
6.9.16. Telemetry access for OpenShift Container Platform
6.9.17. Next steps

6.10. INSTALLING A CLUSTER ON AWS INTO A SECRET OR TOP SECRET REGION
6.10.1. Prerequisites
6.10.2. AWS secret regions
6.10.3. Installation requirements
6.10.4. Private clusters
   6.10.4.1. Private clusters in AWS
   6.10.4.1.1. Limitations
6.10.5. About using a custom VPC
   6.10.5.1. Requirements for using your VPC
   Option 1: Create VPC endpoints
   Option 2: Create a proxy without VPC endpoints
   Option 3: Create a proxy with VPC endpoints
6.10.5.2. VPC validation
6.10.5.3. Division of permissions
6.10.5.4. Isolation between clusters
6.10.5.5. AWS security groups
6.10.6. Internet access for OpenShift Container Platform
6.10.7. Uploading a custom RH COS AMI in AWS
6.10.8. Generating a key pair for cluster node SSH access
6.10.9. Obtaining the installation program
6.10.10. Manually creating the installation configuration file
   6.10.10.1. Tested instance types for AWS
   6.10.10.2. Sample customized install-config.yaml file for AWS
6.10.10.3. Configuring the cluster-wide proxy during installation
6.10.10.4. Applying existing AWS security groups to the cluster
6.10.11. Installing the OpenShift CLI by downloading the binary
   Installing the OpenShift CLI on Linux
   Installing the OpenShift CLI on Windows
   Installing the OpenShift CLI on macOS
6.10.12. Alternatives to storing administrator-level secrets in the kube-system project
   6.10.12.1. Manually creating long-term credentials
6.10.12.2. Configuring an AWS cluster to use short-term credentials
   6.10.12.2.1. Configuring the Cloud Credential Operator utility
6.10.12.2.2. Creating AWS resources with the Cloud Credential Operator utility
   6.10.12.2.2.1. Creating AWS resources with a single command
   6.10.12.2.2.2. Creating AWS resources individually
6.10.12.2.3. Incorporating the Cloud Credential Operator utility manifests
6.10.13. Deploying the cluster
6.10.14. Logging in to the cluster by using the CLI
6.10.15. Logging in to the cluster by using the web console
6.10.16. Telemetry access for OpenShift Container Platform
6.10.17. Next steps

6.11. INSTALLING A CLUSTER ON AWS CHINA
6.11.1. Prerequisites
6.11.2. Installation requirements
6.11.3. Internet access for OpenShift Container Platform
6.11.4. Private clusters
   6.11.4.1. Private clusters in AWS
       6.11.4.1.1. Limitations
6.11.5. About using a custom VPC
   6.11.5.1. Requirements for using your VPC
       Option 1: Create VPC endpoints
       Option 2: Create a proxy without VPC endpoints
       Option 3: Create a proxy with VPC endpoints
   6.11.5.2. VPC validation
   6.11.5.3. Division of permissions
   6.11.5.4. Isolation between clusters
   6.11.5.5. AWS security groups
6.11.6. Generating a key pair for cluster node SSH access
6.11.7. Uploading a custom RHCOS AMI in AWS
6.11.8. Obtaining the installation program
6.11.9. Manually creating the installation configuration file
   6.11.9.1. Sample customized install-config.yaml file for AWS
   6.11.9.2. Minimum resource requirements for cluster installation
   6.11.9.3. Tested instance types for AWS
   6.11.9.4. Tested instance types for AWS on 64-bit ARM infrastructures
   6.11.9.5. Configuring the cluster-wide proxy during installation
   6.11.9.6. Applying existing AWS security groups to the cluster
6.11.10. Installing the OpenShift CLI by downloading the binary
   Installing the OpenShift CLI on Linux
   Installing the OpenShift CLI on Windows
   Installing the OpenShift CLI on macOS
6.11.11. Alternatives to storing administrator-level secrets in the kube-system project
   6.11.11.1. Manually creating long-term credentials
   6.11.11.2. Configuring an AWS cluster to use short-term credentials
       6.11.11.2.1. Configuring the Cloud Credential Operator utility
       6.11.11.2.2. Creating AWS resources with the Cloud Credential Operator utility
           6.11.11.2.2.1. Creating AWS resources with a single command
           6.11.11.2.2.2. Creating AWS resources individually
   6.11.11.2.3. Incorporating the Cloud Credential Operator utility manifests
6.11.12. Deploying the cluster
6.11.13. Logging in to the cluster by using the CLI
6.11.14. Logging in to the cluster by using the web console
6.11.15. Telemetry access for OpenShift Container Platform
6.11.16. Next steps
6.12. INSTALLING A CLUSTER ON USER-PROVISIONED INFRASTRUCTURE IN AWS BY USING CLOUDFORMATION TEMPLATES
   6.12.1. Prerequisites
   6.12.2. Internet access for OpenShift Container Platform
   6.12.3. Requirements for a cluster with user-provisioned infrastructure
       6.12.3.1. Required machines for cluster installation
       6.12.3.2. Minimum resource requirements for cluster installation
       6.12.3.3. Tested instance types for AWS
       6.12.3.4. Tested instance types for AWS on 64-bit ARM infrastructures
       6.12.3.5. Certificate signing requests management
   6.12.4. Required AWS infrastructure components
       6.12.4.1. Other infrastructure components
           Option 1: Create VPC endpoints
           Option 2: Create a proxy without VPC endpoints
### Option 3: Create a proxy with VPC endpoints

1. **Create a VPC in AWS**
   - CloudFormation template for the VPC
   - CloudFormation template for the network and load balancers

2. **Creating the worker nodes in AWS**
   - CloudFormation template for worker machines

3. **Creating the bootstrap node in AWS**
   - CloudFormation template for the bootstrap machine

4. **Initial Operator configuration**
   - Configuring registry storage for AWS with user-provisioned infrastructure
   - Configuring storage for the image registry in non-production clusters

5. **Deleting the bootstrap resources**

6. **Creating the Ingress DNS Records**

7. **Completing an AWS installation on user-provisioned infrastructure**

8. **Telemetry access for OpenShift Container Platform**

9. **Additional resources**

10. **Next steps**

### 6.13. INSTALLING A CLUSTER ON AWS WITH WORKER NODES ON AWS LOCAL ZONES

1. **Prerequisites**

2. **Cluster limitations in AWS Local Zones**

3. **Internet access for OpenShift Container Platform**

4. **Obtaining an AWS Marketplace image**

5. **Installing the OpenShift CLI by downloading the binary**
   - Installing the OpenShift CLI on Linux
   - Installing the OpenShift CLI on Windows
   - Installing the OpenShift CLI on macOS

6. **Logging in to the cluster by using the CLI**

7. **Approving the certificate signing requests for your machines**

8. **Initial Operator configuration**
   - Configuring registry storage for AWS with user-provisioned infrastructure
   - Configuring storage for the image registry in non-production clusters

9. **Deleting the bootstrap resources**

10. **Creating the Ingress DNS Records**

11. **Completing an AWS installation on user-provisioned infrastructure**

12. **Telemetry access for OpenShift Container Platform**

13. **Additional resources**

14. **Next steps**
6.14.9. Creating a VPC in AWS
   6.14.9.1. CloudFormation template for the VPC
6.14.10. Creating networking and load balancing components in AWS
   6.14.10.1. CloudFormation template for the network and load balancers
6.14.11. Creating security group and roles in AWS
   6.14.11.1. CloudFormation template for security objects
6.14.13. RHCOS AMIs for the AWS infrastructure
6.14.15. Creating the control plane machines in AWS
   6.14.15.1. CloudFormation template for control plane machines
6.14.17. Initializing the bootstrap sequence on AWS with user-provisioned infrastructure
6.14.18. Logging in to the cluster by using the CLI
6.14.19. Approving the certificate signing requests for your machines
6.14.20. Initial Operator configuration
   6.14.20.1. Disabling the default OperatorHub catalog sources
   6.14.20.2. Image registry storage configuration
      6.14.20.2.1. Configuring registry storage for AWS with user-provisioned infrastructure
      6.14.20.2.2. Configuring storage for the image registry in non-production clusters
6.14.21. Deleting the bootstrap resources
6.14.23. Completing an AWS installation on user-provisioned infrastructure
6.14.24. Logging in to the cluster by using the web console
6.14.25. Telemetry access for OpenShift Container Platform
6.14.27. Next steps
6.15. INSTALLING A CLUSTER ON AWS WITH REMOTE WORKERS ON AWS OUTPOSTS
6.15.1. Prerequisites
6.15.2. About using a custom VPC
   6.15.2.1. Requirements for using your VPC
      Option 1: Create VPC endpoints
      Option 2: Create a proxy without VPC endpoints
      Option 3: Create a proxy with VPC endpoints
   6.15.2.2. VPC validation
6.15.2.3. Division of permissions
6.15.2.4. Isolation between clusters
6.15.2.5. AWS security groups
6.15.3. Internet access for OpenShift Container Platform
6.15.4. Generating a key pair for cluster node SSH access
6.15.5. Obtaining the installation program
6.15.6. Minimum resource requirements for cluster installation
6.15.7. Identifying your AWS Outposts instance types
6.15.8. Creating the installation configuration file
   6.15.8.1. Sample customized install-config.yaml file for AWS
   6.15.8.2. Applying existing AWS security groups to the cluster
6.15.9. Generating manifest files
   6.15.9.1. Modifying manifest files
6.15.10. Installing the OpenShift CLI by downloading the binary
   Installing the OpenShift CLI on Linux
   Installing the OpenShift CLI on Windows
Installing the OpenShift CLI on macOS 840
6.15.11. Alternatives to storing administrator-level secrets in the kube-system project 840
6.15.11.1. Manually creating long-term credentials 841
6.15.11.2. Configuring an AWS cluster to use short-term credentials 843
6.15.11.2.1. Configuring the Cloud Credential Operator utility 843
6.15.11.2.2. Creating AWS resources with the Cloud Credential Operator utility 846
6.15.11.2.2.1. Creating AWS resources with a single command 846
6.15.11.2.2.2. Creating AWS resources individually 848
6.15.11.2.3. Incorporating the Cloud Credential Operator utility manifests 851
6.15.12. Deploying the cluster 852
6.15.13. Logging in to the cluster by using the CLI 853
6.15.14. Logging in to the cluster by using the web console 854
6.15.15. Telemetry access for OpenShift Container Platform 855
6.15.16. Cluster Limitations 855
6.15.17. Next steps 856
6.16. INSTALLING A THREE-NODE CLUSTER ON AWS 856
6.16.1. Configuring a three-node cluster 856
6.16.2. Next steps 857
6.17. UNINSTALLING A CLUSTER ON AWS 858
6.17.1. Removing a cluster that uses installer-provisioned infrastructure 858
6.17.2. Deleting Amazon Web Services resources with the Cloud Credential Operator utility 858
6.17.3. Deleting a cluster with a configured AWS Local Zone infrastructure 859
6.18. INSTALLATION CONFIGURATION PARAMETERS FOR AWS 861
6.18.1. Available installation configuration parameters for AWS 861
6.18.1.1. Required configuration parameters 861
6.18.1.2. Network configuration parameters 862
6.18.1.3. Optional configuration parameters 864
6.18.1.4. Optional AWS configuration parameters 870

CHAPTER 7. INSTALLING ON AZURE .......................................................... 877
7.1. PREPARING TO INSTALL ON AZURE 877
7.1.1. Prerequisites 877
7.1.2. Requirements for installing OpenShift Container Platform on Azure 877
7.1.3. Choosing a method to install OpenShift Container Platform on Azure 877
7.1.3.1. Installing a cluster on installer-provisioned infrastructure 877
7.1.3.2. Installing a cluster on user-provisioned infrastructure 878
7.1.4. Next steps 878
7.2. CONFIGURING AN AZURE ACCOUNT 878
7.2.1. Azure account limits 878
7.2.2. Configuring a public DNS zone in Azure 881
7.2.3. Increasing Azure account limits 881
7.2.4. Recording the subscription and tenant IDs 882
7.2.5. Supported identities to access Azure resources 884
7.2.5.1. Required Azure roles 884
7.2.5.2. Required Azure permissions for installer-provisioned infrastructure 884
7.2.5.3. Using Azure managed identities 892
7.2.5.4. Creating a service principal 892
7.2.6. Supported Azure Marketplace regions 893
7.2.7. Supported Azure regions 894
Supported Azure public regions 894
Supported Azure Government regions 895
7.2.8. Next steps 895
7.3. ENABLING USER-MANAGED ENCRYPTION FOR AZURE 895
7.3.1. Preparing an Azure Disk Encryption Set
7.3.2. Next steps

7.4. INSTALLING A CLUSTER QUICKLY ON AZURE
7.4.1. Prerequisites
7.4.2. Internet access for OpenShift Container Platform
7.4.3. Generating a key pair for cluster node SSH access
7.4.4. Obtaining the installation program
7.4.5. Deploying the cluster
7.4.6. Installing the OpenShift CLI by downloading the binary
  Installing the OpenShift CLI on Linux
  Installing the OpenShift CLI on Windows
  Installing the OpenShift CLI on macOS
7.4.7. Logging in to the cluster by using the CLI
7.4.8. Telemetry access for OpenShift Container Platform
7.4.9. Next steps

7.5. INSTALLING A CLUSTER ON AZURE WITH CUSTOMIZATIONS
7.5.1. Prerequisites
7.5.2. Internet access for OpenShift Container Platform
7.5.3. Generating a key pair for cluster node SSH access
7.5.4. Using the Azure Marketplace offering
7.5.5. Obtaining the installation program
7.5.6. Configuring the user-defined tags for Azure
7.5.7. Querying user-defined tags for Azure
7.5.8. Creating the installation configuration file
  7.5.8.1. Minimum resource requirements for cluster installation
  7.5.8.2. Tested instance types for Azure
  7.5.8.3. Tested instance types for Azure on 64-bit ARM infrastructures
  7.5.8.4. Enabling trusted launch for Azure VMs
  7.5.8.5. Enabling confidential VMs
  7.5.8.6. Sample customized install-config.yaml file for Azure
  7.5.8.7. Configuring the cluster-wide proxy during installation
7.5.9. Installing the OpenShift CLI by downloading the binary
  Installing the OpenShift CLI on Linux
  Installing the OpenShift CLI on Windows
  Installing the OpenShift CLI on macOS
7.5.10. Alternatives to storing administrator-level secrets in the kube-system project
  7.5.10.1. Manually creating long-term credentials
  7.5.10.2. Configuring an Azure cluster to use short-term credentials
    7.5.10.2.1. Configuring the Cloud Credential Operator utility
    7.5.10.2.2. Creating Azure resources with the Cloud Credential Operator utility
    7.5.10.2.3. Incorporating the Cloud Credential Operator utility manifests
7.5.11. Deploying the cluster
7.5.12. Logging in to the cluster by using the CLI
7.5.13. Telemetry access for OpenShift Container Platform
7.5.14. Next steps

7.6. INSTALLING A CLUSTER ON AZURE WITH NETWORK CUSTOMIZATIONS
7.6.1. Prerequisites
7.6.2. Internet access for OpenShift Container Platform
7.6.3. Generating a key pair for cluster node SSH access
7.6.4. Obtaining the installation program
7.6.5. Creating the installation configuration file
  7.6.5.1. Minimum resource requirements for cluster installation
  7.6.5.2. Tested instance types for Azure
7.6.5.3. Tested instance types for Azure on 64-bit ARM infrastructures
7.6.5.4. Enabling trusted launch for Azure VMs
7.6.5.5. Enabling confidential VMs
7.6.5.6. Sample customized install-config.yaml file for Azure
7.6.5.7. Configuring the cluster-wide proxy during installation
7.6.6. Network configuration phases
7.6.7. Specifying advanced network configuration
7.6.8. Cluster Network Operator configuration
  7.6.8.1. Cluster Network Operator configuration object
    defaultNetwork object configuration
    Configuration for the OpenShift SDN network plugin
    Configuration for the OVN-Kubernetes network plugin
    kubeProxyConfig object configuration
7.6.9. Configuring hybrid networking with OVN-Kubernetes
7.6.10. Installing the OpenShift CLI by downloading the binary
  Installing the OpenShift CLI on Linux
  Installing the OpenShift CLI on Windows
  Installing the OpenShift CLI on macOS
7.6.11. Alternatives to storing administrator-level secrets in the kube-system project
  7.6.11.1. Manually creating long-term credentials
  7.6.11.2. Configuring an Azure cluster to use short-term credentials
    7.6.11.2.1. Configuring the Cloud Credential Operator utility
    7.6.11.2.2. Creating Azure resources with the Cloud Credential Operator utility
    7.6.11.2.3. Incorporating the Cloud Credential Operator utility manifests
7.6.12. Deploying the cluster
7.6.13. Logging in to the cluster by using the CLI
7.6.14. Telemetry access for OpenShift Container Platform
7.6.15. Next steps
7.7. INSTALLING A CLUSTER ON AZURE INTO AN EXISTING VNET
7.7.1. Prerequisites
  7.7.2. About reusing a VNet for your OpenShift Container Platform cluster
    7.7.2.1. Requirements for using your VNet
    7.7.2.1.1. Network security group requirements
    7.7.2.2. Division of permissions
    7.7.2.3. Isolation between clusters
  7.7.3. Internet access for OpenShift Container Platform
  7.7.4. Generating a key pair for cluster node SSH access
  7.7.5. Obtaining the installation program
  7.7.6. Creating the installation configuration file
    7.7.6.1. Minimum resource requirements for cluster installation
    7.7.6.2. Tested instance types for Azure
    7.7.6.3. Tested instance types for Azure on 64-bit ARM infrastructures
    7.7.6.4. Enabling trusted launch for Azure VMs
    7.7.6.5. Enabling confidential VMs
    7.7.6.6. Sample customized install-config.yaml file for Azure
    7.7.6.7. Configuring the cluster-wide proxy during installation
  7.7.7. Installing the OpenShift CLI by downloading the binary
    Installing the OpenShift CLI on Linux
    Installing the OpenShift CLI on Windows
    Installing the OpenShift CLI on macOS
  7.7.8. Alternatives to storing administrator-level secrets in the kube-system project
    7.7.8.1. Manually creating long-term credentials
    7.7.8.2. Configuring an Azure cluster to use short-term credentials
7.9.4. About reusing a VNet for your OpenShift Container Platform cluster

7.9.4.1. Requirements for using your VNet
7.9.4.1.1. Network security group requirements
7.9.4.2. Division of permissions
7.9.4.3. Isolation between clusters
7.9.5. Internet access for OpenShift Container Platform
7.9.6. Generating a key pair for cluster node SSH access
7.9.7. Obtaining the installation program
7.9.8. Manually creating the installation configuration file
7.9.8.1. Minimum resource requirements for cluster installation
7.9.8.2. Tested instance types for Azure
7.9.8.3. Enabling trusted launch for Azure VMs
7.9.8.4. Enabling confidential VMs
7.9.8.5. Sample customized install-config.yaml file for Azure
7.9.8.6. Configuring the cluster-wide proxy during installation
7.9.9. Deploying the cluster
7.9.10. Installing the OpenShift CLI by downloading the binary
7.9.11. Logging in to the cluster by using the CLI
7.9.12. Telemetry access for OpenShift Container Platform
7.9.13. Next steps

7.10. INSTALLING A CLUSTER ON AZURE IN A RESTRICTED NETWORK WITH USER-PROVISIONED INFRASTRUCTURE

7.10.1. About installations in restricted networks
7.10.1.1. Additional limits
7.10.1.2. Internet access for OpenShift Container Platform
7.10.2. Configuring your Azure project
7.10.2.1. Azure account limits
7.10.2.2. Configuring a public DNS zone in Azure
7.10.2.3. Increasing Azure account limits
7.10.2.4. Certificate signing requests management
7.10.2.5. Required Azure roles
7.10.2.6. Required Azure permissions for user-provisioned infrastructure
7.10.2.7. Creating a service principal
7.10.2.8. Supported Azure regions
7.10.2.9. Supported Azure public regions
7.10.3. Requirements for a cluster with user-provisioned infrastructure
7.10.3.1. Required machines for cluster installation
7.10.3.2. Minimum resource requirements for cluster installation
7.10.3.3. Tested instance types for Azure
7.10.3.4. Tested instance types for Azure on 64-bit ARM infrastructures
7.10.4. Using the Azure Marketplace offering
7.10.4.1. Obtaining the installation program
7.10.4.2. Generating a key pair for cluster node SSH access
7.10.5. Creating the installation files for Azure
7.10.5.1. Optional: Creating a separate /var partition
7.10.5.2. Creating the installation configuration file
7.10.5.3. Configuring the cluster-wide proxy during installation
7.10.5.4. Exporting common variables for ARM templates
7.10.5.5. Creating the Kubernetes manifest and Ignition config files
7.10.6. Creating the Azure resource group
7.10.7. Uploading the RH COS cluster image and bootstrap Ignition config file
7.10.8. Example for creating DNS zones
7.10.9. Creating a VNet in Azure
  7.10.9.1. ARM template for the VNet
7.10.10. Deploying the RH COS cluster image for the Azure infrastructure
  7.10.10.1. ARM template for image storage
7.10.11. Networking requirements for user-provisioned infrastructure
  7.10.11.1. Network connectivity requirements
7.10.12. Creating networking and load balancing components in Azure
  7.10.12.1. ARM template for the network and load balancers
7.10.13. Creating the bootstrap machine in Azure
  7.10.13.1. ARM template for the bootstrap machine
7.10.14. Creating the control plane machines in Azure
  7.10.14.1. ARM template for control plane machines
7.10.15. Wait for bootstrap completion and remove bootstrap resources in Azure
7.10.16. Creating additional worker machines in Azure
  7.10.16.1. ARM template for worker machines
7.10.17. Installing the OpenShift CLI by downloading the binary
  Installing the OpenShift CLI on Linux
  Installing the OpenShift CLI on Windows
  Installing the OpenShift CLI on macOS
7.10.18. Logging in to the cluster by using the CLI
7.10.19. Approving the certificate signing requests for your machines
7.10.20. Adding the Ingress DNS records
7.10.21. Completing an Azure installation on user-provisioned infrastructure
7.10.22. Telemetry access for OpenShift Container Platform

7.11. INSTALLING A CLUSTER ON AZURE USING ARM TEMPLATES
7.11.1. Prerequisites
7.11.2. Internet access for OpenShift Container Platform
7.11.3. Configuring your Azure project
  7.11.3.1. Azure account limits
  7.11.3.2. Configuring a public DNS zone in Azure
  7.11.3.3. Increasing Azure account limits
  7.11.3.4. Certificate signing requests management
  7.11.3.5. Recording the subscription and tenant IDs
  7.11.3.6. Supported identities to access Azure resources
  7.11.3.7. Required Azure permissions for user-provisioned infrastructure
  7.11.3.8. Using Azure managed identities
  7.11.3.9. Creating a service principal
  7.11.3.10. Supported Azure regions
    Supported Azure public regions
    Supported Azure Government regions
  7.11.4. Requirements for a cluster with user-provisioned infrastructure
  7.11.4.1. Required machines for cluster installation
  7.11.4.2. Minimum resource requirements for cluster installation
  7.11.4.3. Tested instance types for Azure
  7.11.4.4. Tested instance types for Azure on 64-bit ARM infrastructures
  7.11.5. Using the Azure Marketplace offering
  7.11.6. Obtaining the installation program
  7.11.7. Generating a key pair for cluster node SSH access
  7.11.8. Creating the installation files for Azure
    7.11.8.1. Optional: Creating a separate /var partition
7.11.8.2. Creating the installation configuration file
7.11.8.3. Configuring the cluster-wide proxy during installation
7.11.8.4. Exporting common variables for ARM templates
7.11.8.5. Creating the Kubernetes manifest and Ignition config files
7.11.9. Creating the Azure resource group
7.11.10. Uploading the RHCOS cluster image and bootstrap Ignition config file
7.11.11. Example for creating DNS zones
7.11.12. Creating a VNet in Azure
7.11.12.1. ARM template for the VNet
7.11.13. Deploying the RHCOS cluster image for the Azure infrastructure
7.11.13.1. ARM template for image storage
7.11.14. Networking requirements for user-provisioned infrastructure
7.11.14.1. Network connectivity requirements
7.11.15. Creating networking and load balancing components in Azure
7.11.15.1. ARM template for the network and load balancers
7.11.16. Creating the bootstrap machine in Azure
7.11.16.1. ARM template for the bootstrap machine
7.11.17. Creating the control plane machines in Azure
7.11.17.1. ARM template for control plane machines
7.11.18. Wait for bootstrap completion and remove bootstrap resources in Azure
7.11.19. Creating additional worker machines in Azure
7.11.19.1. ARM template for worker machines
7.11.20. Installing the OpenShift CLI by downloading the binary
    - Installing the OpenShift CLI on Linux
    - Installing the OpenShift CLI on Windows
    - Installing the OpenShift CLI on macOS
7.11.21. Logging in to the cluster by using the CLI
7.11.22. Approving the certificate signing requests for your machines
7.11.23. Adding the Ingress DNS records
7.11.24. Completing an Azure installation on user-provisioned infrastructure
7.11.25. Telemetry access for OpenShift Container Platform

7.12. INSTALLING A CLUSTER ON AZURE IN A RESTRICTED NETWORK
7.12.1. Prerequisites
    - About installations in restricted networks
    - Additional limits
    - User-defined outbound routing
      - Restricted cluster with Azure Firewall
7.12.2. About reusing a VNet for your OpenShift Container Platform cluster
    - Requirements for using your VNet
    - Network security group requirements
    - Division of permissions
    - Isolation between clusters
7.12.4. Internet access for OpenShift Container Platform
7.12.5. Generating a key pair for cluster node SSH access
7.12.6. Creating the installation configuration file
    - Minimum resource requirements for cluster installation
    - Tested instance types for Azure
    - Tested instance types for Azure on 64-bit ARM infrastructures
    - Enabling trusted launch for Azure VMs
    - Enabling confidential VMs
    - Sample customized install-config.yaml file for Azure
    - Configuring the cluster-wide proxy during installation
    - Installing the OpenShift CLI by downloading the binary
Installing the OpenShift CLI on Linux 1231
Installing the OpenShift CLI on Windows 1231
Installing the OpenShift CLI on macOS 1232

7.12.8. Alternatives to storing administrator-level secrets in the kube-system project 1232
  7.12.8.1. Manually creating long-term credentials 1232
  7.12.8.2. Configuring an Azure cluster to use short-term credentials 1235
  7.12.8.2.1. Configuring the Cloud Credential Operator utility 1235
  7.12.8.2.2. Creating Azure resources with the Cloud Credential Operator utility 1237
  7.12.8.2.3. Incorporating the Cloud Credential Operator utility manifests 1239

7.12.9. Deploying the cluster 1240
7.12.10. Logging in to the cluster by using the CLI 1242
7.12.11. Telemetry access for OpenShift Container Platform 1242
7.12.12. Next steps 1243

7.13. INSTALLING A THREE-NODE CLUSTER ON AZURE 1243
  7.13.1. Configuring a three-node cluster 1243
  7.13.2. Next steps 1244

7.14. UNINSTALLING A CLUSTER ON AZURE 1244
  7.14.1. Removing a cluster that uses installer-provisioned infrastructure 1244
  7.14.2. Deleting Microsoft Azure resources with the Cloud Credential Operator utility 1245

7.15. INSTALLATION CONFIGURATION PARAMETERS FOR AZURE 1246
  7.15.1. Available installation configuration parameters for Azure 1246
  7.15.1.1. Required configuration parameters 1246
  7.15.1.2. Network configuration parameters 1247
  7.15.1.3. Optional configuration parameters 1249
  7.15.1.4. Additional Azure configuration parameters 1255

CHAPTER 8. INSTALLING ON AZURE STACK HUB 1272

8.1. PREPARING TO INSTALL ON AZURE STACK HUB 1272
  8.1.1. Prerequisites 1272
  8.1.2. Requirements for installing OpenShift Container Platform on Azure Stack Hub 1272
  8.1.3. Choosing a method to install OpenShift Container Platform on Azure Stack Hub 1272
    8.1.3.1. Installing a cluster on installer-provisioned infrastructure 1272
    8.1.3.2. Installing a cluster on user-provisioned infrastructure 1272
  8.1.4. Next steps 1272

8.2. CONFIGURING AN AZURE STACK HUB ACCOUNT 1273
  8.2.1. Azure Stack Hub account limits 1273
  8.2.2. Configuring a DNS zone in Azure Stack Hub 1274
  8.2.3. Required Azure Stack Hub roles 1275
  8.2.4. Creating a service principal 1275
  8.2.5. Next steps 1277

8.3. INSTALLING A CLUSTER ON AZURE STACK HUB WITH AN INSTALLER-PROVISIONED INFRASTRUCTURE 1278
  8.3.1. Prerequisites 1278
  8.3.2. Internet access for OpenShift Container Platform 1278
  8.3.3. Generating a key pair for cluster node SSH access 1279
  8.3.4. Uploading the RHCOS cluster image 1280
  8.3.5. Obtaining the installation program 1281
  8.3.6. Manually creating the installation configuration file 1282
    8.3.6.1. Sample customized install-config.yaml file for Azure Stack Hub 1283
  8.3.7. Manually manage cloud credentials 1285
  8.3.8. Configuring the cluster to use an internal CA 1287
  8.3.9. Deploying the cluster 1287
  8.3.10. Installing the OpenShift CLI by downloading the binary 1289
Installing the OpenShift CLI on Linux 1289
Installing the OpenShift CLI on Windows 1290
Installing the OpenShift CLI on macOS 1290
8.3.11. Logging in to the cluster by using the CLI 1291
8.3.12. Logging in to the cluster by using the web console 1291
8.3.13. Telemetry access for OpenShift Container Platform 1292
8.3.14. Next steps 1292

8.4. INSTALLING A CLUSTER ON AZURE STACK HUB WITH NETWORK CUSTOMIZATIONS 1293
  8.4.1. Prerequisites 1293
  8.4.2. Internet access for OpenShift Container Platform 1293
  8.4.3. Generating a key pair for cluster node SSH access 1294
  8.4.4. Uploading the RHCOS cluster image 1295
  8.4.5. Obtaining the installation program 1296
  8.4.6. Manually creating the installation configuration file 1297
    8.4.6.1. Sample customized install-config.yaml file for Azure Stack Hub 1298
  8.4.7. Manually manage cloud credentials 1300
  8.4.8. Configuring the cluster to use an internal CA 1302
  8.4.9. Network configuration phases 1302
  8.4.10. Specifying advanced network configuration 1303
  8.4.11. Cluster Network Operator configuration 1304
    8.4.11.1. Cluster Network Operator configuration object 1305
      defaultNetwork object configuration 1306
      Configuration for the OpenShift SDN network plugin 1306
      Configuration for the OVN-Kubernetes network plugin 1307
      kubeProxyConfig object configuration 1312
  8.4.12. Configuring hybrid networking with OVN-Kubernetes 1312
  8.4.13. Deploying the cluster 1314
  8.4.14. Installing the OpenShift CLI by downloading the binary 1315
    Installing the OpenShift CLI on Linux 1315
    Installing the OpenShift CLI on Windows 1316
    Installing the OpenShift CLI on macOS 1316
  8.4.15. Logging in to the cluster by using the CLI 1317
  8.4.16. Logging in to the cluster by using the web console 1318
  8.4.17. Telemetry access for OpenShift Container Platform 1318
  8.4.18. Next steps 1319

8.5. INSTALLING A CLUSTER ON AZURE STACK HUB USING ARM TEMPLATES 1319
  8.5.1. Prerequisites 1319
  8.5.2. Internet access for OpenShift Container Platform 1320
  8.5.3. Configuring your Azure Stack Hub project 1320
    8.5.3.1. Azure Stack Hub account limits 1320
    8.5.3.2. Configuring a DNS zone in Azure Stack Hub 1322
    8.5.3.3. Certificate signing requests management 1322
    8.5.3.4. Required Azure Stack Hub roles 1322
    8.5.3.5. Creating a service principal 1323
  8.5.4. Obtaining the installation program 1325
  8.5.5. Generating a key pair for cluster node SSH access 1326
  8.5.6. Creating the installation files for Azure Stack Hub 1328
    8.5.6.1. Manually creating the installation configuration file 1328
    8.5.6.2. Sample customized install-config.yaml file for Azure Stack Hub 1330
    8.5.6.3. Configuring the cluster-wide proxy during installation 1332
    8.5.6.4. Exporting common variables for ARM templates 1333
    8.5.6.5. Creating the Kubernetes manifest and Ignition config files 1334
    8.5.6.6. Optional: Creating a separate /var partition 1339
8.5.7. Creating the Azure resource group
8.5.8. Uploading the RHCOS cluster image and bootstrap Ignition config file
8.5.9. Example for creating DNS zones
8.5.10. Creating a VNet in Azure Stack Hub
  8.5.10.1. ARM template for the VNet
8.5.11. Deploying the RHCOS cluster image for the Azure Stack Hub infrastructure
  8.5.11.1. ARM template for image storage
8.5.12. Networking requirements for user-provisioned infrastructure
  8.5.12.1. Network connectivity requirements
8.5.13. Creating networking and load balancing components in Azure Stack Hub
  8.5.13.1. ARM template for the network and load balancers
8.5.14. Creating the bootstrap machine in Azure Stack Hub
  8.5.14.1. ARM template for the bootstrap machine
8.5.15. Creating the control plane machines in Azure Stack Hub
  8.5.15.1. ARM template for control plane machines
8.5.16. Wait for bootstrap completion and remove bootstrap resources in Azure Stack Hub
8.5.17. Creating additional worker machines in Azure Stack Hub
  8.5.17.1. ARM template for worker machines
8.5.18. Installing the OpenShift CLI by downloading the binary
  Installing the OpenShift CLI on Linux
  Installing the OpenShift CLI on Windows
  Installing the OpenShift CLI on macOS
8.5.19. Logging in to the cluster by using the CLI
8.5.20. Approving the certificate signing requests for your machines
8.5.21. Adding the Ingress DNS records
8.5.22. Completing an Azure Stack Hub installation on user-provisioned infrastructure

8.6. INSTALLATION CONFIGURATION PARAMETERS FOR AZURE STACK HUB
  8.6.1. Available installation configuration parameters for Azure Stack Hub
    8.6.1.1. Required configuration parameters
    8.6.1.2. Network configuration parameters
    8.6.1.3. Optional configuration parameters
    8.6.1.4. Additional Azure Stack Hub configuration parameters
8.7. UNINSTALLING A CLUSTER ON AZURE STACK HUB
  8.7.1. Removing a cluster that uses installer-provisioned infrastructure

CHAPTER 9. INSTALLING ON GCP

9.1. PREPARING TO INSTALL ON GCP
  9.1.1. Prerequisites
  9.1.2. Requirements for installing OpenShift Container Platform on GCP
  9.1.3. Choosing a method to install OpenShift Container Platform on GCP
    9.1.3.1. Installing a cluster on installer-provisioned infrastructure
    9.1.3.2. Installing a cluster on user-provisioned infrastructure
  9.1.4. Next steps
9.2. CONFIGURING A GCP PROJECT
  9.2.1. Creating a GCP project
  9.2.2. Enabling API services in GCP
  9.2.3. Configuring DNS for GCP
  9.2.4. GCP account limits
  9.2.5. Creating a service account in GCP
    9.2.5.1. Required GCP roles
    9.2.5.2. Required GCP permissions for installer-provisioned infrastructure
    9.2.5.3. Required GCP permissions for shared VPC installations
  9.2.6. Supported GCP regions
9.3. INSTALLING A CLUSTER QUICKLY ON GCP

9.3.1. Prerequisites
9.3.2. Internet access for OpenShift Container Platform
9.3.3. Generating a key pair for cluster node SSH access
9.3.4. Obtaining the installation program
9.3.5. Deploying the cluster
9.3.6. Installing the OpenShift CLI by downloading the binary
   Installing the OpenShift CLI on Linux
   Installing the OpenShift CLI on Windows
   Installing the OpenShift CLI on macOS
9.3.7. Logging in to the cluster by using the CLI
9.3.8. Telemetry access for OpenShift Container Platform
9.3.9. Next steps

9.4. INSTALLING A CLUSTER ON GCP WITH CUSTOMIZATIONS

9.4.1. Prerequisites
9.4.2. Internet access for OpenShift Container Platform
9.4.3. Generating a key pair for cluster node SSH access
9.4.4. Obtaining the installation program
9.4.5. Managing user-defined labels and tags for GCP
   9.4.5.1. Configuring user-defined labels and tags for GCP
   9.4.5.2. Querying user-defined labels and tags for GCP
9.4.6. Creating the installation configuration file
   9.4.6.1. Minimum resource requirements for cluster installation
   9.4.6.2. Tested instance types for GCP
   9.4.6.3. Tested instance types for GCP on 64-bit ARM infrastructures
   9.4.6.4. Using custom machine types
   9.4.6.5. Enabling Shielded VMs
   9.4.6.6. Enabling Confidential VMs
   9.4.6.7. Sample customized install-config.yaml file for GCP
   9.4.6.8. Configuring the cluster-wide proxy during installation
9.4.7. Installing the OpenShift CLI by downloading the binary
   Installing the OpenShift CLI on Linux
   Installing the OpenShift CLI on Windows
   Installing the OpenShift CLI on macOS
9.4.8. Alternatives to storing administrator-level secrets in the kube-system project
   9.4.8.1. Manually creating long-term credentials
   9.4.8.2. Configuring a GCP cluster to use short-term credentials
      9.4.8.2.1. Configuring the Cloud Credential Operator utility
      9.4.8.2.2. Creating GCP resources with the Cloud Credential Operator utility
      9.4.8.2.3. Incorporating the Cloud Credential Operator utility manifests
9.4.9. Using the GCP Marketplace offering
9.4.10. Deploying the cluster
9.4.11. Logging in to the cluster by using the CLI
9.4.12. Telemetry access for OpenShift Container Platform
9.4.13. Next steps

9.5. INSTALLING A CLUSTER ON GCP WITH NETWORK CUSTOMIZATIONS

9.5.1. Prerequisites
9.5.2. Internet access for OpenShift Container Platform
9.5.3. Generating a key pair for cluster node SSH access
9.5.4. Obtaining the installation program
9.5.5. Creating the installation configuration file
   9.5.5.1. Minimum resource requirements for cluster installation
9.7. INSTALLING A CLUSTER ON GCP INTO AN EXISTING VPC
9.7.1. Prerequisites
9.7.2. About using a custom VPC
  9.7.2.1. Requirements for using your VPC
  9.7.2.2. VPC validation
  9.7.2.3. Division of permissions
  9.7.2.4. Isolation between clusters
9.7.3. Internet access for OpenShift Container Platform
9.7.4. Generating a key pair for cluster node SSH access
9.7.5. Obtaining the installation program
9.7.6. Creating the installation configuration file
  9.7.6.1. Minimum resource requirements for cluster installation
  9.7.6.2. Tested instance types for GCP
  9.7.6.3. Tested instance types for GCP on 64-bit ARM infrastructures
  9.7.6.4. Using custom machine types
  9.7.6.5. Enabling Shielded VMs
  9.7.6.6. Enabling Confidential VMs
  9.7.6.7. Sample customized install-config.yaml file for GCP
  9.7.6.8. Create an Ingress Controller with global access on GCP
9.7.7. Additional resources
  9.7.7.1. Configuring the cluster-wide proxy during installation
9.7.8. Installing the OpenShift CLI by downloading the binary
  Installing the OpenShift CLI on Linux
  Installing the OpenShift CLI on Windows
  Installing the OpenShift CLI on macOS
9.7.9. Alternatives to storing administrator-level secrets in the kube-system project
  9.7.9.1. Manually creating long-term credentials
  9.7.9.2. Configuring a GCP cluster to use short-term credentials
    9.7.9.2.1. Configuring the Cloud Credential Operator utility
    9.7.9.2.2. Creating GCP resources with the Cloud Credential Operator utility
    9.7.9.2.3. Incorporating the Cloud Credential Operator utility manifests
9.7.10. Deploying the cluster
9.7.11. Logging in to the cluster by using the CLI
9.7.12. Telemetry access for OpenShift Container Platform
9.7.13. Next steps
9.8. INSTALLING A CLUSTER ON GCP INTO A SHARED VPC
9.8.1. Prerequisites
9.8.2. Internet access for OpenShift Container Platform
9.8.3. Generating a key pair for cluster node SSH access
9.8.4. Obtaining the installation program
9.8.5. Creating the installation files for GCP
  9.8.5.1. Manually creating the installation configuration file
  9.8.5.2. Enabling Shielded VMs
  9.8.5.3. Enabling Confidential VMs
  9.8.5.4. Sample customized install-config.yaml file for shared VPC installation
9.10.1. Prerequisites
9.10.2. Certificate signing requests management
9.10.3. Internet access for OpenShift Container Platform
9.10.4. Configuring your GCP project
  9.10.4.1. Creating a GCP project
  9.10.4.2. Enabling API services in GCP
  9.10.4.3. Configuring DNS for GCP
  9.10.4.4. GCP account limits
  9.10.4.5. Creating a service account in GCP
  9.10.4.6. Required GCP roles
  9.10.4.7. Required GCP permissions for user-provisioned infrastructure
  9.10.4.8. Supported GCP regions
  9.10.4.9. Installing and configuring CLI tools for GCP
9.10.5. Requirements for a cluster with user-provisioned infrastructure
  9.10.5.1. Required machines for cluster installation
  9.10.5.2. Minimum resource requirements for cluster installation
  9.10.5.3. Tested instance types for GCP
  9.10.5.4. Using custom machine types
9.10.6. Creating the installation files for GCP
  9.10.6.1. Optional: Creating a separate /var partition
  9.10.6.2. Creating the installation configuration file
  9.10.6.3. Enabling Shielded VMs
  9.10.6.4. Enabling Confidential VMs
  9.10.6.5. Configuring the cluster-wide proxy during installation
  9.10.6.6. Creating the Kubernetes manifest and Ignition config files
9.10.7. Exporting common variables
  9.10.7.1. Extracting the infrastructure name
  9.10.7.2. Exporting common variables for Deployment Manager templates
9.10.8. Creating a VPC in GCP
  9.10.8.1. Deployment Manager template for the VPC
9.10.9. Networking requirements for user-provisioned infrastructure
  9.10.9.1. Setting the cluster node hostnames through DHCP
  9.10.9.2. Network connectivity requirements
9.10.10. Creating load balancers in GCP
  9.10.10.1. Deployment Manager template for the external load balancer
  9.10.10.2. Deployment Manager template for the internal load balancer
9.10.11. Creating a private DNS zone in GCP
  9.10.11.1. Deployment Manager template for the private DNS
9.10.12. Creating firewall rules in GCP
  9.10.12.1. Deployment Manager template for firewall rules
9.10.13. Creating IAM roles in GCP
  9.10.13.1. Deployment Manager template for IAM roles
9.10.14. Creating the RHCOS cluster image for the GCP infrastructure
9.10.15. Creating the bootstrap machine in GCP
  9.10.15.1. Deployment Manager template for the bootstrap machine
9.10.16. Creating the control plane machines in GCP
  9.10.16.1. Deployment Manager template for control plane machines
9.10.17. Wait for bootstrap completion and remove bootstrap resources in GCP
9.10.18. Creating additional worker machines in GCP
  9.10.18.1. Deployment Manager template for worker machines
9.10.19. Installing the OpenShift CLI by downloading the binary
  Installing the OpenShift CLI on Linux
Installing the OpenShift CLI on Windows
Installing the OpenShift CLI on macOS
9.10.20. Logging in to the cluster by using the CLI
9.10.21. Approving the certificate signing requests for your machines
9.10.22. Optional: Adding the ingress DNS records
9.10.23. Completing a GCP installation on user-provisioned infrastructure
9.10.24. Telemetry access for OpenShift Container Platform
9.10.25. Next steps

9.11. INSTALLING A CLUSTER INTO A SHARED VPC ON GCP USING DEPLOYMENT MANAGER TEMPLATES

9.11.1. Prerequisites
9.11.2. Certificate signing requests management
9.11.3. Internet access for OpenShift Container Platform
9.11.4. Configuring the GCP project that hosts your cluster
  9.11.4.1. Creating a GCP project
  9.11.4.2. Enabling API services in GCP
  9.11.4.3. GCP account limits
  9.11.4.4. Creating a service account in GCP
    9.11.4.4.1. Required GCP roles
  9.11.4.5. Supported GCP regions
  9.11.4.6. Installing and configuring CLI tools for GCP
9.11.5. Requirements for a cluster with user-provisioned infrastructure
  9.11.5.1. Required machines for cluster installation
  9.11.5.2. Minimum resource requirements for cluster installation
  9.11.5.3. Tested instance types for GCP
  9.11.5.4. Using custom machine types
9.11.6. Configuring the GCP project that hosts your shared VPC network
  9.11.6.1. Configuring DNS for GCP
  9.11.6.2. Creating a VPC in GCP
    9.11.6.2.1. Deployment Manager template for the VPC
9.11.7. Creating the installation files for GCP
  9.11.7.1. Manually creating the installation configuration file
  9.11.7.2. Enabling Shielded VMs
  9.11.7.3. Enabling Confidential VMs
  9.11.7.4. Sample customized install-config.yaml file for GCP
  9.11.7.5. Configuring the cluster-wide proxy during installation
  9.11.7.6. Creating the Kubernetes manifest and Ignition config files
9.11.8. Exporting common variables
  9.11.8.1. Extracting the infrastructure name
  9.11.8.2. Exporting common variables for Deployment Manager templates
9.11.9. Networking requirements for user-provisioned infrastructure
  9.11.9.1. Setting the cluster node hostnames through DHCP
  9.11.9.2. Network connectivity requirements
9.11.10. Creating load balancers in GCP
  9.11.10.1. Deployment Manager template for the external load balancer
  9.11.10.2. Deployment Manager template for the internal load balancer
9.11.11. Creating a private DNS zone in GCP
  9.11.11.1. Deployment Manager template for the private DNS
9.11.12. Creating firewall rules in GCP
  9.11.12.1. Deployment Manager template for firewall rules
9.11.13. Creating IAM roles in GCP
  9.11.13.1. Deployment Manager template for IAM roles
9.11.14. Creating the RHCOS cluster image for the GCP infrastructure
9.11.15. Creating the bootstrap machine in GCP
9.11.15.1. Deployment Manager template for the bootstrap machine
9.11.16. Creating the control plane machines in GCP
9.11.16.1. Deployment Manager template for control plane machines
9.11.17. Wait for bootstrap completion and remove bootstrap resources in GCP
9.11.18. Creating additional worker machines in GCP
9.11.18.1. Deployment Manager template for worker machines
9.11.19. Installing the OpenShift CLI by downloading the binary
   Installing the OpenShift CLI on Linux
   Installing the OpenShift CLI on Windows
   Installing the OpenShift CLI on macOS
9.11.20. Logging in to the cluster by using the CLI
9.11.21. Approving the certificate signing requests for your machines
9.11.22. Adding the ingress DNS records
9.11.23. Adding ingress firewall rules
   9.11.23.1. Creating cluster-wide firewall rules for a shared VPC in GCP
9.11.24. Completing a GCP installation on user-provisioned infrastructure
9.11.25. Telemetry access for OpenShift Container Platform
9.11.26. Next steps

9.12. INSTALLING A CLUSTER ON GCP IN A RESTRICTED NETWORK WITH USER-PROVISIONED INFRASTRUCTURE
9.12.1. Prerequisites
9.12.2. About installations in restricted networks
   9.12.2.1. Additional limits
9.12.3. Internet access for OpenShift Container Platform
9.12.4. Configuring your GCP project
   9.12.4.1. Creating a GCP project
   9.12.4.2. Enabling API services in GCP
   9.12.4.3. Configuring DNS for GCP
   9.12.4.4. GCP account limits
   9.12.4.5. Creating a service account in GCP
   9.12.4.6. Required GCP roles
   9.12.4.7. Required GCP permissions for user-provisioned infrastructure
   9.12.4.8. Supported GCP regions
   9.12.4.9. Installing and configuring CLI tools for GCP
9.12.5. Requirements for a cluster with user-provisioned infrastructure
   9.12.5.1. Required machines for cluster installation
   9.12.5.2. Minimum resource requirements for cluster installation
   9.12.5.3. Tested instance types for GCP
   9.12.5.4. Using custom machine types
9.12.6. Creating the installation files for GCP
   9.12.6.1. Optional: Creating a separate /var partition
   9.12.6.2. Creating the installation configuration file
   9.12.6.3. Enabling Shielded VMs
   9.12.6.4. Enabling Confidential VMs
   9.12.6.5. Configuring the cluster–wide proxy during installation
   9.12.6.6. Creating the Kubernetes manifest and Ignition config files
9.12.7. Exporting common variables
   9.12.7.1. Extracting the infrastructure name
   9.12.7.2. Exporting common variables for Deployment Manager templates
9.12.8. Creating a VPC in GCP
9.12.8.1. Deployment Manager template for the VPC
9.12.9. Networking requirements for user-provisioned infrastructure
9.12.9.1. Setting the cluster node hostnames through DHCP
9.12.9.2. Network connectivity requirements
9.12.10. Creating load balancers in GCP
  9.12.10.1. Deployment Manager template for the external load balancer
  9.12.10.2. Deployment Manager template for the internal load balancer
9.12.11. Creating a private DNS zone in GCP
  9.12.11.1. Deployment Manager template for the private DNS
  9.12.12.1. Deployment Manager template for firewall rules
  9.12.13. Creating IAM roles in GCP
  9.12.13.1. Deployment Manager template for IAM roles
9.12.15. Creating the bootstrap machine in GCP
  9.12.15.1. Deployment Manager template for the bootstrap machine
9.12.16. Creating the control plane machines in GCP
  9.12.16.1. Deployment Manager template for control plane machines
9.12.17. Wait for bootstrap completion and remove bootstrap resources in GCP
9.12.18. Creating additional worker machines in GCP
  9.12.18.1. Deployment Manager template for worker machines
9.12.19. Logging in to the cluster by using the CLI
9.12.20. Disabling the default OperatorHub catalog sources
9.12.21. Approving the certificate signing requests for your machines
9.12.22. Optional: Adding the ingress DNS records
9.12.23. Completing a GCP installation on user-provisioned infrastructure
9.12.24. Telemetry access for OpenShift Container Platform
9.12.25. Next steps

9.13. INSTALLING A THREE-NODE CLUSTER ON GCP
  9.13.1. Configuring a three-node cluster
  9.13.2. Next steps

9.14. INSTALLATION CONFIGURATION PARAMETERS FOR GCP
    9.14.1.1. Required configuration parameters
    9.14.1.2. Network configuration parameters
    9.14.1.3. Optional configuration parameters
9.15. UNINSTALLING A CLUSTER ON GCP
  9.15.1. Removing a cluster that uses installer-provisioned infrastructure
  9.15.2. Deleting Google Cloud Platform resources with the Cloud Credential Operator utility

CHAPTER 10. INSTALLING ON IBM CLOUD

10.1. PREPARING TO INSTALL ON IBM CLOUD
  10.1.1. Prerequisites
  10.1.2. Requirements for installing OpenShift Container Platform on IBM Cloud
  10.1.3. Choosing a method to install OpenShift Container Platform on IBM Cloud
    10.1.3.1. Installing a cluster on installer-provisioned infrastructure
  10.1.4. Next steps

10.2. CONFIGURING AN IBM CLOUD ACCOUNT
  10.2.1. Prerequisites
  10.2.2. Quotas and limits on IBM Cloud
    Virtual Private Cloud (VPC)
    Application load balancer
    Floating IP address
    Virtual Server Instances (VSI)
Block Storage Volumes
10.2.3. Configuring DNS resolution
   10.2.3.1. Using IBM Cloud Internet Services for DNS resolution
   10.2.3.2. Using IBM Cloud DNS Services for DNS resolution
10.2.4. IBM Cloud IAM Policies and API Key
   10.2.4.1. Required access policies
   10.2.4.2. Access policy assignment
   10.2.4.3. Creating an API key
10.2.5. Supported IBM Cloud regions
10.2.6. Next steps

10.3. CONFIGURING IAM FOR IBM CLOUD
   10.3.1. Alternatives to storing administrator-level secrets in the kube-system project
   10.3.2. Configuring the Cloud Credential Operator utility
   10.3.3. Next steps
   10.3.4. Additional resources

10.4. INSTALLING A CLUSTER ON IBM CLOUD WITH CUSTOMIZATIONS
   10.4.1. Prerequisites
   10.4.2. Internet access for OpenShift Container Platform
   10.4.3. Generating a key pair for cluster node SSH access
   10.4.4. Obtaining the installation program
   10.4.5. Exporting the API key
   10.4.6. Creating the installation configuration file
      10.4.6.1. Minimum resource requirements for cluster installation
      10.4.6.2. Sample customized install-config.yaml file for IBM Cloud
      10.4.6.3. Configuring the cluster-wide proxy during installation
   10.4.7. Manually creating IAM
   10.4.8. Deploying the cluster
   10.4.9. Installing the OpenShift CLI by downloading the binary
      Installing the OpenShift CLI on Linux
      Installing the OpenShift CLI on Windows
      Installing the OpenShift CLI on macOS
   10.4.10. Logging in to the cluster by using the CLI
   10.4.11. Telemetry access for OpenShift Container Platform
   10.4.12. Next steps

10.5. INSTALLING A CLUSTER ON IBM CLOUD WITH NETWORK CUSTOMIZATIONS
   10.5.1. Prerequisites
   10.5.2. Internet access for OpenShift Container Platform
   10.5.3. Generating a key pair for cluster node SSH access
   10.5.4. Obtaining the installation program
   10.5.5. Exporting the API key
   10.5.6. Creating the installation configuration file
      10.5.6.1. Minimum resource requirements for cluster installation
      10.5.6.2. Sample customized install-config.yaml file for IBM Cloud
      10.5.6.3. Configuring the cluster-wide proxy during installation
   10.5.7. Manually creating IAM
   10.5.8. Network configuration phases
   10.5.9. Specifying advanced network configuration
   10.5.10. Cluster Network Operator configuration
      10.5.10.1. Cluster Network Operator configuration object
      defaultNetwork object configuration
      Configuration for the OpenShift SDN network plugin
      Configuration for the OVN-Kubernetes network plugin
      kubeProxyConfig object configuration

Installing the OpenShift CLI on Linux
Installing the OpenShift CLI on Windows
Installing the OpenShift CLI on macOS
10.4.10. Logging in to the cluster by using the CLI
10.4.11. Telemetry access for OpenShift Container Platform
10.4.12. Next steps
10.5.11. Deploying the cluster
10.5.12. Installing the OpenShift CLI by downloading the binary
    Installing the OpenShift CLI on Linux
    Installing the OpenShift CLI on Windows
    Installing the OpenShift CLI on macOS
10.5.13. Logging in to the cluster by using the CLI
10.5.14. Telemetry access for OpenShift Container Platform
10.5.15. Next steps

10.6. INSTALLING A CLUSTER ON IBM CLOUD INTO AN EXISTING VPC
10.6.1. Prerequisites
10.6.2. About using a custom VPC
    10.6.2.1. Requirements for using your VPC
    10.6.2.2. VPC validation
    10.6.2.3. Isolation between clusters
10.6.3. Internet access for OpenShift Container Platform
10.6.4. Generating a key pair for cluster node SSH access
10.6.5. Obtaining the installation program
10.6.6. Exporting the API key
10.6.7. Creating the installation configuration file
    10.6.7.1. Minimum resource requirements for cluster installation
    10.6.7.2. Sample customized install-config.yaml file for IBM Cloud
    10.6.7.3. Configuring the cluster-wide proxy during installation
10.6.8. Manually creating IAM
10.6.9. Deploying the cluster
10.6.10. Installing the OpenShift CLI by downloading the binary
    Installing the OpenShift CLI on Linux
    Installing the OpenShift CLI on Windows
    Installing the OpenShift CLI on macOS
10.6.11. Logging in to the cluster by using the CLI
10.6.12. Telemetry access for OpenShift Container Platform
10.6.13. Next steps

10.7. INSTALLING A PRIVATE CLUSTER ON IBM CLOUD
10.7.1. Prerequisites
10.7.2. Private clusters
10.7.3. Private clusters in IBM Cloud
    10.7.3.1. Limitations
10.7.4. About using a custom VPC
    10.7.4.1. Requirements for using your VPC
    10.7.4.2. VPC validation
    10.7.4.3. Isolation between clusters
10.7.5. Internet access for OpenShift Container Platform
10.7.6. Generating a key pair for cluster node SSH access
10.7.7. Obtaining the installation program
10.7.8. Exporting the API key
10.7.9. Manually creating the installation configuration file
    10.7.9.1. Minimum resource requirements for cluster installation
    10.7.9.2. Sample customized install-config.yaml file for IBM Cloud
    10.7.9.3. Configuring the cluster-wide proxy during installation
10.7.10. Manually creating IAM
10.7.11. Deploying the cluster
10.7.12. Installing the OpenShift CLI by downloading the binary
    Installing the OpenShift CLI on Linux
    Installing the OpenShift CLI on Windows
Installing the OpenShift CLI on macOS
10.7.13. Logging in to the cluster by using the CLI
10.7.14. Telemetry access for OpenShift Container Platform
10.7.15. Next steps
10.8. INSTALLATION CONFIGURATION PARAMETERS FOR IBM CLOUD
10.8.1. Available installation configuration parameters for IBM Cloud
10.8.1.1. Required configuration parameters
10.8.1.2. Network configuration parameters
10.8.1.3. Optional configuration parameters
10.8.1.4. Additional IBM Cloud configuration parameters
10.9. UNINSTALLING A CLUSTER ON IBM CLOUD
10.9.1. Removing a cluster that uses installer-provisioned infrastructure

CHAPTER 11. INSTALLING ON NUTANIX
11.1. PREPARING TO INSTALL ON NUTANIX
11.1.1. Nutanix version requirements
11.1.2. Environment requirements
11.1.2.1. Required account privileges
11.1.2.2. Cluster limits
11.1.2.3. Cluster resources
11.1.2.4. Networking requirements
11.1.2.4.1. Required IP Addresses
11.1.2.4.2. DNS records
11.1.3. Configuring the Cloud Credential Operator utility
11.2. INSTALLING A CLUSTER ON NUTANIX
11.2.1. Prerequisites
11.2.2. Internet access for OpenShift Container Platform
11.2.3. Internet access for Prism Central
11.2.4. Generating a key pair for cluster node SSH access
11.2.5. Obtaining the installation program
11.2.6. Adding Nutanix root CA certificates to your system trust
11.2.7. Creating the installation configuration file
11.2.7.1. Sample customized install-config.yaml file for Nutanix
11.2.7.2. Configuring the cluster-wide proxy during installation
11.2.8. Installing the OpenShift CLI by downloading the binary
11.2.9. Configuring IAM for Nutanix
11.2.10. Adding config map and secret resources required for Nutanix CCM
11.2.11. Deploying the cluster
11.2.12. Configuring the default storage container
11.2.13. Telemetry access for OpenShift Container Platform
11.2.14. Additional resources
11.2.15. Next steps
11.3. INSTALLING A CLUSTER ON NUTANIX IN A RESTRICTED NETWORK
11.3.1. Prerequisites
11.3.2. About installations in restricted networks
11.3.2.1. Additional limits
11.3.3. Generating a key pair for cluster node SSH access
11.3.4. Adding Nutanix root CA certificates to your system trust
11.3.5. Downloading the RHCOS cluster image
11.3.6. Creating the installation configuration file
11.3.6.1. Sample customized install-config.yaml file for Nutanix
11.3.6.2. Configuring the cluster-wide proxy during installation
11.3.7. Installing the OpenShift CLI by downloading the binary
  - Installing the OpenShift CLI on Linux
  - Installing the OpenShift CLI on Windows
  - Installing the OpenShift CLI on macOS
11.3.8. Configuring IAM for Nutanix
11.3.9. Deploying the cluster
11.3.10. Post installation
  - Disabling the default OperatorHub catalog sources
  - Installing the policy resources into the cluster
  - Configuring the default storage container
11.3.11. Telemetry access for OpenShift Container Platform
11.3.12. Additional resources
11.3.13. Next steps

11.4. INSTALLING A THREE-NODE CLUSTER ON NUTANIX
  - Configuring a three-node cluster
  - Next steps

11.5. UNINSTALLING A CLUSTER ON NUTANIX
  - Removing a cluster that uses installer-provisioned infrastructure

11.6. INSTALLATION CONFIGURATION PARAMETERS FOR NUTANIX
  - Available installation configuration parameters for Nutanix
    - Required configuration parameters
    - Network configuration parameters
    - Optional configuration parameters
    - Additional Nutanix configuration parameters

CHAPTER 12. INSTALLING ON BARE METAL

12.1. PREPARING FOR BARE METAL CLUSTER INSTALLATION
  - Prerequisites
  - Planning a bare metal cluster for OpenShift Virtualization
  - NIC partitioning for SR-IOV devices (Technology Preview)
  - Choosing a method to install OpenShift Container Platform on bare metal
    - Installing a cluster on installer-provisioned infrastructure
    - Installing a cluster on user-provisioned infrastructure

12.2. INSTALLING A USER-PROVISIONED CLUSTER ON BARE METAL
  - Prerequisites
  - Internet access for OpenShift Container Platform
  - Requirements for a cluster with user-provisioned infrastructure
    - Required machines for cluster installation
    - Minimum resource requirements for cluster installation
    - Certificate signing requests management
  - Requirements for baremetal clusters on vSphere
    - Networking requirements for user-provisioned infrastructure
      - Setting the cluster node hostnames through DHCP
      - Network connectivity requirements
        - NTP configuration for user-provisioned infrastructure
    - User-provisioned DNS requirements
      - Example DNS configuration for user-provisioned clusters
    - Load balancing requirements for user-provisioned infrastructure
      - Example load balancer configuration for user-provisioned clusters
    - Preparing the user-provisioned infrastructure
    - Validating DNS resolution for user-provisioned infrastructure
12.2.7. Generating a key pair for cluster node SSH access

12.2.8. Obtaining the installation program

12.2.9. Installing the OpenShift CLI by downloading the binary
   - Installing the OpenShift CLI on Linux
   - Installing the OpenShift CLI on Windows
   - Installing the OpenShift CLI on macOS

12.2.10. Manually creating the installation configuration file
   - Sample install-config.yaml file for bare metal
   - Configuring the cluster-wide proxy during installation
   - Configuring a three-node cluster

12.2.10.1. Sample install-config.yaml file for bare metal

12.2.10.2. Configuring the cluster-wide proxy during installation

12.2.10.3. Configuring a three-node cluster

12.2.11. Creating the Kubernetes manifest and Ignition config files

12.2.12. Installing RHCOS and starting the OpenShift Container Platform bootstrap process
   - Installing RHCOS by using an ISO image
   - Installing RHCOS by using PXE or iPXE booting

12.2.12.1. Using advanced networking options for PXE and ISO installations
   - Disk partitioning
     - Creating a separate /var partition
     - Retaining existing partitions
   - Identifying Ignition configs
   - Default console configuration
   - Enabling the serial console for PXE and ISO installations

12.2.12.2. Configuring the cluster-wide proxy during installation

12.2.12.3. Advanced RHCOS installation configuration
   - Configuring a live RHCOS ISO or PXE install
   - Customizing a live RHCOS ISO image
     - Modifying a live install ISO image to enable the serial console
     -Modifying a live install ISO image to use a custom certificate authority
     -Modifying a live install ISO image with customized network settings
   - Customizing a live RHCOS PXE environment
     - Modifying a live install PXE environment to enable the serial console
     - Modifying a live install PXE environment to use a custom certificate authority
     -Modifying a live install PXE environment with customized network settings
   - Advanced RHCOS installation reference
     - Networking and bonding options for ISO installations
       - Configuring DHCP or static IP addresses
       - Configuring an IP address without a static hostname
       - Specifying multiple network interfaces
       - Configuring default gateway and route
       - Disabling DHCP on a single interface
       - Combining DHCP and static IP configurations
       - Configuring VLANs on individual interfaces
       - Providing multiple DNS servers
       - Bonding multiple network interfaces to a single interface
       - Bonding multiple SR-IOV network interfaces to a dual port NIC interface
       - Using network teaming
       - cores-installer options for ISO and PXE installations
       - coreos.inst boot options for ISO or PXE installations
     - Enabling multipathing with kernel arguments on RHCOS
     - Updating the bootloader using bootupd

12.2.13. Waiting for the bootstrap process to complete

12.2.14. Logging in to the cluster by using the CLI

12.2.15. Approving the certificate signing requests for your machines

12.2.16. Initial Operator configuration
   - Image registry removed during installation
12.2.16.2. Image registry storage configuration

12.2.16.2.1. Configuring registry storage for bare metal and other manual installations

12.2.16.2.2. Configuring storage for the image registry in non-production clusters

12.2.16.2.3. Configuring block registry storage

12.2.17. Completing installation on user-provisioned infrastructure

12.2.18. Telemetry access for OpenShift Container Platform

12.2.19. Next steps

12.3. INSTALLING A USER-PROVISIONED BARE METAL CLUSTER WITH NETWORK CUSTOMIZATIONS

12.3.1. Prerequisites

12.3.2. Internet access for OpenShift Container Platform

12.3.3. Requirements for a cluster with user-provisioned infrastructure

12.3.3.1. Required machines for cluster installation

12.3.3.2. Minimum resource requirements for cluster installation

12.3.3.3. Certificate signing requests management

12.3.3.4. Networking requirements for user-provisioned infrastructure

12.3.3.4.1. Setting the cluster node hostnames through DHCP

12.3.3.4.2. Network connectivity requirements

12.3.3.5. User-provisioned DNS requirements

12.3.3.5.1. Example DNS configuration for user-provisioned clusters

12.3.3.6. Load balancing requirements for user-provisioned infrastructure

12.3.3.6.1. Example load balancer configuration for user-provisioned clusters

12.3.4. Preparing the user-provisioned infrastructure

12.3.5. Validating DNS resolution for user-provisioned infrastructure

12.3.6. Generating a key pair for cluster node SSH access

12.3.7. Obtaining the installation program

12.3.8. Installing the OpenShift CLI by downloading the binary

12.3.9. Manually creating the installation configuration file

12.3.9.1. Sample install-config.yaml file for bare metal

12.3.10. Network configuration phases

12.3.11. Specifying advanced network configuration

12.3.12. Cluster Network Operator configuration

12.3.12.1. Cluster Network Operator configuration object

12.3.12.1.1. defaultNetwork object configuration

12.3.12.1.2. Configuration for the OpenShift SDN network plugin

12.3.12.1.3. Configuration for the OVN-Kubernetes network plugin

12.3.12.1.4. kubeProxyConfig object configuration

12.3.13. Creating the Ignition config files

12.3.14. Installing RHCOS and starting the OpenShift Container Platform bootstrap process

12.3.14.1. Installing RHCOS by using an ISO image

12.3.14.2. Installing RHCOS by using PXE or iPXE booting

12.3.14.3. Advanced RHCOS installation configuration

12.3.14.3.1. Using advanced networking options for PXE and ISO installations

12.3.14.3.2. Disk partitioning

12.3.14.3.2.1. Creating a separate /var partition

12.3.14.3.2.2. Retaining existing partitions

12.3.14.3.3. Identifying Ignition configs

12.3.14.3.4. Default console configuration

12.3.14.3.5. Enabling the serial console for PXE and ISO installations
12.3.14.3.6. Customizing a live RHCOS ISO or PXE install
12.3.14.3.7. Customizing a live RHCOS ISO image
  12.3.14.3.7.1. Modifying a live install ISO image to enable the serial console
  12.3.14.3.7.2. Modifying a live install ISO image to use a custom certificate authority
  12.3.14.3.7.3. Modifying a live install ISO image with customized network settings
12.3.14.3.8. Customizing a live RHCOS PXE environment
  12.3.14.3.8.1. Modifying a live install PXE environment to enable the serial console
  12.3.14.3.8.2. Modifying a live install PXE environment to use a custom certificate authority
  12.3.14.3.8.3. Modifying a live install PXE environment with customized network settings
12.3.14.3.9. Advanced RHCOS installation reference
  12.3.14.3.9.1. Networking and bonding options for ISO installations
    Configuring DHCP or static IP addresses
    Configuring an IP address without a static hostname
    Specifying multiple network interfaces
    Configuring default gateway and route
    Disabling DHCP on a single interface
    Combining DHCP and static IP configurations
    Configuring VLANs on individual interfaces
    Providing multiple DNS servers
    Bonding multiple network interfaces to a single interface
    Bonding multiple SR-IOV network interfaces to a dual port NIC interface
    Using network teaming
  12.3.14.3.9.2. coreos-installer options for ISO and PXE installations
  12.3.14.3.9.3. coreos.inst boot options for ISO or PXE installations
12.3.15. Waiting for the bootstrap process to complete
12.3.16. Logging in to the cluster by using the CLI
12.3.17. Approving the certificate signing requests for your machines
12.3.18. Initial Operator configuration
  12.3.18.1. Image registry removed during installation
  12.3.18.2. Image registry storage configuration
  12.3.18.3. Configuring block registry storage
12.3.19. Completing installation on user-provisioned infrastructure
12.3.20. Telemetry access for OpenShift Container Platform
12.3.21. Next steps
12.4. INSTALLING A USER-PROVISIONED BARE METAL CLUSTER ON A RESTRICTED NETWORK
12.4.1. Prerequisites
12.4.2. About installations in restricted networks
  12.4.2.1. Additional limits
12.4.3. Internet access for OpenShift Container Platform
12.4.4. Requirements for a cluster with user-provisioned infrastructure
  12.4.4.1. Required machines for cluster installation
  12.4.4.2. Minimum resource requirements for cluster installation
  12.4.4.3. Certificate signing requests management
  12.4.4.4. Networking requirements for user-provisioned infrastructure
    12.4.4.4.1. Setting the cluster node hostnames through DHCP
    12.4.4.4.2. Network connectivity requirements
      NTP configuration for user-provisioned infrastructure
  12.4.4.5. User-provisioned DNS requirements
    12.4.4.5.1. Example DNS configuration for user-provisioned clusters
  12.4.4.6. Load balancing requirements for user-provisioned infrastructure
    12.4.4.6.1. Example load balancer configuration for user-provisioned clusters
12.4.5. Preparing the user-provisioned infrastructure

12.4.6. Validating DNS resolution for user-provisioned infrastructure

12.4.7. Generating a key pair for cluster node SSH access

12.4.8. Manually creating the installation configuration file
   12.4.8.1. Sample install-config.yaml file for bare metal
   12.4.8.2. Configuring the cluster-wide proxy during installation
   12.4.8.3. Configuring a three-node cluster

12.4.9. Creating the Kubernetes manifest and Ignition config files

12.4.10. Configuring chrony time service

12.4.11. Installing RHCOS and starting the OpenShift Container Platform bootstrap process
   12.4.11.1. Installing RHCOS by using an ISO image
   12.4.11.2. Installing RHCOS by using PXE or iPXE booting
   12.4.11.3. Advanced RHCOS installation configuration
      12.4.11.3.1. Using advanced networking options for PXE and ISO installations
      12.4.11.3.2. Disk partitioning
      12.4.11.3.2.1. Creating a separate /var partition
      12.4.11.3.2.2. Retaining existing partitions
      12.4.11.3.3. Identifying Ignition configs
      12.4.11.3.4. Default console configuration
      12.4.11.3.5. Enabling the serial console for PXE and ISO installations
      12.4.11.3.6. Customizing a live RHCS ISO or PXE install
      12.4.11.3.7. Customizing a live RHCS ISO image
         12.4.11.3.7.1. Modifying a live install ISO image to enable the serial console
         12.4.11.3.7.2. Modifying a live install ISO image to use a custom certificate authority
         12.4.11.3.7.3. Modifying a live install ISO image with customized network settings
      12.4.11.3.8. Customizing a live RHCS PXE environment
         12.4.11.3.8.1. Modifying a live install PXE environment to enable the serial console
         12.4.11.3.8.2. Modifying a live install PXE environment to use a custom certificate authority
         12.4.11.3.8.3. Modifying a live install PXE environment with customized network settings
      12.4.11.3.9. Advanced RHCOS installation reference
         12.4.11.3.9.1. Networking and bonding options for ISO installations
            Configuring DHCP or static IP addresses
            Configuring an IP address without a static hostname
            Specifying multiple network interfaces
            Configuring default gateway and route
            Disabling DHCP on a single interface
            Combining DHCP and static IP configurations
            Configuring VLANs on individual interfaces
            Providing multiple DNS servers
            Bonding multiple network interfaces to a single interface
            Bonding multiple SR-IOV network interfaces to a dual port NIC interface
            Using network teaming
         12.4.11.3.9.2. cores-installer options for ISO and PXE installations
         12.4.11.3.9.3. cores.inst boot options for ISO or PXE installations
   12.4.11.4. Enabling multipathing with kernel arguments on RHCOS
   12.4.11.5. Updating the bootloader using bootupd
   12.4.11.6. Waiting for the bootstrap process to complete
   12.4.11.7. Logging in to the cluster by using the CLI
   12.4.11.8. Approving the certificate signing requests for your machines
   12.4.11.9. Initial Operator configuration
      12.4.11.10. Disabling the default OperatorHub catalog sources
      12.4.11.11. Image registry storage configuration
         12.4.11.11.1. Changing the image registry’s management state
12.4.15.2.2. Configuring registry storage for bare metal and other manual installations 2208
12.4.15.2.3. Configuring storage for the image registry in non-production clusters 2210
12.4.15.2.4. Configuring block registry storage 2210
12.4.16. Completing installation on user-provisioned infrastructure 2211
12.4.17. Telemetry access for OpenShift Container Platform 2213
12.4.18. Next steps 2213
12.5. SCALING A USER-PROVISIONED CLUSTER WITH THE BARE METAL OPERATOR 2214
12.5.1. About scaling a user-provisioned cluster with the Bare Metal Operator 2214
12.5.1.1. Prerequisites for scaling a user-provisioned cluster 2214
12.5.1.2. Limitations for scaling a user-provisioned cluster 2214
12.5.2. Configuring a provisioning resource to scale user-provisioned clusters 2214
12.5.3. Provisioning new hosts in a user-provisioned cluster by using the BMO 2215
12.5.4. Optional: Managing existing hosts in a user-provisioned cluster by using the BMO 2218
12.5.5. Removing hosts from a user-provisioned cluster by using the BMO 2219
12.6. INSTALLATION CONFIGURATION PARAMETERS FOR BARE METAL 2221
12.6.1. Available installation configuration parameters for bare metal 2221
12.6.1.1. Required configuration parameters 2221
12.6.1.2. Network configuration parameters 2222
12.6.1.3. Optional configuration parameters 2225

CHAPTER 13. INSTALLING ON-PREMISE WITH ASSISTED INSTALLER 2231
13.1. INSTALLING AN ON-PREMISE CLUSTER USING THE ASSISTED INSTALLER 2231
13.1.1. Using the Assisted Installer 2231
13.1.2. API support for the Assisted Installer 2232

CHAPTER 14. INSTALLING AN ON-PREMISE CLUSTER WITH THE AGENT-BASED INSTALLER 2233
14.1. PREPARING TO INSTALL WITH THE AGENT-BASED INSTALLER 2233
14.1.1. About the Agent-based Installer 2233
14.1.2. Understanding Agent-based Installer 2233
14.1.2.1. Agent-based Installer workflow 2234
14.1.2.2. Recommended resources for topologies 2235
14.1.3. About FIPS compliance 2235
14.1.4. Configuring FIPS through the Agent-based Installer 2236
14.1.5. About networking 2236
14.1.5.1. DHCP 2237
14.1.5.2. Static networking 2237
14.1.6. Requirements for a cluster using the platform "none" option 2239
14.1.6.1. Platform "none" DNS requirements 2239
14.1.6.1.1. Example DNS configuration for platform "none" clusters 2241
14.1.6.2. Platform "none" Load balancing requirements 2243
14.1.6.2.1. Example load balancer configuration for platform "none" clusters 2244
14.1.7. Example: Bonds and VLAN interface node network configuration 2246
14.1.8. Example: Bonds and SR-IOV dual-nic node network configuration 2247
14.1.9. Sample install-config.yaml file for bare metal 2250
14.1.10. Validation checks before agent ISO creation 2253
14.1.10.1. ZTP manifests 2253
14.1.11. About root device hints 2253
14.1.12. Next steps 2254
14.2. UNDERSTANDING DISCONNECTED INSTALLATION MIRRORING 2254
14.2.1. Mirroring images for a disconnected installation through the Agent-based Installer 2255
14.2.2. About mirroring the OpenShift Container Platform image repository for a disconnected registry 2255
14.2.2.1. Configuring the Agent-based Installer to use mirrored images 2256
14.3. INSTALLING AN OPENSShift CONTAINER PLATFORM CLUSTER WITH THE AGENT-BASED INSTALLER
14.3.1. Prerequisites
14.3.2. Installing OpenShift Container Platform with the Agent-based Installer
  14.3.2.1. Downloading the Agent-based Installer
  14.3.2.2. Creating the preferred configuration inputs
  14.3.2.3. Optional: Creating additional manifest files
    14.3.2.3.1. Disk partitioning
    14.3.2.3.2. Creating ZTP manifests
    14.3.2.3.3. Optional: Configuring the disk
    14.3.2.3.4. Creating and booting the agent image
    14.3.2.3.5. Verifying that the current installation host can pull release images
    14.3.2.3.6. Tracking and verifying installation progress
  14.3.3. Sample GitOps ZTP custom resources
  14.3.4. Gathering log data from a failed Agent-based installation

14.4. PREPARING PXE ASSETS FOR OPENSIFT CONTAINER PLATFORM
  14.4.1. Prerequisites
  14.4.2. Downloading the Agent-based Installer
  14.4.3. Creating the preferred configuration inputs
  14.4.4. Creating the PXE assets
  14.4.5. Additional resources

14.5. PREPARING AN AGENT-BASED INSTALLED CLUSTER FOR THE MULTICLUSTER ENGINE FOR KUBERNETES OPERATOR
  14.5.1. Prerequisites
  14.5.2. Preparing an Agent-based cluster deployment for the multicluster engine for Kubernetes Operator while disconnected
  14.5.3. Preparing an Agent-based cluster deployment for the multicluster engine for Kubernetes Operator while connected

CHAPTER 15. INSTALLING ON A SINGLE NODE

15.1. PREPARING TO INSTALL ON A SINGLE NODE
  15.1.1. Prerequisites
  15.1.2. About OpenShift on a single node
  15.1.3. Requirements for installing OpenShift on a single node

15.2. INSTALLING OPENSIFT ON A SINGLE NODE
  15.2.1. Installing single-node OpenShift using the Assisted Installer
    15.2.1.1. Generating the discovery ISO with the Assisted Installer
    15.2.1.2. Installing single-node OpenShift with the Assisted Installer
  15.2.2. Installing single-node OpenShift manually
    15.2.2.1. Generating the installation ISO with coreos-installer
    15.2.2.2. Monitoring the cluster installation using openshift-install
  15.2.3. Installing single-node OpenShift on cloud providers
    15.2.3.1. Additional requirements for installing single-node OpenShift on a cloud provider
    15.2.3.2. Supported cloud providers for single-node OpenShift
    15.2.3.3. Installing single-node OpenShift on AWS
    15.2.3.4. Installing single-node OpenShift on Azure
    15.2.3.5. Installing single-node OpenShift on GCP
  15.2.4. Creating a bootable ISO image on a USB drive
  15.2.5. Booting from an HTTP-hosted ISO image using the Redfish API
  15.2.6. Creating a custom live RH COS ISO for remote server access
  15.2.7. Installing single-node OpenShift with IBM Z and IBM LinuxONE
    Hardware requirements
    15.2.7.1. Installing single-node OpenShift with z/VM on IBM Z and IBM LinuxONE
    15.2.7.2. Installing single-node OpenShift with RHEL KVM on IBM Z and IBM LinuxONE
15.2.8. Installing single-node OpenShift with IBM Power

Hardware requirements

15.2.8.1. Setting up basion for single-node OpenShift with IBM Power

15.2.8.2. Installing single-node OpenShift with IBM Power

CHAPTER 16. DEPLOYING INSTALLER-PROVISIONED CLUSTERS ON BARE METAL

16.1. OVERVIEW

16.2. PREREQUISITES

16.2.1. Node requirements

16.2.2. Planning a bare metal cluster for OpenShift Virtualization

16.2.3. Firmware requirements for installing with virtual media

16.2.4. Network requirements

16.2.4.1. Ensuring required ports are open

16.2.4.2. Increase the network MTU

16.2.4.3. Configuring NICs

16.2.4.4. DNS requirements

16.2.4.5. Dynamic Host Configuration Protocol (DHCP) requirements

16.2.4.6. Reserving IP addresses for nodes with the DHCP server

16.2.4.7. Provisioner node requirements

16.2.4.8. Network Time Protocol (NTP)

16.2.4.9. Port access for the out-of-band management IP address

16.2.5. Configuring nodes

Configuring nodes when using the provisioning network

Configuring nodes without the provisioning network

Configuring nodes for Secure Boot manually

16.2.6. Out-of-band management

16.2.7. Required data for installation

16.2.8. Validation checklist for nodes

16.3. SETTING UP THE ENVIRONMENT FOR AN OPENSSHIFT INSTALLATION

16.3.1. Installing RHEL on the provisioner node

16.3.2. Preparing the provisioner node for OpenShift Container Platform installation

16.3.3. Checking NTP server synchronization

16.3.4. Configuring networking

16.3.5. Establishing communication between subnets

16.3.6. Retrieving the OpenShift Container Platform installer

16.3.7. Extracting the OpenShift Container Platform installer

16.3.8. Optional: Creating an RHCOS images cache

16.3.9. Configuring the install-config.yaml file

16.3.9.1. Configuring the install-config.yaml file

16.3.9.2. Additional install-config parameters

Hosts

16.3.9.3. BMC addressing

IPMI

Redfish network boot

Redfish APIs

16.3.9.4. BMC addressing for Dell iDRAC

BMC address formats for Dell iDRAC

Redfish virtual media for Dell iDRAC

Redfish network boot for iDRAC

16.3.9.5. BMC addressing for HPE iLO

Redfish virtual media for HPE iLO

Redfish network boot for HPE iLO

16.3.9.6. BMC addressing for Fujitsu iRMC
16.3.9.7. Root device hints
16.3.9.8. Optional: Setting proxy settings
16.3.9.9. Optional: Deploying with no provisioning network
16.3.9.10. Optional: Deploying with dual-stack networking
16.3.9.11. Optional: Configuring host network interfaces
16.3.9.12. Configuring host network interfaces for subnets
16.3.9.13. Optional: Configuring address generation modes for SLAAC in dual-stack networks
16.3.9.14. Optional: Configuring host network interfaces for dual port NIC
16.3.9.15. Configuring multiple cluster nodes
16.3.9.16. Optional: Configuring managed Secure Boot
16.3.10. Manifest configuration files
16.3.10.1. Creating the OpenShift Container Platform manifests
16.3.10.2. Optional: Configuring NTP for disconnected clusters
16.3.10.3. Configuring network components to run on the control plane
16.3.10.4. Optional: Deploying routers on worker nodes
16.3.10.5. Optional: Configuring the BIOS
16.3.10.6. Optional: Configuring the RAID
16.3.10.7. Optional: Configuring storage on nodes
16.3.11. Creating a disconnected registry
   Prerequisites
   16.3.11.1. Preparing the registry node to host the mirrored registry
   16.3.11.2. Mirroring the OpenShift Container Platform image repository for a disconnected registry
   16.3.11.3. Modify the install-config.yaml file to use the disconnected registry
16.3.12. Validation checklist for installation
16.3.13. Deploying the cluster via the OpenShift Container Platform installer
16.3.14. Following the installation
16.3.15. Verifying static IP address configuration
16.3.16. Preparing to reinstall a cluster on bare metal
16.3.17. Additional resources
16.4. INSTALLER-PROVISIONED POSTINSTALLATION CONFIGURATION
16.4.1. Optional: Configuring NTP for disconnected clusters
16.4.2. Enabling a provisioning network after installation
16.4.3. Configuring an external load balancer
16.5. EXPANDING THE CLUSTER
16.5.1. Preparing the bare metal node
16.5.2. Replacing a bare-metal control plane node
16.5.3. Preparing to deploy with Virtual Media on the baremetal network
16.5.4. Diagnosing a duplicate MAC address when provisioning a new host in the cluster
16.5.5. Provisioning the bare metal node
16.6. TROUBLESHOOTING
16.6.1. Troubleshooting the installer workflow
16.6.2. Troubleshooting install-config.yaml
16.6.3. Bootstrap VM issues
   16.6.3.1. Bootstrap VM cannot boot up the cluster nodes
   16.6.3.2. Inspecting logs
16.6.4. Cluster nodes will not PXE boot
16.6.5. Unable to discover new bare metal hosts using the BMC
16.6.6. The API is not accessible
16.6.7. Troubleshooting worker nodes that cannot join the cluster
16.6.8. Cleaning up previous installations
16.6.9. Issues with creating the registry
16.6.10. Miscellaneous issues
   16.6.10.1. Addressing the runtime network not ready error
16.6.10.2. Addressing the "No disk found with matching rootDeviceHints" error message
16.6.10.3. Cluster nodes not getting the correct IPv6 address over DHCP
16.6.10.4. Cluster nodes not getting the correct hostname over DHCP
16.6.10.5. Routes do not reach endpoints
16.6.10.6. Failed Ignition during Firstboot
16.6.10.7. NTP out of sync
16.6.11. Reviewing the installation

CHAPTER 17. INSTALLING IBM CLOUD BARE METAL (CLASSIC)
17.1. PREREQUISITES
17.1.1. Setting up IBM Cloud Bare Metal (Classic) infrastructure
Use one data center per cluster
Create public and private VLANs
Ensure subnets have sufficient IP addresses
Configuring NICs
Configuring canonical names
Creating DNS entries
Network Time Protocol (NTP)
Configure a DHCP server
Ensure BMC access privileges
Create bare metal servers

17.2. SETTING UP THE ENVIRONMENT FOR AN OPENSSHIFT CONTAINER PLATFORM INSTALLATION
17.2.1. Preparing the provisioner node on IBM Cloud(R) Bare Metal (Classic) infrastructure
17.2.2. Configuring the public subnet
17.2.3. Retrieving the OpenShift Container Platform installer
17.2.4. Extracting the OpenShift Container Platform installer
17.2.5. Configuring the install-config.yaml file
17.2.6. Additional install-config parameters

17.2.7. Root device hints
17.2.8. Creating the OpenShift Container Platform manifests
17.2.9. Deploying the cluster via the OpenShift Container Platform installer
17.2.10. Following the installation

CHAPTER 18. INSTALLING ON IBM Z AND IBM LINUXONE
18.1. PREPARING TO INSTALL ON IBM Z AND IBM LINUXONE
18.1.1. Prerequisites
18.1.2. Choosing a method to install OpenShift Container Platform on IBM Z or IBM LinuxONE
18.1.2.1. User-provisioned infrastructure installation of OpenShift Container Platform on IBM Z

18.2. INSTALLING A CLUSTER WITH Z/VM ON IBM Z AND IBM LINUXONE
18.2.1. Prerequisites
18.2.2. Internet access for OpenShift Container Platform
18.2.3. Requirements for a cluster with user-provisioned infrastructure
18.2.3.1. Required machines for cluster installation
18.2.3.2. Minimum resource requirements for cluster installation
18.2.3.3. Minimum IBM Z system environment
Hardware requirements
Operating system requirements
IBM Z network connectivity requirements
Disk storage for the z/VM guest virtual machines
Storage / Main Memory
18.2.3.4. Preferred IBM Z system environment
Hardware requirements
Operating system requirements
IBM Z network connectivity requirements
Disk storage for the z/VM guest virtual machines
Storage / Main Memory
18.2.3.5. Certificate signing requests management
18.2.3.6. Networking requirements for user-provisioned infrastructure
  18.2.3.6.1. Network connectivity requirements
    NTP configuration for user-provisioned infrastructure
18.2.3.7. User-provisioned DNS requirements
  18.2.3.7.1. Example DNS configuration for user-provisioned clusters
18.2.3.8. Load balancing requirements for user-provisioned infrastructure
  18.2.3.8.1. Example load balancer configuration for user-provisioned clusters
18.2.4. Preparing the user-provisioned infrastructure
18.2.5. Validating DNS resolution for user-provisioned infrastructure
18.2.6. Generating a key pair for cluster node SSH access
18.2.7. Obtaining the installation program
18.2.8. Installing the OpenShift CLI by downloading the binary
  Installing the OpenShift CLI on Linux
  Installing the OpenShift CLI on Windows
  Installing the OpenShift CLI on macOS
18.2.9. Manually creating the installation configuration file
  18.2.9.1. Sample install-config.yaml file for IBM Z
  18.2.9.2. Configuring the cluster-wide proxy during installation
  18.2.9.3. Configuring a three-node cluster
18.2.10. Cluster Network Operator configuration
  18.2.10.1. Cluster Network Operator configuration object
    defaultNetwork object configuration
    Configuration for the OpenShift SDN network plugin
    Configuration for the OVN-Kubernetes network plugin
    kubeProxyConfig object configuration
18.2.11. Creating the Kubernetes manifest and Ignition config files
18.2.12. Configuring NBDE with static IP in an IBM Z or IBM LinuxONE environment
18.2.13. Installing RHCOS and starting the OpenShift Container Platform bootstrap process
  18.2.13.1. Advanced RHCOS installation reference
    18.2.13.1.1. Networking and bonding options for ISO installations
      Configuring DHCP or static IP addresses
      Configuring an IP address without a static hostname
      Specifying multiple network interfaces
      Configuring default gateway and route
      Disabling DHCP on a single interface
      Combining DHCP and static IP configurations
      Configuring VLANs on individual interfaces
      Providing multiple DNS servers
      Bonding multiple network interfaces to a single interface
      Bonding multiple network interfaces to a single interface
      Using network teaming
18.2.14. Waiting for the bootstrap process to complete
18.2.15. Logging in to the cluster by using the CLI
18.2.16. Approving the certificate signing requests for your machines
18.2.17. Initial Operator configuration
  18.2.17.1. Image registry storage configuration
    18.2.17.1.1. Configuring registry storage for IBM Z
    18.2.17.1.2. Configuring storage for the image registry in non-production clusters
18.2.18. Completing installation on user-provisioned infrastructure
18.2.19. Telemetry access for OpenShift Container Platform
18.2.20. Next steps

18.3. INSTALLING A CLUSTER WITH Z/VM ON IBM Z AND IBM LINUXONE IN A RESTRICTED NETWORK

18.3.1. Prerequisites
18.3.2. About installations in restricted networks
  18.3.2.1. Additional limits
18.3.3. Internet access for OpenShift Container Platform
18.3.4. Requirements for a cluster with user-provisioned infrastructure
  18.3.4.1. Required machines for cluster installation
  18.3.4.2. Minimum resource requirements for cluster installation
  18.3.4.3. Minimum IBM Z system environment
    Hardware requirements
    Operating system requirements
    IBM Z network connectivity requirements
    Disk storage for the z/VM guest virtual machines
    Storage / Main Memory
  18.3.4.4. Preferred IBM Z system environment
    Hardware requirements
    Operating system requirements
    IBM Z network connectivity requirements
    Disk storage for the z/VM guest virtual machines
    Storage / Main Memory
  18.3.4.5. Certificate signing requests management
  18.3.4.6. Networking requirements for user-provisioned infrastructure
    18.3.4.6.1. Setting the cluster node hostnames through DHCP
    18.3.4.6.2. Network connectivity requirements
      NTP configuration for user-provisioned infrastructure
  18.3.4.7. User-provisioned DNS requirements
    18.3.4.7.1. Example DNS configuration for user-provisioned clusters
  18.3.4.8. Load balancing requirements for user-provisioned infrastructure
    18.3.4.8.1. Example load balancer configuration for user-provisioned clusters
18.3.5. Preparing the user-provisioned infrastructure
18.3.6. Validating DNS resolution for user-provisioned infrastructure
18.3.7. Generating a key pair for cluster node SSH access
18.3.8. Manually creating the installation configuration file
  18.3.8.1. Sample install-config.yaml file for IBM Z
  18.3.8.2. Configuring the cluster-wide proxy during installation
18.3.9. Cluster Network Operator configuration
  18.3.9.1. Cluster Network Operator configuration object
    defaultNetwork object configuration
    Configuration for the OpenShift SDN network plugin
    Configuration for the OVN-Kubernetes network plugin
    kubeProxyConfig object configuration
18.3.10. Creating the Kubernetes manifest and Ignition config files
18.3.11. Configuring NBDE with static IP in an IBM Z or IBM LinuxONE environment
18.3.12. Installing RHCOS and starting the OpenShift Container Platform bootstrap process
  18.3.12.1. Advanced RHCOS installation reference
    18.3.12.1.1. Networking and bonding options for ISO installations
      Configuring DHCP or static IP addresses
      Configuring an IP address without a static hostname
18.5.4.8. Preferred resource requirements
18.5.4.9. Certificate signing requests management
18.5.4.10. Networking requirements for user-provisioned infrastructure
  18.5.4.10.1. Setting the cluster node hostnames through DHCP
  18.5.4.10.2. Network connectivity requirements
  NTP configuration for user-provisioned infrastructure
18.5.4.11. User-provisioned DNS requirements
  18.5.4.11.1. Example DNS configuration for user-provisioned clusters
18.5.4.12. Load balancing requirements for user-provisioned infrastructure
  18.5.4.12.1. Example load balancer configuration for user-provisioned clusters
18.5.5. Preparing the user-provisioned infrastructure
18.5.6. Validating DNS resolution for user-provisioned infrastructure
18.5.7. Generating a key pair for cluster node SSH access
18.5.8. Manually creating the installation configuration file
  18.5.8.1. Sample install-config.yaml file for IBM Z
  18.5.8.2. Configuring the cluster-wide proxy during installation
  18.5.8.3. Configuring a three-node cluster
18.5.9. Cluster Network Operator configuration
  18.5.9.1. Cluster Network Operator configuration object
  defaultNetwork object configuration
  Configuration for the OpenShift SDN network plugin
  Configuration for the OVN-Kubernetes network plugin
  kubeProxyConfig object configuration
18.5.10. Creating the Kubernetes manifest and Ignition config files
18.5.11. Installing RHcos and starting the OpenShift Container Platform bootstrap process
  18.5.11.1. Installing RHcos using IBM Secure Execution
  18.5.11.2. Configuring NBDE with static IP in an IBM Z or IBM LinuxONE environment
  18.5.11.3. Fast-track installation by using a prepackaged QCOW2 disk image
  18.5.11.4. Full installation on a new QCOW2 disk image
  18.5.11.5. Advanced RHcos installation reference
  18.5.11.5.1. Networking options for ISO installations
  Configuring DHCP or static IP addresses
  Configuring an IP address without a static hostname
  Specifying multiple network interfaces
  Configuring default gateway and route
  Disabling DHCP on a single interface
  Combining DHCP and static IP configurations
  Configuring VLANs on individual interfaces
  Providing multiple DNS servers
18.5.12. Waiting for the bootstrap process to complete
18.5.13. Logging in to the cluster by using the CLI
18.5.14. Approving the certificate signing requests for your machines
18.5.15. Initial Operator configuration
  18.5.15.1. Disabling the default OperatorHub catalog sources
  18.5.15.2. Image registry storage configuration
  18.5.15.2.1. Configuring registry storage for IBM Z
  18.5.15.2.2. Configuring storage for the image registry in non-production clusters
18.5.16. Completing installation on user-provisioned infrastructure
18.5.17. Next steps

18.6. INSTALLATION CONFIGURATION PARAMETERS FOR IBM Z AND IBM LINUXONE
18.6.1. Available installation configuration parameters for IBM Z
  18.6.1.1. Required configuration parameters
  18.6.1.2. Network configuration parameters
CHAPTER 19. INSTALLING ON IBM POWER

19.1. PREPARING TO INSTALL ON IBM POWER

19.1.1. Prerequisites

19.1.2. Choosing a method to install OpenShift Container Platform on IBM Power

19.2. INSTALLING A CLUSTER ON IBM POWER

19.2.1. Prerequisites

19.2.2. Internet access for OpenShift Container Platform

19.2.3. Requirements for a cluster with user-provisioned infrastructure

19.2.3.1. Required machines for cluster installation

19.2.3.2. Minimum resource requirements for cluster installation

19.2.3.3. Minimum IBM Power requirements

Hardware requirements
Operating system requirements
Disk storage for the IBM Power guest virtual machines
Network for the PowerVM guest virtual machines
Storage / main memory

19.2.3.4. Recommended IBM Power system requirements

Hardware requirements
Operating system requirements
Disk storage for the IBM Power guest virtual machines
Network for the PowerVM guest virtual machines
Storage / main memory

19.2.3.5. Certificate signing requests management

19.2.3.6. Networking requirements for user-provisioned infrastructure

19.2.3.6.1. Setting the cluster node hostnames through DHCP

19.2.3.6.2. Network connectivity requirements

NTP configuration for user-provisioned infrastructure

19.2.3.7. User-provisioned DNS requirements

19.2.3.7.1. Example DNS configuration for user-provisioned clusters

19.2.3.8. Load balancing requirements for user-provisioned infrastructure

19.2.3.8.1. Example load balancer configuration for user-provisioned clusters

19.2.4. Preparing the user-provisioned infrastructure

19.2.5. Validating DNS resolution for user-provisioned infrastructure

19.2.6. Generating a key pair for cluster node SSH access

19.2.7. Obtaining the installation program

19.2.8. Installing the OpenShift CLI by downloading the binary

Installing the OpenShift CLI on Linux
Installing the OpenShift CLI on Windows
Installing the OpenShift CLI on macOS

19.2.9. Manually creating the installation configuration file

19.2.9.1. Sample install-config.yaml file for IBM Power

19.2.9.2. Configuring the cluster-wide proxy during installation

19.2.9.3. Configuring a three-node cluster

19.2.10. Cluster Network Operator configuration

19.2.10.1. Cluster Network Operator configuration object

defaultNetwork object configuration

Configuration for the OpenShift SDN network plugin

Configuration for the OVN-Kubernetes network plugin

kubeProxyConfig object configuration

19.2.11. Creating the Kubernetes manifest and Ignition config files

19.2.12. Installing RHCOS and starting the OpenShift Container Platform bootstrap process
19.2.12.1. Installing RHCOS by using an ISO image 2722
19.2.12.1.1. Advanced RHCOS installation reference 2726
19.2.12.1.1.1. Networking and bonding options for ISO installations 2726
  Configuring DHCP or static IP addresses 2726
  Configuring an IP address without a static hostname 2727
  Specifying multiple network interfaces 2727
  Configuring default gateway and route 2727
  Disabling DHCP on a single interface 2727
  Combining DHCP and static IP configurations 2728
  Configuring VLANs on individual interfaces 2728
  Providing multiple DNS servers 2728
  Bonding multiple network interfaces to a single interface 2728
  Bonding multiple SR-IOV network interfaces to a dual port NIC interface 2729
19.2.12.2. Installing RHCOS by using PXE booting 2729
19.2.12.3. Enabling multipathing with kernel arguments on RHCOS 2733
19.2.13. Waiting for the bootstrap process to complete 2734
19.2.14. Logging in to the cluster by using the CLI 2735
19.2.15. Approving the certificate signing requests for your machines 2736
19.2.16. Initial Operator configuration 2739
  19.2.16.1. Image registry storage configuration 2740
    19.2.16.1.1. Configuring registry storage for IBM Power 2740
    19.2.16.1.2. Configuring storage for the image registry in non-production clusters 2741
19.2.17. Completing installation on user-provisioned infrastructure 2742
19.2.18. Telemetry access for OpenShift Container Platform 2744
19.2.19. Next steps 2744
19.3. INSTALLING A CLUSTER ON IBM POWER IN A RESTRICTED NETWORK 2745
  19.3.1. Prerequisites 2745
  19.3.2. About installations in restricted networks 2745
    19.3.2.1. Additional limits 2746
  19.3.3. Internet access for OpenShift Container Platform 2746
  19.3.4. Requirements for a cluster with user-provisioned infrastructure 2746
    19.3.4.1. Required machines for cluster installation 2746
    19.3.4.2. Minimum resource requirements for cluster installation 2747
  19.3.4.3. Minimum IBM Power requirements 2748
    Hardware requirements 2748
    Operating system requirements 2748
    Disk storage for the IBM Power guest virtual machines 2748
    Network for the PowerVM guest virtual machines 2748
    Storage / main memory 2748
  19.3.4.4. Recommended IBM Power system requirements 2749
    Hardware requirements 2749
    Operating system requirements 2749
    Disk storage for the IBM Power guest virtual machines 2749
    Network for the PowerVM guest virtual machines 2749
    Storage / main memory 2749
  19.3.4.5. Certificate signing requests management 2749
  19.3.4.6. Networking requirements for user-provisioned infrastructure 2749
    19.3.4.6.1. Setting the cluster node hostnames through DHCP 2750
    19.3.4.6.2. Network connectivity requirements 2750
      NTP configuration for user-provisioned infrastructure 2751
  19.3.4.7. User-provisioned DNS requirements 2751
    19.3.4.7.1. Example DNS configuration for user-provisioned clusters 2753
  19.3.4.8. Load balancing requirements for user-provisioned infrastructure 2756
19.3.8.1. Example load balancer configuration for user-provisioned clusters
19.3.5. Preparing the user-provisioned infrastructure
19.3.6. Validating DNS resolution for user-provisioned infrastructure
19.3.7. Generating a key pair for cluster node SSH access
19.3.8. Manually creating the installation configuration file
19.3.8.1. Sample install-config.yaml file for IBM Power
19.3.8.2. Configuring the cluster-wide proxy during installation
19.3.8.3. Configuring a three-node cluster
19.3.9. Cluster Network Operator configuration
19.3.9.1. Cluster Network Operator configuration object
   defaultNetwork object configuration
   Configuration for the OpenShift SDN network plugin
   Configuration for the OVN-Kubernetes network plugin
   kubeProxyConfig object configuration
19.3.10. Creating the Kubernetes manifest and Ignition config files
19.3.11. Installing RHCOS and starting the OpenShift Container Platform bootstrap process
19.3.11.1. Installing RHCOS by using an ISO image
   19.3.11.1.1. Advanced RHCOS installation reference
      19.3.11.1.1.1. Networking and bonding options for ISO installations
         Configuring DHCP or static IP addresses
         Configuring an IP address without a static hostname
         Specifying multiple network interfaces
         Configuring default gateway and route
         Disabling DHCP on a single interface
         Combining DHCP and static IP configurations
         Configuring VLANs on individual interfaces
         Providing multiple DNS servers
         Bonding multiple network interfaces to a single interface
         Bonding multiple SR-IOV network interfaces to a dual port NIC interface
   19.3.11.2. Installing RHCOS by using PXE booting
   19.3.11.3. Enabling multipathing with kernel arguments on RHCOS
19.3.12. Waiting for the bootstrap process to complete
19.3.13. Logging in to the cluster by using the CLI
19.3.14. Approving the certificate signing requests for your machines
19.3.15. Initial Operator configuration
   19.3.15.1. Disabling the default OperatorHub catalog sources
   19.3.15.2. Image registry storage configuration
      19.3.15.2.1. Changing the image registry's management state
      19.3.15.2.2. Configuring registry storage for IBM Power
      19.3.15.2.3. Configuring storage for the image registry in non-production clusters
   19.3.16. Completing installation on user-provisioned infrastructure
19.3.17. Next steps
19.4. INSTALLATION CONFIGURATION PARAMETERS FOR IBM POWER
   19.4.1. Available installation configuration parameters for IBM Power
   19.4.1.1. Required configuration parameters
   19.4.1.2. Network configuration parameters
   19.4.1.3. Optional configuration parameters

CHAPTER 20. INSTALLING ON IBM POWER VIRTUAL SERVER

20.1. PREPARING TO INSTALL ON IBM POWER VIRTUAL SERVER
   20.1.1. Prerequisites
   20.1.2. Requirements for installing OpenShift Container Platform on IBM Power Virtual Server
   20.1.3. Choosing a method to install OpenShift Container Platform on IBM Power Virtual Server
20.1.3.1. Installing a cluster on installer-provisioned infrastructure
20.1.4. Configuring the Cloud Credential Operator utility
20.1.5. Next steps

20.2. CONFIGURING AN IBM CLOUD ACCOUNT
20.2.1. Prerequisites
20.2.2. Quotas and limits on IBM Power Virtual Server
    Virtual Private Cloud
    Application load balancer
    Cloud connections
    Dynamic Host Configuration Protocol Service
    Networking
    Virtual Server Instances
20.2.3. Configuring DNS resolution
20.2.4. Using IBM Cloud Internet Services for DNS resolution
20.2.5. IBM Cloud IAM Policies and API Key
    20.2.5.1. Pre-requisite permissions
    20.2.5.2. Cluster-creation permissions
    20.2.5.3. Access policy assignment
    20.2.5.4. Creating an API key
20.2.6. Supported IBM Power Virtual Server regions and zones
20.2.7. Next steps

20.3. CREATING AN IBM POWER VIRTUAL SERVER WORKSPACE
20.3.1. Creating an IBM Power Virtual Server workspace
20.3.2. Next steps

20.4. INSTALLING A CLUSTER ON IBM POWER VIRTUAL SERVER WITH CUSTOMIZATIONS
20.4.1. Prerequisites
20.4.2. Internet access for OpenShift Container Platform
20.4.3. Generating a key pair for cluster node SSH access
20.4.4. Obtaining the installation program
20.4.5. Exporting the API key
20.4.6. Creating the installation configuration file
    20.4.6.1. Sample customized install-config.yaml file for IBM Power Virtual Server
    20.4.6.2. Configuring the cluster-wide proxy during installation
20.4.7. Manually creating IAM
20.4.8. Deploying the cluster
20.4.9. Installing the OpenShift CLI by downloading the binary
    Installing the OpenShift CLI on Linux
    Installing the OpenShift CLI on Windows
    Installing the OpenShift CLI on macOS
20.4.10. Logging in to the cluster by using the CLI
20.4.11. Telemetry access for OpenShift Container Platform
20.4.12. Next steps

20.5. INSTALLING A CLUSTER ON IBM POWER VIRTUAL SERVER INTO AN EXISTING VPC
20.5.1. Prerequisites
20.5.2. About using a custom VPC
    20.5.2.1. Requirements for using your VPC
    20.5.2.2. VPC validation
    20.5.2.3. Isolation between clusters
20.5.3. Internet access for OpenShift Container Platform
20.5.4. Generating a key pair for cluster node SSH access
20.5.5. Obtaining the installation program
20.5.6. Exporting the API key
20.5.7. Creating the installation configuration file
20.7.9. Deploying the cluster
20.7.10. Installing the OpenShift CLI by downloading the binary
   Installing the OpenShift CLI on Linux
   Installing the OpenShift CLI on Windows
   Installing the OpenShift CLI on macOS
20.7.11. Logging in to the cluster by using the CLI
20.7.12. Disabling the default OperatorHub catalog sources
20.7.13. Telemetry access for OpenShift Container Platform
20.7.14. Next steps
20.8. UNINSTALLING A CLUSTER ON IBM POWER VIRTUAL SERVER
   20.8.1. Removing a cluster that uses installer-provisioned infrastructure
20.9. INSTALLATION CONFIGURATION PARAMETERS FOR IBM POWER VIRTUAL SERVER
   20.9.1. Available installation configuration parameters for IBM Power Virtual Server
      20.9.1.1. Required configuration parameters
      20.9.1.2. Network configuration parameters
      20.9.1.3. Optional configuration parameters
CHAPTER 21. INSTALLING ON OPENSTACK
21.1. PREPARING TO INSTALL ON OPENSTACK
   21.1.1. Prerequisites
   21.1.2. Choosing a method to install OpenShift Container Platform on OpenStack
      21.1.2.1. Installing a cluster on installer-provisioned infrastructure
      21.1.2.2. Installing a cluster on user-provisioned infrastructure
   21.1.3. Scanning RHOSP endpoints for legacy HTTPS certificates
      21.1.3.1. Scanning RHOSP endpoints for legacy HTTPS certificates manually
21.2. PREPARING TO INSTALL A CLUSTER THAT USES SR-IOV OR OVS-DPDK ON OPENSTACK
   21.2.1. Requirements for clusters on RHOSP that use either SR-IOV or OVS-DPDK
      21.2.1.1. Requirements for clusters on RHOSP that use SR-IOV
      21.2.1.2. Requirements for clusters on RHOSP that use OVS-DPDK
   21.2.2. Preparing to install a cluster that uses SR-IOV
      21.2.2.1. Creating SR-IOV networks for compute machines
   21.2.3. Preparing to install a cluster that uses OVS-DPDK
   21.2.4. Next steps
21.3. INSTALLING A CLUSTER ON OPENSTACK WITH CUSTOMIZATIONS
   21.3.1. Prerequisites
   21.3.2. Resource guidelines for installing OpenShift Container Platform on RHOSP
      21.3.2.1. Control plane machines
      21.3.2.2. Compute machines
      21.3.2.3. Bootstrap machine
      21.3.2.4. Load balancing requirements for user-provisioned infrastructure
         21.3.2.4.1. Example load balancer configuration for clusters that are deployed with user-managed load balancers
   21.3.3. Internet access for OpenShift Container Platform
   21.3.4. Enabling Swift on RHOSP
   21.3.5. Configuring an image registry with custom storage on clusters that run on RHOSP
   21.3.6. Verifying external network access
   21.3.7. Defining parameters for the installation program
   21.3.8. Setting OpenStack Cloud Controller Manager options
   21.3.9. Obtaining the installation program
   21.3.10. Creating the installation configuration file
      21.3.10.1. Configuring the cluster-wide proxy during installation
      21.3.10.2. Custom subnets in RHOSP deployments
      21.3.10.3. Deploying a cluster with bare metal machines
21.3.10.4. Cluster deployment on RHOSP provider networks
   21.3.10.4.1. RHOSP provider network requirements for cluster installation
   21.3.10.4.2. Deploying a cluster that has a primary interface on a provider network
   21.3.10.5. Sample customized install-config.yaml file for RHOSP
   21.3.10.6. Optional: Configuring a cluster with dual-stack networking
      21.3.10.6.1. Deploying the dual-stack cluster
      21.3.10.7. Installation configuration for a cluster on OpenStack with a user-managed load balancer
   21.3.11. Generating a key pair for cluster node SSH access
   21.3.12. Enabling access to the environment
      21.3.12.1. Enabling access with floating IP addresses
      21.3.12.2. Completing installation without floating IP addresses
   21.3.13. Deploying the cluster
   21.3.14. Verifying cluster status
   21.3.15. Logging in to the cluster by using the CLI
   21.3.16. Telemetry access for OpenShift Container Platform
   21.3.17. Next steps
   21.4. INSTALLING A CLUSTER ON OPENSTACK WITH KURYR
      21.4.1. Prerequisites
      21.4.2. About Kuryr SDN
      21.4.3. Resource guidelines for installing OpenShift Container Platform on RHOSP with Kuryr
         21.4.3.1. Increasing quota
         21.4.3.2. Configuring Neutron
         21.4.3.3. Configuring Octavia
            21.4.3.3.1. The Octavia OVN Driver
         21.4.3.4. Known limitations of installing with Kuryr
            21.4.3.4.1. RHOSP general limitations
            21.4.3.4.2. RHOSP version limitations
            21.4.3.4.3. RHOSP upgrade limitations
         21.4.3.5. Control plane machines
         21.4.3.6. Compute machines
         21.4.3.7. Bootstrap machine
         21.4.3.8. Load balancing requirements for user-provisioned infrastructure
            21.4.3.8.1. Example load balancer configuration for clusters that are deployed with user-managed load balancers
      21.4.4. Internet access for OpenShift Container Platform
      21.4.5. Enabling Swift on RHOSP
      21.4.6. Verifying external network access
      21.4.7. Defining parameters for the installation program
      21.4.8. Setting OpenStack Cloud Controller Manager options
      21.4.9. Obtaining the installation program
      21.4.10. Creating the installation configuration file
         21.4.10.1. Configuring the cluster-wide proxy during installation
         21.4.10.2. Custom subnets in RHOSP deployments
         21.4.10.3. Sample customized install-config.yaml file for RHOSP with Kuryr
         21.4.10.4. Installation configuration for a cluster on OpenStack with a user-managed load balancer
         21.4.10.5. Cluster deployment on RHOSP provider networks
            21.4.10.5.1. RHOSP provider network requirements for cluster installation
            21.4.10.5.2. Deploying a cluster that has a primary interface on a provider network
            21.4.10.6. Kuryr ports pools
         21.4.10.7. Adjusting Kuryr ports pools during installation
      21.4.11. Generating a key pair for cluster node SSH access
      21.4.12. Enabling access to the environment
      21.4.12.1. Enabling access with floating IP addresses
21.6.3.4. Known limitations of installing with Kuryr
   RHOSP general limitations
   RHOSP version limitations
   RHOSP upgrade limitations
21.6.3.5. Control plane machines
21.6.3.6. Compute machines
21.6.3.7. Bootstrap machine
21.6.4. Internet access for OpenShift Container Platform
21.6.5. Downloading playbook dependencies
21.6.6. Downloading the installation playbooks
21.6.7. Obtaining the installation program
21.6.8. Generating a key pair for cluster node SSH access
21.6.9. Creating the Red Hat Enterprise Linux CoreOS (RHCOS) image
21.6.10. Verifying external network access
21.6.11. Enabling access to the environment
   21.6.11.1. Enabling access with floating IP addresses
   21.6.11.2. Completing installation without floating IP addresses
   21.6.12. Defining parameters for the installation program
21.6.13. Creating the installation configuration file
   21.6.13.1. Custom subnets in RHOSP deployments
   21.6.13.2. Sample customized install-config.yaml file for RHOSP with Kuryr
   21.6.13.3. Cluster deployment on RHOSP provider networks
      21.6.13.3.1. RHOSP provider network requirements for cluster installation
      21.6.13.3.2. Deploying a cluster that has a primary interface on a provider network
   21.6.13.4. Kuryr ports pools
   21.6.13.5. Adjusting Kuryr ports pools during installation
   21.6.13.6. Setting a custom subnet for machines
   21.6.13.7. Emptying compute machine pools
   21.6.13.8. Modifying the network type
21.6.14. Creating the Kubernetes manifest and Ignition config files
21.6.15. Preparing the bootstrap Ignition files
21.6.16. Creating control plane Ignition config files on RHOSP
21.6.17. Creating network resources on RHOSP
21.6.18. Creating the bootstrap machine on RHOSP
21.6.19. Creating the control plane machines on RHOSP
21.6.20. Logging in to the cluster by using the CLI
21.6.21. Deleting bootstrap resources from RHOSP
21.6.22. Creating compute machines on RHOSP
21.6.23. Approving the certificate signing requests for your machines
21.6.24. Verifying a successful installation
21.6.25. Telemetry access for OpenShift Container Platform
21.6.26. Next steps

21.7. INSTALLING A CLUSTER ON OPENSTACK IN A RESTRICTED NETWORK
21.7.1. Prerequisites
21.7.2. About installations in restricted networks
   21.7.2.1. Additional limits
21.7.3. Resource guidelines for installing OpenShift Container Platform on RHOSP
   21.7.3.1. Control plane machines
   21.7.3.2. Compute machines
   21.7.3.3. Bootstrap machine
21.7.4. Internet access for OpenShift Container Platform
21.7.5. Enabling Swift on RHOSP
21.7.6. Defining parameters for the installation program

60
21.7.7. Setting OpenStack Cloud Controller Manager options
21.7.8. Creating the RHCOS image for restricted network installations
21.7.9. Creating the installation configuration file
    21.7.9.1. Configuring the cluster-wide proxy during installation
    21.7.9.2. Sample customized install-config.yaml file for restricted OpenStack installations
21.7.10. Generating a key pair for cluster node SSH access
21.7.11. Enabling access to the environment
    21.7.11.1. Enabling access with floating IP addresses
    21.7.11.2. Completing installation without floating IP addresses
21.7.12. Deploying the cluster
21.7.13. Verifying cluster status
21.7.14. Logging in to the cluster by using the CLI
21.7.15. Disabling the default OperatorHub catalog sources
21.7.16. Telemetry access for OpenShift Container Platform
21.7.17. Next steps
21.8. OPENSTACK CLOUD CONTROLLER MANAGER REFERENCE GUIDE
    21.8.1. The OpenStack Cloud Controller Manager
    21.8.2. The OpenStack Cloud Controller Manager (CCM) config map
        21.8.2.1. Load balancer options
        21.8.2.2. Options that the Operator overrides
21.9. UNINSTALLING A CLUSTER ON OPENSTACK
    21.9.1. Removing a cluster that uses installer-provisioned infrastructure
21.10. UNINSTALLING A CLUSTER ON RHOSP FROM YOUR OWN INFRASTRUCTURE
    21.10.1. Downloading playbook dependencies
    21.10.2. Removing a cluster from RHOSP that uses your own infrastructure
21.11. INSTALLATION CONFIGURATION PARAMETERS FOR OPENSTACK
    21.11.1. Available installation configuration parameters for OpenStack
        21.11.1.1. Required configuration parameters
        21.11.1.2. Network configuration parameters
        21.11.1.3. Optional configuration parameters
        21.11.1.4. Additional Red Hat OpenStack Platform (RHOSP) configuration parameters
        21.11.1.5. Optional RHOSP configuration parameters
CHAPTER 22. INSTALLING ON VSPHERE
22.1. PREPARING TO INSTALL ON VSPHERE
    22.1.1. Prerequisites
    22.1.2. Choosing a method to install OpenShift Container Platform on vSphere
        22.1.2.1. Installer-provisioned infrastructure installation of OpenShift Container Platform on vSphere
        22.1.2.2. User-provisioned infrastructure installation of OpenShift Container Platform on vSphere
    22.1.3. VMware vSphere infrastructure requirements
    22.1.4. VMware vSphere CSI Driver Operator requirements
    22.1.5. Configuring the vSphere connection settings
    22.1.6. Uninstalling an installer-provisioned infrastructure installation of OpenShift Container Platform on vSphere
22.2. INSTALLING A CLUSTER ON VSPHERE
    22.2.1. Prerequisites
    22.2.2. Internet access for OpenShift Container Platform
    22.2.3. VMware vSphere infrastructure requirements
    22.2.4. Network connectivity requirements
    22.2.5. VMware vSphere CSI Driver Operator requirements
    22.2.6. vCenter requirements
        Required vCenter account privileges
        Using OpenShift Container Platform with vMotion
Cluster resources
Cluster limits
Networking requirements
Required IP Addresses
DNS records
Static IP addresses for vSphere nodes

22.2.7. Generating a key pair for cluster node SSH access
22.2.8. Obtaining the installation program
22.2.9. Adding vCenter root CA certificates to your system trust
22.2.10. Deploying the cluster
22.2.11. Installing the OpenShift CLI by downloading the binary
   Installing the OpenShift CLI on Linux
   Installing the OpenShift CLI on Windows
   Installing the OpenShift CLI on macOS
22.2.12. Logging in to the cluster by using the CLI
22.2.13. Creating registry storage
   22.2.13.1. Image registry removed during installation
   22.2.13.2. Image registry storage configuration
      22.2.13.2.1. Configuring registry storage for VMware vSphere
      22.2.13.2.2. Configuring block registry storage for VMware vSphere
22.2.14. Backing up VMware vSphere volumes
22.2.15. Telemetry access for OpenShift Container Platform
22.2.16. Configuring an external load balancer
22.2.17. Next steps

22.3. INSTALLING A CLUSTER ON VSPHERE WITH CUSTOMIZATIONS
22.3.1. Prerequisites
22.3.2. Internet access for OpenShift Container Platform
22.3.3. VMware vSphere infrastructure requirements
22.3.4. Network connectivity requirements
22.3.5. VMware vSphere CSI Driver Operator requirements
22.3.6. vCenter requirements
   Required vCenter account privileges
   Using OpenShift Container Platform with vMotion
   Cluster resources
   Cluster limits
   Networking requirements
   Required IP Addresses
   DNS records
   Static IP addresses for vSphere nodes
22.3.7. Generating a key pair for cluster node SSH access
22.3.8. Obtaining the installation program
22.3.9. Adding vCenter root CA certificates to your system trust
22.3.10. VMware vSphere region and zone enablement
22.3.11. Creating the installation configuration file
   22.3.11.1. Sample install-config.yaml file for an installer-provisioned VMware vSphere cluster
   22.3.11.2. Configuring the cluster-wide proxy during installation
   22.3.11.3. Configuring regions and zones for a VMware vCenter
22.3.12. Deploying the cluster
22.3.13. Installing the OpenShift CLI by downloading the binary
   Installing the OpenShift CLI on Linux
   Installing the OpenShift CLI on Windows
   Installing the OpenShift CLI on macOS
22.3.14. Logging in to the cluster by using the CLI
22.3.15. Creating registry storage
  22.3.15.1. Image registry removed during installation
  22.3.15.2. Image registry storage configuration
    22.3.15.2.1. Configuring registry storage for VMware vSphere
    22.3.15.2.2. Configuring block registry storage for VMware vSphere
  22.3.16. Backing up VMware vSphere volumes
  22.3.17. Telemetry access for OpenShift Container Platform
  22.3.18. Configuring an external load balancer
  22.3.19. Next steps

22.4. INSTALLING A CLUSTER ON VSPHERE WITH NETWORK CUSTOMIZATIONS
  22.4.1. Prerequisites
  22.4.2. Internet access for OpenShift Container Platform
  22.4.3. VMware vSphere infrastructure requirements
  22.4.4. Network connectivity requirements
  22.4.5. VMware vSphere CSI Driver Operator requirements
  22.4.6. vCenter requirements
    Required vCenter account privileges
    Using OpenShift Container Platform with vMotion
  Cluster resources
  Cluster limits
  Networking requirements
    Required IP Addresses
    DNS records
    Static IP addresses for vSphere nodes
  22.4.7. Generating a key pair for cluster node SSH access
  22.4.8. Obtaining the installation program
  22.4.9. Adding vCenter root CA certificates to your system trust
  22.4.10. VMware vSphere region and zone enablement
  22.4.11. Creating the installation configuration file
    22.4.11.1. Sample install-config.yaml file for an installer-provisioned VMware vSphere cluster
    22.4.11.2. Configuring the cluster-wide proxy during installation
    22.4.11.3. Optional: Deploying with dual-stack networking
    22.4.11.4. Configuring regions and zones for a VMware vCenter
  22.4.12. Network configuration phases
  22.4.13. Specifying advanced network configuration
  22.4.14. Cluster Network Operator configuration
      defaultNetwork object configuration
      Configuration for the OpenShift SDN network plugin
      Configuration for the OVN-Kubernetes network plugin
      kubeProxyConfig object configuration
  22.4.15. Deploying the cluster
  22.4.16. Installing the OpenShift CLI by downloading the binary
    Installing the OpenShift CLI on Linux
    Installing the OpenShift CLI on Windows
    Installing the OpenShift CLI on macOS
  22.4.17. Logging in to the cluster by using the CLI
  22.4.18. Creating registry storage
    22.4.18.1. Image registry removed during installation
    22.4.18.2. Image registry storage configuration
      22.4.18.2.1. Configuring registry storage for VMware vSphere
      22.4.18.2.2. Configuring block registry storage for VMware vSphere
  22.4.19. Backing up VMware vSphere volumes
22.4.20. Telemetry access for OpenShift Container Platform
22.4.21. Configuring an external load balancer
22.4.22. Configuring network components to run on the control plane
22.4.23. Next steps

22.5. INSTALLING A CLUSTER ON VSphere WITH USER-PROVISIONED INFRASTRUCTURE

22.5.1. Prerequisites
22.5.2. Internet access for OpenShift Container Platform
22.5.3. VMware vSphere infrastructure requirements
22.5.4. VMware vSphere CSI Driver Operator requirements
22.5.5. Requirements for a cluster with user-provisioned infrastructure
22.5.5.1. vCenter requirements
   - Required vCenter account privileges
   - Using OpenShift Container Platform with vMotion
   - Cluster resources
   - Cluster limits
   - Networking requirements
   - Required IP Addresses
   - DNS records
22.5.5.2. Required machines for cluster installation
22.5.5.3. Minimum resource requirements for cluster installation
22.5.5.4. Requirements for encrypting virtual machines
22.5.5.5. Certificate signing requests management
22.5.5.6. Networking requirements for user-provisioned infrastructure
   - Setting the cluster node hostnames through DHCP
   - Network connectivity requirements
   - Ethernet adaptor hardware address requirements
   - NTP configuration for user-provisioned infrastructure
22.5.5.7. User-provisioned DNS requirements
   - Example DNS configuration for user-provisioned clusters
22.5.5.8. Load balancing requirements for user-provisioned infrastructure
   - Example load balancer configuration for user-provisioned clusters
22.5.6. Preparing the user-provisioned infrastructure
22.5.7. Validating DNS resolution for user-provisioned infrastructure
22.5.8. Generating a key pair for cluster node SSH access
22.5.9. VMware vSphere region and zone enablement
22.5.10. Obtaining the installation program
22.5.11. Manually creating the installation configuration file
   - Sample install-config.yaml file for VMware vSphere
   - Configuring the cluster-wide proxy during installation
   - Configuring regions and zones for a VMware vCenter
   - Creating the Kubernetes manifest and Ignition config files
22.5.12. Extracting the infrastructure name
22.5.13. Installing RHCOS and starting the OpenShift Container Platform bootstrap process
22.5.14. Adding more compute machines to a cluster in vSphere
22.5.15. Disk partitioning
   - Creating a separate /var partition
22.5.16. Updating the bootloader using bootupd
22.5.17. Installing the OpenShift CLI by downloading the binary
   - Installing the OpenShift CLI on Linux
   - Installing the OpenShift CLI on Windows
   - Installing the OpenShift CLI on macOS
22.5.18. Waiting for the bootstrap process to complete
22.5.19. Logging in to the cluster by using the CLI
22.5.21. Approving the certificate signing requests for your machines
22.5.22. Initial Operator configuration
22.5.22.1. Image registry removed during installation
22.5.22.2. Image registry storage configuration
   22.5.22.2.1. Configuring registry storage for VMware vSphere
   22.5.22.2.2. Configuring storage for the image registry in non-production clusters
   22.5.22.2.3. Configuring block registry storage for VMware vSphere
22.5.23. Completing installation on user-provisioned infrastructure
22.5.24. Configuring vSphere DRS anti-affinity rules for control plane nodes
22.5.25. Backing up VMware vSphere volumes
22.5.26. Telemetry access for OpenShift Container Platform
22.5.27. Next steps

22.6. INSTALLING A CLUSTER ON VSPHERE WITH NETWORK CUSTOMIZATIONS
22.6.1. Prerequisites
22.6.2. Internet access for OpenShift Container Platform
22.6.3. VMware vSphere infrastructure requirements
22.6.4. VMware vSphere CSI Driver Operator requirements
22.6.5. Requirements for a cluster with user-provisioned infrastructure
   22.6.5.1. vCenter requirements
      Required vCenter account privileges
      Using OpenShift Container Platform with vMotion
      Cluster resources
      Cluster limits
      Networking requirements
      Required IP Addresses
      DNS records
   22.6.5.2. Required machines for cluster installation
   22.6.5.3. Minimum resource requirements for cluster installation
   22.6.5.4. Requirements for encrypting virtual machines
   22.6.5.5. Certificate signing requests management
   22.6.5.6. Networking requirements for user-provisioned infrastructure
      22.6.5.6.1. Setting the cluster node hostnames through DHCP
      22.6.5.6.2. Network connectivity requirements
      Ethernet adaptor hardware address requirements
      NTP configuration for user-provisioned infrastructure
   22.6.5.7. User-provisioned DNS requirements
      22.6.5.7.1. Example DNS configuration for user-provisioned clusters
   22.6.5.8. Load balancing requirements for user-provisioned infrastructure
      22.6.5.8.1. Example load balancer configuration for user-provisioned clusters
   22.6.6. Preparing the user-provisioned infrastructure
   22.6.7. Validating DNS resolution for user-provisioned infrastructure
   22.6.8. Generating a key pair for cluster node SSH access
   22.6.9. VMware vSphere region and zone enablement
   22.6.10. Obtaining the installation program
   22.6.11. Manually creating the installation configuration file
      22.6.11.1. Sample install-config.yaml file for VMware vSphere
      22.6.11.2. Configuring the cluster-wide proxy during installation
      22.6.11.3. Configuring regions and zones for a VMware vCenter
   22.6.12. Network configuration phases
   22.6.13. Specifying advanced network configuration
         defaultNetwork object configuration

Table of Contents
Configuration for the OpenShift SDN network plugin 3372
Configuration for the OVN-Kubernetes network plugin 3373
kubeProxyConfig object configuration 3378
22.6.15. Creating the Ignition config files 3378
22.6.16. Extracting the infrastructure name 3379
22.6.17. Installing RHCOS and starting the OpenShift Container Platform bootstrap process 3380
22.6.18. Adding more compute machines to a cluster in vSphere 3385
22.6.19. Disk partitioning 3386
   Creating a separate /var partition 3387
22.6.20. Updating the bootloader using bootupd 3389
22.6.21. Waiting for the bootstrap process to complete 3390
22.6.22. Logging in to the cluster by using the CLI 3391
22.6.23. Approving the certificate signing requests for your machines 3391
   22.6.23.1. Initial Operator configuration 3394
   22.6.23.2. Image registry removed during installation 3395
   22.6.23.3. Image registry storage configuration 3395
   22.6.23.3.1. Configuring block registry storage for VMware vSphere 3396
22.6.24. Completing installation on user-provisioned infrastructure 3397
22.6.25. Configuring vSphere DRS anti-affinity rules for control plane nodes 3399
22.6.26. Backing up VMware vSphere volumes 3401
22.6.27. Telemetry access for OpenShift Container Platform 3401
22.6.28. Next steps 3401
22.7. INSTALLING A CLUSTER ON VSPHERE IN A RESTRICTED NETWORK 3401
   22.7.1. Prerequisites 3402
   22.7.2. About installations in restricted networks 3402
      22.7.2.1. Additional limits 3403
   22.7.3. Internet access for OpenShift Container Platform 3403
   22.7.4. VMware vSphere infrastructure requirements 3403
   22.7.5. Network connectivity requirements 3404
   22.7.6. VMware vSphere CSI Driver Operator requirements 3405
   22.7.7. vCenter requirements 3406
      Required vCenter account privileges 3406
      Using OpenShift Container Platform with vMotion 3415
      Cluster resources 3415
      Cluster limits 3416
      Networking requirements 3416
      Required IP Addresses 3416
      DNS records 3417
      Static IP addresses for vSphere nodes 3417
   22.7.8. Generating a key pair for cluster node SSH access 3418
   22.7.9. Adding vCenter root CA certificates to your system trust 3420
   22.7.10. Creating the RHcos image for restricted network installations 3421
   22.7.11. VMware vSphere region and zone enablement 3422
   22.7.12. Creating the installation configuration file 3423
      22.7.12.1. Sample install-config.yaml file for an installer-provisioned VMware vSphere cluster 3427
      22.7.12.2. Configuring the cluster-wide proxy during installation 3429
      22.7.12.3. Configuring regions and zones for a VMware vCenter 3431
   22.7.13. Deploying the cluster 3433
   22.7.14. Installing the OpenShift CLI by downloading the binary 3434
      Installing the OpenShift CLI on Linux 3434
      Installing the OpenShift CLI on Windows 3435
      Installing the OpenShift CLI on macOS 3435
   22.7.15. Logging in to the cluster by using the CLI 3436
22.7.16. Disabling the default OperatorHub catalog sources
22.7.17. Creating registry storage
  22.7.17.1. Image registry removed during installation
  22.7.17.2. Image registry storage configuration
    22.7.17.2.1. Configuring registry storage for VMware vSphere
  22.7.18. Telemetry access for OpenShift Container Platform
  22.7.19. Configuring an external load balancer
  22.7.20. Next steps

22.8. INSTALLING A CLUSTER ON VSphere IN A RESTRICTED NETWORK WITH USER-PROVISIONED INFRASTRUCTURE

22.8.1. Prerequisites
  22.8.2. About installations in restricted networks
    22.8.2.1. Additional limits
  22.8.3. Internet access for OpenShift Container Platform
  22.8.4. VMware vsphere infrastructure requirements
  22.8.5. VMware vsphere CSI Driver Operator requirements
  22.8.6. Requirements for a cluster with user-provisioned infrastructure
    22.8.6.1. vCenter requirements
      Required vCenter account privileges
      Using OpenShift Container Platform with vMotion
      Cluster resources
      Cluster limits
      Networking requirements
      Required IP Addresses
      DNS records
    22.8.6.2. Required machines for cluster installation
    22.8.6.3. Minimum resource requirements for cluster installation
    22.8.6.4. Requirements for encrypting virtual machines
    22.8.6.5. Certificate signing requests management
    22.8.6.6. Networking requirements for user-provisioned infrastructure
      22.8.6.6.1. Setting the cluster node hostnames through DHCP
      22.8.6.6.2. Network connectivity requirements
        Ethernet adaptor hardware address requirements
        NTP configuration for user-provisioned infrastructure
    22.8.6.7. User-provisioned DNS requirements
      22.8.6.7.1. Example DNS configuration for user-provisioned clusters
    22.8.6.8. Load balancing requirements for user-provisioned infrastructure
      22.8.6.8.1. Example load balancer configuration for user-provisioned clusters
    22.8.7. Preparing the user-provisioned infrastructure
    22.8.8. Validating DNS resolution for user-provisioned infrastructure

27.1. FIPS VALIDATION IN OPENSHIFT CONTAINER PLATFORM
27.2. FIPS SUPPORT IN COMPONENTS THAT THE CLUSTER USES
   27.2.1. etcd
1.1. ABOUT OPENSФHT CONTAINER PLATFORM INSTALLATION

The OpenShift Container Platform installation program offers four methods for deploying a cluster which are detailed in the following list:

- **Interactive**: You can deploy a cluster with the web-based Assisted Installer. This is an ideal approach for clusters with networks connected to the internet. The Assisted Installer is the easiest way to install OpenShift Container Platform, it provides smart defaults, and it performs pre-flight validations before installing the cluster. It also provides a RESTful API for automation and advanced configuration scenarios.

- **Local Agent-based**: You can deploy a cluster locally with the Agent-based Installer for disconnected environments or restricted networks. It provides many of the benefits of the Assisted Installer, but you must download and configure the Agent-based Installer first. Configuration is done with a command-line interface. This approach is ideal for disconnected environments.

- **Automated**: You can deploy a cluster on installer-provisioned infrastructure. The installation program uses each cluster host’s baseboard management controller (BMC) for provisioning. You can deploy clusters in connected or disconnected environments.

- **Full control**: You can deploy a cluster on infrastructure that you prepare and maintain, which provides maximum customizability. You can deploy clusters in connected or disconnected environments.

Each method deploys a cluster with the following characteristics:

- Highly available infrastructure with no single points of failure, which is available by default.

- Administrators can control what updates are applied and when.

1.1.1. About the installation program

You can use the installation program to deploy each type of cluster. The installation program generates the main assets, such as Ignition config files for the bootstrap, control plane, and compute machines. You can start an OpenShift Container Platform cluster with these three machine configurations, provided you correctly configured the infrastructure.

The OpenShift Container Platform installation program uses a set of targets and dependencies to manage cluster installations. The installation program has a set of targets that it must achieve, and each target has a set of dependencies. Because each target is only concerned with its own dependencies, the installation program can act to achieve multiple targets in parallel with the ultimate target being a running cluster. The installation program recognizes and uses existing components instead of running commands to create them again because the program meets the dependencies.
1.1.2. About Red Hat Enterprise Linux CoreOS (RHCOS)

Post-installation, each cluster machine uses Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system. RHCOS is the immutable container host version of Red Hat Enterprise Linux (RHEL) and features a RHEL kernel with SELinux enabled by default. RHCOS includes the kubelet, which is the Kubernetes node agent, and the CRI-O container runtime, which is optimized for Kubernetes.

Every control plane machine in an OpenShift Container Platform 4.14 cluster must use RHCOS, which includes a critical first-boot provisioning tool called Ignition. This tool enables the cluster to configure the machines. Operating system updates are delivered as a bootable container image, using OSTree as a backend, that is deployed across the cluster by the Machine Config Operator. Actual operating system changes are made in-place on each machine as an atomic operation by using rpm-ostree. Together, these technologies enable OpenShift Container Platform to manage the operating system like it manages any other application on the cluster, by in-place upgrades that keep the entire platform up to date. These in-place updates can reduce the burden on operations teams.

If you use RHCOS as the operating system for all cluster machines, the cluster manages all aspects of its components and machines, including the operating system. Because of this, only the installation program and the Machine Config Operator can change machines. The installation program uses Ignition config files to set the exact state of each machine, and the Machine Config Operator completes more changes to the machines, such as the application of new certificates or keys, after installation.

1.1.3. Glossary of common terms for OpenShift Container Platform installing

The glossary defines common terms that relate to the installation content. Read the following list of terms to better understand the installation process.

Assisted Installer
An installer hosted at console.redhat.com that provides a web-based user interface or a RESTful API for creating a cluster configuration. The Assisted Installer generates a discovery image. Cluster machines boot with the discovery image, which installs RHCOS and an agent. Together, the Assisted Installer and agent provide preinstallation validation and installation for the cluster.

Agent-based Installer
An installer similar to the Assisted Installer, but you must download the Agent-based Installer first. The Agent-based Installer is ideal for disconnected environments.

Bootstrap node
A temporary machine that runs a minimal Kubernetes configuration required to deploy the OpenShift Container Platform control plane.

Control plane
A container orchestration layer that exposes the API and interfaces to define, deploy, and manage the lifecycle of containers. Also known as control plane machines.

Compute node
Nodes that are responsible for executing workloads for cluster users. Also known as worker nodes.

Disconnected installation
In some situations, parts of a data center might not have access to the internet, even through proxy servers. You can still install the OpenShift Container Platform in these environments, but you must download the required software and images and make them available to the disconnected environment.

The OpenShift Container Platform installation program
A program that provisions the infrastructure and deploys a cluster.

Installer-provisioned infrastructure
The installation program deploys and configures the infrastructure that the cluster runs on.

Ignition config files
A file that the Ignition tool uses to configure Red Hat Enterprise Linux CoreOS (RHCOS) during operating system initialization. The installation program generates different Ignition configuration files to initialize bootstrap, control plane, and worker nodes.

Kubernetes manifests
Specifications of a Kubernetes API object in a JSON or YAML format. A configuration file can include deployments, config maps, secrets, daemonsets, and so on.

Kubelet
A primary node agent that runs on each node in the cluster to ensure that containers are running in a pod.

Load balancers
A load balancer serves as the single point of contact for clients. Load balancers for the API distribute incoming traffic across control plane nodes.

Machine Config Operator
An Operator that manages and applies configurations and updates of the base operating system and container runtime, including everything between the kernel and kubelet, for the nodes in the cluster.

Operators
The preferred method of packaging, deploying, and managing a Kubernetes application in an OpenShift Container Platform cluster. An operator takes human operational knowledge and encodes it into software that is easily packaged and shared with customers.

User-provisioned infrastructure
You can install OpenShift Container Platform on infrastructure that you provide. You can use the installation program to generate the assets required to provision the cluster infrastructure, create the cluster infrastructure, and then deploy the cluster to the infrastructure that you provided.

1.1.4. Installation process

Except for the Assisted Installer, when you install an OpenShift Container Platform cluster, you must download the installation program from the appropriate Cluster Type page on the OpenShift Cluster Manager Hybrid Cloud Console. This console manages:

- REST API for accounts.
- Registry tokens, which are the pull secrets that you use to obtain the required components.
- Cluster registration, which associates the cluster identity to your Red Hat account to facilitate the gathering of usage metrics.

In OpenShift Container Platform 4.14, the installation program is a Go binary file that performs a series of file transformations on a set of assets. The way you interact with the installation program differs depending on your installation type. Consider the following installation use cases:

- To deploy a cluster with the Assisted Installer, you must configure the cluster settings by using the Assisted Installer. There is no installation program to download and configure. After you finish setting the cluster configuration, you download a discovery ISO and then boot cluster machines with that image. You can install clusters with the Assisted Installer on Nutanix, vSphere, and bare metal with full integration, and other platforms without integration. If you install on bare metal, you must provide all of the cluster infrastructure and resources, including the networking, load balancing, storage, and individual cluster machines.

- To deploy clusters with the Agent-based Installer, you can download the Agent-based Installer first. You can then configure the cluster and generate a discovery image. You boot cluster machines with the discovery image, which installs an agent that communicates with the installation program and handles the provisioning for you instead of you interacting with the installation program or setting up a provisioner machine yourself. You must provide all of the cluster infrastructure and resources, including the networking, load balancing, storage, and individual cluster machines. This approach is ideal for disconnected environments.

- For clusters with installer-provisioned infrastructure, you delegate the infrastructure bootstrapping and provisioning to the installation program instead of doing it yourself. The installation program creates all of the networking, machines, and operating systems that are required to support the cluster, except if you install on bare metal. If you install on bare metal, you must provide all of the cluster infrastructure and resources, including the bootstrap machine, networking, load balancing, storage, and individual cluster machines.

- If you provision and manage the infrastructure for your cluster, you must provide all of the cluster infrastructure and resources, including the bootstrap machine, networking, load balancing, storage, and individual cluster machines.

For the installation program, the program uses three sets of files during installation: an installation configuration file that is named `install-config.yaml`, Kubernetes manifests, and Ignition config files for your machine types.
IMPORTANT

You can modify Kubernetes and the Ignition config files that control the underlying RHCOS operating system during installation. However, no validation is available to confirm the suitability of any modifications that you make to these objects. If you modify these objects, you might render your cluster non-functional. Because of this risk, modifying Kubernetes and Ignition config files is not supported unless you are following documented procedures or are instructed to do so by Red Hat support.

The installation configuration file is transformed into Kubernetes manifests, and then the manifests are wrapped into Ignition config files. The installation program uses these Ignition config files to create the cluster.

The installation configuration files are all pruned when you run the installation program, so be sure to back up all the configuration files that you want to use again.

IMPORTANT

You cannot modify the parameters that you set during installation, but you can modify many cluster attributes after installation.

The installation process with the Assisted Installer

Installation with the Assisted Installer involves creating a cluster configuration interactively by using the web-based user interface or the RESTful API. The Assisted Installer user interface prompts you for required values and provides reasonable default values for the remaining parameters, unless you change them in the user interface or with the API. The Assisted Installer generates a discovery image, which you download and use to boot the cluster machines. The image installs RHCOS and an agent, and the agent handles the provisioning for you. You can install OpenShift Container Platform with the Assisted Installer and full integration on Nutanix, vSphere, and bare metal. Additionally, you can install OpenShift Container Platform with the Assisted Installer on other platforms without integration.

OpenShift Container Platform manages all aspects of the cluster, including the operating system itself. Each machine boots with a configuration that references resources hosted in the cluster that it joins. This configuration allows the cluster to manage itself as updates are applied.

If possible, use the Assisted Installer feature to avoid having to download and configure the Agent-based Installer.

The installation process with Agent-based infrastructure

Agent-based installation is similar to using the Assisted Installer, except that you must initially download and install the Agent-based Installer. An Agent-based installation is useful when you want the convenience of the Assisted Installer, but you need to install a cluster in a disconnected environment.

If possible, use the Agent-based installation feature to avoid having to create a provisioner machine with a bootstrap VM, and then provision and maintain the cluster infrastructure.

The installation process with installer-provisioned infrastructure

The default installation type uses installer-provisioned infrastructure. By default, the installation program acts as an installation wizard, prompting you for values that it cannot determine on its own and providing reasonable default values for the remaining parameters. You can also customize the installation process to support advanced infrastructure scenarios. The installation program provisions the underlying infrastructure for the cluster.

You can install either a standard cluster or a customized cluster. With a standard cluster, you provide minimum details that are required to install the cluster. With a customized cluster, you can specify more details about the platform, such as the number of machines that the control plane uses, the type of
virtual machine that the cluster deploys, or the CIDR range for the Kubernetes service network.

If possible, use this feature to avoid having to provision and maintain the cluster infrastructure. In all other environments, you use the installation program to generate the assets that you require to provision your cluster infrastructure.

With installer-provisioned infrastructure clusters, OpenShift Container Platform manages all aspects of the cluster, including the operating system itself. Each machine boots with a configuration that references resources hosted in the cluster that it joins. This configuration allows the cluster to manage itself as updates are applied.

The installation process with user-provisioned infrastructure
You can also install OpenShift Container Platform on infrastructure that you provide. You use the installation program to generate the assets that you require to provision the cluster infrastructure, create the cluster infrastructure, and then deploy the cluster to the infrastructure that you provided.

If you do not use infrastructure that the installation program provisioned, you must manage and maintain the cluster resources yourself. The following list details some of these self-managed resources:

- The underlying infrastructure for the control plane and compute machines that make up the cluster
- Load balancers
- Cluster networking, including the DNS records and required subnets
- Storage for the cluster infrastructure and applications

If your cluster uses user-provisioned infrastructure, you have the option of adding RHEL compute machines to your cluster.

Installation process details
When a cluster is provisioned, each machine in the cluster requires information about the cluster. OpenShift Container Platform uses a temporary bootstrap machine during initial configuration to provide the required information to the permanent control plane. The temporary bootstrap machine boots by using an Ignition config file that describes how to create the cluster. The bootstrap machine creates the control plane machines that make up the control plane. The control plane machines then create the compute machines, which are also known as worker machines. The following figure illustrates this process:
Figure 1.2. Creating the bootstrap, control plane, and compute machines

After the cluster machines initialize, the bootstrap machine is destroyed. All clusters use the bootstrap process to initialize the cluster, but if you provision the infrastructure for your cluster, you must complete many of the steps manually.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

- Consider using Ignition config files within 12 hours after they are generated, because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

Bootstrapping a cluster involves the following steps:

1. The bootstrap machine boots and starts hosting the remote resources required for the control plane machines to boot. If you provision the infrastructure, this step requires manual intervention.

2. The bootstrap machine starts a single-node etcd cluster and a temporary Kubernetes control plane.

3. The control plane machines fetch the remote resources from the bootstrap machine and finish booting. If you provision the infrastructure, this step requires manual intervention.
4. The temporary control plane schedules the production control plane to the production control plane machines.

5. The Cluster Version Operator (CVO) comes online and installs the etcd Operator. The etcd Operator scales up etcd on all control plane nodes.

6. The temporary control plane shuts down and passes control to the production control plane.

7. The bootstrap machine injects OpenShift Container Platform components into the production control plane.

8. The installation program shuts down the bootstrap machine. If you provision the infrastructure, this step requires manual intervention.

9. The control plane sets up the compute nodes.

10. The control plane installs additional services in the form of a set of Operators.

The result of this bootstrapping process is a running OpenShift Container Platform cluster. The cluster then downloads and configures remaining components needed for the day-to-day operations, including the creation of compute machines in supported environments.

1.1.5. Verifying node state after installation

The OpenShift Container Platform installation completes when the following installation health checks are successful:

- The provisioner can access the OpenShift Container Platform web console.
- All control plane nodes are ready.
- All cluster Operators are available.

**NOTE**

After the installation completes, the specific cluster Operators responsible for the worker nodes continuously attempt to provision all worker nodes. Some time is required before all worker nodes report as READY. For installations on bare metal, wait a minimum of 60 minutes before troubleshooting a worker node. For installations on all other platforms, wait a minimum of 40 minutes before troubleshooting a worker node. A DEGRADED state for the cluster Operators responsible for the worker nodes depends on the Operators’ own resources and not on the state of the nodes.

After your installation completes, you can continue to monitor the condition of the nodes in your cluster.

**Prerequisites**

- The installation program resolves successfully in the terminal.

**Procedure**

1. Show the status of all worker nodes:

   $ oc get nodes
Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>example-compute1.example.com</td>
<td>Ready</td>
<td>worker</td>

Additional resources

- Getting the BareMetalHost resource
- Following the installation
- Validating an installation
- Agent-based Installer
- Assisted Installer for OpenShift Container Platform

Installation scope

The scope of the OpenShift Container Platform installation program is intentionally narrow. It is designed for simplicity and ensured success. You can complete many more configuration tasks after installation completes.

Additional resources

- See Available cluster customizations for details about OpenShift Container Platform configuration resources.

1.1.6. OpenShift Local overview

OpenShift Local supports rapid application development to get started building OpenShift Container Platform clusters. OpenShift Local is designed to run on a local computer to simplify setup and testing, and to emulate the cloud development environment locally with all of the tools needed to develop container-based applications.
Regardless of the programming language you use, OpenShift Local hosts your application and brings a minimal, preconfigured Red Hat OpenShift Container Platform cluster to your local PC without the need for a server-based infrastructure.

On a hosted environment, OpenShift Local can create microservices, convert them into images, and run them in Kubernetes-hosted containers directly on your laptop or desktop running Linux, macOS, or Windows 10 or later.

For more information about OpenShift Local, see Red Hat OpenShift Local Overview.

1.2. SUPPORTED PLATFORMS FOR OPENSHIFT CONTAINER PLATFORM CLUSTERS

In OpenShift Container Platform 4.14, you can install a cluster that uses installer-provisioned infrastructure on the following platforms:

- Alibaba Cloud
- Amazon Web Services (AWS)
- Bare metal
- Google Cloud Platform (GCP)
- IBM Cloud®
- Microsoft Azure
- Microsoft Azure Stack Hub
- Nutanix
- Red Hat OpenStack Platform (RHOSP)
  - The latest OpenShift Container Platform release supports both the latest RHOSP long-life release and intermediate release. For complete RHOSP release compatibility, see the OpenShift Container Platform on RHOSP support matrix.
- VMware vSphere

For these clusters, all machines, including the computer that you run the installation process on, must have direct internet access to pull images for platform containers and provide telemetry data to Red Hat.

**IMPORTANT**

After installation, the following changes are not supported:

- Mixing cloud provider platforms.
- Mixing cloud provider components. For example, using a persistent storage framework from a another platform on the platform where you installed the cluster.

In OpenShift Container Platform 4.14, you can install a cluster that uses user-provisioned infrastructure on the following platforms:
• AWS
• Azure
• Azure Stack Hub
• Bare metal
• GCP
• IBM Power®
• IBM Z® or IBM® LinuxONE
• RHOSP
  • The latest OpenShift Container Platform release supports both the latest RHOSP long-life release and intermediate release. For complete RHOSP release compatibility, see the OpenShift Container Platform on RHOSP support matrix.
• VMware Cloud on AWS
• VMware vSphere

Depending on the supported cases for the platform, you can perform installations on user-provisioned infrastructure, so that you can run machines with full internet access, place your cluster behind a proxy, or perform a disconnected installation.

In a disconnected installation, you can download the images that are required to install a cluster, place them in a mirror registry, and use that data to install your cluster. While you require internet access to pull images for platform containers, with a disconnected installation on vSphere or bare metal infrastructure, your cluster machines do not require direct internet access.

The OpenShift Container Platform 4.x Tested Integrations page contains details about integration testing for different platforms.

Additional resources

• See Supported installation methods for different platforms for more information about the types of installations that are available for each supported platform.

• See Selecting a cluster installation method and preparing it for users for information about choosing an installation method and preparing the required resources.
CHAPTER 2. SELECTING A CLUSTER INSTALLATION METHOD AND PREPARING IT FOR USERS

Before you install OpenShift Container Platform, decide what kind of installation process to follow and verify that you have all of the required resources to prepare the cluster for users.

2.1. SELECTING A CLUSTER INSTALLATION TYPE

Before you install an OpenShift Container Platform cluster, you need to select the best installation instructions to follow. Think about your answers to the following questions to select the best option.

2.1.1. Do you want to install and manage an OpenShift Container Platform cluster yourself?

If you want to install and manage OpenShift Container Platform yourself, you can install it on the following platforms:

- Alibaba Cloud
- Amazon Web Services (AWS) on 64-bit x86 instances
- Amazon Web Services (AWS) on 64-bit ARM instances
- Microsoft Azure on 64-bit x86 instances
- Microsoft Azure on 64-bit ARM instances
- Microsoft Azure Stack Hub
- Google Cloud Platform (GCP) on 64-bit x86 instances
- Google Cloud Platform (GCP) on 64-bit ARM instances
- Red Hat OpenStack Platform (RHOSP)
- IBM Cloud®
- IBM Z® or IBM® LinuxONE
- IBM Z® or IBM® LinuxONE for Red Hat Enterprise Linux (RHEL) KVM
- IBM Power®
- IBM Power® Virtual Server
- Nutanix
- VMware vSphere
- Bare metal or other platform agnostic infrastructure

You can deploy an OpenShift Container Platform 4 cluster to both on-premise hardware and to cloud hosting services, but all of the machines in a cluster must be in the same data center or cloud hosting service.
If you want to use OpenShift Container Platform but do not want to manage the cluster yourself, you have several managed service options. If you want a cluster that is fully managed by Red Hat, you can use OpenShift Dedicated or OpenShift Online. You can also use OpenShift as a managed service on Azure, AWS, IBM Cloud®, or Google Cloud. For more information about managed services, see the OpenShift Products page. If you install an OpenShift Container Platform cluster with a cloud virtual machine as a virtual bare metal, the corresponding cloud-based storage is not supported.

### 2.1.2. Have you used OpenShift Container Platform 3 and want to use OpenShift Container Platform 4?

If you used OpenShift Container Platform 3 and want to try OpenShift Container Platform 4, you need to understand how different OpenShift Container Platform 4 is. OpenShift Container Platform 4 weaves the Operators that package, deploy, and manage Kubernetes applications and the operating system that the platform runs on, Red Hat Enterprise Linux CoreOS (RHCOS), together seamlessly. Instead of deploying machines and configuring their operating systems so that you can install OpenShift Container Platform on them, the RHCOS operating system is an integral part of the OpenShift Container Platform cluster. Deploying the operating system for the cluster machines is part of the installation process for OpenShift Container Platform. See Differences between OpenShift Container Platform 3 and 4.

Because you need to provision machines as part of the OpenShift Container Platform cluster installation process, you cannot upgrade an OpenShift Container Platform 3 cluster to OpenShift Container Platform 4. Instead, you must create a new OpenShift Container Platform 4 cluster and migrate your OpenShift Container Platform 3 workloads to them. For more information about migrating, see Migrating from OpenShift Container Platform 3 to 4 overview. Because you must migrate to OpenShift Container Platform 4, you can use any type of production cluster installation process to create your new cluster.

### 2.1.3. Do you want to use existing components in your cluster?

Because the operating system is integral to OpenShift Container Platform, it is easier to let the installation program for OpenShift Container Platform stand up all of the infrastructure. These are called installer provisioned infrastructure installations. In this type of installation, you can provide some existing infrastructure to the cluster, but the installation program deploys all of the machines that your cluster initially needs.

You can deploy an installer-provisioned infrastructure cluster without specifying any customizations to the cluster or its underlying machines to Alibaba Cloud, AWS, Azure, Azure Stack Hub, GCP, Nutanix.

If you need to perform basic configuration for your installer-provisioned infrastructure cluster, such as the instance type for the cluster machines, you can customize an installation for Alibaba Cloud, AWS, Azure, GCP, Nutanix.

For installer-provisioned infrastructure installations, you can use an existing VPC in AWS, vNet in Azure, or VPC in GCP. You can also reuse part of your networking infrastructure so that your cluster in AWS, Azure, GCP can coexist with existing IP address allocations in your environment and integrate with existing MTU and VXLAN configurations. If you have existing accounts and credentials on these clouds, you can re-use them, but you might need to modify the accounts to have the required permissions to install OpenShift Container Platform clusters on them.

You can use the installer-provisioned infrastructure method to create appropriate machine instances on your hardware for RHOSP, RHOSP with Kuryr, vSphere, and bare metal. Additionally, for vSphere, you can also customize additional network parameters during installation.

If you want to reuse extensive cloud infrastructure, you can complete a user-provisioned infrastructure installation. With these installations, you manually deploy the machines that your cluster requires during the installation process. If you perform a user-provisioned infrastructure installation on AWS, Azure,
Azure Stack Hub, you can use the provided templates to help you stand up all of the required components. You can also reuse a shared VPC on GCP. Otherwise, you can use the provider-agnostic installation method to deploy a cluster into other clouds.

You can also complete a user-provisioned infrastructure installation on your existing hardware. If you use RHOSP, IBM Z® or IBM® LinuxONE, IBM Z® and IBM® LinuxONE with RHEL KVM, IBM Power, or vSphere, use the specific installation instructions to deploy your cluster. If you use other supported hardware, follow the bare metal installation procedure. For some of these platforms, such as RHOSP, vSphere, and bare metal, you can also customize additional network parameters during installation.

2.1.4. Do you need extra security for your cluster?

If you use a user-provisioned installation method, you can configure a proxy for your cluster. The instructions are included in each installation procedure.

If you want to prevent your cluster on a public cloud from exposing endpoints externally, you can deploy a private cluster with installer-provisioned infrastructure on AWS, Azure, or GCP.

If you need to install your cluster that has limited access to the internet, such as a disconnected or restricted network cluster, you can mirror the installation packages and install the cluster from them. Follow detailed instructions for user provisioned infrastructure installations into restricted networks for AWS, GCP, IBM Z® or IBM® LinuxONE, IBM Z® or IBM® LinuxONE with RHEL KVM, vSphere, or bare metal. You can also install a cluster into a restricted network using installer-provisioned infrastructure by following detailed instructions for AWS, GCP, Nutanix, RHOSP, and vSphere.

If you need to deploy your cluster to an AWS GovCloud region, AWS China region, or Azure government region, you can configure those custom regions during an installer-provisioned infrastructure installation.

You can also configure the cluster machines to use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation during installation.

**IMPORTANT**

When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RH COS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures.

2.2. PREPARING YOUR CLUSTER FOR USERS AFTER INSTALLATION

Some configuration is not required to install the cluster but recommended before your users access the cluster. You can customize the cluster itself by customizing the Operators that make up your cluster and integrate you cluster with other required systems, such as an identity provider.

For a production cluster, you must configure the following integrations:

- Persistent storage
- An identity provider
- Monitoring core OpenShift Container Platform components

2.3. PREPARING YOUR CLUSTER FOR WORKLOADS
Depending on your workload needs, you might need to take extra steps before you begin deploying applications. For example, after you prepare infrastructure to support your application build strategy, you might need to make provisions for low-latency workloads or to protect sensitive workloads. You can also configure monitoring for application workloads. If you plan to run Windows workloads, you must enable hybrid networking with OVN-Kubernetes during the installation process; hybrid networking cannot be enabled after your cluster is installed.

2.4. SUPPORTED INSTALLATION METHODS FOR DIFFERENT PLATFORMS

You can perform different types of installations on different platforms.

NOTE

Not all installation options are supported for all platforms, as shown in the following tables. A checkmark indicates that the option is supported and links to the relevant section.

Table 2.1. Installer-provisioned infrastructure options

CHAPTER 3. CLUSTER CAPABILITIES

Cluster administrators can use cluster capabilities to enable or disable optional components prior to installation. Cluster administrators can enable cluster capabilities at anytime after installation.

NOTE

Cluster administrators cannot disable a cluster capability after it is enabled.

3.1. SELECTING CLUSTER CAPABILITIES

You can select cluster capabilities by following one of the installation methods that include customizing your cluster, such as "Installing a cluster on AWS with customizations" or "Installing a cluster on GCP with customizations".

During a customized installation, you create an install-config.yaml file that contains the configuration parameters for your cluster.

NOTE

If you customize your cluster by enabling or disabling specific cluster capabilities, you are responsible for manually maintaining your install-config.yaml file. New OpenShift Container Platform updates might declare new capability handles for existing components, or introduce new components altogether. Users who customize their install-config.yaml file should consider periodically updating their install-config.yaml file as OpenShift Container Platform is updated.

You can use the following configuration parameters to select cluster capabilities:

```yaml
capabilities:
  baselineCapabilitySet: v4.11
  additionalEnabledCapabilities:
    - CSISnapshot
    - Console
    - Storage
```

1. Defines a baseline set of capabilities to install. Valid values are None, vCurrent and v4.x. If you select None, all optional capabilities will be disabled. The default value is vCurrent, which enables all optional capabilities.

2. Defines a list of capabilities to explicitly enable. These will be enabled in addition to the capabilities specified in baselineCapabilitySet.

NOTE

v4.x refers to any value up to and including the current cluster version. For example, valid values for a OpenShift Container Platform 4.12 cluster are v4.11 and v4.12.
In this example, the default capability is set to **v4.11**. The `additionalEnabledCapabilities` field enables additional capabilities over the default **v4.11** capability set.

The following table describes the `baselineCapabilitySet` values.

**Table 3.1. Cluster capabilities `baselineCapabilitySet` values description**

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>vCurrent</strong></td>
<td>Specify this option when you want to automatically add new, default capabilities that are introduced in new releases.</td>
</tr>
<tr>
<td><strong>v4.11</strong></td>
<td>Specify this option when you want to enable the default capabilities for OpenShift Container Platform 4.11. By specifying <strong>v4.11</strong>, capabilities that are introduced in newer versions of OpenShift Container Platform are not enabled. The default capabilities in OpenShift Container Platform 4.11 are <strong>baremetal</strong>, <strong>MachineAPI</strong>, <strong>marketplace</strong>, and <strong>openshift-samples</strong>.</td>
</tr>
<tr>
<td><strong>v4.12</strong></td>
<td>Specify this option when you want to enable the default capabilities for OpenShift Container Platform 4.12. By specifying <strong>v4.12</strong>, capabilities that are introduced in newer versions of OpenShift Container Platform are not enabled. The default capabilities in OpenShift Container Platform 4.12 are <strong>baremetal</strong>, <strong>MachineAPI</strong>, <strong>marketplace</strong>, <strong>openshift-samples</strong>, <strong>Console</strong>, <strong>Insights</strong>, <strong>Storage</strong>, and <strong>CSISnapshot</strong>.</td>
</tr>
<tr>
<td><strong>v4.13</strong></td>
<td>Specify this option when you want to enable the default capabilities for OpenShift Container Platform 4.13. By specifying <strong>v4.13</strong>, capabilities that are introduced in newer versions of OpenShift Container Platform are not enabled. The default capabilities in OpenShift Container Platform 4.13 are <strong>baremetal</strong>, <strong>MachineAPI</strong>, <strong>marketplace</strong>, <strong>openshift-samples</strong>, <strong>Console</strong>, <strong>Insights</strong>, <strong>Storage</strong>, <strong>CSISnapshot</strong>, and <strong>NodeTuning</strong>.</td>
</tr>
</tbody>
</table>
Specify when the other sets are too large, and you do not need any capabilities or want to fine-tune via `additionalEnabledCapabilities`.

### Additional resources
- Installing a cluster on AWS with customizations
- Installing a cluster on GCP with customizations

## 3.2. OPTIONAL CLUSTER CAPABILITIES IN OPENSSHIFT CONTAINER PLATFORM 4.14

Currently, cluster Operators provide the features for these optional capabilities. The following summarizes the features provided by each capability and what functionality you lose if it is disabled.

### Additional resources
- Cluster Operators reference

### 3.2.1. Bare-metal capability

#### Purpose
The Cluster Baremetal Operator provides the features for the `baremetal` capability.

The Cluster Baremetal Operator (CBO) deploys all the components necessary to take a bare-metal server to a fully functioning worker node ready to run OpenShift Container Platform compute nodes. The CBO ensures that the metal3 deployment, which consists of the Bare Metal Operator (BMO) and Ironic containers, runs on one of the control plane nodes within the OpenShift Container Platform cluster. The CBO also listens for OpenShift Container Platform updates to resources that it watches and takes appropriate action.

The bare-metal capability is required for deployments using installer-provisioned infrastructure. Disabling the bare-metal capability can result in unexpected problems with these deployments.

It is recommended that cluster administrators only disable the bare-metal capability during installations with user-provisioned infrastructure that do not have any `BareMetalHost` resources in the cluster.

**IMPORTANT**

If the bare-metal capability is disabled, the cluster cannot provision or manage bare-metal nodes. Only disable the capability if there are no `BareMetalHost` resources in your deployment. The `baremetal` capability depends on the `MachineAPI` capability. If you enable the `baremetal` capability, you must also enable `MachineAPI`.

### Additional resources
- Deploying installer-provisioned clusters on bare metal
- Preparing for bare metal cluster installation
3.2.2. Build capability

Purpose
The Build capability enables the Build API. The Build API manages the lifecycle of Build and BuildConfig objects.

IMPORTANT
If the Build capability is disabled, the cluster cannot use Build or BuildConfig resources. Disable the capability only if Build and BuildConfig resources are not required in the cluster.

3.2.3. Cluster storage capability

Purpose
The Cluster Storage Operator provides the features for the Storage capability.

The Cluster Storage Operator sets OpenShift Container Platform cluster-wide storage defaults. It ensures a default storageclass exists for OpenShift Container Platform clusters. It also installs Container Storage Interface (CSI) drivers which enable your cluster to use various storage backends.

IMPORTANT
If the cluster storage capability is disabled, the cluster will not have a default storageclass or any CSI drivers. Users with administrator privileges can create a default storageclass and manually install CSI drivers if the cluster storage capability is disabled.

Notes
- The storage class that the Operator creates can be made non-default by editing its annotation, but this storage class cannot be deleted as long as the Operator runs.

3.2.4. Console capability

Purpose
The Console Operator provides the features for the Console capability.

The Console Operator installs and maintains the OpenShift Container Platform web console on a cluster. The Console Operator is installed by default and automatically maintains a console.

Additional resources
- Web console overview

3.2.5. CSI snapshot controller capability

Purpose
The Cluster CSI Snapshot Controller Operator provides the features for the CSISnapshot capability.

The Cluster CSI Snapshot Controller Operator installs and maintains the CSI Snapshot Controller. The CSI Snapshot Controller is responsible for watching the VolumeSnapshot CRD objects and manages the creation and deletion lifecycle of volume snapshots.
Additional resources

- CSI volume snapshots

### 3.2.6. DeploymentConfig capability

**Purpose**
The DeploymentConfig capability enables and manages the DeploymentConfig API.

**IMPORTANT**
If the DeploymentConfig capability is disabled, the cluster cannot use DeploymentConfig resources. Disable the capability only if DeploymentConfig resources are not required in the cluster.

### 3.2.7. Insights capability

**Purpose**
The Insights Operator provides the features for the Insights capability.

The Insights Operator gathers OpenShift Container Platform configuration data and sends it to Red Hat. The data is used to produce proactive insights recommendations about potential issues that a cluster might be exposed to. These insights are communicated to cluster administrators through Insights Advisor on console.redhat.com.

**Notes**
Insights Operator complements OpenShift Container Platform Telemetry.

**Additional resources**

- Using Insights Operator

### 3.2.8. Machine API capability

**Purpose**
The machine-api-operator, cluster-autoscaler-operator, and cluster-control-plane-machine-set-operator Operators provide the features for the MachineAPI capability. You can disable this capability only if you install a cluster with user-provisioned infrastructure.

The Machine API capability is responsible for all machine configuration and management in the cluster. If you disable the Machine API capability during installation, you need to manage all machine-related tasks manually.

**Additional resources**

- Overview of machine management
- Machine API Operator
- Cluster Autoscaler Operator
- Control Plane Machine Set Operator

### 3.2.9. Marketplace capability
Purpose
The Marketplace Operator provides the features for the **marketplace** capability.

The Marketplace Operator simplifies the process for bringing off-cluster Operators to your cluster by using a set of default Operator Lifecycle Manager (OLM) catalogs on the cluster. When the Marketplace Operator is installed, it creates the `openshift-marketplace` namespace. OLM ensures catalog sources installed in the `openshift-marketplace` namespace are available for all namespaces on the cluster.

If you disable the **marketplace** capability, the Marketplace Operator does not create the `openshift-marketplace` namespace. Catalog sources can still be configured and managed on the cluster manually, but OLM depends on the `openshift-marketplace` namespace in order to make catalogs available to all namespaces on the cluster. Users with elevated permissions to create namespaces prefixed with `openshift-`, such as system or cluster administrators, can manually create the `openshift-marketplace` namespace.

If you enable the **marketplace** capability, you can enable and disable individual catalogs by configuring the Marketplace Operator.

**Additional resources**

- Red Hat-provided Operator catalogs

### 3.2.10. Node Tuning capability

**Purpose**
The Node Tuning Operator provides features for the **NodeTuning** capability.

The Node Tuning Operator helps you manage node-level tuning by orchestrating the TuneD daemon and achieves low latency performance by using the Performance Profile controller. The majority of high-performance applications require some level of kernel tuning. The Node Tuning Operator provides a unified management interface to users of node-level sysctls and more flexibility to add custom tuning specified by user needs.

If you disable the NodeTuning capability, some default tuning settings will not be applied to the control-plane nodes. This might limit the scalability and performance of large clusters with over 900 nodes or 900 routes.

**Additional resources**

- Using the Node Tuning Operator

### 3.2.11. OpenShift samples capability

**Purpose**
The Cluster Samples Operator provides the features for the **openshift-samples** capability.

The Cluster Samples Operator manages the sample image streams and templates stored in the `openshift` namespace.

On initial start up, the Operator creates the default samples configuration resource to initiate the creation of the image streams and templates. The configuration object is a cluster scoped object with the key `cluster` and type `configs.samples`.

---

98
The image streams are the Red Hat Enterprise Linux CoreOS (RHCOS)-based OpenShift Container Platform image streams pointing to images on registry.redhat.io. Similarly, the templates are those categorized as OpenShift Container Platform templates.

If you disable the samples capability, users cannot access the image streams, samples, and templates it provides. Depending on your deployment, you might want to disable this component if you do not need it.

Additional resources
- Configuring the Cluster Samples Operator

3.2.12. Cluster Image Registry capability

Purpose
The Cluster Image Registry Operator provides features for the ImageRegistry capability.

The Cluster Image Registry Operator manages a singleton instance of the OpenShift image registry. It manages all configuration of the registry, including creating storage.

On initial start up, the Operator creates a default image-registry resource instance based on the configuration detected in the cluster. This indicates what cloud storage type to use based on the cloud provider.

If insufficient information is available to define a complete image-registry resource, then an incomplete resource is defined and the Operator updates the resource status with information about what is missing.

The Cluster Image Registry Operator runs in the openshift-image-registry namespace and it also manages the registry instance in that location. All configuration and workload resources for the registry reside in that namespace.

If you disable the ImageRegistry capability, you can reduce the overall resource footprint of OpenShift Container Platform in Telco environments. Depending on your deployment, you can disable this component if you do not need it.

- Image Registry Operator in OpenShift Container Platform

3.3. ADDITIONAL RESOURCES
- Enabling cluster capabilities after installation
CHAPTER 4. DISCONNECTED INSTALLATION MIRRORING

4.1. ABOUT DISCONNECTED INSTALLATION MIRRORING

You can use a mirror registry to ensure that your clusters only use container images that satisfy your organizational controls on external content. Before you install a cluster on infrastructure that you provision in a restricted network, you must mirror the required container images into that environment. To mirror container images, you must have a registry for mirroring.

4.1.1. Creating a mirror registry

If you already have a container image registry, such as Red Hat Quay, you can use it as your mirror registry. If you do not already have a registry, you can create a mirror registry using the mirror registry for Red Hat OpenShift.

4.1.2. Mirroring images for a disconnected installation

You can use one of the following procedures to mirror your OpenShift Container Platform image repository to your mirror registry:

- Mirroring images for a disconnected installation
- Mirroring images for a disconnected installation using the oc-mirror plugin

4.2. CREATING A MIRROR REGISTRY WITH MIRROR REGISTRY FOR RED HAT OPENSHIFT

The mirror registry for Red Hat OpenShift is a small and streamlined container registry that you can use as a target for mirroring the required container images of OpenShift Container Platform for disconnected installations.

If you already have a container image registry, such as Red Hat Quay, you can skip this section and go straight to Mirroring the OpenShift Container Platform image repository.

4.2.1. Prerequisites

- An OpenShift Container Platform subscription.
- Red Hat Enterprise Linux (RHEL) 8 and 9 with Podman 3.4.2 or later and OpenSSL installed.
- Fully qualified domain name for the Red Hat Quay service, which must resolve through a DNS server.
- Key-based SSH connectivity on the target host. SSH keys are automatically generated for local installs. For remote hosts, you must generate your own SSH keys.
- 2 or more vCPUs.
- 8 GB of RAM.
IMPORTANT

These requirements are based on local testing results with only release images and Operator images. Storage requirements can vary based on your organization’s needs. You might require more space, for example, when you mirror multiple z-streams. You can use standard Red Hat Quay functionality or the proper API callout to remove unnecessary images and free up space.

4.2.2. Mirror registry for Red Hat OpenShift introduction

For disconnected deployments of OpenShift Container Platform, a container registry is required to carry out the installation of the clusters. To run a production-grade registry service on such a cluster, you must create a separate registry deployment to install the first cluster. The mirror registry for Red Hat OpenShift addresses this need and is included in every OpenShift subscription. It is available for download on the OpenShift console Downloads page.

The mirror registry for Red Hat OpenShift allows users to install a small-scale version of Red Hat Quay and its required components using the mirror-registry command line interface (CLI) tool. The mirror registry for Red Hat OpenShift is deployed automatically with preconfigured local storage and a local database. It also includes auto-generated user credentials and access permissions with a single set of inputs and no additional configuration choices to get started.

The mirror registry for Red Hat OpenShift provides a pre-determined network configuration and reports deployed component credentials and access URLs upon success. A limited set of optional configuration inputs like fully qualified domain name (FQDN) services, superuser name and password, and custom TLS certificates are also provided. This provides users with a container registry so that they can easily create an offline mirror of all OpenShift Container Platform release content when running OpenShift Container Platform in restricted network environments.

Use of the mirror registry for Red Hat OpenShift is optional if another container registry is already available in the install environment.

4.2.2.1. Mirror registry for Red Hat OpenShift limitations

The following limitations apply to the mirror registry for Red Hat OpenShift:

- The mirror registry for Red Hat OpenShift is not a highly-available registry and only local file system storage is supported. It is not intended to replace Red Hat Quay or the internal image registry for OpenShift Container Platform.

- The mirror registry for Red Hat OpenShift is only supported for hosting images that are required to install a disconnected OpenShift Container Platform cluster, such as Release images or Red Hat Operator images. It uses local storage on your Red Hat Enterprise Linux (RHEL) machine, and storage supported by RHEL is supported by the mirror registry for Red Hat OpenShift.

- Support for Red Hat product images that are pushed to the mirror registry for Red Hat OpenShift for bootstrapping purposes are covered by valid subscriptions for each respective product. A list of exceptions to further enable the bootstrap experience can be found on the Self-managed Red Hat OpenShift sizing and subscription guide.

- Content built by customers should not be hosted by the mirror registry for Red Hat OpenShift.

- Using the mirror registry for Red Hat OpenShift with more than one cluster is discouraged because multiple clusters can create a single point of failure when updating your cluster fleet. It is advised to leverage the mirror registry for Red Hat OpenShift to install a cluster that can host...
a production-grade, highly-available registry such as Red Hat Quay, which can serve OpenShift Container Platform content to other clusters.

4.2.3. Mirroring on a local host with mirror registry for Red Hat OpenShift

This procedure explains how to install the mirror registry for Red Hat OpenShift on a local host using the mirror-registry installer tool. By doing so, users can create a local host registry running on port 443 for the purpose of storing a mirror of OpenShift Container Platform images.

**NOTE**

Installing the mirror registry for Red Hat OpenShift using the mirror-registry CLI tool makes several changes to your machine. After installation, a $HOME/quay-install directory is created, which has installation files, local storage, and the configuration bundle. Trusted SSH keys are generated in case the deployment target is the local host, and systemd files on the host machine are set up to ensure that container runtimes are persistent. Additionally, an initial user named init is created with an automatically generated password. All access credentials are printed at the end of the install routine.

**Procedure**

1. Download the mirror-registry.tar.gz package for the latest version of the mirror registry for Red Hat OpenShift found on the OpenShift console Downloads page.

2. Install the mirror registry for Red Hat OpenShift on your local host with your current user account by using the mirror-registry tool. For a full list of available flags, see "mirror registry for Red Hat OpenShift flags".

   ```bash
   $ ./mirror-registry install \
   --quayHostname <host_example_com> \
   --quayRoot <example_directory_name>
   ``

3. Use the user name and password generated during installation to log into the registry by running the following command:

   ```bash
   $ podman login -u init \
   -p <password> \
   <host_example_com>:8443> \
   --tls-verify=false
   ``

   You can avoid running `--tls-verify=false` by configuring your system to trust the generated rootCA certificates. See "Using SSL to protect connections to Red Hat Quay" and "Configuring the system to trust the certificate authority" for more information.

4. You can mirror OpenShift Container Platform images after logging in. Depending on your needs, see either the "Mirroring the OpenShift Container Platform image repository" or the "Mirroring Operator catalogs for use with disconnected clusters" sections of this document.

**NOTE**

You can also log in by accessing the UI at https://<host.example.com>:8443 after installation.
NOTE

If there are issues with images stored by the *mirror registry for Red Hat OpenShift* due to storage layer problems, you can remirror the OpenShift Container Platform images, or reinstall mirror registry on more stable storage.

4.2.4. Updating mirror registry for Red Hat OpenShift from a local host

This procedure explains how to update the *mirror registry for Red Hat OpenShift* from a local host using the `upgrade` command. Updating to the latest version ensures new features, bug fixes, and security vulnerability fixes.

**IMPORTANT**

When updating, there is intermittent downtime of your mirror registry, as it is restarted during the update process.

**Prerequisites**

- You have installed the *mirror registry for Red Hat OpenShift* on a local host.

**Procedure**

- If you are upgrading the *mirror registry for Red Hat OpenShift* from 1.2.z → 1.3.0, and your installation directory is the default at `/etc/quay-install`, you can enter the following command:

  ```shell
  $ sudo ./mirror-registry upgrade -v
  ```

  **NOTE**

  - *mirror registry for Red Hat OpenShift* migrates Podman volumes for Quay storage, Postgres data, and `/etc/quay-install` data to the new `$HOME/quay-install` location. This allows you to use *mirror registry for Red Hat OpenShift* without the `--quayRoot` flag during future upgrades.
  - Users who upgrade *mirror registry for Red Hat OpenShift* with the `./mirror-registry upgrade -v` flag must include the same credentials used when creating their mirror registry. For example, if you installed the *mirror registry for Red Hat OpenShift* with `--quayHostname <host_example_com>` and `--quayRoot <example_directory_name>`, you must include that string to properly upgrade the mirror registry.

- If you are upgrading the *mirror registry for Red Hat OpenShift* from 1.2.z → 1.3.0 and you used a specified directory in your 1.2.z deployment, you must pass in the new `--pgStorage` and `--quayStorage` flags. For example:

  ```shell
  $ sudo ./mirror-registry upgrade --quayHostname <host_example_com> --quayRoot <example_directory_name> --pgStorage <example_directory_name>/pg-data --quayStorage <example_directory_name>/quay-storage -v
  ```

4.2.5. Mirroring on a remote host with mirror registry for Red Hat OpenShift

This procedure explains how to install the *mirror registry for Red Hat OpenShift* on a remote host using:

```shell
$ sudo ./mirror-registry upgrade -v
$ sudo ./mirror-registry upgrade --quayHostname <host_example_com> --quayRoot <example_directory_name> --pgStorage <example_directory_name>/pg-data --quayStorage <example_directory_name>/quay-storage -v
```
This procedure explains how to install the *mirror registry for Red Hat OpenShift* on a remote host using the *mirror-registry* tool. By doing so, users can create a registry to hold a mirror of OpenShift Container Platform images.

**NOTE**

Installing the *mirror registry for Red Hat OpenShift* using the *mirror-registry* CLI tool makes several changes to your machine. After installation, a `$HOME/quay-install` directory is created, which has installation files, local storage, and the configuration bundle. Trusted SSH keys are generated in case the deployment target is the local host, and systemd files on the host machine are set up to ensure that container runtimes are persistent. Additionally, an initial user named *init* is created with an automatically generated password. All access credentials are printed at the end of the install routine.

**Procedure**

1. Download the *mirror-registry.tar.gz* package for the latest version of the *mirror registry for Red Hat OpenShift* found on the OpenShift console [Downloads] page.

   ```
   $ ./mirror-registry install -v \
   --targetHostname <host_example_com> \
   --targetUsername <example_user> \
   -k ~/.ssh/my_ssh_key \
   --quayHostname <host_example_com> \
   --quayRoot <example_directory_name>
   ```

2. Install the *mirror registry for Red Hat OpenShift* on your local host with your current user account by using the *mirror-registry* tool. For a full list of available flags, see "mirror registry for Red Hat OpenShift flags".

3. Use the user name and password generated during installation to log into the mirror registry by running the following command:

   ```
   $ podman login -u init \
   -p <password> \
   <host_example_com>:8443 \
   --tls-verify=false
   ```

   ![](image)
   You can avoid running `--tls-verify=false` by configuring your system to trust the generated rootCA certificates. See "Using SSL to protect connections to Red Hat Quay" and "Configuring the system to trust the certificate authority" for more information.

   **NOTE**

   You can also log in by accessing the UI at `https://<host.example.com>:8443` after installation.

4. You can mirror OpenShift Container Platform images after logging in. Depending on your needs, see either the "Mirroring the OpenShift Container Platform image repository" or the "Mirroring Operator catalogs for use with disconnected clusters" sections of this document.
NOTE
If there are issues with images stored by the mirror registry for Red Hat OpenShift due to storage layer problems, you can remirror the OpenShift Container Platform images, or reinstall mirror registry on more stable storage.

4.2.6. Updating mirror registry for Red Hat OpenShift from a remote host

This procedure explains how to update the mirror registry for Red Hat OpenShift from a remote host using the upgrade command. Updating to the latest version ensures bug fixes and security vulnerability fixes.

IMPORTANT
When updating, there is intermittent downtime of your mirror registry, as it is restarted during the update process.

Prerequisites

- You have installed the mirror registry for Red Hat OpenShift on a remote host.

Procedure

- To upgrade the mirror registry for Red Hat OpenShift from a remote host, enter the following command:

```
$ ./mirror-registry upgrade -v --targetHostname <remote_host_url> --targetUsername <user_name> -k ~/.ssh/my_ssh_key
```

NOTE
Users who upgrade the mirror registry for Red Hat OpenShift with the ./mirror-registry upgrade -v flag must include the same credentials used when creating their mirror registry. For example, if you installed the mirror registry for Red Hat OpenShift with --quayHostname <host_example_com> and --quayRoot <example_directory_name>, you must include that string to properly upgrade the mirror registry.

4.2.7. Replacing mirror registry for Red Hat OpenShift SSL/TLS certificates

In some cases, you might want to update your SSL/TLS certificates for the mirror registry for Red Hat OpenShift. This is useful in the following scenarios:

- If you are replacing the current mirror registry for Red Hat OpenShift certificate.
- If you are using the same certificate as the previous mirror registry for Red Hat OpenShift installation.
- If you are periodically updating the mirror registry for Red Hat OpenShift certificate.

Use the following procedure to replace mirror registry for Red Hat OpenShift SSL/TLS certificates.

Prerequisites
You have downloaded the ./mirror-registry binary from the OpenShift console Downloads page.

**Procedure**

1. Enter the following command to install the mirror registry for Red Hat OpenShift:

```bash
$ ./mirror-registry install
--quayHostname <host_example_com>
--quayRoot <example_directory_name>
```

This installs the mirror registry for Red Hat OpenShift to the $HOME/quay-install directory.

2. Prepare a new certificate authority (CA) bundle and generate new ssl.key and ssl.crt key files. For more information, see Using SSL/TLS.

3. Assign /$HOME/quay-install an environment variable, for example, QUAY, by entering the following command:

```bash
$ export QUAY=/$HOME/quay-install
```

4. Copy the new ssl.crt file to the /$HOME/quay-install directory by entering the following command:

```bash
$ cp ~/ssl.crt $QUAY/quay-config
```

5. Copy the new ssl.key file to the /$HOME/quay-install directory by entering the following command:

```bash
$ cp ~/ssl.key $QUAY/quay-config
```

6. Restart the quay-app application pod by entering the following command:

```bash
$ systemctl restart quay-app
```

### 4.2.8. Uninstalling the mirror registry for Red Hat OpenShift

- You can uninstall the mirror registry for Red Hat OpenShift from your local host by running the following command:

```bash
$ ./mirror-registry uninstall -v
--quayRoot <example_directory_name>
```

**NOTE**

- Deleting the mirror registry for Red Hat OpenShift will prompt the user before deletion. You can use --autoApprove to skip this prompt.

- Users who install the mirror registry for Red Hat OpenShift with the --quayRoot flag must include the --quayRoot flag when uninstalling. For example, if you installed the mirror registry for Red Hat OpenShift with --quayRoot example_directory_name, you must include that string to properly uninstall the mirror registry.
### 4.2.9. Mirror registry for Red Hat OpenShift flags

The following flags are available for the `mirror registry for Red Hat OpenShift`:

<table>
<thead>
<tr>
<th>Flags</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--autoApprove</code></td>
<td>A boolean value that disables interactive prompts. If set to <code>true</code>, the <code>quayRoot</code> directory is automatically deleted when uninstalling the mirror registry. Defaults to <code>false</code> if left unspecified.</td>
</tr>
<tr>
<td><code>--initPassword</code></td>
<td>The password of the init user created during Quay installation. Must be at least eight characters and contain no whitespace.</td>
</tr>
<tr>
<td><code>--initUser string</code></td>
<td>Shows the username of the initial user. Defaults to <code>init</code> if left unspecified.</td>
</tr>
<tr>
<td><code>--no-color, -c</code></td>
<td>Allows users to disable color sequences and propagate that to Ansible when running install, uninstall, and upgrade commands.</td>
</tr>
<tr>
<td><code>--pgStorage</code></td>
<td>The folder where Postgres persistent storage data is saved. Defaults to the <code>pg-storage</code> Podman volume. Root privileges are required to uninstall.</td>
</tr>
<tr>
<td><code>--quayHostname</code></td>
<td>The fully-qualified domain name of the mirror registry that clients will use to contact the registry. Equivalent to <code>SERVER_HOSTNAME</code> in the Quay <code>config.yaml</code>. Must resolve by DNS. Defaults to <code>&lt;targetHostname&gt;:8443</code> if left unspecified.</td>
</tr>
<tr>
<td><code>--quayStorage</code></td>
<td>The folder where Quay persistent storage data is saved. Defaults to the <code>quay-storage</code> Podman volume. Root privileges are required to uninstall.</td>
</tr>
<tr>
<td><code>--quayRoot, -r</code></td>
<td>The directory where container image layer and configuration data is saved, including <code>rootCA.key</code>, <code>rootCA.pem</code>, and <code>rootCA.srl</code> certificates. Defaults to <code>$HOME/quay-install</code> if left unspecified.</td>
</tr>
<tr>
<td><code>--ssh-key, -k</code></td>
<td>The path of your SSH identity key. Defaults to <code>~/.ssh/quay_installer</code> if left unspecified.</td>
</tr>
<tr>
<td><code>--sslCert</code></td>
<td>The path to the SSL/TLS public key / certificate. Defaults to <code>{quayRoot}/quay-config</code> and is auto-generated if left unspecified.</td>
</tr>
<tr>
<td><code>--sslCheckSkip</code></td>
<td>Skips the check for the certificate hostname against the <code>SERVER_HOSTNAME</code> in the <code>config.yaml</code> file.</td>
</tr>
<tr>
<td><code>--sslKey</code></td>
<td>The path to the SSL/TLS private key used for HTTPS communication. Defaults to <code>{quayRoot}/quay-config</code> and is auto-generated if left unspecified.</td>
</tr>
<tr>
<td><code>--targetHostName, -H</code></td>
<td>The hostname of the target you want to install Quay to. Defaults to <code>$HOST</code>, for example, a local host, if left unspecified.</td>
</tr>
<tr>
<td><code>--targetUsername, -u</code></td>
<td>The user on the target host which will be used for SSH. Defaults to <code>$USER</code>, for example, the current user if left unspecified.</td>
</tr>
</tbody>
</table>
## Flags

<table>
<thead>
<tr>
<th>Flags</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--verbose, -v</td>
<td>Shows debug logs and Ansible playbook outputs.</td>
</tr>
<tr>
<td>--version</td>
<td>Shows the version for the mirror registry for Red Hat OpenShift</td>
</tr>
</tbody>
</table>

1. **--quayHostname** must be modified if the public DNS name of your system is different from the local hostname. Additionally, the **--quayHostname** flag does not support installation with an IP address. Installation with a hostname is required.

2. **--sslCheckSkip** is used in cases when the mirror registry is set behind a proxy and the exposed hostname is different from the internal Quay hostname. It can also be used when users do not want the certificates to be validated against the provided Quay hostname during installation.

### 4.2.10. Mirror registry for Red Hat OpenShift release notes

The **mirror registry for Red Hat OpenShift** is a small and streamlined container registry that you can use as a target for mirroring the required container images of OpenShift Container Platform for disconnected installations.

These release notes track the development of the **mirror registry for Red Hat OpenShift** in OpenShift Container Platform.

For an overview of the **mirror registry for Red Hat OpenShift**, see [Creating a mirror registry with mirror registry for Red Hat OpenShift](#).

#### 4.2.10.1. Mirror registry for Red Hat OpenShift 1.3.10

Issued: 2023-12-07

**Mirror registry for Red Hat OpenShift** is now available with Red Hat Quay 3.8.14.

The following advisory is available for the **mirror registry for Red Hat OpenShift**:

- RHBA-2023:7628 - mirror registry for Red Hat OpenShift 1.3.10

#### 4.2.10.2. Mirror registry for Red Hat OpenShift 1.3.9

Issued: 2023-09-19

**Mirror registry for Red Hat OpenShift** is now available with Red Hat Quay 3.8.12.

The following advisory is available for the **mirror registry for Red Hat OpenShift**:

- RHBA-2023:5241 - mirror registry for Red Hat OpenShift 1.3.9

#### 4.2.10.3. Mirror registry for Red Hat OpenShift 1.3.8

Issued: 2023-08-16
Mirror registry for Red Hat OpenShift is now available with Red Hat Quay 3.8.11.
The following advisory is available for the mirror registry for Red Hat OpenShift:

- RHBA-2023:4622 - mirror registry for Red Hat OpenShift 1.3.8

4.2.10.4. Mirror registry for Red Hat OpenShift 1.3.7
Issued: 2023-07-19

Mirror registry for Red Hat OpenShift is now available with Red Hat Quay 3.8.10.
The following advisory is available for the mirror registry for Red Hat OpenShift:

- RHBA-2023:4087 - mirror registry for Red Hat OpenShift 1.3.7

4.2.10.5. Mirror registry for Red Hat OpenShift 1.3.6
Issued: 2023-05-30

Mirror registry for Red Hat OpenShift is now available with Red Hat Quay 3.8.8.
The following advisory is available for the mirror registry for Red Hat OpenShift:

- RHBA-2023:3302 - mirror registry for Red Hat OpenShift 1.3.6

4.2.10.6. Mirror registry for Red Hat OpenShift 1.3.5
Issued: 2023-05-18

Mirror registry for Red Hat OpenShift is now available with Red Hat Quay 3.8.7.
The following advisory is available for the mirror registry for Red Hat OpenShift:

- RHBA-2023:3225 - mirror registry for Red Hat OpenShift 1.3.5

4.2.10.7. Mirror registry for Red Hat OpenShift 1.3.4
Issued: 2023-04-25

Mirror registry for Red Hat OpenShift is now available with Red Hat Quay 3.8.6.
The following advisory is available for the mirror registry for Red Hat OpenShift:

- RHBA-2023:1914 - mirror registry for Red Hat OpenShift 1.3.4

4.2.10.8. Mirror registry for Red Hat OpenShift 1.3.3
Issued: 2023-04-05

Mirror registry for Red Hat OpenShift is now available with Red Hat Quay 3.8.5.
The following advisory is available for the mirror registry for Red Hat OpenShift:

- RHBA-2023:1528 - mirror registry for Red Hat OpenShift 1.3.3
4.2.10.9. Mirror registry for Red Hat OpenShift 1.3.2
Issued: 2023-03-21

*Mirror registry for Red Hat OpenShift* is now available with Red Hat Quay 3.8.4.
The following advisory is available for the *mirror registry for Red Hat OpenShift*:

- RHBA-2023:1376 - mirror registry for Red Hat OpenShift 1.3.2

4.2.10.10. Mirror registry for Red Hat OpenShift 1.3.1
Issued: 2023-03-7

*Mirror registry for Red Hat OpenShift* is now available with Red Hat Quay 3.8.3.
The following advisory is available for the *mirror registry for Red Hat OpenShift*:

- RHBA-2023:1086 - mirror registry for Red Hat OpenShift 1.3.1

4.2.10.11. Mirror registry for Red Hat OpenShift 1.3.0
Issued: 2023-02-20

*Mirror registry for Red Hat OpenShift* is now available with Red Hat Quay 3.8.1.
The following advisory is available for the *mirror registry for Red Hat OpenShift*:

- RHBA-2023:0558 - mirror registry for Red Hat OpenShift 1.3.0

4.2.10.11.1. New features

- *Mirror registry for Red Hat OpenShift* is now supported on Red Hat Enterprise Linux (RHEL) 9 installations.

- IPv6 support is now available on *mirror registry for Red Hat OpenShift* local host installations. IPv6 is currently unsupported on *mirror registry for Red Hat OpenShift* remote host installations.

- A new feature flag, `--quayStorage`, has been added. With this flag, users with root privileges can manually set the location of their Quay persistent storage.

- A new feature flag, `--pgStorage`, has been added. With this flag, users with root privileges can manually set the location of their Postgres persistent storage.

- Previously, users were required to have root privileges (`sudo`) to install *mirror registry for Red Hat OpenShift*. With this update, `sudo` is no longer required to install *mirror registry for Red Hat OpenShift*.

When *mirror registry for Red Hat OpenShift* was installed with `sudo`, an `/etc/quay-install` directory that contained installation files, local storage, and the configuration bundle was created. With the removal of the `sudo` requirement, installation files and the configuration bundle are now installed to `$HOME/quay-install`. Local storage, for example Postgres and Quay, are now stored in named volumes automatically created by Podman.

To override the default directories that these files are stored in, you can use the command line arguments for *mirror registry for Red Hat OpenShift*. For more information about *mirror registry for Red Hat OpenShift* command line arguments, see "*Mirror registry for Red Hat OpenShift*".
flags“.

4.2.10.11.2. Bug fixes

- Previously, the following error could be returned when attempting to uninstall mirror registry for Red Hat OpenShift: "Error: no container with name or ID "quay-postgres" found: no such container". "stdout": "", "stdout_lines": []". With this update, the order that mirror registry for Red Hat OpenShift services are stopped and uninstalled have been changed so that the error no longer occurs when uninstalling mirror registry for Red Hat OpenShift. For more information, see PROJQUAY-4629.

4.2.10.12. Mirror registry for Red Hat OpenShift 1.2.9

Mirror registry for Red Hat OpenShift is now available with Red Hat Quay 3.7.10.

The following advisory is available for the mirror registry for Red Hat OpenShift:

- RHBA-2022:7369 - mirror registry for Red Hat OpenShift 1.2.9

4.2.10.13. Mirror registry for Red Hat OpenShift 1.2.8

Mirror registry for Red Hat OpenShift is now available with Red Hat Quay 3.7.9.

The following advisory is available for the mirror registry for Red Hat OpenShift:

- RHBA-2022:7065 - mirror registry for Red Hat OpenShift 1.2.8

4.2.10.14. Mirror registry for Red Hat OpenShift 1.2.7

Mirror registry for Red Hat OpenShift is now available with Red Hat Quay 3.7.8.

The following advisory is available for the mirror registry for Red Hat OpenShift:

- RHBA-2022:6500 - mirror registry for Red Hat OpenShift 1.2.7

4.2.10.14.1. Bug fixes

- Previously, getFQDN() relied on the fully-qualified domain name (FQDN) library to determine its FQDN, and the FQDN library tried to read the /etc/hosts folder directly. Consequently, on some Red Hat Enterprise Linux CoreOS (RHCOS) installations with uncommon DNS configurations, the FQDN library would fail to install and abort the installation. With this update, mirror registry for Red Hat OpenShift uses hostname to determine the FQDN. As a result, the FQDN library does not fail to install. (PROJQUAY-4139)

4.2.10.15. Mirror registry for Red Hat OpenShift 1.2.6

Mirror registry for Red Hat OpenShift is now available with Red Hat Quay 3.7.7.

The following advisory is available for the mirror registry for Red Hat OpenShift:

- RHBA-2022:6278 - mirror registry for Red Hat OpenShift 1.2.6

4.2.10.15.1. New features

- A new feature flag, --no-color (\-c) has been added. This feature flag allows users to disable color
A new feature flag, `--no-color (-c)` has been added. This feature flag allows users to disable color sequences and propagate that to Ansible when running install, uninstall, and upgrade commands.

4.2.10.16. Mirror registry for Red Hat OpenShift 1.2.5

*Mirror registry for Red Hat OpenShift* is now available with Red Hat Quay 3.7.6.

The following advisory is available for the *mirror registry for Red Hat OpenShift*:

- RHBA-2022:6071 - mirror registry for Red Hat OpenShift 1.2.5

4.2.10.17. Mirror registry for Red Hat OpenShift 1.2.4

*Mirror registry for Red Hat OpenShift* is now available with Red Hat Quay 3.7.5.

The following advisory is available for the *mirror registry for Red Hat OpenShift*:

- RHBA-2022:5884 - mirror registry for Red Hat OpenShift 1.2.4

4.2.10.18. Mirror registry for Red Hat OpenShift 1.2.3

*Mirror registry for Red Hat OpenShift* is now available with Red Hat Quay 3.7.4.

The following advisory is available for the *mirror registry for Red Hat OpenShift*:

- RHBA-2022:5649 - mirror registry for Red Hat OpenShift 1.2.3

4.2.10.19. Mirror registry for Red Hat OpenShift 1.2.2

*Mirror registry for Red Hat OpenShift* is now available with Red Hat Quay 3.7.3.

The following advisory is available for the *mirror registry for Red Hat OpenShift*:

- RHBA-2022:5501 - mirror registry for Red Hat OpenShift 1.2.2

4.2.10.20. Mirror registry for Red Hat OpenShift 1.2.1

*Mirror registry for Red Hat OpenShift* is now available with Red Hat Quay 3.7.2.

The following advisory is available for the *mirror registry for Red Hat OpenShift*:

- RHBA-2022:4986 - mirror registry for Red Hat OpenShift 1.2.1

4.2.10.21. Mirror registry for Red Hat OpenShift 1.2.0

*Mirror registry for Red Hat OpenShift* is now available with Red Hat Quay 3.7.1.

The following advisory is available for the *mirror registry for Red Hat OpenShift*:

- RHBA-2022:4986 - mirror registry for Red Hat OpenShift 1.2.0

4.2.10.21.1. Bug fixes

- Previously, all components and workers running inside of the Quay pod Operator had log levels set to `DEBUG`. As a result, large traffic logs were created that consumed unnecessary space.
With this update, log levels are set to **WARN** by default, which reduces traffic information while emphasizing problem scenarios. (**PROJQUAY-3504**)

### 4.2.10.22. Mirror registry for Red Hat OpenShift 1.1.0

The following advisory is available for the *mirror registry for Red Hat OpenShift*:

- RHBA-2022:0956 - mirror registry for Red Hat OpenShift 1.0

#### 4.2.10.22.1. New features

- A new command, **mirror-registry upgrade** has been added. This command upgrades all container images without interfering with configurations or data.

  **NOTE**
  
  If *quayRoot* was previously set to something other than default, it must be passed into the upgrade command.

#### 4.2.10.22.2. Bug fixes

- Previously, the absence of *quayHostname* or *targetHostname* did not default to the local hostname. With this update, *quayHostname* and *targetHostname* now default to the local hostname if they are missing. (**PROJQUAY-3079**)

- Previously, the command `./mirror-registry --version` returned an **unknown flag** error. Now, running `./mirror-registry --version` returns the current version of the *mirror registry for Red Hat OpenShift*. (**PROJQUAY-3086**)

- Previously, users could not set a password during installation, for example, when running `./mirror-registry install --initUser <user_name> --initPassword <password> --verbose`. With this update, users can set a password during installation. (**PROJQUAY-3149**)

- Previously, the *mirror registry for Red Hat OpenShift* did not recreate pods if they were destroyed. Now, pods are recreated if they are destroyed. (**PROJQUAY-3261**)

### 4.2.11. Troubleshooting mirror registry for Red Hat OpenShift

To assist in troubleshooting *mirror registry for Red Hat OpenShift*, you can gather logs of systemd services installed by the mirror registry. The following services are installed:

- quay-app.service
- quay-postgres.service
- quay-redis.service
- quay-pod.service

**Prerequisites**

- You have installed *mirror registry for Red Hat OpenShift*.

**Procedure**
If you installed mirror registry for Red Hat OpenShift with root privileges, you can get the status information of its systemd services by entering the following command:

```
$ sudo systemctl status <service>
```

If you installed mirror registry for Red Hat OpenShift as a standard user, you can get the status information of its systemd services by entering the following command:

```
$ systemctl --user status <service>
```

Additional resources

- Using SSL to protect connections to Red Hat Quay
- Configuring the system to trust the certificate authority
- Mirroring the OpenShift Container Platform image repository
- Mirroring Operator catalogs for use with disconnected clusters

### 4.3. MIRRORING IMAGES FOR A DISCONNECTED INSTALLATION

You can ensure your clusters only use container images that satisfy your organizational controls on external content. Before you install a cluster on infrastructure that you provision in a restricted network, you must mirror the required container images into that environment. To mirror container images, you must have a registry for mirroring.

**IMPORTANT**

You must have access to the internet to obtain the necessary container images. In this procedure, you place your mirror registry on a mirror host that has access to both your network and the internet. If you do not have access to a mirror host, use the Mirroring Operator catalogs for use with disconnected clusters procedure to copy images to a device you can move across network boundaries with.

#### 4.3.1. Prerequisites

- You must have a container image registry that supports Docker v2-2 in the location that will host the OpenShift Container Platform cluster, such as one of the following registries:
  - Red Hat Quay
  - JFrog Artifactory
  - Sonatype Nexus Repository
  - Harbor

  If you have an entitlement to Red Hat Quay, see the documentation on deploying Red Hat Quay for proof-of-concept purposes or by using the Red Hat Quay Operator. If you need additional assistance selecting and installing a registry, contact your sales representative or Red Hat support.

- If you do not already have an existing solution for a container image registry, subscribers of OpenShift Container Platform are provided a mirror registry for Red Hat OpenShift. The mirror...
4.3.2. About the mirror registry

You can mirror the images that are required for OpenShift Container Platform installation and subsequent product updates to a container mirror registry such as Red Hat Quay, JFrog Artifactory, Sonatype Nexus Repository, or Harbor. If you do not have access to a large-scale container registry, you can use the mirror registry for Red Hat OpenShift, a small-scale container registry included with OpenShift Container Platform subscriptions.

You can use any container registry that supports Docker v2-2, such as Red Hat Quay, the mirror registry for Red Hat OpenShift, Artifactory, Sonatype Nexus Repository, or Harbor. Regardless of your chosen registry, the procedure to mirror content from Red Hat hosted sites on the internet to an isolated image registry is the same. After you mirror the content, you configure each cluster to retrieve this content from your mirror registry.

**IMPORTANT**

The OpenShift image registry cannot be used as the target registry because it does not support pushing without a tag, which is required during the mirroring process.

If choosing a container registry that is not the mirror registry for Red Hat OpenShift, it must be reachable by every machine in the clusters that you provision. If the registry is unreachable, installation, updating, or normal operations such as workload relocation might fail. For that reason, you must run mirror registries in a highly available way, and the mirror registries must at least match the production availability of your OpenShift Container Platform clusters.

When you populate your mirror registry with OpenShift Container Platform images, you can follow two scenarios. If you have a host that can access both the internet and your mirror registry, but not your cluster nodes, you can directly mirror the content from that machine. This process is referred to as connected mirroring. If you have no such host, you must mirror the images to a file system and then bring that host or removable media into your restricted environment. This process is referred to as disconnected mirroring.

For mirrored registries, to view the source of pulled images, you must review the Trying to access log entry in the CRI-O logs. Other methods to view the image pull source, such as using the crictl images command on a node, show the non-mirrored image name, even though the image is pulled from the mirrored location.

**NOTE**

Red Hat does not test third party registries with OpenShift Container Platform.

Additional information

For information about viewing the CRI-O logs to view the image source, see Viewing the image pull source.

4.3.3. Preparing your mirror host

Before you perform the mirror procedure, you must prepare the host to retrieve content and push it to the remote location.
4.3.3.1. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of oc.

### Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

**Procedure**

2. Select the architecture from the Product Variant drop-down list.
3. Select the appropriate version from the Version drop-down list.
4. Click Download Now next to the OpenShift v4.14 Linux Client entry and save the file.
5. Unpack the archive:
   
   ```
   $ tar xvf <file>
   ```
6. Place the oc binary in a directory that is on your PATH.
   
   To check your PATH, execute the following command:
   
   ```
   $ echo $PATH
   ```

**Verification**

- After you install the OpenShift CLI, it is available using the oc command:

  ```
  $ oc <command>
  ```

### Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version from the Version drop-down list.
3. Click Download Now next to the OpenShift v4.14 Windows Client entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the oc binary to a directory that is on your PATH.
To check your **PATH**, open the command prompt and execute the following command:

```
C:\> path
```

**Verification**

- After you install the OpenShift CLI, it is available using the **oc** command:

```
C:\> oc <command>
```

**Installing the OpenShift CLI on macOS**

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version from the **Version** drop-down list.

3. Click **Download Now** next to the **OpenShift v4.14 macOS Client** entry and save the file.

   **NOTE**

   For macOS arm64, choose the **OpenShift v4.14 macOS arm64 Client** entry.

4. Unpack and unzip the archive.

5. Move the **oc** binary to a directory on your **PATH**.

   To check your **PATH**, open a terminal and execute the following command:

   ```
   $ echo $PATH
   ```

**Verification**

- After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

**4.3.4. Configuring credentials that allow images to be mirrored**

Create a container image registry credentials file that allows mirroring images from Red Hat to your mirror.
WARNING
Do not use this image registry credentials file as the pull secret when you install a cluster. If you provide this file when you install cluster, all of the machines in the cluster will have write access to your mirror registry.

WARNING
This process requires that you have write access to a container image registry on the mirror registry and adds the credentials to a registry pull secret.

Prerequisites

- You configured a mirror registry to use in your disconnected environment.
- You identified an image repository location on your mirror registry to mirror images into.
- You provisioned a mirror registry account that allows images to be uploaded to that image repository.

Procedure

Complete the following steps on the installation host:

1. Download your `registry.redhat.io` pull secret from the Red Hat OpenShift Cluster Manager.

2. Make a copy of your pull secret in JSON format:

   $ cat ./pull-secret | jq . > <path>/<pull_secret_file_in_json>  

   Specify the path to the folder to store the pull secret in and a name for the JSON file that you create.

   The contents of the file resemble the following example:

   ```json
   {
     "auths": {
       "cloud.openshift.com": {
         "auth": "b3BlbnNo...",
         "email": "you@example.com"
       },
       "quay.io": {
         "auth": "b3BlbnNo...",
         "email": "you@example.com"
       },
       "registry.connect.redhat.com": {
   ```
3. Generate the base64-encoded user name and password or token for your mirror registry:

   $ echo -n '<user_name>:<password>' | base64 -w0
   BGVtbYk3ZHAtqXs=

   1 For <user_name> and <password>, specify the user name and password that you configured for your registry.

4. Edit the JSON file and add a section that describes your registry to it:

   "auths": {
     "<mirror_registry>": {
       "auth": "<credentials>",
       "email": "you@example.com"
     }
   }

   1 For <mirror_registry>, specify the registry domain name, and optionally the port, that your mirror registry uses to serve content. For example, registry.example.com or registry.example.com:8443

   2 For <credentials>, specify the base64-encoded user name and password for the mirror registry.

   The file resembles the following example:

   { 
     "auths": {
       "registry.example.com": {
         "auth": "BGVtbYk3ZHAtqXs=",
         "email": "you@example.com"
       },
       "cloud.openshift.com": {
         "auth": "b3BlbnNo...",
         "email": "you@example.com"
       },
       "quay.io": {
         "auth": "b3BlbnNo...",
         "email": "you@example.com"
       },
       "registry.connect.redhat.com": {
         "auth": "NTE3Njg5Nj...",
         "email": "you@example.com"
       } 
   }
4.3.5. Mirroring the OpenShift Container Platform image repository

Mirror the OpenShift Container Platform image repository to your registry to use during cluster installation or upgrade.

Prerequisites

- Your mirror host has access to the internet.
- You configured a mirror registry to use in your restricted network and can access the certificate and credentials that you configured.
- You downloaded the pull secret from the Red Hat OpenShift Cluster Manager and modified it to include authentication to your mirror repository.
- If you use self-signed certificates, you have specified a Subject Alternative Name in the certificates.

Procedure

Complete the following steps on the mirror host:

1. Review the OpenShift Container Platform downloads page to determine the version of OpenShift Container Platform that you want to install and determine the corresponding tag on the Repository Tags page.

2. Set the required environment variables:
   a. Export the release version:

   ```
   $ OCP_RELEASE=<release_version>
   
   For <release_version>, specify the tag that corresponds to the version of OpenShift Container Platform to install, such as 4.5.4.
   
   b. Export the local registry name and host port:

   ```
   $ LOCAL_REGISTRY='<local_registry_host_name>:<local_registry_host_port>'

   For <local_registry_host_name>, specify the registry domain name for your mirror repository, and for <local_registry_host_port>, specify the port that it serves content on.

   c. Export the local repository name:

   ```
   $ LOCAL_REPOSITORY='<local_repository_name>'

   For <local_repository_name>, specify the name of the repository to create in your registry, such as ocp4/openshift4.
d. Export the name of the repository to mirror:

```bash
$ PRODUCT_REPO='openshift-release-dev'
```

For a production release, you must specify `openshift-release-dev`.

e. Export the path to your registry pull secret:

```bash
$ LOCAL_SECRET_JSON='<path_to_pull_secret>'
```

For `<path_to_pull_secret>`, specify the absolute path to and file name of the pull secret for your mirror registry that you created.

f. Export the release mirror:

```bash
$ RELEASE_NAME="ocp-release"
```

For a production release, you must specify `ocp-release`.

g. Export the type of architecture for your cluster:

```bash
$ ARCHITECTURE=<cluster_architecture>  
```

Specify the architecture of the cluster, such as `x86_64`, `aarch64`, `s390x`, or `ppc64le`.

h. Export the path to the directory to host the mirrored images:

```bash
$ REMOVABLE_MEDIA_PATH=<path>  
```

Specify the full path, including the initial forward slash (`/`) character.

3. Mirror the version images to the mirror registry:

- If your mirror host does not have internet access, take the following actions:
  
  i. Connect the removable media to a system that is connected to the internet.
  
  ii. Review the images and configuration manifests to mirror:

```bash
$ oc adm release mirror -a ${LOCAL_SECRET_JSON}  
  --from=quay.io/${PRODUCT_REPO}/${RELEASE_NAME}:${OCP_RELEASE}-
  --to=${LOCAL_REGISTRY}/${REMOTE_REPOSITORY}  
  --to-release-image=${LOCAL_REGISTRY}/${REMOTE_REPOSITORY}:${OCP_RELEASE}-
  --from-release-image=${LOCAL_REGISTRY}/${REMOTE_REPOSITORY}:${OCP_RELEASE}-
  --dry-run
```

iii. Record the entire `imageContentSources` section from the output of the previous command. The information about your mirrors is unique to your mirrored repository, and you must add the `imageContentSources` section to the `install-config.yaml` file during installation.

iv. Mirror the images to a directory on the removable media:
Take the media to the restricted network environment and upload the images to the local container registry. For `REMOVABLE_MEDIA_PATH`, you must use the same path that you specified when you mirrored the images.

**IMPORTANT**

Running `oc image mirror` might result in the following error: `error: unable to retrieve source image`. This error occurs when image indexes include references to images that no longer exist on the image registry. Image indexes might retain older references to allow users running those images an upgrade path to newer points on the upgrade graph. As a temporary workaround, you can use the `--skip-missing` option to bypass the error and continue downloading the image index. For more information, see [Service Mesh Operator mirroring failed](#).

- If the local container registry is connected to the mirror host, take the following actions:
  
i. Directly push the release images to the local registry by using following command:

    ```
    $ oc adm release mirror -a ${LOCAL_SECRET_JSON} --to-dir=${REMOVABLE_MEDIA_PATH}/mirror
    quay.io/${PRODUCT_REPO}/${RELEASE_NAME}:${OCP_RELEASE}-${ARCHITECTURE}
    $ oc image mirror -a ${LOCAL_SECRET_JSON} --from-dir=${REMOVABLE_MEDIA_PATH}/mirror
    "file://openshift/release:${OCP_RELEASE}***"
    ${LOCAL_REGISTRY}/${LOCAL_REPOSITORY}
    $$
    $ oc adm release mirror -a ${LOCAL_SECRET_JSON}  
    --from=quay.io/${PRODUCT_REPO}/${RELEASE_NAME}:${OCP_RELEASE}-${ARCHITECTURE} 
    --to=${LOCAL_REGISTRY}/${LOCAL_REPOSITORY} 
    --to-release-image=${LOCAL_REGISTRY}/${LOCAL_REPOSITORY}:${OCP_RELEASE}-${ARCHITECTURE}
    ```

    This command pulls the release information as a digest, and its output includes the `imageContentSources` data that you require when you install your cluster.

  ii. Record the entire `imageContentSources` section from the output of the previous command. The information about your mirrors is unique to your mirrored repository, and you must add the `imageContentSources` section to the `install-config.yaml` file during installation.

**NOTE**

The image name gets patched to Quay.io during the mirroring process, and the podman images will show Quay.io in the registry on the bootstrap virtual machine.
4. To create the installation program that is based on the content that you mirrored, extract it and pin it to the release:

- If your mirror host does not have internet access, run the following command:

  ```bash
  $ oc adm release extract -a ${LOCAL_SECRET_JSON} --icsp-file=<file> \ --
  command=openshift-install
  "${LOCAL_REGISTRY}/${LOCAL_REPOSITORY}:${OCP_RELEASE}"
  ```

- If the local container registry is connected to the mirror host, run the following command:

  ```bash
  $ oc adm release extract -a ${LOCAL_SECRET_JSON} --command=openshift-install
  "${LOCAL_REGISTRY}/${LOCAL_REPOSITORY}:${OCP_RELEASE}-${ARCHITECTURE}"
  ```

**IMPORTANT**

To ensure that you use the correct images for the version of OpenShift Container Platform that you selected, you must extract the installation program from the mirrored content.

You must perform this step on a machine with an active internet connection.

5. For clusters using installer-provisioned infrastructure, run the following command:

  ```bash
  $ openshift-install
  ```

### 4.3.6. The Cluster Samples Operator in a disconnected environment

In a disconnected environment, you must take additional steps after you install a cluster to configure the Cluster Samples Operator. Review the following information in preparation.

#### 4.3.6.1. Cluster Samples Operator assistance for mirroring

During installation, OpenShift Container Platform creates a config map named `imagestreamtag-to-image` in the `openshift-cluster-samples-operator` namespace. The `imagestreamtag-to-image` config map contains an entry, the populating image, for each image stream tag.

The format of the key for each entry in the data field in the config map is `<image_stream_name>_<image_stream_tag_name>`.

During a disconnected installation of OpenShift Container Platform, the status of the Cluster Samples Operator is set to **Removed**. If you choose to change it to **Managed**, it installs samples.

**NOTE**

The use of samples in a network-restricted or discontinued environment may require access to services external to your network. Some example services include: Github, Maven Central, npm, RubyGems, PyPi and others. There might be additional steps to take that allow the cluster samples operators’s objects to reach the services they require.

You can use this config map as a reference for which images need to be mirrored for your image streams to import.
While the Cluster Samples Operator is set to \textbf{Removed}, you can create your mirrored registry, or determine which existing mirrored registry you want to use.

- Mirror the samples you want to the mirrored registry using the new config map as your guide.
- Add any of the image streams you did not mirror to the \texttt{skippedImagestreams} list of the Cluster Samples Operator configuration object.
- Set \texttt{samplesRegistry} of the Cluster Samples Operator configuration object to the mirrored registry.
- Then set the Cluster Samples Operator to \textbf{Managed} to install the image streams you have mirrored.

\section*{4.3.7. Mirroring Operator catalogs for use with disconnected clusters}

You can mirror the Operator contents of a Red Hat-provided catalog, or a custom catalog, into a container image registry using the \texttt{oc adm catalog mirror} command. The target registry must support Docker v2-2. For a cluster on a restricted network, this registry can be one that the cluster has network access to, such as a mirror registry created during a restricted network cluster installation.

\begin{itemize}
\item \textbf{IMPORTANT}
\begin{itemize}
\item The OpenShift image registry cannot be used as the target registry because it does not support pushing without a tag, which is required during the mirroring process.
\item Running \texttt{oc adm catalog mirror} might result in the following error: \texttt{error: unable to retrieve source image}. This error occurs when image indexes include references to images that no longer exist on the image registry. Image indexes might retain older references to allow users running those images an upgrade path to newer points on the upgrade graph. As a temporary workaround, you can use the \texttt{--skip-missing} option to bypass the error and continue downloading the image index. For more information, see \texttt{Service Mesh Operator mirroring failed}.
\end{itemize}
\end{itemize}

The \texttt{oc adm catalog mirror} command also automatically mirrors the index image that is specified during the mirroring process, whether it be a Red Hat-provided index image or your own custom-built index image, to the target registry. You can then use the mirrored index image to create a catalog source that allows Operator Lifecycle Manager (OLM) to load the mirrored catalog onto your OpenShift Container Platform cluster.

\section*{Additional resources}
- Using Operator Lifecycle Manager on restricted networks

\section*{4.3.7.1. Prerequisites}

Mirroring Operator catalogs for use with disconnected clusters has the following prerequisites:

- Workstation with unrestricted network access.
- \texttt{podman} version 1.9.3 or later.
- If you want to filter, or \texttt{prune}, an existing catalog and selectively mirror only a subset of Operators, see the following sections:
4.3.7.2. Extracting and mirroring catalog contents

The `oc adm catalog mirror` command extracts the contents of an index image to generate the manifests required for mirroring. The default behavior of the command generates manifests, then automatically mirrors all of the image content from the index image, as well as the index image itself, to your mirror registry.

Alternatively, if your mirror registry is on a completely disconnected, or airgapped, host, you can first mirror the content to removable media, move the media to the disconnected environment, then mirror the content from the media to the registry.

4.3.7.2.1. Mirroring catalog contents to registries on the same network

If your mirror registry is co-located on the same network as your workstation with unrestricted network access, take the following actions on your workstation.

**Procedure**

1. If your mirror registry requires authentication, run the following command to log in to the registry:

   ```
   $ podman login <mirror_registry>
   ```

2. Run the following command to extract and mirror the content to the mirror registry:

   ```
   $ oc adm catalog mirror \
   <index_image> \[1\] \
   <mirror_registry>:<port>[/<repository>] \[2\] \
   -a ${REG_CREDS} \[3\]
   ```
Specify the index image for the catalog that you want to mirror.

Specify the fully qualified domain name (FQDN) for the target registry to mirror the Operator contents to. The mirror registry `<repository>` can be any existing repository, or namespace, on the registry, for example `olm-mirror` as outlined in the prerequisites. If there is an existing repository found during mirroring, the repository name is added to the resulting image name. If you do not want the image name to include the repository name, omit the `<repository>` value from this line, for example `<mirror_registry>:<port>`.

Optional: If required, specify the location of your registry credentials file. `{REG_CREDS}` is required for `registry.redhat.io`.

Optional: If you do not want to configure trust for the target registry, add the `--insecure` flag.

Optional: Specify which platform and architecture of the index image to select when multiple variants are available. Images are passed as `'<platform>/<arch>[/<variant>]'`. This does not apply to images referenced by the index. Valid values are `linux/amd64`, `linux/ppc64le`, `linux/s390x`, `linux/arm64`.

Optional: Generate only the manifests required for mirroring without actually mirroring the image content to a registry. This option can be useful for reviewing what will be mirrored, and lets you make any changes to the mapping list, if you require only a subset of packages. You can then use the `mapping.txt` file with the `oc image mirror` command to mirror the modified list of images in a later step. This flag is intended for only advanced selective mirroring of content from the catalog.

Example output

```
src image has index label for database path: /database/index.db
using database path mapping: /database/index.db:/tmp/153048078
wrote database to /tmp/153048078
...  
wrote mirroring manifests to manifests-redhat-operator-index-1614211642
```

1 Directory for the temporary `index.db` database generated by the command.

2 Record the manifests directory name that is generated. This directory is referenced in subsequent procedures.

**NOTE**

Red Hat Quay does not support nested repositories. As a result, running the `oc adm catalog mirror` command will fail with a `401 unauthorized` error. As a workaround, you can use the `--max-components=2` option when running the `oc adm catalog mirror` command to disable the creation of nested repositories. For more information on this workaround, see the Unauthorized error thrown while using catalog mirror command with Quay registry Knowledgebase Solution.
Additional resources

- Architecture and operating system support for Operators

4.3.7.2.2. Mirroring catalog contents to airgapped registries

If your mirror registry is on a completely disconnected, or airgapped, host, take the following actions.

Procedure

1. Run the following command on your workstation with unrestricted network access to mirror the content to local files:

   ```bash
   $ oc adm catalog mirror \
   <index_image> \ 
   file://local/index \ 
   -a ${REG_CREDS} \ 
   --insecure \ 
   --index-filter-by-os='<platform>/<arch>'
   
   1 Specify the index image for the catalog that you want to mirror.
   2 Specify the content to mirror to local files in your current directory.
   3 Optional: If required, specify the location of your registry credentials file.
   4 Optional: If you do not want to configure trust for the target registry, add the `--insecure` flag.
   5 Optional: Specify which platform and architecture of the index image to select when multiple variants are available. Images are specified as `<platform>/<arch>[/<variant>]`. This does not apply to images referenced by the index. Valid values are `linux/amd64`, `linux/ppc64le`, `linux/s390x`, `linux/arm64`, and `*`.

   Example output

   ```
   ...
   info: Mirroring completed in 5.93s (5.915MB/s)
   wrote mirroring manifests to manifests-my-index-1614985528
   ```

   To upload local images to a registry, run:

   ```bash
   oc adm catalog mirror file://local/index/myrepo/my-index:v1 REGISTRY/REPOSITORY
   ```

   1 Record the manifests directory name that is generated. This directory is referenced in subsequent procedures.
   2 Record the expanded `file://` path that is based on your provided index image. This path is referenced in a subsequent step.

   This command creates a `v2/` directory in your current directory.

2. Copy the `v2/` directory to removable media.
3. Physically remove the media and attach it to a host in the disconnected environment that has access to the mirror registry.

4. If your mirror registry requires authentication, run the following command on your host in the disconnected environment to log in to the registry:

   ```
   $ podman login <mirror_registry>
   ```

5. Run the following command from the parent directory containing the v2/ directory to upload the images from local files to the mirror registry:

   ```
   $ oc adm catalog mirror
   -a ${REG_CREDS}
   --insecure
   --index-filter-by-os='<platform>/<arch>'
   ```

   1. Specify the file:// path from the previous command output.

   2. Specify the fully qualified domain name (FQDN) for the target registry to mirror the Operator contents to. The mirror registry <repository> can be any existing repository, or namespace, on the registry, for example `olm-mirror` as outlined in the prerequisites. If there is an existing repository found during mirroring, the repository name is added to the resulting image name. If you do not want the image name to include the repository name, omit the <repository> value from this line, for example `<mirror_registry>:<port>`.

   3. Optional: If required, specify the location of your registry credentials file.

   4. Optional: If you do not want to configure trust for the target registry, add the --insecure flag.

   5. Optional: Specify which platform and architecture of the index image to select when multiple variants are available. Images are specified as `<platform>/<arch>[/<variant>]`. This does not apply to images referenced by the index. Valid values are `linux/amd64`, `linux/ppc64le`, `linux/s390x`, `linux/arm64`, and `*`.

   NOTE

   Red Hat Quay does not support nested repositories. As a result, running the `oc adm catalog mirror` command will fail with a 401 unauthorized error. As a workaround, you can use the `--max-components=2` option when running the `oc adm catalog mirror` command to disable the creation of nested repositories. For more information on this workaround, see the Unauthorized error thrown while using catalog mirror command with Quay registry Knowledgebase Solution.

6. Run the `oc adm catalog mirror` command again. Use the newly mirrored index image as the source and the same mirror registry target used in the previous step:

   ```
   $ oc adm catalog mirror
   <mirror_registry>:<port>/<index_image>
   ```
The **--manifests-only** flag is required for this step so that the command does not copy all of the mirrored content again.

### IMPORTANT

This step is required because the image mappings in the `imageContentSourcePolicy.yaml` file generated during the previous step must be updated from local paths to valid mirror locations. Failure to do so will cause errors when you create the `ImageContentSourcePolicy` object in a later step.

After you mirror the catalog, you can continue with the remainder of your cluster installation. After your cluster installation has finished successfully, you must specify the manifests directory from this procedure to create the `ImageContentSourcePolicy` and `CatalogSource` objects. These objects are required to enable installation of Operators from OperatorHub.

### Additional resources

- Architecture and operating system support for Operators

### 4.3.7.3. Generated manifests

After mirroring Operator catalog content to your mirror registry, a manifests directory is generated in your current directory.

If you mirrored content to a registry on the same network, the directory name takes the following pattern:

```
manifests-<index_image_name>-<random_number>
```

If you mirrored content to a registry on a disconnected host in the previous section, the directory name takes the following pattern:

```
manifests-index/<repository>/<index_image_name>-<random_number>
```

### NOTE

The manifests directory name is referenced in subsequent procedures.

The manifests directory contains the following files, some of which might require further modification:

- The `catalogSource.yaml` file is a basic definition for a `CatalogSource` object that is pre-populated with your index image tag and other relevant metadata. This file can be used as is or modified to add the catalog source to your cluster.
If you mirrored the content to local files, you must modify your `catalogSource.yaml` file to remove any backslash (`/`) characters from the `metadata.name` field. Otherwise, when you attempt to create the object, it fails with an "invalid resource name" error.

- The `imageContentSourcePolicy.yaml` file defines an `ImageContentSourcePolicy` object that can configure nodes to translate between the image references stored in Operator manifests and the mirrored registry.

**NOTE**

If your cluster uses an `ImageContentSourcePolicy` object to configure repository mirroring, you can use only global pull secrets for mirrored registries. You cannot add a pull secret to a project.

- The `mapping.txt` file contains all of the source images and where to map them in the target registry. This file is compatible with the `oc image mirror` command and can be used to further customize the mirroring configuration.

**IMPORTANT**

If you used the `--manifests-only` flag during the mirroring process and want to further trim the subset of packages to mirror, see the steps in the Mirroring a package manifest format catalog image procedure of the OpenShift Container Platform 4.7 documentation about modifying your `mapping.txt` file and using the `oc image mirror` command.

### 4.3.7.4. Postinstallation requirements

After you mirror the catalog, you can continue with the remainder of your cluster installation. After your cluster installation has finished successfully, you must specify the manifests directory from this procedure to create the `ImageContentSourcePolicy` and `CatalogSource` objects. These objects are required to populate and enable installation of Operators from OperatorHub.

**Additional resources**

- Populating OperatorHub from mirrored Operator catalogs
- Updating or filtering a file-based catalog image

### 4.3.8. Next steps

- Install a cluster on infrastructure that you provision in your restricted network, such as on VMware vSphere, bare metal, or Amazon Web Services.

### 4.3.9. Additional resources

- See Gathering data about specific features for more information about using must-gather.
4.4. MIRRORING IMAGES FOR A DISCONNECTED INSTALLATION USING THE OC-MIRROR PLUGIN

Running your cluster in a restricted network without direct internet connectivity is possible by installing the cluster from a mirrored set of OpenShift Container Platform container images in a private registry. This registry must be running at all times as long as the cluster is running. See the Prerequisites section for more information.

You can use the oc-mirror OpenShift CLI (oc) plugin to mirror images to a mirror registry in your fully or partially disconnected environments. You must run oc-mirror from a system with internet connectivity in order to download the required images from the official Red Hat registries.

The following steps outline the high-level workflow on how to use the oc-mirror plugin to mirror images to a mirror registry:

1. Create an image set configuration file.
2. Mirror the image set to the mirror registry by using one of the following methods:
   - Mirror an image set directly to the mirror registry.
   - Mirror an image set to disk, transfer the image set to the target environment, then upload the image set to the target mirror registry.
3. Configure your cluster to use the resources generated by the oc-mirror plugin.
4. Repeat these steps to update your mirror registry as necessary.

4.4.1. About the oc-mirror plugin

You can use the oc-mirror OpenShift CLI (oc) plugin to mirror all required OpenShift Container Platform content and other images to your mirror registry by using a single tool. It provides the following features:

- Provides a centralized method to mirror OpenShift Container Platform releases, Operators, helm charts, and other images.
- Maintains update paths for OpenShift Container Platform and Operators.
- Uses a declarative image set configuration file to include only the OpenShift Container Platform releases, Operators, and images that your cluster needs.
- Performs incremental mirroring, which reduces the size of future image sets.
- Prunes images from the target mirror registry that were excluded from the image set configuration since the previous execution.
- Optionally generates supporting artifacts for OpenShift Update Service (OSUS) usage.

When using the oc-mirror plugin, you specify which content to mirror in an image set configuration file. In this YAML file, you can fine-tune the configuration to only include the OpenShift Container Platform releases and Operators that your cluster needs. This reduces the amount of data that you need to download and transfer. The oc-mirror plugin can also mirror arbitrary helm charts and additional container images to assist users in seamlessly synchronizing their workloads onto mirror registries.

The first time you run the oc-mirror plugin, it populates your mirror registry with the required content to perform your disconnected cluster installation or update. In order for your disconnected cluster to
continue receiving updates, you must keep your mirror registry updated. To update your mirror registry, you run the oc-mirror plugin using the same configuration as the first time you ran it. The oc-mirror plugin references the metadata from the storage backend and only downloads what has been released since the last time you ran the tool. This provides update paths for OpenShift Container Platform and Operators and performs dependency resolution as required.

**IMPORTANT**

When using the oc-mirror CLI plugin to populate a mirror registry, any further updates to the mirror registry must be made using the oc-mirror tool.

### 4.4.2. oc-mirror compatibility and support

The oc-mirror plugin supports mirroring OpenShift Container Platform payload images and Operator catalogs for OpenShift Container Platform versions 4.10 and later.

**NOTE**

On aarch64, ppc64le, and s390x architectures the oc-mirror plugin is only supported for OpenShift Container Platform versions 4.14 and later.

Use the latest available version of the oc-mirror plugin regardless of which versions of OpenShift Container Platform you need to mirror.

**IMPORTANT**

If you used the Technology Preview OCI local catalogs feature for the oc-mirror plugin for OpenShift Container Platform 4.12, you can no longer use the OCI local catalogs feature of the oc-mirror plugin to copy a catalog locally and convert it to OCI format as a first step to mirroring to a fully disconnected cluster.

### 4.4.3. About the mirror registry

You can mirror the images that are required for OpenShift Container Platform installation and subsequent product updates to a container mirror registry that supports Docker v2-2, such as Red Hat Quay. If you do not have access to a large-scale container registry, you can use the mirror registry for Red Hat OpenShift, which is a small-scale container registry included with OpenShift Container Platform subscriptions.

Regardless of your chosen registry, the procedure to mirror content from Red Hat hosted sites on the internet to an isolated image registry is the same. After you mirror the content, you configure each cluster to retrieve this content from your mirror registry.

**IMPORTANT**

The OpenShift image registry cannot be used as the target registry because it does not support pushing without a tag, which is required during the mirroring process.

If choosing a container registry that is not the mirror registry for Red Hat OpenShift, it must be reachable by every machine in the clusters that you provision. If the registry is unreachable, installation, updating, or normal operations such as workload relocation might fail. For that reason, you must run mirror registries in a highly available way, and the mirror registries must at least match the production availability of your OpenShift Container Platform clusters.
When you populate your mirror registry with OpenShift Container Platform images, you can follow two scenarios. If you have a host that can access both the internet and your mirror registry, but not your cluster nodes, you can directly mirror the content from that machine. This process is referred to as connected mirroring. If you have no such host, you must mirror the images to a file system and then bring that host or removable media into your restricted environment. This process is referred to as disconnected mirroring.

For mirrored registries, to view the source of pulled images, you must review the Trying to access log entry in the CRI-O logs. Other methods to view the image pull source, such as using the crictl images command on a node, show the non-mirrored image name, even though the image is pulled from the mirrored location.

**NOTE**

Red Hat does not test third party registries with OpenShift Container Platform.

Additional resources

- For information about viewing the CRI-O logs to view the image source, see Viewing the image pull source.

### 4.4.4. Prerequisites

- You must have a container image registry that supports Docker v2-2 in the location that will host the OpenShift Container Platform cluster, such as Red Hat Quay.

**NOTE**

If you use Red Hat Quay, you must use version 3.6 or later with the oc-mirror plugin. If you have an entitlement to Red Hat Quay, see the documentation on deploying Red Hat Quay for proof-of-concept purposes or by using the Red Hat Quay Operator. If you need additional assistance selecting and installing a registry, contact your sales representative or Red Hat Support.

If you do not already have an existing solution for a container image registry, subscribers of OpenShift Container Platform are provided a mirror registry for Red Hat OpenShift. The mirror registry for Red Hat OpenShift is included with your subscription and is a small-scale container registry that can be used to mirror the required container images of OpenShift Container Platform in disconnected installations.

### 4.4.5. Preparing your mirror hosts

Before you can use the oc-mirror plugin to mirror images, you must install the plugin and create a container image registry credentials file to allow the mirroring from Red Hat to your mirror.

#### 4.4.5.1. Installing the oc-mirror OpenShift CLI plugin

To use the oc-mirror OpenShift CLI plugin to mirror registry images, you must install the plugin. If you are mirroring image sets in a fully disconnected environment, ensure that you install the oc-mirror plugin on the host with internet access and the host in the disconnected environment with access to the mirror registry.

**Prerequisites**
• You have installed the OpenShift CLI (oc).

Procedure

1. Download the oc-mirror CLI plugin.
   b. Under the OpenShift disconnected installation tools section, click Download for OpenShift Client (oc) mirror plugin and save the file.

2. Extract the archive:
   ```
   $ tar xvzf oc-mirror.tar.gz
   ```

3. If necessary, update the plugin file to be executable:
   ```
   $ chmod +x oc-mirror
   ```

   **NOTE**
   Do not rename the oc-mirror file.

4. Install the oc-mirror CLI plugin by placing the file in your PATH, for example, /usr/local/bin:
   ```
   $ sudo mv oc-mirror /usr/local/bin/.
   ```

Verification

• Run oc mirror help to verify that the plugin was successfully installed:
   ```
   $ oc mirror help
   ```

Additional resources

• Installing and using CLI plugins

4.4.5.2. Configuring credentials that allow images to be mirrored

Create a container image registry credentials file that allows mirroring images from Red Hat to your mirror.

**WARNING**

Do not use this image registry credentials file as the pull secret when you install a cluster. If you provide this file when you install cluster, all of the machines in the cluster will have write access to your mirror registry.
**WARNING**

This process requires that you have write access to a container image registry on the mirror registry and adds the credentials to a registry pull secret.

**Prerequisites**

- You configured a mirror registry to use in your disconnected environment.
- You identified an image repository location on your mirror registry to mirror images into.
- You provisioned a mirror registry account that allows images to be uploaded to that image repository.

**Procedure**

Complete the following steps on the installation host:

1. Download your `registry.redhat.io` pull secret from the Red Hat OpenShift Cluster Manager.

2. Make a copy of your pull secret in JSON format:

   ```sh
   $ cat ./pull-secret | jq . > <path>/<pull_secret_file_in_json>
   ```

   Specify the path to the folder to store the pull secret in and a name for the JSON file that you create.

   The contents of the file resemble the following example:

   ```json
   {
     "auths": {
       "cloud.openshift.com": {
         "auth": "b3BlbnNo...",
         "email": "you@example.com"
       },
       "quay.io": {
         "auth": "b3BlbnNo...",
         "email": "you@example.com"
       },
       "registry.connect.redhat.com": {
         "auth": "NTE3Njg5Nj...",
         "email": "you@example.com"
       },
       "registry.redhat.io": {
         "auth": "NTE3Njg5Nj...",
         "email": "you@example.com"
       }
     }
   }
   ```

3. Save the file either as `~/.docker/config.json` or `$XDG_RUNTIME_DIR/containers/auth.json`. 
4. Generate the base64-encoded user name and password or token for your mirror registry:

```bash
$ echo -n '<user_name>:<password>' | base64 -w0
```

1  For `<user_name>` and `<password>`, specify the user name and password that you configured for your registry.

5. Edit the JSON file and add a section that describes your registry to it:

```json
"auths": {
  "<mirror_registry>": {
    "auth": "<credentials>",
    "email": "you@example.com"
  },
  "cloud.openshift.com": {
    "auth": "b3BlbnNo...",
    "email": "you@example.com"
  },
  "quay.io": {
    "auth": "b3BlbnNo...",
    "email": "you@example.com"
  },
  "registry.connect.redhat.com": {
    "auth": "NTE3Njg5Nj...",
    "email": "you@example.com"
  },
  "registry.redhat.io": {
    "auth": "NTE3Njg5Nj...",
    "email": "you@example.com"
  }
}
```

1  For `<mirror_registry>`, specify the registry domain name, and optionally the port, that your mirror registry uses to serve content. For example, `registry.example.com` or `registry.example.com:8443`

2  For `<credentials>`, specify the base64-encoded user name and password for the mirror registry.

The file resembles the following example:

```json
{
  "auths": {
    "registry.example.com": {
      "auth": "BGVtbYk3ZHAtqXs=
    "email": "you@example.com"
  },
    "cloud.openshift.com": {
      "auth": "b3BlbnNo...",
      "email": "you@example.com"
  },
    "quay.io": {
      "auth": "b3BlbnNo...",
      "email": "you@example.com"
  },
    "registry.connect.redhat.com": {
      "auth": "NTE3Njg5Nj...",
      "email": "you@example.com"
    },
    "registry.redhat.io": {
      "auth": "NTE3Njg5Nj...",
      "email": "you@example.com"
    }
}
```

4.4.6. Creating the image set configuration
Before you can use the oc-mirror plugin to mirror image sets, you must create an image set configuration file. This image set configuration file defines which OpenShift Container Platform releases, Operators, and other images to mirror, along with other configuration settings for the oc-mirror plugin.

You must specify a storage backend in the image set configuration file. This storage backend can be a local directory or a registry that supports Docker v2-2. The oc-mirror plugin stores metadata in this storage backend during image set creation.

**IMPORTANT**

Do not delete or modify the metadata that is generated by the oc-mirror plugin. You must use the same storage backend every time you run the oc-mirror plugin for the same mirror registry.

**Prerequisites**

- You have created a container image registry credentials file. For instructions, see Configuring credentials that allow images to be mirrored.

**Procedure**

1. Use the `oc mirror init` command to create a template for the image set configuration and save it to a file called `imageset-config.yaml`:

   ```
   $ oc mirror init --registry example.com/mirror/oc-mirror-metadata > imageset-config.yaml
   ```

   Replace `example.com/mirror/oc-mirror-metadata` with the location of your registry for the storage backend.

2. Edit the file and adjust the settings as necessary:

   ```yaml
   kind: ImageSetConfiguration
   apiVersion: mirror.openshift.io/v1alpha2
   archiveSize: 4
   storageConfig:
     registry:
       imageURL: example.com/mirror/oc-mirror-metadata
       skipTLS: false
   mirror:
     platform:
       channels:
         - name: stable-4.14
           type: ocp
           graph: true
       operators:
       packages:
         - name: serverless-operator
   channels:
     - name: stable
   ```
Add `archiveSize` to set the maximum size, in GiB, of each file within the image set.

Set the back-end location to save the image set metadata to. This location can be a registry or local directory. It is required to specify `storageConfig` values.

Set the registry URL for the storage backend.

Set the channel to retrieve the OpenShift Container Platform images from.

Add `graph: true` to build and push the graph-data image to the mirror registry. The graph-data image is required to create OpenShift Update Service (OSUS). The `graph: true` field also generates the `UpdateService` custom resource manifest. The `oc` command-line interface (CLI) can use the `UpdateService` custom resource manifest to create OSUS. For more information, see About the OpenShift Update Service.

Set the Operator catalog to retrieve the OpenShift Container Platform images from.

Specify only certain Operator packages to include in the image set. Remove this field to retrieve all packages in the catalog.

Specify only certain channels of the Operator packages to include in the image set. You must always include the default channel for the Operator package even if you do not use the bundles in that channel. You can find the default channel by running the following command: `oc mirror list operators --catalog=<catalog_name> --package=<package_name>`.

Specify any additional images to include in image set.

**NOTE**

The `graph: true` field also mirrors the `ubi-micro` image along with other mirrored images.

See Image set configuration parameters for the full list of parameters and Image set configuration examples for various mirroring use cases.

3. Save the updated file.
   This image set configuration file is required by the `oc mirror` command when mirroring content.

Additional resources

- Image set configuration parameters
- Image set configuration examples
- Using the OpenShift Update Service in a disconnected environment

4.4.7. Mirroring an image set to a mirror registry

```yaml
additionallImages:
  - name: registry.redhat.io/ubi9/ubi:latest
    helm: {}
```

You can use the oc-mirror CLI plugin to mirror images to a mirror registry in a **partially disconnected environment** or in a **fully disconnected environment**.

These procedures assume that you already have your mirror registry set up.

### 4.4.7.1. Mirroring an image set in a partially disconnected environment

In a partially disconnected environment, you can mirror an image set directly to the target mirror registry.

#### 4.4.7.1.1. Mirroring from mirror to mirror

You can use the oc-mirror plugin to mirror an image set directly to a target mirror registry that is accessible during image set creation.

You are required to specify a storage backend in the image set configuration file. This storage backend can be a local directory or a Docker v2 registry. The oc-mirror plugin stores metadata in this storage backend during image set creation.

**IMPORTANT**

Do not delete or modify the metadata that is generated by the oc-mirror plugin. You must use the same storage backend every time you run the oc-mirror plugin for the same mirror registry.

**Prerequisites**

- You have access to the internet to obtain the necessary container images.
- You have installed the OpenShift CLI (**oc**).
- You have installed the **oc-mirror** CLI plugin.
- You have created the image set configuration file.

**Procedure**

- Run the **oc mirror** command to mirror the images from the specified image set configuration to a specified registry:

  ```
  $ oc mirror --config=./imageset-config.yaml 1
  docker://registry.example:5000 2
  ```

  1. Pass in the image set configuration file that was created. This procedure assumes that it is named **imageset-config.yaml**.

  2. Specify the registry to mirror the image set file to. The registry must start with **docker://**. If you specify a top-level namespace for the mirror registry, you must also use this same namespace on subsequent executions.

**Verification**

1. Navigate into the **oc-mirror-workspace**/ directory that was generated.

2. Navigate into the results directory, for example, **results-1639608409**/.
3. Verify that YAML files are present for the `ImageContentSourcePolicy` and `CatalogSource` resources.

**NOTE**

The `repositoryDigestMirrors` section of the `ImageContentSourcePolicy` YAML file is used for the `install-config.yaml` file during installation.

**Next steps**

- Configure your cluster to use the resources generated by `oc-mirror`.

**Troubleshooting**

- Unable to retrieve source image.

4.4.7.2. Mirroring an image set in a fully disconnected environment

To mirror an image set in a fully disconnected environment, you must first **mirror the image set to disk**, then **mirror the image set file on disk to a mirror**.

4.4.7.2.1. Mirroring from mirror to disk

You can use the `oc-mirror` plugin to generate an image set and save the contents to disk. The generated image set can then be transferred to the disconnected environment and mirrored to the target registry.

**IMPORTANT**

Depending on the configuration specified in the image set configuration file, using `oc-mirror` to mirror images might download several hundreds of gigabytes of data to disk.

The initial image set download when you populate the mirror registry is often the largest. Because you only download the images that changed since the last time you ran the command, when you run the `oc-mirror` plugin again, the generated image set is often smaller.

You are required to specify a storage backend in the image set configuration file. This storage backend can be a local directory or a docker v2 registry. The `oc-mirror` plugin stores metadata in this storage backend during image set creation.

**IMPORTANT**

Do not delete or modify the metadata that is generated by the `oc-mirror` plugin. You must use the same storage backend every time you run the `oc-mirror` plugin for the same mirror registry.

**Prerequisites**

- You have access to the internet to obtain the necessary container images.
You have installed the OpenShift CLI (oc).

You have installed the oc-mirror CLI plugin.

You have created the image set configuration file.

Procedure

- Run the oc mirror command to mirror the images from the specified image set configuration to disk:

  ```
  $ oc mirror --config=./imageset-config.yaml  
  file://<path_to_output_directory>
  ```

1. Pass in the image set configuration file that was created. This procedure assumes that it is named imageset-config.yaml.

2. Specify the target directory where you want to output the image set file. The target directory path must start with file://.

Verification

1. Navigate to your output directory:

   ```
   $ cd <path_to_output_directory>
   ```

2. Verify that an image set .tar file was created:

   ```
   $ ls
   ```

   Example output

   ```
   mirror_seq1_000000.tar
   ```

Next steps

- Transfer the image set .tar file to the disconnected environment.

Troubleshooting

- Unable to retrieve source image.

4.4.7.2.2. Mirroring from disk to mirror

You can use the oc-mirror plugin to mirror the contents of a generated image set to the target mirror registry.

Prerequisites

- You have installed the OpenShift CLI (oc) in the disconnected environment.

- You have installed the oc-mirror CLI plugin in the disconnected environment.
- You have generated the image set file by using the `oc mirror` command.
- You have transferred the image set file to the disconnected environment.

**Procedure**

- Run the `oc mirror` command to process the image set file on disk and mirror the contents to a target mirror registry:

  ```
  $ oc mirror --from=./mirror_seq1_000000.tar docker://registry.example:5000
  
  1. Pass in the image set .tar file to mirror, named `mirror_seq1_000000.tar` in this example. If an `archiveSize` value was specified in the image set configuration file, the image set might be broken up into multiple .tar files. In this situation, you can pass in a directory that contains the image set .tar files.

  2. Specify the registry to mirror the image set file to. The registry must start with `docker://`. If you specify a top-level namespace for the mirror registry, you must also use this same namespace on subsequent executions.

  This command updates the mirror registry with the image set and generates the `ImageContentSourcePolicy` and `CatalogSource` resources.

**Verification**

1. Navigate into the `oc-mirror-workspace/` directory that was generated.

2. Navigate into the results directory, for example, `results-1639608409/`.

3. Verify that YAML files are present for the `ImageContentSourcePolicy` and `CatalogSource` resources.

**Next steps**

- Configure your cluster to use the resources generated by oc-mirror.

**Troubleshooting**

- **Unable to retrieve source image**.

### 4.4.8. Configuring your cluster to use the resources generated by oc-mirror

After you have mirrored your image set to the mirror registry, you must apply the generated `ImageContentSourcePolicy`, `CatalogSource`, and release image signature resources into the cluster.

The `ImageContentSourcePolicy` resource associates the mirror registry with the source registry and redirects image pull requests from the online registries to the mirror registry. The `CatalogSource` resource is used by Operator Lifecycle Manager (OLM) to retrieve information about the available Operators in the mirror registry. The release image signatures are used to verify the mirrored release images.

**Prerequisites**
You have mirrored the image set to the registry mirror in the disconnected environment.

- You have access to the cluster as a user with the `cluster-admin` role.

**Procedure**

1. Log in to the OpenShift CLI as a user with the `cluster-admin` role.

2. Apply the YAML files from the results directory to the cluster by running the following command:

   ```bash
   $ oc apply -f ./oc-mirror-workspace/results-1639608409/
   ```

3. If you mirrored release images, apply the release image signatures to the cluster by running the following command:

   ```bash
   $ oc apply -f ./oc-mirror-workspace/results-1639608409/release-signatures/
   ```

   **NOTE**

   If you are mirroring Operators instead of clusters, you do not need to run `$ oc apply -f ./oc-mirror-workspace/results-1639608409/release-signatures/`. Running that command will return an error, as there are no release image signatures to apply.

**Verification**

1. Verify that the `ImageContentSourcePolicy` resources were successfully installed by running the following command:

   ```bash
   $ oc get imagecontentsourcepolicy --all-namespaces
   ```

2. Verify that the `CatalogSource` resources were successfully installed by running the following command:

   ```bash
   $ oc get catalogsource --all-namespaces
   ```

**4.4.9. Keeping your mirror registry content updated**

After your target mirror registry is populated with the initial image set, be sure to update it regularly so that it has the latest content. You can optionally set up a cron job, if possible, so that the mirror registry is updated on a regular basis.

Ensure that you update your image set configuration to add or remove OpenShift Container Platform and Operator releases as necessary. Any images that are removed are pruned from the mirror registry.

**4.4.9.1. About updating your mirror registry content**

When you run the oc-mirror plugin again, it generates an image set that only contains new and updated images since the previous execution. Because it only pulls in the differences since the previous image set was created, the generated image set is often smaller and faster to process than the initial image set.
IMPORTANT

Generated image sets are sequential and must be pushed to the target mirror registry in order. You can derive the sequence number from the file name of the generated image set archive file.

Adding new and updated images
Depending on the settings in your image set configuration, future executions of oc-mirror can mirror additional new and updated images. Review the settings in your image set configuration to ensure that you are retrieving new versions as necessary. For example, you can set the minimum and maximum versions of Operators to mirror if you want to restrict to specific versions. Alternatively, you can set the minimum version as a starting point to mirror, but keep the version range open so you keep receiving new Operator versions on future executions of oc-mirror. Omitting any minimum or maximum version gives you the full version history of an Operator in a channel. Omitting explicitly named channels gives you all releases in all channels of the specified Operator. Omitting any named Operator gives you the entire catalog of all Operators and all their versions ever released.

All these constraints and conditions are evaluated against the publicly released content by Red Hat on every invocation of oc-mirror. This way, it automatically picks up new releases and entirely new Operators. Constraints can be specified by only listing a desired set of Operators, which will not automatically add other newly released Operators into the mirror set. You can also specify a particular release channel, which limits mirroring to just this channel and not any new channels that have been added. This is important for Operator products, such as Red Hat Quay, that use different release channels for their minor releases. Lastly, you can specify a maximum version of a particular Operator, which causes the tool to only mirror the specified version range so that you do not automatically get any newer releases past the maximum version mirrored. In all these cases, you must update the image set configuration file to broaden the scope of the mirroring of Operators to get other Operators, new channels, and newer versions of Operators to be available in your target registry.

It is recommended to align constraints like channel specification or version ranges with the release strategy that a particular Operator has chosen. For example, when the Operator uses a stable channel, you should restrict mirroring to that channel and potentially a minimum version to find the right balance between download volume and getting stable updates regularly. If the Operator chooses a release version channel scheme, for example stable-3.7, you should mirror all releases in that channel. This allows you to keep receiving patch versions of the Operator, for example 3.7.1. You can also regularly adjust the image set configuration to add channels for new product releases, for example stable-3.8.

Pruning images
Images are pruned automatically from the target mirror registry if they are no longer included in the latest image set that was generated and mirrored. This allows you to easily manage and clean up unneeded content and reclaim storage resources.

If there are OpenShift Container Platform releases or Operator versions that you no longer need, you can modify your image set configuration to exclude them, and they will be pruned from the mirror registry upon mirroring. This can be done by adjusting a minimum or maximum version range setting per Operator in the image set configuration file or by deleting the Operator from the list of Operators to mirror from the catalog. You can also remove entire Operator catalogs or entire OpenShift Container Platform releases from the configuration file.

IMPORTANT

If there are no new or updated images to mirror, the excluded images are not pruned from the target mirror registry. Additionally, if an Operator publisher removes an Operator version from a channel, the removed versions are pruned from the target mirror registry.
To disable automatic pruning of images from the target mirror registry, pass the `--skip-pruning` flag to the `oc mirror` command.

### 4.4.9.2. Updating your mirror registry content

After you publish the initial image set to the mirror registry, you can use the oc-mirror plugin to keep your disconnected clusters updated.

Depending on your image set configuration, oc-mirror automatically detects newer releases of OpenShift Container Platform and your selected Operators that have been released after you completed the initial mirror. It is recommended to run oc-mirror at regular intervals, for example in a nightly cron job, to receive product and security updates on a timely basis.

**Prerequisites**

- You have used the oc-mirror plugin to mirror the initial image set to your mirror registry.
- You have access to the storage backend that was used for the initial execution of the oc-mirror plugin.

**NOTE**

You must use the same storage backend as the initial execution of oc-mirror for the same mirror registry. Do not delete or modify the metadata image that is generated by the oc-mirror plugin.

**Procedure**

1. If necessary, update your image set configuration file to pick up new OpenShift Container Platform and Operator versions. See *Image set configuration examples* for example mirroring use cases.

2. Follow the same steps that you used to mirror your initial image set to the mirror registry. For instructions, see *Mirroring an image set in a partially disconnected environment* or *Mirroring an image set in a fully disconnected environment*.

**IMPORTANT**

- You must provide the same storage backend so that only a differential image set is created and mirrored.
- If you specified a top-level namespace for the mirror registry during the initial image set creation, then you must use this same namespace every time you run the oc-mirror plugin for the same mirror registry.

3. Configure your cluster to use the resources generated by oc-mirror.

**Additional resources**

- *Image set configuration examples*
- *Mirroring an image set in a partially disconnected environment*
- *Mirroring an image set in a fully disconnected environment*
• Configuring your cluster to use the resources generated by oc-mirror

4.4.10. Performing a dry run

You can use oc-mirror to perform a dry run, without actually mirroring any images. This allows you to review the list of images that would be mirrored, as well as any images that would be pruned from the mirror registry. It also allows you to catch any errors with your image set configuration early or use the generated list of images with other tools to carry out the mirroring operation.

Prerequisites

• You have access to the internet to obtain the necessary container images.
• You have installed the OpenShift CLI (oc).
• You have installed the oc-mirror CLI plugin.
• You have created the image set configuration file.

Procedure

1. Run the oc mirror command with the --dry-run flag to perform a dry run:

```
$ oc mirror --config=./imageset-config.yaml \
  docker://registry.example:5000            \
  --dry-run
```

   1 Pass in the image set configuration file that was created. This procedure assumes that it is named imageset-config.yaml.
   2 Specify the mirror registry. Nothing is mirrored to this registry as long as you use the --dry-run flag.
   3 Use the --dry-run flag to generate the dry run artifacts and not an actual image set file.

Example output

```
Checking push permissions for registry.example:5000
Creating directory: oc-mirror-workspace/src/publish
Creating directory: oc-mirror-workspace/src/v2
Creating directory: oc-mirror-workspace/src/charts
Creating directory: oc-mirror-workspace/src/release-signatures
No metadata detected, creating new workspace
wrote mirroring manifests to oc-mirror-workspace/operators.1658342351/manifests-redhat-operator-index
...
info: Planning completed in 31.48s
info: Dry run complete
Writing image mapping to oc-mirror-workspace/mapping.txt
```

2. Navigate into the workspace directory that was generated:

```
-
```
3. Review the `mapping.txt` file that was generated.  
   This file contains a list of all images that would be mirrored.

4. Review the `pruning-plan.json` file that was generated.  
   This file contains a list of all images that would be pruned from the mirror registry when the 
   image set is published.

   **NOTE**
   The `pruning-plan.json` file is only generated if your oc-mirror command points 
   to your mirror registry and there are images to be pruned.

### 4.4.11. Including local OCI Operator catalogs

While mirroring OpenShift Container Platform releases, Operator catalogs, and additional images from a 
registry to a partially disconnected cluster, you can include Operator catalog images from a local file- 
based catalog on disk. The local catalog must be in the Open Container Initiative (OCI) format.

The local catalog and its contents are mirrored to your target mirror registry based on the filtering 
information in the image set configuration file.

   **IMPORTANT**
   When mirroring local OCI catalogs, any OpenShift Container Platform releases or 
   additional images that you want to mirror along with the local OCI-formatted catalog 
   must be pulled from a registry.

   You cannot mirror OCI catalogs along with an oc-mirror image set file on disk.

One example use case for using the OCI feature is if you have a CI/CD system building an OCI catalog to 
a location on disk, and you want to mirror that OCI catalog along with an OpenShift Container Platform 
release to your mirror registry.

   **NOTE**
   If you used the Technology Preview OCI local catalogs feature for the oc-mirror plugin 
   for OpenShift Container Platform 4.12, you can no longer use the OCI local catalogs 
   feature of the oc-mirror plugin to copy a catalog locally and convert it to OCI format as a 
   first step to mirroring to a fully disconnected cluster.

**Prerequisites**

- You have access to the internet to obtain the necessary container images.
- You have installed the OpenShift CLI (`oc`).
- You have installed the `oc-mirror` CLI plugin.

**Procedure**

1. Create the image set configuration file and adjust the settings as necessary.

```bash
$ cd oc-mirror-workspace/
```
The following example image set configuration mirrors an OCI catalog on disk along with an OpenShift Container Platform release and a UBI image from `registry.redhat.io`.

```yaml
kind: ImageSetConfiguration
apiVersion: mirror.openshift.io/v1alpha2
storageConfig:
  local:
    path: /home/user/metadata
  mirror:
    platform:
      channels:
        - name: stable-4.14
          type: ocp
          graph: false
    operators:
      - catalog: oci:///home/user/oc-mirror/my-oci-catalog
        targetCatalog: my-namespace/redhat-operator-index
        packages:
            packages:
              - name: rhacs-operator
    additionalImages:
      - name: registry.redhat.io/ubi9/ubi:latest
```

1. Set the back-end location to save the image set metadata to. This location can be a registry or local directory. It is required to specify `storageConfig` values.

2. Optionally, include an OpenShift Container Platform release to mirror from `registry.redhat.io`.

3. Specify the absolute path to the location of the OCI catalog on disk. The path must start with `oci://` when using the OCI feature.

4. Optionally, specify an alternative namespace and name to mirror the catalog as.

5. Optionally, specify additional Operator catalogs to pull from a registry.

6. Optionally, specify additional images to pull from a registry.

2. Run the `oc mirror` command to mirror the OCI catalog to a target mirror registry:

   ```bash
   $ oc mirror --config=./imageset-config.yaml \
   docker://registry.example:5000
   ```

   1. Pass in the image set configuration file. This procedure assumes that it is named `imageset-config.yaml`.

   2. Specify the registry to mirror the content to. The registry must start with `docker://`. If you specify a top-level namespace for the mirror registry, you must also use this same namespace on subsequent executions.

   Optionally, you can specify other flags to adjust the behavior of the OCI feature:
---oci-insecure-signature-policy
Do not push signatures to the target mirror registry.

---oci-registries-config
Specify the path to a TOML-formatted **registries.conf** file. You can use this to mirror from a different registry, such as a pre-production location for testing, without having to change the image set configuration file. This flag only affects local OCI catalogs, not any other mirrored content.

**Example registries.conf file**

```
[[registry]]
  location = "registry.redhat.io:5000"
  insecure = false
  blocked = false
  mirror-by-digest-only = true
  prefix = ""
[[registry.mirror]]
  location = "preprod-registry.example.com"
  insecure = false
```

Next steps

- Configure your cluster to use the resources generated by oc-mirror.

**Additional resources**

- Configuring your cluster to use the resources generated by oc-mirror

4.4.12. Image set configuration parameters

The oc-mirror plugin requires an image set configuration file that defines what images to mirror. The following table lists the available parameters for the **ImageSetConfiguration** resource.

**Table 4.1. ImageSetConfiguration parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the <strong>ImageSetConfiguration</strong> content.</td>
<td>String. For example: <strong>mirror.openshift.io/v1alpha2</strong>.</td>
</tr>
<tr>
<td>archiveSize</td>
<td>The maximum size, in GiB, of each archive file within the image set.</td>
<td>Integer. For example: <strong>4</strong></td>
</tr>
<tr>
<td>mirror</td>
<td>The configuration of the image set.</td>
<td>Object</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>---------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------</td>
</tr>
<tr>
<td>mirror.additionalImages</td>
<td>The additional images configuration of the image set.</td>
<td>Array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>additionalImages:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- name: registry.redhat.io/ubi8/ubi:latest</td>
</tr>
<tr>
<td>mirror.additionalImages.name</td>
<td>The tag or digest of the image to mirror.</td>
<td>String. For example:</td>
</tr>
<tr>
<td>mirror.blockedImages</td>
<td>The full tag, digest, or pattern of images to block from mirroring.</td>
<td>Array of strings. For example:</td>
</tr>
<tr>
<td>mirror.helm</td>
<td>The helm configuration of the image set. Note that the oc-mirror plugin supports only helm charts that do not require user input when rendered.</td>
<td>Object</td>
</tr>
<tr>
<td>mirror.helm.local</td>
<td>The local helm charts to mirror.</td>
<td>Array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>local:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- name: podinfo</td>
</tr>
<tr>
<td></td>
<td></td>
<td>path: /test/podinfo-5.0.0.tar.gz</td>
</tr>
<tr>
<td>mirror.helm.local.name</td>
<td>The name of the local helm chart to mirror.</td>
<td>String. For example:</td>
</tr>
<tr>
<td>mirror.helm.local.path</td>
<td>The path of the local helm chart to mirror.</td>
<td>String. For example:</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------------------------------------------</td>
<td>--------------------------------------------------</td>
<td>------------------------------------------</td>
</tr>
<tr>
<td>mirror.helm.repositories</td>
<td>The remote helm repositories to mirror from.</td>
<td>Array of objects.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>mirror.helm.repositories.name</td>
<td>The name of the helm repository to mirror from.</td>
<td>String. For example: <strong>podinfo</strong>.</td>
</tr>
<tr>
<td>mirror.helm.repositories.url</td>
<td>The URL of the helm repository to mirror from.</td>
<td>String. For example: <strong><a href="https://example.github.io/podinfo">https://example.github.io/podinfo</a></strong>.</td>
</tr>
<tr>
<td>mirror.helm.repositories.charts</td>
<td>The remote helm charts to mirror.</td>
<td>Array of objects.</td>
</tr>
<tr>
<td>mirror.helm.repositories.charts.name</td>
<td>The name of the helm chart to mirror.</td>
<td>String. For example: <strong>podinfo</strong>.</td>
</tr>
<tr>
<td>mirror.helm.repositories.charts.version</td>
<td>The version of the named helm chart to mirror.</td>
<td>String. For example: <strong>5.0.0</strong>.</td>
</tr>
</tbody>
</table>

**CHAPTER 4. DISCONNECTED INSTALLATION MIRRORING**
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>

<td>packages:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- name: elasticsearch-operator</td>
</tr>
<tr>
<td></td>
<td></td>
<td>minVersion: 5.2.3-31</td>
</tr>
<tr>
<td>mirror.operators.packages.name</td>
<td>The Operator package name to include in the image set</td>
<td>String. For example: elasticsearch-operator.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td><code>mirror.operators.packages.channels</code></td>
<td>The Operator package channel configuration.</td>
<td>Object</td>
</tr>
<tr>
<td><code>mirror.operators.packages.channels.name</code></td>
<td>The Operator channel name, unique within a package, to include in the image set.</td>
<td>String. For example: <code>fast</code> or <code>stable-v4.14</code></td>
</tr>
<tr>
<td><code>mirror.operators.packages.channels.maxVersion</code></td>
<td>The highest version of the Operator mirror across all channels in which it exists. See the following note for further information.</td>
<td>String. For example: <code>5.2.3-31</code></td>
</tr>
<tr>
<td><code>mirror.operators.packages.channels.minBundle</code></td>
<td>The name of the minimum bundle to include, plus all bundles in the update graph to the channel head. Set this field only if the named bundle has no semantic version metadata.</td>
<td>String. For example: <code>bundleName</code></td>
</tr>
<tr>
<td><code>mirror.operators.packages.channels.minVersion</code></td>
<td>The lowest version of the Operator to mirror across all channels in which it exists. See the following note for further information.</td>
<td>String. For example: <code>5.2.3-31</code></td>
</tr>
<tr>
<td><code>mirror.operators.packages.maxVersion</code></td>
<td>The highest version of the Operator to mirror across all channels in which it exists. See the following note for further information.</td>
<td>String. For example: <code>5.2.3-31</code></td>
</tr>
<tr>
<td><code>mirror.operators.packages.minVersion</code></td>
<td>The lowest version of the Operator to mirror across all channels in which it exists. See the following note for further information.</td>
<td>String. For example: <code>5.2.3-31</code></td>
</tr>
<tr>
<td><code>mirror.operators.skipDependencies</code></td>
<td>If true, dependencies of bundles are not included.</td>
<td>Boolean. The default value is false.</td>
</tr>
<tr>
<td><code>mirror.operators.targetCatalog</code></td>
<td>An alternative name and optional namespace hierarchy to mirror the referenced catalog as.</td>
<td>String. For example: <code>my-namespace/my-operator-catalog</code></td>
</tr>
<tr>
<td><code>mirror.operators.targetName</code></td>
<td>An alternative name to mirror the referenced catalog as.</td>
<td>String. For example: <code>my-operator-catalog</code></td>
</tr>
</tbody>
</table>

The `targetName` parameter is deprecated. Use the `targetCatalog` parameter instead.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>mirror.operators.targetTag</td>
<td>An alternative tag to append to the <code>targetName</code> or <code>targetCatalog</code>.</td>
<td>String. For example: <code>v1</code></td>
</tr>
<tr>
<td>mirror.platform</td>
<td>The platform configuration of the image set.</td>
<td>Object</td>
</tr>
<tr>
<td>mirror.platform.architectures</td>
<td>The architecture of the platform release payload to mirror.</td>
<td>Array of strings. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>architectures:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- amd64</td>

<td><code>storageConfig.registry</code></td>
<td>The registry back-end configuration of the image set.</td>
<td>Object</td>
</tr>
<tr>
<td><code>storageConfig.registry.imageURL</code></td>
<td>The back-end registry URI. Can optionally include a namespace reference in the URI.</td>
<td>String. For example: <strong>quay.io/myuser/imageset:metadata</strong>.</td>
</tr>
<tr>
<td><code>storageConfig.registry.skipTLS</code></td>
<td>Optionally skip TLS verification of the referenced back-end registry.</td>
<td>Boolean. The default value is <strong>false</strong>.</td>
</tr>
</tbody>
</table>
NOTE

Using the minVersion and maxVersion properties to filter for a specific Operator version range can result in a multiple channel heads error. The error message will state that there are multiple channel heads. This is because when the filter is applied, the update graph of the operator is truncated.

The Operator Lifecycle Manager requires that every operator channel contains versions that form an update graph with exactly one end point, that is, the latest version of the operator. When applying the filter range that graph can turn into two or more separate graphs or a graph that has more than one end point.

To avoid this error, do not filter out the latest version of an operator. If you still run into the error, depending on the operator, either the maxVersion property needs to be increased or the minVersion property needs to be decreased. Because every operator graph can be different, you might need to adjust these values, according to the procedure, until the error is gone.

4.4.13. Image set configuration examples

The following ImageSetConfiguration file examples show the configuration for various mirroring use cases.

Use case: Including the shortest OpenShift Container Platform update path
The following ImageSetConfiguration file uses a local storage backend and includes all OpenShift Container Platform versions along the shortest update path from the minimum version of 4.11.37 to the maximum version of 4.12.15.

Example ImageSetConfiguration file

```yaml
apiVersion: mirror.openshift.io/v1alpha2
kind: ImageSetConfiguration
storageConfig:
  local:
    path: /home/user/metadata
mirror:
  platform:
    channels:
    - name: stable-4.12
      minVersion: 4.11.37
      maxVersion: 4.12.15
      shortestPath: true
```

Use case: Including all versions of OpenShift Container Platform from a minimum to the latest version for multi-architecture releases
The following ImageSetConfiguration file uses a registry storage backend and includes all OpenShift Container Platform versions starting at a minimum version of 4.13.4 to the latest version in the channel. On every invocation of oc-mirror with this image set configuration, the latest release of the stable-4.13 channel is evaluated, so running oc-mirror at regular intervals ensures that you automatically receive the latest releases of OpenShift Container Platform images.

By setting the value of platform.architectures to multi, you can ensure that the mirroring is supported for multi-architecture releases.

Example ImageSetConfiguration file

-
Use case: Including Operator versions from a minimum to the latest
The following **ImageSetConfiguration** file uses a local storage backend and includes only the Red Hat Advanced Cluster Security for Kubernetes Operator, versions starting at 4.0.1 and later in the **stable** channel.

**NOTE**

When you specify a minimum or maximum version range, you might not receive all Operator versions in that range.

By default, oc-mirror excludes any versions that are skipped or replaced by a newer version in the Operator Lifecycle Manager (OLM) specification. Operator versions that are skipped might be affected by a CVE or contain bugs. Use a newer version instead. For more information on skipped and replaced versions, see creating an update graph with OLM.

To receive all Operator versions in a specified range, you can set the **mirror.operators.full** field to **true**.

**Example ImageSetConfiguration file**

```yaml
apiVersion: mirror.openshift.io/v1alpha2
kind: ImageSetConfiguration
storageConfig:
  registry:
    imageURL: example.com/mirror/oc-mirror-metadata
    skipTLS: false
  mirror:
    platform:
      architectures:
        - "multi"
      channels:
        - name: stable-4.13
          minVersion: 4.13.4
          maxVersion: 4.13.6

apiVersion: mirror.openshift.io/v1alpha2
kind: ImageSetConfiguration
storageConfig:
  local:
    path: /home/user/metadata
  mirror:
    operators:
        packages:
          - name: rhacs-operator
            channels:
              - name: stable
                minVersion: 4.0.1
```

**NOTE**

To specify a maximum version instead of the latest, set the **mirror.operators.packages.channels.maxVersion** field.
Use case: Including the Nutanix CSI Operator
The following **ImageSetConfiguration** file uses a local storage backend and includes the Nutanix CSI Operator, the OpenShift Update Service (OSUS) graph image, and an additional Red Hat Universal Base Image (UBI).

Example ImageSetConfiguration file

```yaml
kind: ImageSetConfiguration
apiVersion: mirror.openshift.io/v1alpha2
storageConfig:
  registry:
    imageURL: mylocalregistry/ocp-mirror/openshift4
    skipTLS: false
mirror:
  platform:
    channels:
      - name: stable-4.11
        type: ocp
        graph: true
    operators:
        packages:
          - name: nutanixcsioperator
            channels:
              - name: stable
            additionalImages:
              - name: registry.redhat.io/ubi9/ubi:latest
```

Use case: Including the default Operator channel
The following **ImageSetConfiguration** file includes the **stable-5.7** and **stable** channels for the OpenShift Elasticsearch Operator. Even if only the packages from the **stable-5.7** channel are needed, the **stable** channel must also be included in the **ImageSetConfiguration** file, because it is the default channel for the Operator. You must always include the default channel for the Operator package even if you do not use the bundles in that channel.

TIP
You can find the default channel by running the following command: **oc mirror list operators --catalog=<catalog_name> --package=<package_name>**.

Example ImageSetConfiguration file

```yaml
apiVersion: mirror.openshift.io/v1alpha2
kind: ImageSetConfiguration
storageConfig:
  registry:
    imageURL: example.com/mirror/oc-mirror-metadata
    skipTLS: false
mirror:
  operators:
      packages:
        - name: elasticsearch-operator
```
Use case: Including an entire catalog (all versions)
The following `ImageSetConfiguration` file sets the `mirror.operators.full` field to `true` to include all versions for an entire Operator catalog.

Example `ImageSetConfiguration` file

```yaml
channels:
- name: stable-5.7
- name: stable

apiVersion: mirror.openshift.io/v1alpha2
kind: ImageSetConfiguration
storageConfig:
  registry:
    imageUrl: example.com/mirror/oc-mirror-metadata
    skipTLS: false
  mirror:
    operators:
      full: true
```

Use case: Including an entire catalog (channel heads only)
The following `ImageSetConfiguration` file includes the channel heads for an entire Operator catalog.

By default, for each Operator in the catalog, oc-mirror includes the latest Operator version (channel head) from the default channel. If you want to mirror all Operator versions, and not just the channel heads, you must set the `mirror.operators.full` field to `true`.

This example also uses the `targetCatalog` field to specify an alternative namespace and name to mirror the catalog as.

Example `ImageSetConfiguration` file

```yaml
channels:
- name: stable

apiVersion: mirror.openshift.io/v1alpha2
kind: ImageSetConfiguration
storageConfig:
  registry:
    imageUrl: example.com/mirror/oc-mirror-metadata
    skipTLS: false
  mirror:
    operators:
      targetCatalog: my-namespace/my-operator-catalog
```

Use case: Including arbitrary images and helm charts
The following `ImageSetConfiguration` file uses a registry storage backend and includes helm charts and an additional Red Hat Universal Base Image (UBI).

Example `ImageSetConfiguration` file

```yaml
apiVersion: mirror.openshift.io/v1alpha2
kind: ImageSetConfiguration
archiveSize: 4
storageConfig:
```

The following tables describe the `oc mirror` subcommands and flags:

**Table 4.2. oc mirror subcommands**

<table>
<thead>
<tr>
<th>Subcommand</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>completion</td>
<td>Generate the autocompletion script for the specified shell.</td>
</tr>
<tr>
<td>describe</td>
<td>Output the contents of an image set.</td>
</tr>
<tr>
<td>help</td>
<td>Show help about any subcommand.</td>
</tr>
<tr>
<td>init</td>
<td>Output an initial image set configuration template.</td>
</tr>
<tr>
<td>list</td>
<td>List available platform and Operator content and their version.</td>
</tr>
<tr>
<td>version</td>
<td>Output the oc-mirror version.</td>
</tr>
</tbody>
</table>

**Table 4.3. oc mirror flags**

<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-c, --config &lt;string&gt;</td>
<td>Specify the path to an image set configuration file.</td>
</tr>
<tr>
<td>--continue-on-error</td>
<td>If any non image-pull related error occurs, continue and attempt to mirror as much as possible.</td>
</tr>
</tbody>
</table>

```
registry:

- [About cluster updates in a disconnected environment](#)
CHAPTER 5. INSTALLING ON ALIBABA

5.1. PREPARING TO INSTALL ON ALIBABA CLOUD

IMPORTANT

Alibaba Cloud on OpenShift Container Platform is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see Technology Preview Features Support Scope.

5.1.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.

5.1.2. Requirements for installing OpenShift Container Platform on Alibaba Cloud

Before installing OpenShift Container Platform on Alibaba Cloud, you must configure and register your domain, create a Resource Access Management (RAM) user for the installation, and review the supported Alibaba Cloud data center regions and zones for the installation.

5.1.3. Registering and Configuring Alibaba Cloud Domain

To install OpenShift Container Platform, the Alibaba Cloud account you use must have a dedicated public hosted zone in your account. This zone must be authoritative for the domain. This service provides cluster DNS resolution and name lookup for external connections to the cluster.

Procedure

1. Identify your domain, or subdomain, and registrar. You can transfer an existing domain and registrar or obtain a new one through Alibaba Cloud or another source.

   NOTE

   If you purchase a new domain through Alibaba Cloud, it takes time for the relevant DNS changes to propagate. For more information about purchasing domains through Alibaba Cloud, see Alibaba Cloud domains.

2. If you are using an existing domain and registrar, migrate its DNS to Alibaba Cloud. See Domain name transfer in the Alibaba Cloud documentation.

3. Configure DNS for your domain. This includes:
   - Registering a generic domain name.
Completing real-name verification for your domain name.

Applying for an Internet Content Provider (ICP) filing.

Enabling domain name resolution.
Use an appropriate root domain, such as openshiftcorp.com, or subdomain, such as clusters.openshiftcorp.com.

4. If you are using a subdomain, follow the procedures of your company to add its delegation records to the parent domain.

5.1.4. Supported Alibaba regions

You can deploy an OpenShift Container Platform cluster to the regions listed in the Alibaba Regions and zones documentation.

5.1.5. Next steps

- Create the required Alibaba Cloud resources.

5.2. CREATING THE REQUIRED ALIBABA CLOUD RESOURCES

Before you install OpenShift Container Platform, you must use the Alibaba Cloud console to create a Resource Access Management (RAM) user that has sufficient permissions to install OpenShift Container Platform into your Alibaba Cloud. This user must also have permissions to create new RAM users. You can also configure and use the ccoctl tool to create new credentials for the OpenShift Container Platform components with the permissions that they require.

**IMPORTANT**

Alibaba Cloud on OpenShift Container Platform is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see Technology Preview Features Support Scope.

5.2.1. Creating the required RAM user

You must have a Alibaba Cloud Resource Access Management (RAM) user for the installation that has sufficient privileges. You can use the Alibaba Cloud Resource Access Management console to create a new user or modify an existing user. Later, you create credentials in OpenShift Container Platform based on this user's permissions.

When you configure the RAM user, be sure to consider the following requirements:

- The user must have an Alibaba Cloud AccessKey ID and AccessKey secret pair.
  
  - For a new user, you can select Open API Access for the Access Mode when creating the user. This mode generates the required AccessKey pair.
For an existing user, you can add an AccessKey pair or you can obtain the AccessKey pair for that user.

NOTE
When created, the AccessKey secret is displayed only once. You must immediately save the AccessKey pair because the AccessKey pair is required for API calls.

- Add the AccessKey ID and secret to the `~/.alibabacloud/credentials` file on your local computer. Alibaba Cloud automatically creates this file when you log in to the console. The Cloud Credential Operator (CCO) utility, ccoutil, uses these credentials when processing Credential Request objects.

For example:

```
[default]                          # Default client
type = access_key                  # Certification type: access_key
access_key_id = LTAI5t8cefXKmt                # Key
access_key_secret = wYx56mszAN4Uunfh            # Secret
```

1. Add your AccessKeyId and AccessKeySecret here.

- The RAM user must have the AdministratorAccess policy to ensure that the account has sufficient permission to create the OpenShift Container Platform cluster. This policy grants permissions to manage all Alibaba Cloud resources.

When you attach the AdministratorAccess policy to a RAM user, you grant that user full access to all Alibaba Cloud services and resources. If you do not want to create a user with full access, create a custom policy with the following actions that you can add to your RAM user for installation. These actions are sufficient to install OpenShift Container Platform.

TIP

You can copy and paste the following JSON code into the Alibaba Cloud console to create a custom policy. For information on creating custom policies, see Create a custom policy in the Alibaba Cloud documentation.

**Example 5.1. Example custom policy JSON file**

```json
{
  "Version": "1",
  "Statement": [
    {
      "Action": [
        "tag:ListTagResources",

"ram:ListAccessKeys",
"ram:CreateAccessKey"
]
5.2.2. Configuring the Cloud Credential Operator utility

To assign RAM users and policies that provide long-term RAM AccessKeys (AKs) for each in-cluster component, extract and prepare the Cloud Credential Operator (CCO) utility (ccoctl) binary.

NOTE

The ccoctl utility is a Linux binary that must run in a Linux environment.

Prerequisites

- You have access to an OpenShift Container Platform account with cluster administrator access.
- You have installed the OpenShift CLI (oc).

Procedure

1. Obtain the OpenShift Container Platform release image by running the following command:

   ```bash
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
   ```

2. Obtain the CCO container image from the OpenShift Container Platform release image by running the following command:

   ```bash
   $ CCO_IMAGE=$(oc adm release info --image-for='cloud-credential-operator' $RELEASE_IMAGE -a ~/.pull-secret)
   ```

   NOTE

   Ensure that the architecture of the $RELEASE_IMAGE matches the architecture of the environment in which you will use the ccoctl tool.

3. Extract the ccoctl binary from the CCO container image within the OpenShift Container Platform release image by running the following command:

   ```bash
   $ oc image extract $CCO_IMAGE --file="/usr/bin/ccoctl" -a ~/.pull-secret
   ```

4. Change the permissions to make ccoctl executable by running the following command:

   ```bash
   $ chmod +x /usr/bin/ccoctl
   ```
Verification

- To verify that `ccoctl` is ready to use, display the help file by running the following command:

  ```$ ccoctl --help```

**Output of ccoctl --help**

OpenShift credentials provisioning tool

Usage:

```
ccoctl [command]
```

Available Commands:

- `alibabacloud` Manage credentials objects for alibaba cloud
- `aws` Manage credentials objects for AWS cloud
- `azure` Manage credentials objects for Azure
- `gcp` Manage credentials objects for Google cloud
- `help` Help about any command
- `ibmcloud` Manage credentials objects for IBM Cloud
- `nutanix` Manage credentials objects for Nutanix

Flags:

```
-h, --help   help for ccoctl
```

Use "ccoctl [command] --help" for more information about a command.

**Additional resources**

- [Preparing to update a cluster with manually maintained credentials](#)

**5.2.3. Next steps**

- Install a cluster on Alibaba Cloud infrastructure that is provisioned by the OpenShift Container Platform installation program, by using one of the following methods:
  
  - **Installing a cluster quickly on Alibaba Cloud** You can install a cluster quickly by using the default configuration options.
  
  - **Installing a customized cluster on Alibaba Cloud** The installation program allows for some customization to be applied at the installation stage. Many other customization options are available post-installation.

**5.3. INSTALLING A CLUSTER QUICKLY ON ALIBABA CLOUD**

In OpenShift Container Platform version 4.14, you can install a cluster on Alibaba Cloud that uses the default configuration options.
Alibaba Cloud on OpenShift Container Platform is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see Technology Preview Features Support Scope.

5.3.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You registered your domain.
- If you use a firewall, you configured it to allow the sites that your cluster requires access to.
- You have created the required Alibaba Cloud resources.
- If the cloud Resource Access Management (RAM) APIs are not accessible in your environment, or if you do not want to store an administrator-level credential secret in the kube-system namespace, you can manually create and maintain Resource Access Management (RAM) credentials.

5.3.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager Hybrid Cloud Console to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

5.3.3. Generating a key pair for cluster node SSH access
During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>  
   ```

   Specify the path and file name, such as ~/.ssh/id_ed25519, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   ```bash
   $ cat <path>/<file_name>.pub
   ```

   For example, run the following to view the ~/.ssh/id_ed25519.pub public key:

   ```bash
   $ cat ~/.ssh/id_ed25519.pub
   ```
3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

**NOTE**

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

a. If the `ssh-agent` process is not already running for your local user, start it as a background task:

   ```
   $ eval "$(ssh-agent -s)"
   ```

   **Example output**

   ```
   Agent pid 31874
   ```

   **NOTE**

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the `ssh-agent`:

   ```
   $ ssh-add <path>/<file_name>
   ```

   Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

   **Example output**

   ```
   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
   ```

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

**5.3.4. Obtaining the installation program**

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

**Prerequisites**

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

**Procedure**
1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

   **IMPORTANT**

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   **IMPORTANT**

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ tar -xvf openshift-install-linux.tar.gz
   $ ./openshift-install create install-config --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 5.3.5. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Alibaba Cloud.

**Prerequisites**

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Create the `install-config.yaml` file.

   a. Change to the directory that contains the installation program and run the following command:

   ```
   $ ./openshift-install create install-config --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the directory name to store the files that the installation program creates.
When specifying the directory:

- Verify that the directory has the `execute` permission. This permission is required to run Terraform binaries under the installation directory.
- Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

**NOTE**

Always delete the `~/.powervs` directory to avoid reusing a stale configuration. Run the following command:

```
$ rm -rf ~/.powervs
```

b. At the prompts, provide the configuration details for your cloud:

i. Optional: Select an SSH key to use to access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

ii. Select `alibabacloud` as the platform to target.

iii. Select the region to deploy the cluster to.

iv. Select the base domain to deploy the cluster to. The base domain corresponds to the public DNS zone that you created for your cluster.

v. Provide a descriptive name for your cluster.

2. Installing the cluster into Alibaba Cloud requires that the Cloud Credential Operator (CCO) operate in manual mode. Modify the `install-config.yaml` file to set the `credentialsMode` parameter to `Manual`:

**Example install-config.yaml configuration file with credentialsMode set to Manual**

```yaml
apiVersion: v1
baseDomain: cluster1.example.com
credentialsMode: Manual
compute:
  - architecture: amd64
    hyperthreading: Enabled
    ...
```

1. Add this line to set the `credentialsMode` to `Manual`. 

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

**IMPORTANT**

The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

### 5.3.6. Generating the required installation manifests

You must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

**Procedure**

1. Generate the manifests by running the following command from the directory that contains the installation program:

   ```
   $ openshift-install create manifests --dir <installation_directory>
   ```

   where:

   `<installation_directory>`
   
   Specifies the directory in which the installation program creates files.

### 5.3.7. Creating credentials for OpenShift Container Platform components with the `ccoctl` tool

You can use the OpenShift Container Platform Cloud Credential Operator (CCO) utility to automate the creation of Alibaba Cloud RAM users and policies for each in-cluster component.

**NOTE**

By default, `ccoctl` creates objects in the directory in which the commands are run. To create the objects in a different directory, use the `--output-dir` flag. This procedure uses `<path_to_ccoctl_output_dir>` to refer to this directory.

**Prerequisites**

You must have:

- Extracted and prepared the `ccoctl` binary.
- Created a RAM user with sufficient permission to create the OpenShift Container Platform cluster.
- Added the AccessKeyId (`access_key_id`) and AccessKeySecret (`access_key_secret`) of that RAM user into the `~/.alibabacloud/credentials` file on your local computer.

**Procedure**

1. Set a `$RELEASE_IMAGE` variable with the release image from your installation file by running the following command:

   ```
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
   ```
2. Extract the list of CredentialsRequest objects from the OpenShift Container Platform release image by running the following command:

```bash
$ oc adm release extract \ 
  --from=$RELEASE_IMAGE \ 
  --credentials-requests \ 
  --included \  
  --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \ 
  --to=<path_to_directory_for_credentials_requests>
```

1. The `--included` parameter includes only the manifests that your specific cluster configuration requires.
2. Specify the location of the `install-config.yaml` file.
3. Specify the path to the directory where you want to store the CredentialsRequest objects. If the specified directory does not exist, this command creates it.

NOTE

This command might take a few moments to run.

3. Use the `ccoctl` tool to process all CredentialsRequest objects by running the following command:

   a. Run the following command to use the tool:

```
$ ccoctl alibabacloud create-ram-users \ 
  --name <name> \  
  --region=<alibaba_region> \  
  --credentials-requests-dir=<path_to_credentials_requests_directory> \  
  --output-dir=<path_to_ccoctl_output_dir>
```

1. Specify the name used to tag any cloud resources that are created for tracking.
2. Specify the Alibaba Cloud region in which cloud resources will be created.
3. Specify the directory containing the files for the component CredentialsRequest objects.
4. Specify the directory where the generated component credentials secrets will be placed.

NOTE

If your cluster uses Technology Preview features that are enabled by the `TechPreviewNoUpgrade` feature set, you must include the `--enable-tech-preview` parameter.

Example output

---
A RAM user can have up to two AccessKeys at the same time. If you run `ccoctl alibabacloud create-ram-users` more than twice, the previously generated manifests secret becomes stale and you must reapply the newly generated secrets.

b. Verify that the OpenShift Container Platform secrets are created:

```
ls <path_to_ccoctl_output_dir>/manifests
```

Example output

```
openshift-cluster-csi-drivers-alibaba-disk-credentials-credentials.yaml
openshift-image-registry-installer-cloud-credentials-credentials.yaml
openshift-ingress-operator-cloud-credentials-credentials.yaml
openshift-machine-api-alibabacloud-credentials-credentials.yaml
```

You can verify that the RAM users and policies are created by querying Alibaba Cloud. For more information, refer to Alibaba Cloud documentation on listing RAM users and policies.

4. Copy the generated credential files to the target manifests directory:

```
cp ./<path_to_ccoctl_output_dir>/manifests/*credentials.yaml ./<path_to_installation_dir>/manifests/
```

where:

- `<path_to_ccoctl_output_dir>`
  - Specifies the directory created by the `ccoctl alibabacloud create-ram-users` command.

- `<path_to_installation_dir>`
  - Specifies the directory in which the installation program creates files.

5.3.8. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.
**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

**Prerequisites**

- You have configured an account with the cloud platform that hosts your cluster.
- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.

**Procedure**

- Change to the directory that contains the installation program and initialize the cluster deployment:

```bash
$ ./openshift-install create cluster --dir <installation_directory> \   
--log-level=info
```

1. For `<installation_directory>`, specify the location of your customized `./install-config.yaml` file.

2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

**Verification**

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the `kubeadmin` user.
- Credential information also outputs to `<installation_directory>/openshift_install.log`.

**IMPORTANT**

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

**Example output**

```
...  
INFO Install complete!  
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/instal_dir/auth/kubeconfig'  
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com  
INFO Login to the console with user: "kubeadmin", and password: "password"  
INFO Time elapsed: 36m22s  
```
5.3.9. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of oc.

### Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

**Procedure**

2. Select the architecture from the **Product Variant** drop-down list.

3. Select the appropriate version from the **Version** drop-down list.

4. Click **Download Now** next to the **OpenShift v4.14 Linux Client** entry and save the file.

5. Unpack the archive:

   ```bash
   $ tar xvf <file>
   ```

6. Place the oc binary in a directory that is on your **PATH**.

   To check your **PATH**, execute the following command:

   ```bash
   $ echo $PATH
   ```

**Verification**

- After you install the OpenShift CLI, it is available using the oc command:

  ```bash
  $ oc <command>
  ```
Installing the OpenShift CLI on Windows
You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

Procedure

2. Select the appropriate version from the Version drop-down list.
3. Click Download Now next to the OpenShift v4.14 Windows Client entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the oc binary to a directory that is on your PATH.
   To check your PATH, open the command prompt and execute the following command:

   ```
   C:\> path
   ```

Verification

- After you install the OpenShift CLI, it is available using the oc command:

  ```
  C:\> oc <command>
  ```

Installing the OpenShift CLI on macOS
You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.

Procedure

2. Select the appropriate version from the Version drop-down list.
3. Click Download Now next to the OpenShift v4.14 macOS Client entry and save the file.
4. Unpack and unzip the archive.
5. Move the oc binary to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:

   ```
   $ echo $PATH
   ```

Verification

- After you install the OpenShift CLI, it is available using the oc command:
5.3.10. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster kubeconfig file. The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the oc CLI.

Procedure

1. Export the kubeadmin credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run oc commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   ```

   Example output

   ```
   system:admin
   ```

5.3.11. Logging in to the cluster by using the web console

The kubeadmin user exists by default after an OpenShift Container Platform installation. You can log in to your cluster as the kubeadmin user by using the OpenShift Container Platform web console.

Prerequisites

- You have access to the installation host.
- You completed a cluster installation and all cluster Operators are available.

Procedure

1. Obtain the password for the kubeadmin user from the kubeadmin-password file on the installation host:

   ```bash
   $ cat <installation_directory>/auth/kubeadmin-password
   ```
2. List the OpenShift Container Platform web console route:

   ```bash
   $ oc get routes -n openshift-console | grep 'console-openshift'
   ```

   **Example output**

   ```
   console console-openshift-console.apps.<cluster_name>.<base_domain> console
   https reencrypt/Redirect None
   ```

3. Navigate to the route detailed in the output of the preceding command in a web browser and log in as the `kubeadmin` user.

### 5.3.12. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager Hybrid Cloud Console.

After you confirm that your OpenShift Cluster Manager Hybrid Cloud Console inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- See Accessing the web console for more details about accessing and understanding the OpenShift Container Platform web console.

- See About remote health monitoring for more information about the Telemetry service

### 5.3.13. Next steps

- Validating an installation.

- Customize your cluster.

- If necessary, you can opt out of remote health reporting.

## 5.4. INSTALLING A CLUSTER ON ALIBABA CLOUD WITH CUSTOMIZATIONS
In OpenShift Container Platform version 4.14, you can install a customized cluster on infrastructure that the installation program provisions on Alibaba Cloud. To customize the installation, you modify parameters in the `install-config.yaml` file before you install the cluster.

**NOTE**

The scope of the OpenShift Container Platform installation configurations is intentionally narrow. It is designed for simplicity and ensured success. You can complete many more OpenShift Container Platform configuration tasks after an installation completes.

**IMPORTANT**

Alibaba Cloud on OpenShift Container Platform is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see Technology Preview Features Support Scope.

### 5.4.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You registered your domain.
- If you use a firewall, you configured it to allow the sites that your cluster requires access to.
- If the cloud Resource Access Management (RAM) APIs are not accessible in your environment, or if you do not want to store an administrator-level credential secret in the `kube-system` namespace, you can manually create and maintain Resource Access Management (RAM) credentials.

### 5.4.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager Hybrid Cloud Console to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.
IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

5.4.3. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The ./openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

NOTE

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> ①

   ① Specify the path and file name, such as ~/.ssh/id_ed25519, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

NOTE

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.
2. View the public SSH key:

```bash
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

```bash
$ cat ~/.ssh/id_ed25519.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

   **NOTE**
   
   On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

   a. If the `ssh-agent` process is not already running for your local user, start it as a background task:

   ```bash
   $ eval "$(ssh-agent -s)"
   ```

   **Example output**

   ```
   Agent pid 31874
   ```

   **NOTE**

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the `ssh-agent`:

   ```bash
   $ ssh-add <path>/<file_name>  
   ```

   Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`.

   **Example output**

   ```
   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
   ```

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

**5.4.4. Obtaining the installation program**

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.
Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

   **IMPORTANT**

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   **IMPORTANT**

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ tar -xvf openshift-install-linux.tar.gz
   ```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

5.4.4.1. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Alibaba Cloud.

Prerequisites

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Create the `install-config.yaml` file.

   a. Change to the directory that contains the installation program and run the following command:
1. $ ./openshift-install create install-config --dir <installation_directory>  

For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

When specifying the directory:

- Verify that the directory has the `execute` permission. This permission is required to run Terraform binaries under the installation directory.
- Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

**NOTE**

Always delete the `~/.powervs` directory to avoid reusing a stale configuration. Run the following command:

```
$ rm -rf ~/.powervs
```

b. At the prompts, provide the configuration details for your cloud:

i. Optional: Select an SSH key to use to access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

ii. Select `alibabacloud` as the platform to target.

iii. Select the region to deploy the cluster to.

iv. Select the base domain to deploy the cluster to. The base domain corresponds to the public DNS zone that you created for your cluster.

v. Provide a descriptive name for your cluster.

2. Installing the cluster into Alibaba Cloud requires that the Cloud Credential Operator (CCO) operate in manual mode. Modify the `install-config.yaml` file to set the `credentialsMode` parameter to `Manual`:

**Example install-config.yaml configuration file with credentialsMode set to Manual**

```yaml
apiVersion: v1
baseDomain: cluster1.example.com
credentialsMode: Manual
compute:
```
Add this line to set the `credentialsMode` to `Manual`.

3. Modify the `install-config.yaml` file. You can find more information about the available parameters in the "Installation configuration parameters" section.

4. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

**IMPORTANT**

The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

**Additional resources**

- Installation configuration parameters for Alibaba Cloud

5.4.4.2. Generating the required installation manifests

You must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

**Procedure**

1. Generate the manifests by running the following command from the directory that contains the installation program:

   ```
   $ openshift-install create manifests --dir <installation_directory>
   ```

   where:

   `<installation_directory>`
   Specifies the directory in which the installation program creates files.

5.4.4.3. Creating credentials for OpenShift Container Platform components with the `ccoctl` tool

You can use the OpenShift Container Platform Cloud Credential Operator (CCO) utility to automate the creation of Alibaba Cloud RAM users and policies for each in-cluster component.

**NOTE**

By default, `ccoctl` creates objects in the directory in which the commands are run. To create the objects in a different directory, use the `--output-dir` flag. This procedure uses `<path_to_ccoctl_output_dir>` to refer to this directory.

**Prerequisites**

You must have:
• Extracted and prepared the `ccoctl` binary.

• Created a RAM user with sufficient permission to create the OpenShift Container Platform cluster.

• Added the AccessKeyId (`access_key_id`) and AccessKeySecret (`access_key_secret`) of that RAM user into the `~/.alibabacloud/credentials` file on your local computer.

**Procedure**

1. Set a `$RELEASE_IMAGE` variable with the release image from your installation file by running the following command:

   ```bash
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
   ```

2. Extract the list of `CredentialsRequest` objects from the OpenShift Container Platform release image by running the following command:

   ```bash
   $ oc adm release extract \
     --from=$RELEASE_IMAGE \
     --credentials-requests \
     --included \
     --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \
     --to=<path_to_directory_for_credentials_requests>
   ```

   1. The `--included` parameter includes only the manifests that your specific cluster configuration requires.

   2. Specify the location of the `install-config.yaml` file.

   3. Specify the path to the directory where you want to store the `CredentialsRequest` objects. If the specified directory does not exist, this command creates it.

   **NOTE**

   This command might take a few moments to run.

3. Use the `ccoctl` tool to process all `CredentialsRequest` objects by running the following command:

   a. Run the following command to use the tool:

   ```bash
   $ ccoctl alibabacloud create-ram-users \
     --name <name> \
     --region=<alibaba_region> \
     --credentials-requests-dir=<path_to_credentials_requests_directory> \
     --output-dir=<path_to_ccoctl_output_dir>
   ```

   1. Specify the name used to tag any cloud resources that are created for tracking.

   2. Specify the Alibaba Cloud region in which cloud resources will be created.

   3. Specify the directory containing the files for the component `CredentialsRequest`
Specify the directory containing the files for the component `CredentialsRequest` objects.

Specify the directory where the generated component credentials secrets will be placed.

4. **NOTE**

If your cluster uses Technology Preview features that are enabled by the `TechPreviewNoUpgrade` feature set, you must include the `--enable-tech-preview` parameter.

**Example output**

```
2022/02/11 16:18:26 Created RAM User: user1-alicloud-openshift-machine-api-alibabacloud-credentials
2022/02/11 16:18:27 Ready for creating new ram policy user1-alicloud-openshift-machine-api-alibabacloud-credentials-policy-policy
2022/02/11 16:18:27 RAM policy user1-alicloud-openshift-machine-api-alibabacloud-credentials-policy-policy has created
2022/02/11 16:18:28 Policy user1-alicloud-openshift-machine-api-alibabacloud-credentials-policy-policy has attached on user user1-alicloud-openshift-machine-api-alibabacloud-credentials
2022/02/11 16:18:29 Created access keys for RAM User: user1-alicloud-openshift-machine-api-alibabacloud-credentials
2022/02/11 16:18:29 Saved credentials configuration to: user1-alicloud/manifests/openshift-machine-api-alibabacloud-credentials-credentials.yaml
```

**NOTE**

A RAM user can have up to two AccessKeys at the same time. If you run `ccoctl alibabacloud create-ram-users` more than twice, the previously generated manifests secret becomes stale and you must reapply the newly generated secrets.

b. Verify that the OpenShift Container Platform secrets are created:

```
$ ls <path_to_ccoctl_output_dir>/manifests
```

**Example output**

```
openshift-cluster-csi-drivers-alibaba-disk-credentials-credentials.yaml
openshift-image-registry-installer-cloud-credentials-credentials.yaml
openshift-ingress-operator-cloud-credentials-credentials.yaml
openshift-machine-api-alibabacloud-credentials-credentials.yaml
```

You can verify that the RAM users and policies are created by querying Alibaba Cloud. For more information, refer to Alibaba Cloud documentation on listing RAM users and policies.

4. Copy the generated credential files to the target manifests directory:
where:

<path_to_ccoctl_output_dir>

Specifies the directory created by the ccoctl alibabacloud create-ram-users command.

<path_to_installation_dir>

Specifies the directory in which the installation program creates files.

5.4.4.4. Sample customized install-config.yaml file for Alibaba Cloud

You can customize the installation configuration file (install-config.yaml) to specify more details about your cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: alicloud-dev.devcluster.openshift.com
credentialsMode: Manual
compute:
  - architecture: amd64
    hyperthreading: Enabled
    name: worker
    platform: {}
    replicas: 3
controlPlane:
  architecture: amd64
  hyperthreading: Enabled
  name: master
  platform: {}
  replicas: 3
metadata:
  creationTimestamp: null
  name: test-cluster
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
      hostPrefix: 23
  machineNetwork:
    - cidr: 10.0.0.0/16
  networkType: OVNKubernetes
  serviceNetwork:
    - 172.30.0.0/16
platform:
  alibabacloud:
    defaultMachinePlatform: 
      instanceType: ecs.g6.xlarge
      systemDiskCategory: cloud_efficiency
      systemDiskSize: 200
      region: ap-southeast-1
      resourceGroupID: rg-acfnw6j3hyai
      vpcID: vpc-0xdfjerdibmaqtvjob2b
      vswitchIDs:
        - vsw-0xi8ycgw8wv5rhviwdq5
```
Required. The installation program prompts you for a cluster name.

The cluster network plugin to install. The supported values are **OVNKubernetes** and **OpenShiftSDN**. The default value is **OVNKubernetes**.

Optional. Specify parameters for machine pools that do not define their own platform configuration.

Required. The installation program prompts you for the region to deploy the cluster to.

Optional. Specify an existing resource group where the cluster should be installed.

Required. The installation program prompts you for the pull secret.

Optional. The installation program prompts you for the SSH key value that you use to access the machines in your cluster.

Optional. These are example vswitchID values.

5.4.4.5. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**Prerequisites**

- You have an existing `install-config.yaml` file.

- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The **Proxy** object **status.noProxy** field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (169.254.169.254).

**Procedure**

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

```
- vsw-0xiy6v3z2tedv009b4pz2
  publish: External
  pullSecret: {'auths': {'cloud.openshift.com': {'auth': ...}}}
  sshKey: | ssh-rsa AAAA...
```

```bash
 8
```
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:@<ip>:<port>  
  httpsProxy: https://<username>:@<ip>:<port>  
noProxy: example.com  
additionalTrustBundle: |  
  -----BEGIN CERTIFICATE-----
  <MY_TRUSTED_CA_CERT>
  -----END CERTIFICATE-----
additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle>  

1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.
2. A proxy URL to use for creating HTTPS connections outside the cluster.
3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.
4. If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the trustedCA field of the Proxy object. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.
5. Optional: The policy to determine the configuration of the Proxy object to reference the user-ca-bundle config map in the trustedCA field. The allowed values are Proxyonly and Always. Use Proxyonly to reference the user-ca-bundle config map only when http/https proxy is configured. Use Always to always reference the user-ca-bundle config map. The default value is Proxyonly.

NOTE
The installation program does not support the proxy readinessEndpoints field.

NOTE
If the installer times out, restart and then complete the deployment by using the wait-for command of the installer. For example:

$ ./openshift-install wait-for install-complete --log-level debug

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.
NOTE

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

5.4.5. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.
- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.

Procedure

- Change to the directory that contains the installation program and initialize the cluster deployment:

  ```
  $ ./openshift-install create cluster --dir <installation_directory> \[1
  --log-level=info \[2
  
  \[1] For `<installation_directory>`, specify the location of your customized `./install-config.yaml` file.
  
  \[2] To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.
  ```

Verification

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the **kubeadmin** user.
- Credential information also outputs to `<installation_directory>/openshift_install.log`.

**IMPORTANT**

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

Example output

-
The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

5.4.6. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

IMPORTANT

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of oc.

Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure

2. Select the architecture from the Product Variant drop-down list.

3. Select the appropriate version from the Version drop-down list.

4. Click Download Now next to the OpenShift v4.14 Linux Client entry and save the file.

5. Unpack the archive:

   $ tar xvf <file>

6. Place the oc binary in a directory that is on your PATH.
To check your **PATH**, execute the following command:

```
$ echo $PATH
```

**Verification**

- After you install the OpenShift CLI, it is available using the `oc` command:

```
$ oc <command>
```

**Installing the OpenShift CLI on Windows**

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version from the **Version** drop-down list.

3. Click **Download Now** next to the **OpenShift v4.14 Windows Client** entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the **oc** binary to a directory that is on your **PATH**.

   To check your **PATH**, open the command prompt and execute the following command:

   ```
   C:\> path
   ```

**Verification**

- After you install the OpenShift CLI, it is available using the `oc` command:

  ```
  C:\> oc <command>
  ```

**Installing the OpenShift CLI on macOS**

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version from the **Version** drop-down list.

3. Click **Download Now** next to the **OpenShift v4.14 macOS Client** entry and save the file.

   **NOTE**

   For macOS arm64, choose the **OpenShift v4.14 macOS arm64 Client** entry.

4. Unpack and unzip the archive.
5. Move the `oc` binary to a directory on your PATH. To check your PATH, open a terminal and execute the following command:

```bash
$ echo $PATH
```

**Verification**

- After you install the OpenShift CLI, it is available using the `oc` command:

```bash
$ oc <command>
```

### 5.4.7. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadm` credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   ```

   **Example output**

   ```text
   system:admin
   ```

### 5.4.8. Logging in to the cluster by using the web console

The `kubeadm` user exists by default after an OpenShift Container Platform installation. You can log in to your cluster as the `kubeadm` user by using the OpenShift Container Platform web console.

**Prerequisites**

- You have access to the installation host.
- You completed a cluster installation and all cluster Operators are available.
Procedure

1. Obtain the password for the **kubeadmin** user from the **kubeadmin-password** file on the installation host:

   ```bash
   $ cat <installation_directory>/auth/kubeadmin-password
   ```

   **NOTE**
   Alternatively, you can obtain the **kubeadmin** password from the `<installation_directory>/openshift_install.log` log file on the installation host.

2. List the OpenShift Container Platform web console route:

   ```bash
   $ oc get routes -n openshift-console | grep 'console-openshift'
   ```

   **NOTE**
   Alternatively, you can obtain the OpenShift Container Platform route from the `<installation_directory>/openshift_install.log` log file on the installation host.

   **Example output**

   ```
   console    console-openshift-console.apps.<cluster_name>.<base_domain>    console
   https      reencrypt/Redirect   None
   ```

3. Navigate to the route detailed in the output of the preceding command in a web browser and log in as the **kubeadmin** user.

### 5.4.9. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to **OpenShift Cluster Manager Hybrid Cloud Console**.

After you confirm that your **OpenShift Cluster Manager Hybrid Cloud Console** inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use `subscription watch` to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

### Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service.
- See [Accessing the web console](#) for more details about accessing and understanding the OpenShift Container Platform web console
- See [Accessing the web console](#) for more details about accessing and understanding the OpenShift Container Platform web console.

### 5.4.10. Next steps

---

**CHAPTER 5. INSTALLING ON ALIBABA**

199
Validating an installation.

Customize your cluster.

If necessary, you can opt out of remote health reporting.

5.5. INSTALLING A CLUSTER ON ALIBABA CLOUD WITH NETWORK CUSTOMIZATIONS

In OpenShift Container Platform 4.14, you can install a cluster on Alibaba Cloud with customized network configuration options. By customizing your network configuration, your cluster can coexist with existing IP address allocations in your environment and integrate with existing MTU and VXLAN configurations.

You must set most of the network configuration parameters during installation, and you can modify only `kubeProxy` configuration parameters in a running cluster.

**IMPORTANT**

Alibaba Cloud on OpenShift Container Platform is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see Technology Preview Features Support Scope.

5.5.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You registered your domain.
- If you use a firewall, you configured it to allow the sites that your cluster requires access to.
- If the cloud Resource Access Management (RAM) APIs are not accessible in your environment, or if you do not want to store an administrator-level credential secret in the `kube-system` namespace, you can manually create and maintain Resource Access Management (RAM) credentials.

5.5.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager Hybrid Cloud Console to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
Access Quay.io to obtain the packages that are required to install your cluster.

Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 5.5.3. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the `core` user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user `core`. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>
   ```

   Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.
NOTE
If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   $ cat <path>/<file_name>.pub

   For example, run the following to view the ~/.ssh/id_ed25519.pub public key:

   $ cat ~/.ssh/id_ed25519.pub

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the ./openshift-install gather command.

   NOTE
   On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.

   a. If the ssh-agent process is not already running for your local user, start it as a background task:

      $ eval "$(ssh-agent -s)"

      Example output

      Agent pid 31874

   NOTE
   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the ssh-agent:

   $ ssh-add <path>/<file_name>

   1 Specify the path and file name for your SSH private key, such as ~/.ssh/id_ed25519

   Example output

   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

Next steps
• When you install OpenShift Container Platform, provide the SSH public key to the installation program.

5.5.4. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

Prerequisites

• You have a computer that runs Linux or macOS, with 500 MB of local disk space.

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

   IMPORTANT

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   IMPORTANT

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   $ tar -xvf openshift-install-linux.tar.gz

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

5.5.5. Network configuration phases

There are two phases prior to OpenShift Container Platform installation where you can customize the network configuration.

Phase 1
You can customize the following network-related fields in the `install-config.yaml` file before you create the manifest files:

- `networking.networkType`
- `networking.clusterNetwork`
- `networking.serviceNetwork`
- `networking.machineNetwork`

For more information on these fields, refer to `Installation configuration parameters`.

**NOTE**

Set the `networking.machineNetwork` to match the CIDR that the preferred NIC resides in.

**IMPORTANT**

The CIDR range `172.17.0.0/16` is reserved by libVirt. You cannot use this range or any range that overlaps with this range for any networks in your cluster.

**Phase 2**

After creating the manifest files by running `openshift-install create manifests`, you can define a customized Cluster Network Operator manifest with only the fields you want to modify. You can use the manifest to specify advanced network configuration.

You cannot override the values specified in phase 1 in the `install-config.yaml` file during phase 2. However, you can further customize the network plugin during phase 2.

### 5.5.5.1. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on

**Prerequisites**

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. **Create the `install-config.yaml` file.**
   
   a. Change to the directory that contains the installation program and run the following command:

   ```
   $ ./openshift-install create install-config --dir <installation_directory>
   ```

   **For `<installation_directory>`**, specify the directory name to store the files that the installation program creates.

   When specifying the directory:
• Verify that the directory has the `execute` permission. This permission is required to run Terraform binaries under the installation directory.

• Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

```
NOTE
Always delete the `~/.powervs` directory to avoid reusing a stale configuration. Run the following command:

```
$ rm -rf ~/.powervs
```

b. At the prompts, provide the configuration details for your cloud:

i. Optional: Select an SSH key to use to access your cluster machines.

```
NOTE
For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.
```

ii. Enter a descriptive name for your cluster.

2. Modify the `install-config.yaml` file. You can find more information about the available parameters in the "Installation configuration parameters" section.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

```
IMPORTANT
The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.
```

Additional resources

• Installation configuration parameters for Alibaba Cloud

5.5.5.2. Generating the required installation manifests

You must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

Procedure

1. Generate the manifests by running the following command from the directory that contains the installation program:
$ openshift-install create manifests --dir <installation_directory>

where:

<installation_directory>

Specifies the directory in which the installation program creates files.

NOTE

By default, ccoctl creates objects in the directory in which the commands are run. To create the objects in a different directory, use the --output-dir flag. This procedure uses <path_to_ccocctl_output_dir> to refer to this directory.

Prerequisites

You must have:

- Extracted and prepared the ccoctl binary.

Procedure

1. Set a $RELEASE_IMAGE variable with the release image from your installation file by running the following command:

   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')

2. Extract the list of CredentialsRequest objects from the OpenShift Container Platform release image by running the following command:

   $ oc adm release extract \
   --from=$RELEASE_IMAGE \
   --credentials-requests \
   --included 1 \
   --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml 2 \
   --to=<path_to_directory_for_credentials_requests> 3

   1 The --included parameter includes only the manifests that your specific cluster configuration requires.
   2 Specify the location of the install-config.yaml file.
   3 Specify the path to the directory where you want to store the CredentialsRequest objects. If the specified directory does not exist, this command creates it.

NOTE

This command might take a few moments to run.

5.5.5.3. Sample customized install-config.yaml file for Alibaba Cloud

You can customize the installation configuration file (install-config.yaml) to specify more details about your cluster’s platform or modify the values of the required parameters.
Required. The installation program prompts you for a cluster name.

The cluster network plugin to install. The supported values are OVNKubernetes and OpenShiftSDN. The default value is OVNKubernetes.

Optional. Specify parameters for machine pools that do not define their own platform configuration.

Required. The installation program prompts you for the region to deploy the cluster to.
Optional. Specify an existing resource group where the cluster should be installed.

Required. The installation program prompts you for the pull secret.

Optional. The installation program prompts you for the SSH key value that you use to access the 
machines in your cluster.

Optional. These are example vswitchID values.

5.5.5.4. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object’s **spec.noProxy** field to bypass the proxy if necessary.

**NOTE**

The **Proxy** object **status.noProxy** field is populated with the values of the **networking.machineNetwork[].cidr**, **networking.clusterNetwork[].cidr**, and **networking.serviceNetwork[]** fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object **status.noProxy** field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your **install-config.yaml** file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
     httpProxy: http://<username>:<pswd>@<ip>:<port> ¹
     httpsProxy: https://<username>:<pswd>@<ip>:<port> ²
     noProxy: example.com ³
     additionalTrustBundle: |
       -----BEGIN CERTIFICATE-----
       <MY_TRUSTED_CA_CERT>
       -----END CERTIFICATE-----
     additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> ⁵
   
   ¹ A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be **http**.
   ² A proxy URL to use for creating HTTPS connections outside the cluster.
   ³ A list of IP addresses or domains that do not need to be proxied.
   ⁴ Base64-encoded certificate to be used as an additional trust bundle.
   ⁵ A policy to add to the additional trust bundle.
2. A proxy URL to use for creating HTTPS connections outside the cluster.

3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.

4. If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the trustedCA field of the Proxy object. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

5. Optional: The policy to determine the configuration of the Proxy object to reference the user-ca-bundle config map in the trustedCA field. The allowed values are Proxyonly and Always. Use Proxyonly to reference the user-ca-bundle config map only when http/https proxy is configured. Use Always to always reference the user-ca-bundle config map. The default value is Proxyonly.

**NOTE**

The installation program does not support the proxy readinessEndpoints field.

**NOTE**

If the installer times out, restart and then complete the deployment by using the wait-for command of the installer. For example:

```bash
$ ./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

**NOTE**

Only the Proxy object named cluster is supported, and no additional proxies can be created.

### 5.5.6. Cluster Network Operator configuration

The configuration for the cluster network is specified as part of the Cluster Network Operator (CNO) configuration and stored in a custom resource (CR) object that is named cluster. The CR specifies the fields for the Network API in the operator.openshift.io API group.

The CNO configuration inherits the following fields during cluster installation from the Network API in the Network.config.openshift.io API group and these fields cannot be changed:

- clusterNetwork
IP address pools from which pod IP addresses are allocated.

**serviceNetwork**
- IP address pool for services.

**defaultNetwork.type**
- Cluster network plugin, such as OpenShift SDN or OVN-Kubernetes.

You can specify the cluster network plugin configuration for your cluster by setting the fields for the `defaultNetwork` object in the CNO object named `cluster`.

### 5.5.6.1. Cluster Network Operator configuration object

The fields for the Cluster Network Operator (CNO) are described in the following table:

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>metadata.name</td>
<td>string</td>
<td>The name of the CNO object. This name is always <code>cluster</code>.</td>
</tr>
<tr>
<td>spec.clusterNetwork</td>
<td>array</td>
<td>A list specifying the blocks of IP addresses from which pod IP addresses are allocated and the subnet prefix length assigned to each individual node in the cluster. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>spec:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>clusterNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- cidr: 10.128.0.0/19</td>
</tr>
<tr>
<td></td>
<td></td>
<td>hostPrefix: 23</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- cidr: 10.128.32.0/19</td>
</tr>
<tr>
<td></td>
<td></td>
<td>hostPrefix: 23</td>
</tr>
<tr>
<td></td>
<td></td>
<td>You can customize this field only in the <code>install-config.yaml</code> file before you create the manifests. The value is read-only in the manifest file.</td>
</tr>
<tr>
<td>spec.serviceNetwork</td>
<td>array</td>
<td>A block of IP addresses for services. The OpenShift SDN and OVN-Kubernetes network plugins support only a single IP address block for the service network. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>spec:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>serviceNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- 172.30.0.0/14</td>
</tr>
<tr>
<td></td>
<td></td>
<td>You can customize this field only in the <code>install-config.yaml</code> file before you create the manifests. The value is read-only in the manifest file.</td>
</tr>
<tr>
<td>spec.defaultNetwork</td>
<td>object</td>
<td>Configures the network plugin for the cluster network.</td>
</tr>
</tbody>
</table>

---

OpenShift Container Platform 4.14 Installing
The fields for the **spec.kubeProxy Config** object specify the kube-proxy configuration. If you are using the OVN-Kubernetes cluster network plugin, the kube-proxy configuration has no effect.

### defaultNetwork object configuration

The values for the **defaultNetwork** object are defined in the following table:

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>string</td>
<td>Either <strong>OpenShiftSDN</strong> or <strong>OVNKubernetes</strong>. The Red Hat OpenShift Networking network plugin is selected during installation. This value cannot be changed after cluster installation.</td>
</tr>
</tbody>
</table>

**NOTE**

OpenShift Container Platform uses the OVN-Kubernetes network plugin by default.

- **openshiftSDNConfig** object
  - This object is only valid for the OpenShift SDN network plugin.

- **ovnKubernetesConfig** object
  - This object is only valid for the OVN-Kubernetes network plugin.

### Configuration for the OpenShift SDN network plugin

The following table describes the configuration fields for the OpenShift SDN network plugin:

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mode</td>
<td>string</td>
<td>Configures the network isolation mode for OpenShift SDN. The default value is <strong>NetworkPolicy</strong>. The values <strong>Multitenant</strong> and <strong>Subnet</strong> are available for backwards compatibility with OpenShift Container Platform 3.x but are not recommended. This value cannot be changed after cluster installation.</td>
</tr>
</tbody>
</table>
The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.

If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.

If your cluster requires different MTU values for different nodes, you must set this value to 50 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1450.

This value cannot be changed after cluster installation.

The port to use for all VXLAN packets. The default value is 4789. This value cannot be changed after cluster installation.

If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number.

On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port 9000 and port 9999.

Example OpenShift SDN configuration

defaultNetwork:
  type: OpenShiftSDN
  openshiftSDNConfig:
    mode: NetworkPolicy
    mtu: 1450
    vxlanPort: 4789

Configuration for the OVN-Kubernetes network plugin
The following table describes the configuration fields for the OVN-Kubernetes network plugin:

Table 5.4. ovnKubernetesConfig object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mtu</td>
<td>integer</td>
<td>The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU. If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes. If your cluster requires different MTU values for different nodes, you must set this value to 50 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1450. This value cannot be changed after cluster installation.</td>
</tr>
<tr>
<td>vxlanPort</td>
<td>integer</td>
<td>The port to use for all VXLAN packets. The default value is 4789. This value cannot be changed after cluster installation. If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number. On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port 9000 and port 9999.</td>
</tr>
</tbody>
</table>
The maximum transmission unit (MTU) for the Geneve (Generic Network Virtualization Encapsulation) overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.

If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.

If your cluster requires different MTU values for different nodes, you must set this value to 100 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1400.

The port to use for all Geneve packets. The default value is 6081. This value cannot be changed after cluster installation.

Specify an empty object to enable IPsec encryption.

Specify a configuration object for customizing network policy audit logging. If unset, the defaults audit log settings are used.

Optional: Specify a configuration object for customizing how egress traffic is sent to the node gateway.

**NOTE**

While migrating egress traffic, you can expect some disruption to workloads and service traffic until the Cluster Network Operator (CNO) successfully rolls out the changes.

</table>
If your existing network infrastructure overlaps with the 100.64.0.0/16 IPv4 subnet, you can specify a different IP address range for internal use by OVN-Kubernetes. You must ensure that the IP address range does not overlap with any other subnet used by your OpenShift Container Platform installation. The IP address range must be larger than the maximum number of nodes that can be added to the cluster. For example, if the clusterNetwork.cidr value is 10.128.0.0/14 and the clusterNetwork.hostPrefix value is /23, then the maximum number of nodes is $2^{(23-14)}=512$.

This field cannot be changed after installation.

The default value is **100.64.0.0/16**.

5.5.7. Specifying advanced network configuration

You can use advanced network configuration for your network plugin to integrate your cluster into your existing network environment. You can specify advanced network configuration only before you install the cluster.

IMPORTANT

Customizing your network configuration by modifying the OpenShift Container Platform manifest files created by the installation program is not supported. Applying a manifest file that you create, as in the following procedure, is supported.

Prerequisites

- You have created the install-config.yaml file and completed any modifications to it.

Procedure

1. Change to the directory that contains the installation program and create the manifests:
1. Run the following command:

```
$ ./openshift-install create manifests --dir <installation_directory>
```

This command populates the `<installation_directory>` with the necessary manifests. The `<installation_directory>` specifies the name of the directory that contains the `install-config.yaml` file for your cluster.

2. Create a stub manifest file for the advanced network configuration that is named `cluster-network-03-config.yml` in the `<installation_directory>/manifests/` directory:

```
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
  name: cluster
spec:
```

3. Specify the advanced network configuration for your cluster in the `cluster-network-03-config.yml` file, such as in the following examples:

**Specify a different VXLAN port for the OpenShift SDN network provider**

```
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
  name: cluster
spec:
  defaultNetwork:
    openshiftSDNConfig:
      vxlanPort: 4800
```

**Enable IPsec for the OVN-Kubernetes network provider**

```
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
  name: cluster
spec:
  defaultNetwork:
    ovnKubernetesConfig:
      ipsecConfig: {}
```

4. Optional: Back up the `manifests/cluster-network-03-config.yml` file. The installation program consumes the `manifests/` directory when you create the Ignition config files.

### 5.5.8. Configuring hybrid networking with OVN-Kubernetes

You can configure your cluster to use hybrid networking with the OVN-Kubernetes network plugin. This allows a hybrid cluster that supports different node networking configurations.

**NOTE**

This configuration is necessary to run both Linux and Windows nodes in the same cluster.

**Prerequisites**
You defined **OVNKubernetes** for the **networking.networkType** parameter in the **install-config.yaml** file. See the installation documentation for configuring OpenShift Container Platform network customizations on your chosen cloud provider for more information.

### Procedure

1. Change to the directory that contains the installation program and create the manifests:

   ```bash
   ./openshift-install create manifests --dir <installation_directory>
   ```

   where:

   `<installation_directory>`
   
   Specifies the name of the directory that contains the **install-config.yaml** file for your cluster.

2. Create a stub manifest file for the advanced network configuration that is named **cluster-network-03-config.yml** in the `<installation_directory>/manifests/` directory:

   ```bash
   cat <<EOF > <installation_directory>/manifests/cluster-network-03-config.yml
   apiVersion: operator.openshift.io/v1
   kind: Network
   metadata:
     name: cluster
   spec:
   EOF
   ```

   where:

   `<installation_directory>`
   
   Specifies the directory name that contains the **manifests/** directory for your cluster.

3. Open the **cluster-network-03-config.yml** file in an editor and configure OVN-Kubernetes with hybrid networking, such as in the following example:

   **Specify a hybrid networking configuration**

   ```yaml
   apiVersion: operator.openshift.io/v1
   kind: Network
   metadata:
     name: cluster
   spec:
     defaultNetwork:
       ovnkubernetesConfig:
         hybridOverlayConfig:
           hybridClusterNetwork: 1
             - cidr: 10.132.0.0/14
               hostPrefix: 23
               hybridOverlayVXLANPort: 9898 2
   ```

   1. Specify the CIDR configuration used for nodes on the additional overlay network. The **hybridClusterNetwork** CIDR cannot overlap with the **clusterNetwork** CIDR.

   2. Specify a custom VXLAN port for the additional overlay network. This is required for
NOTE

Windows Server Long-Term Servicing Channel (LTSC): Windows Server 2019 is not supported on clusters with a custom `hybridOverlayVXLANPort` value because this Windows server version does not support selecting a custom VXLAN port.

4. Save the `cluster-network-03-config.yml` file and quit the text editor.

5. Optional: Back up the `manifests/cluster-network-03-config.yml` file. The installation program deletes the `manifests/` directory when creating the cluster.

### 5.5.9. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

**Prerequisites**

- You have configured an account with the cloud platform that hosts your cluster.
- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.

**Procedure**

- Change to the directory that contains the installation program and initialize the cluster deployment:

  ```
  $ ./openshift-install create cluster --dir <installation_directory> \
  --log-level=info
  
  1
  
  1 For `<installation_directory>`, specify the location of your customized `./install-config.yaml` file.

  2 To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.
  ```

**Verification**

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the `kubeadm` user.
- Credential information also outputs to `<installation_directory>/openshift_install.log`. 
IMPORTANT

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

Example output

... INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s

IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

5.5.10. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

IMPORTANT

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of oc.

Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure

2. Select the architecture from the Product Variant drop-down list.
3. Select the appropriate version from the Version drop-down list.
4. Click **Download Now** next to the **OpenShift v4.14 Linux Client** entry and save the file.

5. Unpack the archive:

   ```
   $ tar xvf <file>
   ```

6. Place the **oc** binary in a directory that is on your **PATH**.
   To check your **PATH**, execute the following command:

   ```
   $ echo $PATH
   ```

**Verification**

- After you install the OpenShift CLI, it is available using the **oc** command:

  ```
  $ oc <command>
  ```

**Installing the OpenShift CLI on Windows**

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version from the **Version** drop-down list.

3. Click **Download Now** next to the **OpenShift v4.14 Windows Client** entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the **oc** binary to a directory that is on your **PATH**.
   To check your **PATH**, open the command prompt and execute the following command:

   ```
   C:\> path
   ```

**Verification**

- After you install the OpenShift CLI, it is available using the **oc** command:

  ```
  C:\> oc <command>
  ```

**Installing the OpenShift CLI on macOS**

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version from the **Version** drop-down list.

3. Click **Download Now** next to the **OpenShift v4.14 macOS Client** entry and save the file.
NOTE
For macOS arm64, choose the OpenShift v4.14 macOS arm64 Client entry.

4. Unpack and unzip the archive.

5. Move the oc binary to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:

   ```
   $ echo $PATH
   ```

Verification

- After you install the OpenShift CLI, it is available using the oc command:

  ```
  $ oc <command>
  ```

5.5.11. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster kubeconfig file. The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the oc CLI.

Procedure

1. Export the kubeadmin credentials:

   ```
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   **For <installation_directory>, specify the path to the directory that you stored the installation files in.**

2. Verify you can run oc commands successfully using the exported configuration:

   ```
   $ oc whoami
   ```

   **Example output**

   ```
   system:admin
   ```

5.5.12. Logging in to the cluster by using the web console

The kubeadmin user exists by default after an OpenShift Container Platform installation. You can log in to your cluster as the kubeadmin user by using the OpenShift Container Platform web console.
Prerequisites

- You have access to the installation host.
- You completed a cluster installation and all cluster Operators are available.

Procedure

1. Obtain the password for the `kubeadmin` user from the `kubeadmin-password` file on the installation host:

   ```bash
   $ cat <installation_directory>/auth/kubeadmin-password
   
   NOTE
   Alternatively, you can obtain the `kubeadmin` password from the `<installation_directory>/openshift_install.log` log file on the installation host.

2. List the OpenShift Container Platform web console route:

   ```bash
   $ oc get routes -n openshift-console | grep 'console-openshift'
   
   NOTE
   Alternatively, you can obtain the OpenShift Container Platform route from the `<installation_directory>/openshift_install.log` log file on the installation host.

   Example output
   
   ```
   console     console-openshift-console.apps.<cluster_name>.<base_domain> console
   https   reencrypt/Redirect   None
   ```

3. Navigate to the route detailed in the output of the preceding command in a web browser and log in as the `kubeadmin` user.

5.5.13. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager Hybrid Cloud Console.

After you confirm that your OpenShift Cluster Manager Hybrid Cloud Console inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use `subscription watch` to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service.
- See Accessing the web console for more details about accessing and understanding the OpenShift Container Platform web console.
5.5.14. Next steps

- Validate an installation.
- Customize your cluster.
- If necessary, you can opt out of remote health reporting.

5.6. INSTALLING A CLUSTER ON ALIBABA CLOUD INTO AN EXISTING VPC

In OpenShift Container Platform version 4.14, you can install a cluster into an existing Alibaba Virtual Private Cloud (VPC) on Alibaba Cloud Services. The installation program provisions the required infrastructure, which can then be customized. To customize the VPC installation, modify the parameters in the 'install-config.yaml' file before you install the cluster.

**NOTE**

The scope of the OpenShift Container Platform installation configurations is intentionally narrow. It is designed for simplicity and ensured success. You can complete many more OpenShift Container Platform configuration tasks after an installation completes.

**IMPORTANT**

Alibaba Cloud on OpenShift Container Platform is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see [Technology Preview Features Support Scope](#).

5.6.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You registered your domain.
- If you use a firewall, you configured it to allow the sites that your cluster requires access to.
- If the cloud Resource Access Management (RAM) APIs are not accessible in your environment, or if you do not want to store an administrator-level credential secret in the `kube-system` namespace, you can manually create and maintain Resource Access Management (RAM) credentials.
5.6.2. Using a custom VPC

In OpenShift Container Platform 4.14, you can deploy a cluster into existing subnets in an existing Virtual Private Cloud (VPC) in the Alibaba Cloud Platform. By deploying OpenShift Container Platform into an existing Alibaba VPC, you can avoid limit constraints in new accounts and more easily adhere to your organization’s operational constraints. If you cannot obtain the infrastructure creation permissions that are required to create the VPC yourself, use this installation option. You must configure networking using vSwitches.

5.6.2.1. Requirements for using your VPC

The union of the VPC CIDR block and the machine network CIDR must be non-empty. The vSwitches must be within the machine network.

The installation program does not create the following components:

- VPC
- vSwitches
- Route table
- NAT gateway

NOTE

The installation program requires that you use the cloud-provided DNS server. Using a custom DNS server is not supported and causes the installation to fail.

5.6.2.2. VPC validation

To ensure that the vSwitches you provide are suitable, the installation program confirms the following data:

- All the vSwitches that you specify must exist.
- You have provided one or more vSwitches for control plane machines and compute machines.
- The vSwitches’ CIDRs belong to the machine CIDR that you specified.

5.6.2.3. Division of permissions

Some individuals can create different resources in your cloud than others. For example, you might be able to create application-specific items, like instances, buckets, and load balancers, but not networking-related components, such as VPCs or vSwitches.

5.6.2.4. Isolation between clusters

If you deploy OpenShift Container Platform into an existing network, the isolation of cluster services is reduced in the following ways:

- You can install multiple OpenShift Container Platform clusters in the same VPC.
- ICMP ingress is allowed to the entire network.
TCP 22 ingress (SSH) is allowed to the entire network.

Control plane TCP 6443 ingress (Kubernetes API) is allowed to the entire network.

Control plane TCP 22623 ingress (MCS) is allowed to the entire network.

5.6.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager Hybrid Cloud Console to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- Access Quay.io to obtain the packages that are required to install your cluster.

- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

5.6.4. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the `core` user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user `core`. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.
Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>  
   ```

   Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the `x86_64`, `ppc64le`, and `s390x` architectures, do not create a key that uses the `ed25519` algorithm. Instead, create a key that uses the `rsa` or `ecdsa` algorithm.

2. View the public SSH key:

   ```
   $ cat <path>/<file_name>.pub  
   ```

   For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

   ```
   $ cat ~/.ssh/id_ed25519.pub  
   ```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

   **NOTE**

   On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

   a. If the `ssh-agent` process is not already running for your local user, start it as a background task:

   ```
   $ eval "$(ssh-agent -s)"  
   ```

   **Example output**

   ```
   Agent pid 31874  
   ```

   **NOTE**

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the `ssh-agent`:
Specify the path and file name for your SSH private key, such as ~/.ssh/id_ed25519

Example output

Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

5.6.5. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

$ tar -xvf openshift-install-linux.tar.gz
5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

5.6.5.1. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Alibaba Cloud.

Prerequisites

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Create the `install-config.yaml` file.

   a. Change to the directory that contains the installation program and run the following command:

      ```bash
      $ ./openshift-install create install-config --dir <installation_directory>
      ```

      For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

      When specifying the directory:

      - Verify that the directory has the `execute` permission. This permission is required to run Terraform binaries under the installation directory.

      - Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

      **NOTE**

      Always delete the `~/.powervs` directory to avoid reusing a stale configuration. Run the following command:

      ```bash
      $ rm -rf ~/.powervs
      ```

   b. At the prompts, provide the configuration details for your cloud:

      i. Optional: Select an SSH key to use to access your cluster machines.
NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

ii. Select `alibabacloud` as the platform to target.

iii. Select the region to deploy the cluster to.

iv. Select the base domain to deploy the cluster to. The base domain corresponds to the public DNS zone that you created for your cluster.

v. Provide a descriptive name for your cluster.

2. Installing the cluster into Alibaba Cloud requires that the Cloud Credential Operator (CCO) operate in manual mode. Modify the `install-config.yaml` file to set the credentialsMode parameter to Manual:

   **Example install-config.yaml configuration file with credentialsMode set to Manual**

   ```yaml
   apiVersion: v1
   baseDomain: cluster1.example.com
   credentialsMode: Manual
   compute:
     - architecture: amd64
       hyperthreading: Enabled
   ...
   ```

   1 Add this line to set the credentialsMode to Manual.

3. Modify the `install-config.yaml` file. You can find more information about the available parameters in the "Installation configuration parameters" section.

4. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

**IMPORTANT**

The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

Additional resources

- Installation configuration parameters for Alibaba Cloud

5.6.5.2. Sample customized install-config.yaml file for Alibaba Cloud

You can customize the installation configuration file (`install-config.yaml`) to specify more details about your cluster’s platform or modify the values of the required parameters.

```yaml
apiVersion: v1
baseDomain: alicloud-dev.devcluster.openshift.com
credentialsMode: Manual
```
compute:
- architecture: amd64
- hyperthreading: Enabled
  name: worker
- platform: {}
- replicas: 3
controlPlane:
- architecture: amd64
- hyperthreading: Enabled
  name: master
- platform: {}
- replicas: 3
metadata:
- creationTimestamp: null
- name: test-cluster
networking:
- clusterNetwork:
  - cidr: 10.128.0.0/14
    hostPrefix: 23
  machineNetwork:
  - cidr: 10.0.0.0/16
    networkType: OVNKubernetes
  serviceNetwork:
  - 172.30.0.0/16
platform:
- alibabacloud:
  - defaultMachinePlatform:
    - instanceType: ecs.g6.xlarge
    - systemDiskCategory: cloud_efficiency
    - systemDiskSize: 200
    - region: ap-southeast-1
  - resourceGroupID: rg-acfnw6j3hyai
  - vpcID: vpc-0xfjdjerdibmaqvtjob2b
  - vswitchIDs: 
    - vsw-0xi8ycgwc8wv5rhviwdq5
    - vsw-0xiy6v3z2tedv009b4pz2
  publish: External
pullSecret: |"auths": {"cloud.openshift.com": {"auth": ... }}'
sshKey: |
  ssh-rsa AAAA...
Optional. The installation program prompts you for the SSH key value that you use to access the machines in your cluster.

Optional. These are example vswitchID values.

5.6.5.3. Generating the required installation manifests

You must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

Procedure

1. Generate the manifests by running the following command from the directory that contains the installation program:

   $ openshift-install create manifests --dir <installation_directory>

   where:

   `<installation_directory>`
   
   Specifies the directory in which the installation program creates files.

5.6.5.4. Configuring the Cloud Credential Operator utility

To create and manage cloud credentials from outside of the cluster when the Cloud Credential Operator (CCO) is operating in manual mode, extract and prepare the CCO utility (`ccoctl`) binary.

NOTE

The `ccoctl` utility is a Linux binary that must run in a Linux environment.

Prerequisites

- You have access to an OpenShift Container Platform account with cluster administrator access.
- You have installed the OpenShift CLI (`oc`).

Procedure

1. Obtain the OpenShift Container Platform release image by running the following command:

   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')

2. Obtain the CCO container image from the OpenShift Container Platform release image by running the following command:

   $ CCO_IMAGE=$(oc adm release info --image-for='cloud-credential-operator' $RELEASE_IMAGE -a ~/.pull-secret)
NOTE

Ensure that the architecture of the $RELEASE_IMAGE matches the architecture of the environment in which you will use the ccoctl tool.

3. Extract the ccoctl binary from the CCO container image within the OpenShift Container Platform release image by running the following command:

```bash
$ oc image extract $CCO_IMAGE --file="/usr/bin/ccocctl" -a ~/.pull-secret
```

4. Change the permissions to make ccoctl executable by running the following command:

```bash
$ chmod 775 ccoctl
```

Verification

- To verify that ccoctl is ready to use, display the help file by running the following command:

```bash
$ ccoctl --help
```

Output of ccoctl --help

OpenShift credentials provisioning tool

Usage:

ccocctl [command]

Available Commands:

- alibabacloud Manage credentials objects for alibaba cloud
- aws Manage credentials objects for AWS cloud
- azure Manage credentials objects for Azure
- gcp Manage credentials objects for Google cloud
- help Help about any command
- ibmcloud Manage credentials objects for IBM Cloud
- nutanix Manage credentials objects for Nutanix

Flags:

- -h, --help help for ccoctl

Use "ccoctl [command] --help" for more information about a command.

5.6.5.5. Creating credentials for OpenShift Container Platform components with the ccoctl tool

You can use the OpenShift Container Platform Cloud Credential Operator (CCO) utility to automate the creation of Alibaba Cloud RAM users and policies for each in-cluster component.

NOTE

By default, ccoctl creates objects in the directory in which the commands are run. To create the objects in a different directory, use the --output-dir flag. This procedure uses <path_to_ccoctl_output_dir> to refer to this directory.
Prerequisites
You must have:

- Extracted and prepared the **ccoctl** binary.
- Created a RAM user with sufficient permission to create the OpenShift Container Platform cluster.
- Added the AccessKeyID (**access_key_id**) and AccessKeySecret (**access_key_secret**) of that RAM user into the `~/.alibabacloud/credentials` file on your local computer.

Procedure

1. Set a `$RELEASE_IMAGE` variable with the release image from your installation file by running the following command:

   ```
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
   ```

2. Extract the list of **CredentialsRequest** objects from the OpenShift Container Platform release image by running the following command:

   ```
   $ oc adm release extract \
   --from=$RELEASE_IMAGE \
   --credentials-requests \
   --included \
   --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \
   --to=<path_to_directory_for_credentials_requests>
   ```

   - **1** The `--included` parameter includes only the manifests that your specific cluster configuration requires.
   - **2** Specify the location of the `install-config.yaml` file.
   - **3** Specify the path to the directory where you want to store the **CredentialsRequest** objects. If the specified directory does not exist, this command creates it.

   **NOTE**
   This command might take a few moments to run.

3. Use the **ccoctl** tool to process all **CredentialsRequest** objects by running the following command:
   a. Run the following command to use the tool:

      ```
      $ ccoctl alibabacloud create-ram-users \
      --name <name> \
      --region=<alibaba_region> \
      --credentials-requests-dir=<path_to_credentials_requests_directory> \
      --output-dir=<path_to_ccoctl_output_dir>
      ```

      - **1** Specify the name used to tag any cloud resources that are created for tracking.
Specify the Alibaba Cloud region in which cloud resources will be created.

Specify the directory containing the files for the component `CredentialsRequest` objects.

Specify the directory where the generated component credentials secrets will be placed.

**NOTE**

If your cluster uses Technology Preview features that are enabled by the `TechPreviewNoUpgrade` feature set, you must include the `--enable-tech-preview` parameter.

**Example output**

2022/02/11 16:18:26 Created RAM User: user1-alicloud-openshift-machine-api-alibabacloud-credentials
2022/02/11 16:18:27 Ready for creating new ram policy user1-alicloud-openshift-machine-api-alibabacloud-credentials-policy-policy
2022/02/11 16:18:27 RAM policy user1-alicloud-openshift-machine-api-alibabacloud-credentials-policy-policy has created
2022/02/11 16:18:28 Policy user1-alicloud-openshift-machine-api-alibabacloud-credentials-policy-policy has attached on user user1-alicloud-openshift-machine-api-alibabacloud-credentials
2022/02/11 16:18:29 Created access keys for RAM User: user1-alicloud-openshift-machine-api-alibabacloud-credentials
2022/02/11 16:18:29 Saved credentials configuration to: user1-alicloud/manifests/openshift-machine-api-alibabacloud-credentials-credentials.yaml

**NOTE**

A RAM user can have up to two AccessKeys at the same time. If you run `ccoctl alibabacloud create-ram-users` more than twice, the previously generated manifests secret becomes stale and you must reapply the newly generated secrets.

b. Verify that the OpenShift Container Platform secrets are created:

```bash
$ ls <path_to_ccoctl_output_dir>/manifests
```

**Example output**

```
openshift-cluster-csi-drivers-alibaba-disk-credentials-credentials.yaml
openshift-image-registry-installer-cloud-credentials-credentials.yaml
openshift-ingress-operator-cloud-credentials-credentials.yaml
openshift-machine-api-alibabacloud-credentials-credentials.yaml
```

You can verify that the RAM users and policies are created by querying Alibaba Cloud. For more information, refer to Alibaba Cloud documentation on listing RAM users and policies.
4. Copy the generated credential files to the target manifests directory:

```
$ cp ./<path_to_ccoctl_output_dir>/manifests/*credentials.yaml
   ./<path_to_installation_dir>/manifests/
```

where:

- `<path_to_ccoctl_output_dir>`
  - Specifies the directory created by the `ccoctl alibabacloud create-ram-users` command.

- `<path_to_installation_dir>`
  - Specifies the directory in which the installation program creates files.

5.6.6. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

**Prerequisites**

- You have configured an account with the cloud platform that hosts your cluster.
- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.

**Procedure**

- Change to the directory that contains the installation program and initialize the cluster deployment:

```
$ ./openshift-install create cluster --dir <installation_directory> \  
   --log-level=info
```

1. For `<installation_directory>`, specify the location of your customized `./install-config.yaml` file.

2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

**Verification**

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the `kubeadmin` user.
- Credential information also outputs to `<installation_directory>/openshift_install.log`. 

237
IMPORTANT

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

Example output

... INFO Install complete! INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig' INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com INFO Login to the console with user: "kubeadmin", and password: "password" INFO Time elapsed: 36m22s

IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

5.6.7. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

IMPORTANT

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of oc.

Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure

2. Select the architecture from the Product Variant drop-down list.

3. Select the appropriate version from the Version drop-down list.
4. Click **Download Now** next to the **OpenShift v4.14 Linux Client** entry and save the file.

5. Unpack the archive:

   ```bash
   $ tar xvf <file>
   ```

6. Place the **oc** binary in a directory that is on your **PATH**.
   To check your **PATH**, execute the following command:

   ```bash
   $ echo $PATH
   ```

**Verification**

- After you install the OpenShift CLI, it is available using the **oc** command:

  ```bash
  $ oc <command>
  ```

**Installing the OpenShift CLI on Windows**

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version from the **Version** drop-down list.

3. Click **Download Now** next to the **OpenShift v4.14 Windows Client** entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the **oc** binary to a directory that is on your **PATH**.
   To check your **PATH**, open the command prompt and execute the following command:

   ```bash
   C:\> path
   ```

**Verification**

- After you install the OpenShift CLI, it is available using the **oc** command:

  ```bash
  C:\> oc <command>
  ```

**Installing the OpenShift CLI on macOS**

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version from the **Version** drop-down list.

3. Click **Download Now** next to the **OpenShift v4.14 macOS Client** entry and save the file.
NOTE
For macOS arm64, choose the OpenShift v4.14 macOS arm64 Client entry.

4. Unpack and unzip the archive.

5. Move the oc binary to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:

   ```
   $ echo $PATH
   ```

Verification
- After you install the OpenShift CLI, it is available using the oc command:

  ```
  $ oc <command>
  ```

5.6.8. Logging in to the cluster by using the CLI
You can log in to your cluster as a default system user by exporting the cluster kubeconfig file. The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites
- You deployed an OpenShift Container Platform cluster.
- You installed the oc CLI.

Procedure
1. Export the kubeadmin credentials:

   ```
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For <installation_directory>, specify the path to the directory that you stored the installation files in.

2. Verify you can run oc commands successfully using the exported configuration:

   ```
   $ oc whoami
   ```

   Example output

   system:admin

5.6.9. Logging in to the cluster by using the web console
The kubeadmin user exists by default after an OpenShift Container Platform installation. You can log in to your cluster as the kubeadmin user by using the OpenShift Container Platform web console.
Chapter 5. Installing on Alibaba

Prerequisites

- You have access to the installation host.
- You completed a cluster installation and all cluster Operators are available.

Procedure

1. Obtain the password for the `kubeadmin` user from the `kubeadmin-password` file on the installation host:

   ```sh
   $ cat <installation_directory>/auth/kubeadmin-password
   
   NOTE
   Alternatively, you can obtain the `kubeadmin` password from the `<installation_directory>/openshift_install.log` log file on the installation host.

2. List the OpenShift Container Platform web console route:

   ```sh
   $ oc get routes -n openshift-console | grep 'console-openshift'
   
   NOTE
   Alternatively, you can obtain the OpenShift Container Platform route from the `<installation_directory>/openshift_install.log` log file on the installation host.

   Example output

   ```
   console     console-openshift-console.apps.<cluster_name>.<base_domain>            console
   https   reencrypt/Redirect   None
   ```

3. Navigate to the route detailed in the output of the preceding command in a web browser and log in as the `kubeadmin` user.

5.6.10. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager Hybrid Cloud Console inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use `subscription watch` to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service.
- See Accessing the web console for more details about accessing and understanding the OpenShift Container Platform web console.
5.6.11. Next steps

- Validating an installation.
- Customize your cluster.
- If necessary, you can opt out of remote health reporting.

5.7. INSTALLATION CONFIGURATION PARAMETERS FOR ALIBABA CLOUD

Before you deploy an OpenShift Container Platform cluster on Alibaba Cloud, you provide parameters to customize your cluster and the platform that hosts it. When you create the `install-config.yaml` file, you provide values for the required parameters through the command line. You can then modify the `install-config.yaml` file to customize your cluster further.

5.7.1. Available installation configuration parameters for Alibaba Cloud

The following tables specify the required, optional, and Alibaba Cloud-specific installation configuration parameters that you can set as part of the installation process.

**NOTE**

After installation, you cannot modify these parameters in the `install-config.yaml` file.

5.7.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

**Table 5.8. Required parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion:</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is <code>v1</code>. The installation program may also support older API versions.</td>
<td>String</td>
</tr>
</tbody>
</table>
**baseDomain:** The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the `baseDomain` and `metadata.name` parameter values that uses the `<metadata.name>`, `<baseDomain>` format.

A fully-qualified domain or subdomain name, such as `example.com`.

**metadata:** Kubernetes resource `ObjectMeta`, from which only the `name` parameter is consumed.

**metadata:** The name of the cluster. DNS records for the cluster are all subdomains of `{{.metadata.name}}.{{.baseDomain}}`.

String of lowercase letters, hyphens (-), and periods (.), such as `dev`.

**platform:** The configuration for the specific platform upon which to perform the installation: `alibabacloud`, `aws`, `baremetal`, `azure`, `gcp`, `ibmcloud`, `nutanix`, `openstack`, `powervs`, `vsphere`, or `{}`. For additional information about `platform` parameters, consult the table for your specific platform that follows.

Object
Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.

```json
{
  "auths":{
    "cloud.openshift.com":{
      "auth": "b3Blb=",
      "email": "you@example.com"
    },
    "quay.io":{
      "auth": "b3Blb=",
      "email": "you@example.com"
    }
  }
}
```

### 5.7.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

**NOTE**

Globalnet is not supported with Red Hat OpenShift Data Foundation disaster recovery solutions. For regional disaster recovery scenarios, ensure that you use a nonoverlapping range of private IP addresses for the cluster and service networks in each cluster.

**Table 5.9. Network parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking:</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
</tbody>
</table>

**NOTE**

You cannot modify parameters specified by the `networking` object after installation.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking: networkType:</td>
<td>The Red Hat OpenShift Networking network plugin to install.</td>
<td>Either OpenShiftSDN or OVNKubernetes. OpenShiftSDN is a CNI plugin for all-Linux networks. OVNKubernetes is a CNI plugin for Linux networks and hybrid networks that contain both Linux and Windows servers. The default value is OVNKubernetes.</td>
</tr>
<tr>
<td>networking:</td>
<td>The IP address blocks for pods.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td>clusterNetwork:</td>
<td>The default value is 10.128.0.0/14 with a host prefix of /23.</td>
<td>networking:</td>

</tr>
<tr>
<td></td>
<td></td>
<td>hostPrefix: 23</td>
</tr>
<tr>
<td>networking:</td>
<td>Required if you use networking.clusterNetwork. An IP address block.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>The subnet prefix length to assign to each individual node. For example, if</td>
<td>A subnet prefix.</td>
</tr>
<tr>
<td></td>
<td>hostPrefix is set to 23 then each node is assigned a /23 subnet out of the</td>
<td>The default value is 23.</td>
</tr>
<tr>
<td></td>
<td>given cidr. A hostPrefix value of 23 provides 510 (2^(32 - 23) - 2) pod</td>
<td></td>
</tr>
<tr>
<td></td>
<td>IP addresses.</td>
<td></td>
</tr>
<tr>
<td>networking:</td>
<td>The IP address block for services. The default value is 172.30.0.0/16.</td>
<td>An array with an IP address block in CIDR format. For example:</td>
</tr>
<tr>
<td>serviceNetwork:</td>
<td>The OpenShift SDN and OVNKubernetes network plugins support only a single IP</td>
<td>networking:</td>
</tr>
<tr>
<td></td>
<td>address block for the service network.</td>
<td>serviceNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- 172.30.0.0/16</td>
</tr>
<tr>
<td>networking:</td>
<td>The IP address blocks for machines.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td>machineNetwork:</td>
<td>If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td>networking:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>machineNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- cidr: 10.0.0.0/16</td>
</tr>
</tbody>
</table>
networking:
  machineNetwork:
    cidr:
      Required if you use `networking.machineNetwork`. An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt and IBM Power® Virtual Server. For libvirt, the default value is 192.168.126.0/24. For IBM Power® Virtual Server, the default value is 192.168.0.0/24.

NOTE
Set the `networking.machineNetwork` to match the CIDR that the preferred NIC resides in.

5.7.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking:</td>
<td></td>
<td></td>
</tr>
<tr>

</tbody>
</table>
Enable or disable FIPS mode. The default is **false** (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see *Installing the system in FIPS mode*. When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures.

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.

<table>
<thead>
<tr>
<th>Parameter</th>

<td>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</td>
<td>Internal or External. The default value is External. Setting this field to Internal is not supported on non-cloud platforms. IMPORTANT If the value of the field is set to Internal, the cluster will become non-functional. For more information, refer to BZ#1953035.</td>
</tr>
<tr>
<td>sshKey:</td>
<td>The SSH key to authenticate access to your cluster machines.</td>
<td>For example, sshKey: ssh-ed25519 AAAA...</td>
</tr>
</tbody>
</table>

1. Not all CCO modes are supported for all cloud providers. For more information about CCO modes, see the “Managing cloud provider credentials” entry in the Authentication and authorization content.
### 5.7.1.4. Additional Alibaba Cloud configuration parameters

Additional Alibaba Cloud configuration parameters are described in the following table. The `alibabacloud` parameters are the configuration used when installing on Alibaba Cloud. The `defaultMachinePlatform` parameters are the default configuration used when installing on Alibaba Cloud for machine pools that do not define their own platform configuration.

These parameters apply to both compute machines and control plane machines where specified.

**NOTE**

If defined, the parameters `compute.platform.alibabacloud` and `controlPlane.platform.alibabacloud` will overwrite `platform.alibabacloud.defaultMachinePlatform` settings for compute machines and control plane machines respectively.

**Table 5.11. Optional Alibaba Cloud parameters**

5.8. UNINSTALLING A CLUSTER ON ALIBABA CLOUD

You can remove a cluster that you deployed to Alibaba Cloud.

5.8.1. Removing a cluster that uses installer-provisioned infrastructure

You can remove a cluster that uses installer-provisioned infrastructure from your cloud.

**NOTE**

After uninstallation, check your cloud provider for any resources not removed properly, especially with User Provisioned Infrastructure (UPI) clusters. There might be resources that the installer did not create or that the installer is unable to access.

**Prerequisites**

- You have a copy of the installation program that you used to deploy the cluster.
- You have the files that the installation program generated when you created your cluster.

**Procedure**

1. From the directory that contains the installation program on the computer that you used to install the cluster, run the following command:

   ```bash
   $ ./openshift-install destroy cluster \
   --dir <installation_directory> --log-level info
   ```

   1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.
   2. To view different details, specify `warn`, `debug`, or `error` instead of `info`. 
NOTE

You must specify the directory that contains the cluster definition files for your cluster. The installation program requires the `metadata.json` file in this directory to delete the cluster.

2. Optional: Delete the `<installation_directory>` directory and the OpenShift Container Platform installation program.
CHAPTER 6. INSTALLING ON AWS

6.1. PREPARING TO INSTALL ON AWS

6.1.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.

6.1.2. Requirements for installing OpenShift Container Platform on AWS

Before installing OpenShift Container Platform on Amazon Web Services (AWS), you must create an AWS account. See Configuring an AWS account for details about configuring an account, account limits, account permissions, IAM user setup, and supported AWS regions.

If the cloud identity and access management (IAM) APIs are not accessible in your environment, or if you do not want to store an administrator-level credential secret in the kube-system namespace, see Manually creating long-term credentials for AWS or configuring an AWS cluster to use short-term credentials with Amazon Web Services Security Token Service (AWS STS).

6.1.3. Choosing a method to install OpenShift Container Platform on AWS

You can install OpenShift Container Platform on installer-provisioned or user-provisioned infrastructure. The default installation type uses installer-provisioned infrastructure, where the installation program provisions the underlying infrastructure for the cluster. You can also install OpenShift Container Platform on infrastructure that you provision. If you do not use infrastructure that the installation program provisions, you must manage and maintain the cluster resources yourself.

See Installation process for more information about installer-provisioned and user-provisioned installation processes.

6.1.3.1. Installing a cluster on a single node

Installing OpenShift Container Platform on a single node alleviates some of the requirements for high availability and large scale clusters. However, you must address the requirements for installing on a single node, and the additional requirements for installing single-node OpenShift on a cloud provider. After addressing the requirements for single node installation, use the Installing a customized cluster on AWS procedure to install the cluster. The installing single-node OpenShift manually section contains an exemplary install-config.yaml file when installing an OpenShift Container Platform cluster on a single node.

6.1.3.2. Installing a cluster on installer-provisioned infrastructure

You can install a cluster on AWS infrastructure that is provisioned by the OpenShift Container Platform installation program, by using one of the following methods:

- Installing a cluster quickly on AWS You can install OpenShift Container Platform on AWS infrastructure that is provisioned by the OpenShift Container Platform installation program. You can install a cluster quickly by using the default configuration options.
Installing a customized cluster on AWS You can install a customized cluster on AWS infrastructure that the installation program provisions. The installation program allows for some customization to be applied at the installation stage. Many other customization options are available post-installation.

Installing a cluster on AWS with network customizations You can customize your OpenShift Container Platform network configuration during installation, so that your cluster can coexist with your existing IP address allocations and adhere to your network requirements.

Installing a cluster on AWS in a restricted network You can install OpenShift Container Platform on AWS on installer-provisioned infrastructure by using an internal mirror of the installation release content. You can use this method to install a cluster that does not require an active internet connection to obtain the software components.

Installing a cluster on an existing Virtual Private Cloud You can install OpenShift Container Platform on an existing AWS Virtual Private Cloud (VPC). You can use this installation method if you have constraints set by the guidelines of your company, such as limits when creating new accounts or infrastructure.

Installing a private cluster on an existing VPC You can install a private cluster on an existing AWS VPC. You can use this method to deploy OpenShift Container Platform on an internal network that is not visible to the internet.

Installing a cluster on AWS into a government or secret region OpenShift Container Platform can be deployed into AWS regions that are specifically designed for US government agencies at the federal, state, and local level, as well as contractors, educational institutions, and other US customers that must run sensitive workloads in the cloud.

6.1.3.3. Installing a cluster on user-provisioned infrastructure

You can install a cluster on AWS infrastructure that you provision, by using one of the following methods:

Installing a cluster on AWS infrastructure that you provide You can install OpenShift Container Platform on AWS infrastructure that you provide. You can use the provided CloudFormation templates to create stacks of AWS resources that represent each of the components required for an OpenShift Container Platform installation.

Installing a cluster on AWS in a restricted network with user-provisioned infrastructure You can install OpenShift Container Platform on AWS infrastructure that you provide by using an internal mirror of the installation release content. You can use this method to install a cluster that does not require an active internet connection to obtain the software components. You can also use this installation method to ensure that your clusters only use container images that satisfy your organizational controls on external content. While you can install OpenShift Container Platform by using the mirrored content, your cluster still requires internet access to use the AWS APIs.

6.1.4. Next steps

Configuring an AWS account

6.2. CONFIGURING AN AWS ACCOUNT

Before you can install OpenShift Container Platform, you must configure an Amazon Web Services (AWS) account.
6.2.1. Configuring Route 53

To install OpenShift Container Platform, the Amazon Web Services (AWS) account you use must have a dedicated public hosted zone in your Route 53 service. This zone must be authoritative for the domain. The Route 53 service provides cluster DNS resolution and name lookup for external connections to the cluster.

Procedure

1. Identify your domain, or subdomain, and registrar. You can transfer an existing domain and registrar or obtain a new one through AWS or another source.

   **NOTE**
   
   If you purchase a new domain through AWS, it takes time for the relevant DNS changes to propagate. For more information about purchasing domains through AWS, see Registering Domain Names Using Amazon Route 53 in the AWS documentation.

2. If you are using an existing domain and registrar, migrate its DNS to AWS. See Making Amazon Route 53 the DNS Service for an Existing Domain in the AWS documentation.

3. Create a public hosted zone for your domain or subdomain. See Creating a Public Hosted Zone in the AWS documentation. Use an appropriate root domain, such as openshiftcorp.com, or subdomain, such as clusters.openshiftcorp.com.

4. Extract the new authoritative name servers from the hosted zone records. See Getting the Name Servers for a Public Hosted Zone in the AWS documentation.

5. Update the registrar records for the AWS Route 53 name servers that your domain uses. For example, if you registered your domain to a Route 53 service in a different accounts, see the following topic in the AWS documentation: Adding or Changing Name Servers or Glue Records.

6. If you are using a subdomain, add its delegation records to the parent domain. This gives Amazon Route 53 responsibility for the subdomain. Follow the delegation procedure outlined by the DNS provider of the parent domain. See Creating a subdomain that uses Amazon Route 53 as the DNS service without migrating the parent domain in the AWS documentation for an example high level procedure.

6.2.1.1. Ingress Operator endpoint configuration for AWS Route 53

If you install in either Amazon Web Services (AWS) GovCloud (US) US-West or US-East region, the Ingress Operator uses **us-gov-west-1** region for Route53 and tagging API clients.

The Ingress Operator uses **https://tagging.us-gov-west-1.amazonaws.com** as the tagging API endpoint if a tagging custom endpoint is configured that includes the string ‘us-gov-east-1’.

For more information on AWS GovCloud (US) endpoints, see the Service Endpoints in the AWS documentation about GovCloud (US).

**IMPORTANT**

Private, disconnected installations are not supported for AWS GovCloud when you install in the **us-gov-east-1** region.
Example Route 53 configuration

```yaml
platform:
  aws:
    region: us-gov-west-1
    serviceEndpoints:
      - name: ec2
        url: https://ec2.us-gov-west-1.amazonaws.com
      - name: elasticloadbalancing
        url: https://elasticloadbalancing.us-gov-west-1.amazonaws.com
      - name: route53
        url: https://route53.us-gov.amazonaws.com
      - name: tagging
        url: https://tagging.us-gov-west-1.amazonaws.com
```

1. Route 53 defaults to [https://route53.us-gov.amazonaws.com](https://route53.us-gov.amazonaws.com) for both AWS GovCloud (US) regions.

2. Only the US-West region has endpoints for tagging. Omit this parameter if your cluster is in another region.

### 6.2.2. AWS account limits

The OpenShift Container Platform cluster uses a number of Amazon Web Services (AWS) components, and the default [Service Limits](https://aws.amazon.com/service-quotas/) affect your ability to install OpenShift Container Platform clusters. If you use certain cluster configurations, deploy your cluster in certain AWS regions, or run multiple clusters from your account, you might need to request additional resources for your AWS account.

The following table summarizes the AWS components whose limits can impact your ability to install and run OpenShift Container Platform clusters.

<table>
<thead>
<tr>
<th>Component</th>
<th>Number of clusters available by default</th>
<th>Default AWS limit</th>
<th>Description</th>
</tr>
</thead>
</table>
By default, each cluster creates the following instances:

- One bootstrap machine, which is removed after installation
- Three control plane nodes
- Three worker nodes

These instance type counts are within a new account’s default limit. To deploy more worker nodes, enable autoscaling, deploy large workloads, or use a different instance type, review your account limits to ensure that your cluster can deploy the machines that you need.

In most regions, the worker machines use an `m6i.large` instance and the bootstrap and control plane machines use `m6i.xlarge` instances. In some regions, including all regions that do not support these instance types, `m5.large` and `m5.xlarge` instances are used instead.

---

### Elastic IPs (EIPs)

<table>
<thead>
<tr>
<th>Number of clusters available by default</th>
<th>Default AWS limit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Varies</td>
<td>Varies</td>
<td>By default, each cluster creates the following instances:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- One bootstrap machine, which is removed after installation</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Three control plane nodes</td>
</tr>
<tr>
<td></td>
<td></td>

</tr>
<tr>
<td></td>
<td></td>
<td>These instance type counts are within a new account’s default limit. To deploy more worker nodes, enable autoscaling, deploy large workloads, or use a different instance type, review your account limits to ensure that your cluster can deploy the machines that you need.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>In most regions, the worker machines use an <code>m6i.large</code> instance and the bootstrap and control plane machines use <code>m6i.xlarge</code> instances. In some regions, including all regions that do not support these instance types, <code>m5.large</code> and <code>m5.xlarge</code> instances are used instead.</td>
</tr>
</tbody>
</table>

To provision the cluster in a highly available configuration, the installation program creates a public and private subnet for each availability zone within a region. Each private subnet requires a NAT Gateway, and each NAT gateway requires a separate elastic IP. Review the AWS region map to determine how many availability zones are in each region. To take advantage of the default high availability, install the cluster in a region with at least three availability zones. To install a cluster in a region with more than five availability zones, you must increase the EIP limit.

**IMPORTANT**

To use the `us-east-1` region, you must increase the EIP limit for your account.

### Virtual Private Clouds (VPCs)

<table>
<thead>
<tr>

### 6.2.3. Required AWS permissions for the IAM user

**NOTE**

Your IAM user must have the permission `tag:GetResources` in the region `us-east-1` to delete the base cluster resources. As part of the AWS API requirement, the OpenShift Container Platform installation program performs various actions in this region.

When you attach the **AdministratorAccess** policy to the IAM user that you create in Amazon Web Services (AWS), you grant that user all of the required permissions. To deploy all components of an OpenShift Container Platform cluster, the IAM user requires the following permissions:
Example 6.1. Required EC2 permissions for installation

- ec2:AuthorizeSecurityGroupEgress
- ec2:AuthorizeSecurityGroupIngress
- ec2:CopyImage
- ec2:CreateNetworkInterface
- ec2:AttachNetworkInterface
- ec2:CreateSecurityGroup
- ec2:CreateTags
- ec2:CreateVolume
- ec2:DeleteSecurityGroup
- ec2:DeleteSnapshot
- ec2:DeleteTags
- ec2:DeregisterImage
- ec2:DescribeAccountAttributes
- ec2:DescribeAddresses
- ec2:DescribeAvailabilityZones
- ec2:DescribeDhcpOptions
- ec2:DescribeImages
- ec2:DescribeInstanceAttribute
- ec2:DescribeInstanceCreditSpecifications
- ec2:DescribeInstances
- ec2:DescribeInstanceTypes
- ec2:DescribeInternetGateways
- ec2:DescribeKeyPairs
- ec2:DescribeNatGateways
- ec2:DescribeNetworkAcls
- ec2:DescribeNetworkInterfaces
- ec2:DescribePrefixLists
- ec2:DescribeRegions
Example 6.2. Required permissions for creating network resources during installation

- ec2:AllocateAddress
- ec2:AssociateAddress
- ec2:AssociateDhcpOptions
- ec2:AssociateRouteTable
- ec2:AttachInternetGateway
- ec2:CreateDhcpOptions
- ec2:CreateInternetGateway
- ec2:CreateNatGateway
- ec2:CreateRoute
- ec2:CreateRouteTable
- ec2:CreateSubnet
• ec2:CreateVpc
• ec2:CreateVpcEndpoint
• ec2:ModifySubnetAttribute
• ec2:ModifyVpcAttribute

NOTE
If you use an existing VPC, your account does not require these permissions for creating network resources.

Example 6.3. Required Elastic Load Balancing permissions (ELB) for installation
• elasticloadbalancing:AddTags
• elasticloadbalancing:ApplySecurityGroupsToLoadBalancer
• elasticloadbalancing:AttachLoadBalancerToSubnets
• elasticloadbalancing:ConfigureHealthCheck
• elasticloadbalancing:CreateLoadBalancer
• elasticloadbalancing:CreateLoadBalancerListeners
• elasticloadbalancing:DeleteLoadBalancer
• elasticloadbalancing:DeregisterInstancesFromLoadBalancer
• elasticloadbalancing:DescribeInstanceHealth
• elasticloadbalancing:DescribeLoadBalancerAttributes
• elasticloadbalancing:DescribeLoadBalancers
• elasticloadbalancing:DescribeTags
• elasticloadbalancing:ModifyLoadBalancerAttributes
• elasticloadbalancing:RegisterInstancesWithLoadBalancer
• elasticloadbalancing:SetLoadBalancerPoliciesOfListener

Example 6.4. Required Elastic Load Balancing permissions (ELBv2) for installation
• elasticloadbalancing:AddTags
• elasticloadbalancing:CreateListener
• elasticloadbalancing:CreateLoadBalancer
• elasticloadbalancing:CreateTargetGroup
• elasticloadbalancing:DeleteLoadBalancer
• elasticloadbalancing:DeregisterTargets
• elasticloadbalancing:DescribeListeners
• elasticloadbalancing:DescribeLoadBalancerAttributes
• elasticloadbalancing:DescribeLoadBalancers
• elasticloadbalancing:DescribeTargetGroupAttributes
• elasticloadbalancing:DescribeTargetHealth
• elasticloadbalancing:ModifyLoadBalancerAttributes
• elasticloadbalancing:ModifyTargetGroup
• elasticloadbalancing:ModifyTargetGroupAttributes
• elasticloadbalancing:RegisterTargets

Example 6.5. Required IAM permissions for installation

• iam:AddRoleToInstanceProfile
• iam:CreateInstanceProfile
• iam:CreateRole
• iam:DeleteInstanceProfile
• iam:DeleteRole
• iam:DeleteRolePolicy
• iam:GetInstanceProfile
• iam:GetRole
• iam:GetRolePolicy
• iam:GetUser
• iam:ListInstanceProfilesForRole
• iam:ListRoles
• iam:ListUsers
• iam:PassRole
• iam:PutRolePolicy
• iam:RemoveRoleFromInstanceProfile
• iam:SimulatePrincipalPolicy
• iam:TagRole

NOTE
If you have not created a load balancer in your AWS account, the IAM user also requires the `iam:CreateServiceLinkedRole` permission.

Example 6.6. Required Route 53 permissions for installation

• route53:ChangeResourceRecordSets

• route53:ChangeTagsForResource

• route53:CreateHostedZone

• route53:DeleteHostedZone

• route53:GetChange

• route53:GetHostedZone

• route53:GetHostedZones

• route53:GetHostedZonesByName

• route53:GetResourceRecordSets

• route53:GetTagsForResource

• route53:GetHostedZoneComment

Example 6.7. Required S3 permissions for installation

• s3:CreateBucket

• s3:DeleteBucket

• s3:GetAccelerateConfiguration

• s3:GetBucketAcl

• s3:GetBucketCors

• s3:GetBucketLocation

• s3:GetBucketLogging

• s3:GetBucketPolicy

• s3:GetBucketObjectLockConfiguration

• s3:GetBucketReplication

• s3:GetBucketRequestPayment
Example 6.8. S3 permissions that cluster Operators require

- s3:GetBucketTagging
- s3:GetBucketVersioning
- s3:GetBucketWebsite
- s3:GetEncryptionConfiguration
- s3:GetLifecycleConfiguration
- s3:GetReplicationConfiguration
- s3:ListBucket
- s3:PutBucketAcl
- s3:PutBucketTagging
- s3:PutEncryptionConfiguration

Example 6.9. Required permissions to delete base cluster resources

- autoscaling:DescribeAutoScalingGroups
- ec2:DeletePlacementGroup
- ec2:DeleteNetworkInterface
- ec2:DeleteVolume
- elasticloadbalancing:DeleteTargetGroup
- elasticloadbalancing:DescribeTargetGroups
- iam:DeleteAccessKey
- iam:DeleteUser
Example 6.10. Required permissions to delete network resources

- ec2:DeleteDhcpOptions
- ec2:DeleteInternetGateway
- ec2:DeleteNatGateway
- ec2:DeleteRoute
- ec2:DeleteRouteTable
- ec2:DeleteSubnet
- ec2:DeleteVpc
- ec2:DeleteVpcEndpoints
- ec2:DetachInternetGateway
- ec2:DisassociateRouteTable
- ec2:ReleaseAddress
- ec2:ReplaceRouteTableAssociation

NOTE

If you use an existing VPC, your account does not require these permissions to delete network resources. Instead, your account only requires the tag:UntagResources permission to delete network resources.

Example 6.11. Required permissions to delete a cluster with shared instance roles

- iam:UntagRole

Example 6.12. Additional IAM and S3 permissions that are required to create manifests
• iam:DeleteAccessKey
• iam:DeleteUser
• iam:DeleteUserPolicy
• iam:GetUserPolicy
• iam:ListAccessKeys
• iam:PutUserPolicy
• iam:TagUser
• s3:PutBucketPublicAccessBlock
• s3:GetBucketPublicAccessBlock
• s3:PutLifecycleConfiguration
• s3:HeadBucket
• s3:ListBucketMultipartUploads
• s3:AbortMultipartUpload

NOTE
If you are managing your cloud provider credentials with mint mode, the IAM user also requires the `iam:CreateAccessKey` and `iam:CreateUser` permissions.

Example 6.13. Optional permissions for instance and quota checks for installation

• ec2:DescribeInstanceTypeOfferings
• servicequotas:ListAWSDefaultServiceQuotas

Example 6.14. Optional permissions for the cluster owner account when installing a cluster on a shared VPC

• sts:AssumeRole

6.2.4. Creating an IAM user

Each Amazon Web Services (AWS) account contains a root user account that is based on the email address you used to create the account. This is a highly-privileged account, and it is recommended to use it for only initial account and billing configuration, creating an initial set of users, and securing the account.

Before you install OpenShift Container Platform, create a secondary IAM administrative user. As you complete the Creating an IAM User in Your AWS Account procedure in the AWS documentation, set the following options:
Procedure

1. Specify the IAM user name and select **Programmatic access**.

2. Attach the **AdministratorAccess** policy to ensure that the account has sufficient permission to create the cluster. This policy provides the cluster with the ability to grant credentials to each OpenShift Container Platform component. The cluster grants the components only the credentials that they require.

   **NOTE**

   While it is possible to create a policy that grants the all of the required AWS permissions and attach it to the user, this is not the preferred option. The cluster will not have the ability to grant additional credentials to individual components, so the same credentials are used by all components.

3. Optional: Add metadata to the user by attaching tags.

4. Confirm that the user name that you specified is granted the **AdministratorAccess** policy.

5. Record the access key ID and secret access key values. You must use these values when you configure your local machine to run the installation program.

   **IMPORTANT**

   You cannot use a temporary session token that you generated while using a multi-factor authentication device to authenticate to AWS when you deploy a cluster. The cluster continues to use your current AWS credentials to create AWS resources for the entire life of the cluster, so you must use key-based, long-term credentials.

6.2.5. IAM Policies and AWS authentication

By default, the installation program creates instance profiles for the bootstrap, control plane, and compute instances with the necessary permissions for the cluster to operate.

However, you can create your own IAM roles and specify them as part of the installation process. You might need to specify your own roles to deploy the cluster or to manage the cluster after installation. For example:

- Your organization’s security policies require that you use a more restrictive set of permissions to install the cluster.

- After the installation, the cluster is configured with an Operator that requires access to additional services.

If you choose to specify your own IAM roles, you can take the following steps:

- Begin with the default policies and adapt as required. For more information, see "Default permissions for IAM instance profiles".

- Use the AWS Identity and Access Management Access Analyzer (IAM Access Analyzer) to create a policy template that is based on the cluster’s activity. For more information see, "Using AWS IAM Analyzer to create policy templates".
6.2.5.1. Default permissions for IAM instance profiles

By default, the installation program creates IAM instance profiles for the bootstrap, control plane and worker instances with the necessary permissions for the cluster to operate.

The following lists specify the default permissions for control plane and compute machines:

Example 6.15. Default IAM role permissions for control plane instance profiles

- ec2:AttachVolume
- ec2:AuthorizeSecurityGroupIngress
- ec2:CreateSecurityGroup
- ec2:CreateTags
- ec2:CreateVolume
- ec2:DeleteSecurityGroup
- ec2:DeleteVolume
- ec2:Describe*
- ec2:DetachVolume
- ec2:ModifyInstanceAttribute
- ec2:ModifyVolume
- ec2:RevokeSecurityGroupIngress
- elasticloadbalancing:AddTags
- elasticloadbalancing:AttachLoadBalancerToSubnets
- elasticloadbalancing:ApplySecurityGroupsToLoadBalancer
- elasticloadbalancing:CreateListener
- elasticloadbalancing:CreateLoadBalancer
- elasticloadbalancing:CreateLoadBalancerPolicy
- elasticloadbalancing:CreateLoadBalancerListeners
- elasticloadbalancing:CreateTargetGroup
- elasticloadbalancing:ConfigureHealthCheck
- elasticloadbalancing:DeleteListener
- elasticloadbalancing:DeleteLoadBalancer
- elasticloadbalancing:DeleteLoadBalancerListeners
- elasticloadbalancing:DeleteTargetGroup
Example 6.16. Default IAM role permissions for compute instance profiles

- `ec2:DescribeInstances`
- `ec2:DescribeRegions`

6.2.5.2. Specifying an existing IAM role

Instead of allowing the installation program to create IAM instance profiles with the default permissions, you can use the `install-config.yaml` file to specify an existing IAM role for control plane and compute instances.

**Prerequisites**

- You have an existing `install-config.yaml` file.

**Procedure**

1. Update `compute.platform.aws.iamRole` with an existing role for the control plane machines.

Sample `install-config.yaml` file with an IAM role for compute instances

```yaml
compute:
- hyperthreading: Enabled
name: worker
```
2. Update **controlPlane.platform.aws.iamRole** with an existing role for the compute machines.

Sample install-config.yaml file with an IAM role for control plane instances

```yaml
controlPlane:
  hyperthreading: Enabled
  name: master
  platform:
    aws:
      iamRole: ExampleRole
```

3. Save the file and reference it when installing the OpenShift Container Platform cluster.

Additional resources

- See **Deploying the cluster**.

### 6.2.5.3. Using AWS IAM Analyzer to create policy templates

The minimal set of permissions that the control plane and compute instance profiles require depends on how the cluster is configured for its daily operation.

One way to determine which permissions the cluster instances require is to use the AWS Identity and Access Management Access Analyzer (IAM Access Analyzer) to create a policy template:

- A policy template contains the permissions the cluster has used over a specified period of time.
- You can then use the template to create policies with fine-grained permissions.

**Procedure**

The overall process could be:

1. Ensure that CloudTrail is enabled. CloudTrail records all of the actions and events in your AWS account, including the API calls that are required to create a policy template. For more information, see the AWS documentation for [working with CloudTrail](https://aws.amazon.com/documentation/cloudtrail/).

2. Create an instance profile for control plane instances and an instance profile for compute instances. Be sure to assign each role a permissive policy, such as **PowerUserAccess**. For more information, see the AWS documentation for [creating instance profile roles](https://aws.amazon.com/documentation/iam/).

3. Install the cluster in a development environment and configure it as required. Be sure to deploy all of applications the cluster will host in a production environment.

4. Test the cluster thoroughly. Testing the cluster ensures that all of the required API calls are logged.

5. Use the IAM Access Analyzer to create a policy template for each instance profile. For more information, see the AWS documentation for [generating policies based on the CloudTrail logs](https://aws.amazon.com/documentation/iam/).

6. Create and add a fine-grained policy to each instance profile.
7. Remove the permissive policy from each instance profile.

8. Deploy a production cluster using the existing instance profiles with the new policies.

**NOTE**

You can add IAM Conditions to your policy to make it more restrictive and compliant with your organization security requirements.

6.2.6. Supported AWS Marketplace regions

Installing an OpenShift Container Platform cluster using an AWS Marketplace image is available to customers who purchase the offer in North America.

While the offer must be purchased in North America, you can deploy the cluster to any of the following supported partitions:

- Public
- GovCloud

**NOTE**

Deploying a OpenShift Container Platform cluster using an AWS Marketplace image is not supported for the AWS secret regions or China regions.

6.2.7. Supported AWS regions

You can deploy an OpenShift Container Platform cluster to the following regions.

**NOTE**

Your IAM user must have the permission `tag:GetResources` in the region `us-east-1` to delete the base cluster resources. As part of the AWS API requirement, the OpenShift Container Platform installation program performs various actions in this region.

6.2.7.1. AWS public regions

The following AWS public regions are supported:

- `af-south-1` (Cape Town)
- `ap-east-1` (Hong Kong)
- `ap-northeast-1` (Tokyo)
- `ap-northeast-2` (Seoul)
- `ap-northeast-3` (Osaka)
- `ap-south-1` (Mumbai)
- `ap-south-2` (Hyderabad)
- `ap-southeast-1` (Singapore)
• ap-southeast-2 (Sydney)
• ap-southeast-3 (Jakarta)
• ap-southeast-4 (Melbourne)
• ca-central-1 (Central)
• eu-central-1 (Frankfurt)
• eu-central-2 (Zurich)
• eu-north-1 (Stockholm)
• eu-south-1 (Milan)
• eu-south-2 (Spain)
• eu-west-1 (Ireland)
• eu-west-2 (London)
• eu-west-3 (Paris)
• me-central-1 (UAE)
• me-south-1 (Bahrain)
• sa-east-1 (São Paulo)
• us-east-1 (N. Virginia)
• us-east-2 (Ohio)
• us-west-1 (N. California)
• us-west-2 (Oregon)

6.2.7.2. AWS GovCloud regions

The following AWS GovCloud regions are supported:

• us-gov-west-1
• us-gov-east-1

6.2.7.3. AWS SC2S and C2S secret regions

The following AWS secret regions are supported:

• us-isob-east-1 Secret Commercial Cloud Services (SC2S)
• us-iso-east-1 Commercial Cloud Services (C2S)

6.2.7.4. AWS China regions

The following AWS China regions are supported:
6.2.8. Next steps

- Install an OpenShift Container Platform cluster:
  - Quickly install a cluster with default options on installer-provisioned infrastructure
  - Install a cluster with cloud customizations on installer-provisioned infrastructure
  - Install a cluster with network customizations on installer-provisioned infrastructure
  - Installing a cluster on user-provisioned infrastructure in AWS by using CloudFormation templates
  - Installing a cluster on AWS with remote workers on AWS Outposts

6.3. INSTALLING A CLUSTER QUICKLY ON AWS

In OpenShift Container Platform version 4.14, you can install a cluster on Amazon Web Services (AWS) that uses the default configuration options.

6.3.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You configured an AWS account to host the cluster.

**IMPORTANT**

If you have an AWS profile stored on your computer, it must not use a temporary session token that you generated while using a multi-factor authentication device. The cluster continues to use your current AWS credentials to create AWS resources for the entire life of the cluster, so you must use key-based, long-term credentials. To generate appropriate keys, see Managing Access Keys for IAM Users in the AWS documentation. You can supply the keys when you run the installation program.

- If you use a firewall, you configured it to allow the sites that your cluster requires access to.

6.3.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager Hybrid Cloud Console to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

6.3.3. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the `core` user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user `core`. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `/openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>  
   ```

   Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in your `~/.ssh` directory.
NOTE

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   ```bash
   $ cat <path>/<file_name>.pub
   ```

   For example, run the following to view the ~/.ssh/id_ed25519.pub public key:

   ```bash
   $ cat ~/.ssh/id_ed25519.pub
   ```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the ./openshift-install gather command.

   NOTE

   On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.

   a. If the ssh-agent process is not already running for your local user, start it as a background task:

   ```bash
   $ eval "$(ssh-agent -s)"
   ```

   Example output

   ```bash
   Agent pid 31874
   ```

   NOTE

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the ssh-agent:

   ```bash
   $ ssh-add <path>/<file_name>
   ```

   Specify the path and file name for your SSH private key, such as ~/.ssh/id_ed25519

   Example output

   ```bash
   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
   ```

Next steps
When you install OpenShift Container Platform, provide the SSH public key to the installation program.

6.3.4. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

   IMPORTANT

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   IMPORTANT

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ tar -xvf openshift-install-linux.tar.gz
   ```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

6.3.5. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.
IMPORTANT

You can run the `create cluster` command of the installation program only once, during initial installation.

Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.
- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.

Procedure

1. Change to the directory that contains the installation program and initialize the cluster deployment:

   ```
   $ ./openshift-install create cluster --dir <installation_directory> \
   --log-level=info
   ```

   1. For `<installation_directory>`, specify the directory name to store the files that the installation program creates.
   2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

   When specifying the directory:
   
   - Verify that the directory has the `execute` permission. This permission is required to run Terraform binaries under the installation directory.
   - Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Provide values at the prompts:

   a. Optional: Select an SSH key to use to access your cluster machines.

   ```
   $ ./openshift-install create cluster --dir <installation_directory> \
   --log-level=info
   ```

   **NOTE**

   For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

   b. Select `aws` as the platform to target.
c. If you do not have an Amazon Web Services (AWS) profile stored on your computer, enter the AWS access key ID and secret access key for the user that you configured to run the installation program.

**NOTE**

The AWS access key ID and secret access key are stored in 
`~/.aws/credentials` in the home directory of the current user on the installation host. You are prompted for the credentials by the installation program if the credentials for the exported profile are not present in the file. Any credentials that you provide to the installation program are stored in the file.

d. Select the AWS region to deploy the cluster to.

e. Select the base domain for the Route 53 service that you configured for your cluster.

f. Enter a descriptive name for your cluster.

g. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

3. Optional: Remove or disable the **AdministratorAccess** policy from the IAM account that you used to install the cluster.

**NOTE**

The elevated permissions provided by the **AdministratorAccess** policy are required only during installation.

**Verification**

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the **kubeadmin** user.

- Credential information also outputs to `<installation_directory>/.openshift_install.log`.

**IMPORTANT**

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

**Example output**

```
... INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```
IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

Additional resources

- See Configuration and credential file settings in the AWS documentation for more information about AWS profile and credential configuration.

6.3.6. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (`oc`) to interact with OpenShift Container Platform from a command-line interface. You can install `oc` on Linux, Windows, or macOS.

IMPORTANT

If you installed an earlier version of `oc`, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of `oc`.

Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (`oc`) binary on Linux by using the following procedure.

Procedure

2. Select the architecture from the Product Variant drop-down list.

3. Select the appropriate version from the Version drop-down list.

4. Click Download Now next to the OpenShift v4.14 Linux Client entry and save the file.

5. Unpack the archive:

   ```
   $ tar xvf <file>
   ```

6. Place the `oc` binary in a directory that is on your PATH.

   To check your PATH, execute the following command:

   ```
   $ echo $PATH
   ```
Verifications

- After you install the OpenShift CLI, it is available using the `oc` command:

  $ oc <command>

**Installing the OpenShift CLI on Windows**

You can install the OpenShift CLI (`oc`) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version from the Version drop-down list.
3. Click Download Now next to the OpenShift v4.14 Windows Client entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the `oc` binary to a directory that is on your PATH.
   To check your PATH, open the command prompt and execute the following command:

   C:\> path

**Verifications**

- After you install the OpenShift CLI, it is available using the `oc` command:

  C:\> oc <command>

**Installing the OpenShift CLI on macOS**

You can install the OpenShift CLI (`oc`) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version from the Version drop-down list.
3. Click Download Now next to the OpenShift v4.14 macOS Client entry and save the file.
4. Unpack and unzip the archive.
5. Move the `oc` binary to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:

   $ echo $PATH

**NOTE**

For macOS arm64, choose the OpenShift v4.14 macOS arm64 Client entry.
Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

  ```bash
  $ oc <command>
  ```

6.3.7. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

Procedure

1. Export the **kubeadmin** credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   ```

   Example output

   ```
   system:admin
   ```

6.3.8. Logging in to the cluster by using the web console

The **kubeadmin** user exists by default after an OpenShift Container Platform installation. You can log in to your cluster as the **kubeadmin** user by using the OpenShift Container Platform web console.

Prerequisites

- You have access to the installation host.
- You completed a cluster installation and all cluster Operators are available.

Procedure

1. Obtain the password for the **kubeadmin** user from the **kubeadmin-password** file on the installation host:
2. List the OpenShift Container Platform web console route:

```
$ oc get routes -n openshift-console | grep 'console-openshift'
```

Example output

```
console  console-openshift-console.apps.<cluster_name>.<base_domain>  console
https   reencrypt/Redirect   None
```

3. Navigate to the route detailed in the output of the preceding command in a web browser and log in as the `kubeadmin` user.

Additional resources

- See [Accessing the web console](#) for more details about accessing and understanding the OpenShift Container Platform web console.

### 6.3.9. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to **OpenShift Cluster Manager Hybrid Cloud Console**.

After you confirm that your **OpenShift Cluster Manager Hybrid Cloud Console** inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, **use subscription watch** to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

### 6.3.10. Next steps

- **Validating an installation**.
- **Customize your cluster**.
- If necessary, you can **opt out of remote health reporting**.
• If necessary, you can remove cloud provider credentials.

6.4. INSTALLING A CLUSTER ON AWS WITH CUSTOMIZATIONS

In OpenShift Container Platform version 4.14, you can install a customized cluster on infrastructure that the installation program provisions on Amazon Web Services (AWS). To customize the installation, you modify parameters in the `install-config.yaml` file before you install the cluster.

**NOTE**

The scope of the OpenShift Container Platform installation configurations is intentionally narrow. It is designed for simplicity and ensured success. You can complete many more OpenShift Container Platform configuration tasks after an installation completes.

6.4.1. Prerequisites

• You reviewed details about the OpenShift Container Platform installation and update processes.

• You read the documentation on selecting a cluster installation method and preparing it for users.

• You configured an AWS account to host the cluster.

**IMPORTANT**

If you have an AWS profile stored on your computer, it must not use a temporary session token that you generated while using a multi-factor authentication device. The cluster continues to use your current AWS credentials to create AWS resources for the entire life of the cluster, so you must use long-term credentials. To generate appropriate keys, see Managing Access Keys for IAM Users in the AWS documentation. You can supply the keys when you run the installation program.

• If you use a firewall, you configured it to allow the sites that your cluster requires access to.

6.4.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

• Access OpenShift Cluster Manager Hybrid Cloud Console to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

• Access Quay.io to obtain the packages that are required to install your cluster.

• Obtain the packages that are required to perform cluster updates.
IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

6.4.3. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The ./openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

NOTE

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> ¹

   ¹ Specify the path and file name, such as ~/.ssh/id_ed25519, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

NOTE

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.
2. View the public SSH key:

$ cat <path>/<file_name>.pub

For example, run the following to view the ~/.ssh/id_ed25519.pub public key:

$ cat ~/.ssh/id_ed25519.pub

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the ./openshift-install gather command.

NOTE
On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.

a. If the ssh-agent process is not already running for your local user, start it as a background task:

$ eval "$(ssh-agent -s)"

Example output

Agent pid 31874

NOTE
If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the ssh-agent:

$ ssh-add <path>/<file_name> 1

1 Specify the path and file name for your SSH private key, such as ~/.ssh/id_ed25519

Example output

Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

6.4.4. Obtaining an AWS Marketplace image
If you are deploying an OpenShift Container Platform cluster using an AWS Marketplace image, you must first subscribe through AWS. Subscribing to the offer provides you with the AMI ID that the installation program uses to deploy worker nodes.

**Prerequisites**

- You have an AWS account to purchase the offer. This account does not have to be the same account that is used to install the cluster.

**Procedure**

1. Complete the OpenShift Container Platform subscription from the AWS Marketplace.

2. Record the AMI ID for your specific region. As part of the installation process, you must update the `install-config.yaml` file with this value before deploying the cluster.

**Sample install-config.yaml file with AWS Marketplace worker nodes**

```yaml
apiVersion: v1
baseDomain: example.com
compute:
  - hyperthreading: Enabled
    name: worker
    platform:
      aws:
        amiID: ami-06c4d345f7c207239
        type: m5.4xlarge
        replicas: 3
    metadata:
      name: test-cluster
      platform:
        aws:
          region: us-east-2
    sshKey: ssh-ed25519 AAAA...
    pullSecret: "{"auths": ...}"
```

1. The AMI ID from your AWS Marketplace subscription.
2. Your AMI ID is associated with a specific AWS region. When creating the installation configuration file, ensure that you select the same AWS region that you specified when configuring your subscription.

**6.4.5. Obtaining the installation program**

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

**Prerequisites**

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

**Procedure**
1. Access the **Infrastructure Provider** page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

   **IMPORTANT**
   
   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   **IMPORTANT**
   
   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   `$ tar -xvf openshift-install-linux.tar.gz`

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 6.4.6. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Amazon Web Services (AWS).

**Prerequisites**

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Create the **install-config.yaml** file.

   a. Change to the directory that contains the installation program and run the following command:

   ```
   $ ./openshift-install create install-config --dir `<installation_directory>`
   ```

   For `<installation_directory>`, specify the directory name to store the files that the installation program creates.
When specifying the directory:

- Verify that the directory has the **execute** permission. This permission is required to run Terraform binaries under the installation directory.

- Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

**NOTE**

Always delete the `~/.powervs` directory to avoid reusing a stale configuration. Run the following command:

```
$ rm -rf ~/.powervs
```

b. At the prompts, provide the configuration details for your cloud:

i. Optional: Select an SSH key to use to access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

ii. Select **AWS** as the platform to target.

iii. If you do not have an Amazon Web Services (AWS) profile stored on your computer, enter the AWS access key ID and secret access key for the user that you configured to run the installation program.

iv. Select the AWS region to deploy the cluster to.

v. Select the base domain for the Route 53 service that you configured for your cluster.

vi. Enter a descriptive name for your cluster.

2. Modify the `install-config.yaml` file. You can find more information about the available parameters in the "Installation configuration parameters" section.

**NOTE**

If you are installing a three-node cluster, be sure to set the `compute.replicas` parameter to **0**. This ensures that the cluster’s control planes are schedulable. For more information, see "Installing a three-node cluster on AWS".

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.
IMPORTANT

The install-config.yaml file is consumed during the installation process. If you want to reuse the file, you must back it up now.

Additional resources

- Installation configuration parameters for AWS

### 6.4.6.1. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS, RHEL 8.6 and later [3]</td>
<td>2</td>
<td>8 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
</tbody>
</table>

1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or hyperthreading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: (threads per core × cores) × sockets = vCPUs.

2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.

3. As with all user-provisioned installations, if you choose to use RHEL compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and has been removed in OpenShift Container Platform 4.10 and later.

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

Additional resources

- Optimizing storage

### 6.4.6.2. Tested instance types for AWS

The following Amazon Web Services (AWS) instance types have been tested with OpenShift Container Platform.
NOTE

Use the machine types included in the following charts for your AWS instances. If you use an instance type that is not listed in the chart, ensure that the instance size you use matches the minimum resource requirements that are listed in "Minimum resource requirements for cluster installation".

Example 6.17. Machine types based on 64-bit x86 architecture

- c4.*
- c5.*
- c5a.*
- i3.*
- m4.*
- m5.*
- m5a.*
- m6i.*
- r4.*
- r5.*
- r5a.*
- r6i.*
- t3.*
- t3a.*

6.4.6.3. Tested instance types for AWS on 64-bit ARM infrastructures

The following Amazon Web Services (AWS) 64-bit ARM instance types have been tested with OpenShift Container Platform.

NOTE

Use the machine types included in the following charts for your AWS ARM instances. If you use an instance type that is not listed in the chart, ensure that the instance size you use matches the minimum resource requirements that are listed in "Minimum resource requirements for cluster installation".

Example 6.18. Machine types based on 64-bit ARM architecture

- c6g.*
- m6g.*
6.4.6.4. Sample customized install-config.yaml file for AWS

You can customize the installation configuration file (install-config.yaml) to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

**IMPORTANT**

This sample YAML file is provided for reference only. You must obtain your install-config.yaml file by using the installation program and modify it.

```yaml
apiVersion: v1
baseDomain: example.com
credentialsMode: Mint
controlPlane:  
  hypethreading: Enabled
  name: master
  platform:
    aws:
      lbType: NLB
      zones:
        - us-west-2a
        - us-west-2b
      rootVolume:
        iops: 4000
        size: 500
        type: io1
      metadataService:
        authentication: Optional
        type: m6i.xlarge
      replicas: 3
      compute:
        - hypethreading: Enabled
        name: worker
        platform:
          aws:
            rootVolume:
              iops: 2000
              size: 500
              type: io1
            metadataService:
              authentication: Optional
              type: c5.4xlarge
            zones:
              - us-west-2c
            replicas: 3
            metadata:
              name: test-cluster
            networking:
              clusterNetwork:
                - cidr: 10.128.0.0/14
              hostPrefix: 23
              machineNetwork:
```
Required. The installation program prompts you for this value.

Optional: Add this parameter to force the Cloud Credential Operator (CCO) to use the specified mode. By default, the CCO uses the root credentials in the `kube-system` namespace to dynamically try to determine the capabilities of the credentials. For details about CCO modes, see the "About the Cloud Credential Operator" section in the Authentication and authorization guide.

If you do not provide these parameters and values, the installation program provides the default value.

The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, `-`, and the first line of the controlPlane section must not. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading, or hyperthreading. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores. You can disable it by setting the parameter value to `Disabled`. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger instance types, such as `m4.2xlarge` or `m5.2xlarge`, for your machines if you disable simultaneous multithreading.

To configure faster storage for etcd, especially for larger clusters, set the storage type as `io1` and set `iops` to 2000.

Whether to require the Amazon EC2 Instance Metadata Service v2 (IMDSv2). To require IMDSv2, set the parameter value to `Required`. To allow the use of both IMDSv1 and IMDSv2, set the parameter value to `Optional`. If no value is specified, both IMDSv1 and IMDSv2 are allowed.
The IMDS configuration for control plane machines that is set during cluster installation can only be changed by using the AWS CLI. The IMDS configuration for compute machines can be changed by using compute machine sets.

The cluster network plugin to install. The supported values are **OVNKubernetes** and **OpenShiftSDN**. The default value is **OVNKubernetes**.

The ID of the AMI used to boot machines for the cluster. If set, the AMI must belong to the same region as the cluster.

The AWS service endpoints. Custom endpoints are required when installing to an unknown AWS region. The endpoint URL must use the **https** protocol and the host must trust the certificate.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see [Installing the system in FIPS mode](#). When running Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures.

You can optionally provide the **sshKey** value that you use to access the machines in your cluster.

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

### 6.4.6.5. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the install-config.yaml file.

#### Prerequisites

- You have an existing **install-config.yaml** file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object’s **spec.noProxy** field to bypass the proxy if necessary.
NOTE

The Proxy object status.noProxy field is populated with the values of the networking.machineNetwork[].cidr, networking.clusterNetwork[].cidr, and networking.serviceNetwork[] fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object status.noProxy field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your install-config.yaml file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port>  
  httpsProxy: https://<username>:<pswd>@<ip>:<port> 
  noProxy: ec2.<aws_region>.amazonaws.com,elasticloadbalancing.<aws_region>.amazonaws.com,s3.<aws_region>.amazonaws.com
  additionalTrustBundle: |
      -----BEGIN CERTIFICATE-----
      <MY_TRUSTED_CA_CERT>
      -----END CERTIFICATE-----
  additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle>
```

1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.

2. A proxy URL to use for creating HTTPS connections outside the cluster.

3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations. If you have added the Amazon EC2 Elastic Load Balancing, and S3 VPC endpoints to your VPC, you must add these endpoints to the noProxy field.

4. If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the trustedCA field of the Proxy object. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

5. Optional: The policy to determine the configuration of the Proxy object to reference the user-ca-bundle config map in the trustedCA field. The allowed values are Proxyonly and Always. Use Proxyonly to reference the user-ca-bundle config map only when http/https proxy is configured. Use Always to always reference the user-ca-bundle config map. The default value is Proxyonly.
NOTE
The installation program does not support the proxy `readinessEndpoints` field.

NOTE
If the installer times out, restart and then complete the deployment by using the `wait-for` command of the installer. For example:

```
$ ./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

NOTE
Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

6.4.7. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

IMPORTANT
If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of oc.

Installing the OpenShift CLI on Linux
You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure

2. Select the architecture from the Product Variant drop-down list.

3. Select the appropriate version from the Version drop-down list.

4. Click Download Now next to the OpenShift v4.14 Linux Client entry and save the file.

5. Unpack the archive:

```
$ tar xvf <file>
```

6. Place the oc binary in a directory that is on your PATH.

To check your PATH, execute the following command:
After you install the OpenShift CLI, it is available using the `oc` command:

```
$ oc <command>
```

### Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (`oc`) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version from the [Version](https://お客様の運用環境への設定項目) drop-down list.
3. Click [Download Now](https://お客様の運用環境への設定項目) next to the [OpenShift v4.14 Windows Client](https://お客様の運用環境への設定項目) entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the `oc` binary to a directory that is on your `PATH`.
   
   To check your `PATH`, open the command prompt and execute the following command:

   ```bash
   C:\> path
   ```

### Verification

- After you install the OpenShift CLI, it is available using the `oc` command:

  ```bash
  C:\> oc <command>
  ```

### Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (`oc`) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version from the [Version](https://お客様の運用環境への設定項目) drop-down list.
3. Click [Download Now](https://お客様の運用環境への設定項目) next to the [OpenShift v4.14 macOS Client](https://お客様の運用環境への設定項目) entry and save the file.
4. Unpack and unzip the archive.
5. Move the `oc` binary to a directory on your `PATH`.
   
   To check your `PATH`, open a terminal and execute the following command:

   ```bash
   $ echo $PATH
   $$ oc <command>
   ```

**NOTE**

For macOS arm64, choose the [OpenShift v4.14 macOS arm64 Client](https://お客様の運用環境への設定項目) entry.
After you install the OpenShift CLI, it is available using the `oc` command:

```bash
$ oc <command>
```

### 6.4.8. Alternatives to storing administrator-level secrets in the kube-system project

By default, administrator secrets are stored in the `kube-system` project. If you configured the `credentialsMode` parameter in the `install-config.yaml` file to `Manual`, you must use one of the following alternatives:

- To manage long-term cloud credentials manually, follow the procedure in [Manually creating long-term credentials](#).
- To implement short-term credentials that are managed outside the cluster for individual components, follow the procedures in [Configuring an AWS cluster to use short-term credentials](#).

#### 6.4.8.1. Manually creating long-term credentials

The Cloud Credential Operator (CCO) can be put into manual mode prior to installation in environments where the cloud identity and access management (IAM) APIs are not reachable, or the administrator prefers not to store an administrator-level credential secret in the cluster `kube-system` namespace.

**Procedure**

1. If you did not set the `credentialsMode` parameter in the `install-config.yaml` configuration file to `Manual`, modify the value as shown:

   **Sample configuration file snippet**

   ```yaml
   apiVersion: v1
   baseDomain: example.com
   credentialsMode: Manual
   # ...
   ```

2. If you have not previously created installation manifest files, do so by running the following command:

   ```bash
   $ openshift-install create manifests --dir <installation_directory>
   ```

   where `<installation_directory>` is the directory in which the installation program creates files.

3. Set a `$RELEASE_IMAGE` variable with the release image from your installation file by running the following command:

   ```bash
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
   ```
4. Extract the list of **CredentialsRequest** custom resources (CRs) from the OpenShift Container Platform release image by running the following command:

```bash
$ oc adm release extract \ 
  --from=$RELEASE_IMAGE \ 
  --credentials-requests \ 
  --included \ 
  --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \ 
  --to=<path_to_directory_for_credentials_requests>
```

1. The **--included** parameter includes only the manifests that your specific cluster configuration requires.

2. Specify the location of the **install-config.yaml** file.

3. Specify the path to the directory where you want to store the **CredentialsRequest** objects. If the specified directory does not exist, this command creates it.

This command creates a YAML file for each **CredentialsRequest** object.

**Sample CredentialsRequest object**

```yaml
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
  name: <component_credentials_request>
  namespace: openshift-cloud-credential-operator
...
spec:
  providerSpec:
    apiVersion: cloudcredential.openshift.io/v1
    kind: AWSProviderSpec
    statementEntries:
      - effect: Allow
        action:
        - iam:GetUser
        - iam:GetUserPolicy
        - iam:ListAccessKeys
        resource: ***
...
```

5. Create YAML files for secrets in the **openshift-install** manifests directory that you generated previously. The secrets must be stored using the namespace and secret name defined in the **spec.secretRef** for each **CredentialsRequest** object.

**Sample CredentialsRequest object with secrets**

```yaml
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
  name: <component_credentials_request>
  namespace: openshift-cloud-credential-operator
...
spec:
```
Before upgrading a cluster that uses manually maintained credentials, you must ensure that the CCO is in an upgradeable state.

### 6.4.8.2. Configuring an AWS cluster to use short-term credentials

To install a cluster that is configured to use the AWS Security Token Service (STS), you must configure the CCO utility and create the required AWS resources for your cluster.

#### 6.4.8.2.1. Configuring the Cloud Credential Operator utility

To create and manage cloud credentials from outside of the cluster when the Cloud Credential Operator (CCO) is operating in manual mode, extract and prepare the CCO utility (`ccoctl`) binary.

**NOTE**

The `ccoctl` utility is a Linux binary that must run in a Linux environment.

### Prerequisites

- You have access to an OpenShift Container Platform account with cluster administrator access.
- You have installed the OpenShift CLI (`oc`).
- You have created an AWS account for the `ccoctl` utility to use with the following permissions:

**Example 6.19. Required AWS permissions**

```yaml
providerSpec:
  apiVersion: cloudcredential.openshift.io/v1
  kind: AWSProviderSpec
  statementEntries:
    - effect: Allow
      action:
        - s3:CreateBucket
        - s3:DeleteBucket
      resource: "*"

secretRef:
  name: <component_secret>
  namespace: <component_namespace>
```

```yaml
apiVersion: v1
kind: Secret
metadata:
  name: <component_secret>
  namespace: <component_namespace>
data:
  aws_access_key_id: <base64_encoded_aws_access_key_id>
  aws_secret_access_key: <base64_encoded_aws_secret_access_key>
```
Required **iam** permissions
- `iam:CreateOpenIDConnectProvider`
- `iam:CreateRole`
- `iam:DeleteOpenIDConnectProvider`
- `iam:DeleteRole`
- `iam:DeleteRolePolicy`
- `iam:GetOpenIDConnectProvider`
- `iam:GetRole`
- `iam:GetUser`
- `iam:ListOpenIDConnectProviders`
- `iam:ListRolePolicies`
- `iam:ListRoles`
- `iam:PutRolePolicy`
- `iam:TagOpenIDConnectProvider`
- `iam:TagRole`

Required **s3** permissions
- `s3:CreateBucket`
- `s3:DeleteBucket`
- `s3:DeleteObject`
- `s3:GetBucketAcl`
- `s3:GetBucketTagging`
- `s3:GetObject`
- `s3:GetObjectAcl`
- `s3:GetObjectTagging`
- `s3:ListBucket`
- `s3:PutBucketAcl`
- `s3:PutBucketPolicy`
- `s3:PutBucketPublicAccessBlock`
- `s3:PutBucketTagging`
If you plan to store the OIDC configuration in a private S3 bucket that is accessed by the IAM identity provider through a public CloudFront distribution URL, the AWS account that runs the `ccoctl` utility requires the following additional permissions:

Example 6.20. Additional permissions for a private S3 bucket with CloudFront

- `cloudfront:CreateCloudFrontOriginAccessIdentity`
- `cloudfront:CreateDistribution`
- `cloudfront:DeleteCloudFrontOriginAccessIdentity`
- `cloudfront:DeleteDistribution`
- `cloudfront:GetCloudFrontOriginAccessIdentity`
- `cloudfront:GetCloudFrontOriginAccessIdentityConfig`
- `cloudfront:GetDistribution`
- `cloudfront:TagResource`
- `cloudfront:UpdateDistribution`

**NOTE**

These additional permissions support the use of the `--create-private-s3-bucket` option when processing credentials requests with the `ccoctl aws create-all` command.

**Procedure**

1. Obtain the OpenShift Container Platform release image by running the following command:
   
   ```bash
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
   ```

2. Obtain the CCO container image from the OpenShift Container Platform release image by running the following command:
$ CCO_IMAGE=$(oc adm release info --image-for='cloud-credential-operator'
$RELEASE_IMAGE -a ~/.pull-secret)

NOTE

Ensure that the architecture of the $RELEASE_IMAGE matches the architecture of the environment in which you will use the ccoctl tool.

3. Extract the ccoctl binary from the CCO container image within the OpenShift Container Platform release image by running the following command:

   $ oc image extract $CCO_IMAGE --file="/usr/bin/ccoctl" -a ~/.pull-secret

4. Change the permissions to make ccoctl executable by running the following command:

   $ chmod 775 ccoctl

Verification

- To verify that ccoctl is ready to use, display the help file by running the following command:

  $ ccoctl --help

Output of ccoctl --help

OpenShift credentials provisioning tool

Usage:
ccoctl [command]

Available Commands:
alibabacloud Manage credentials objects for alibaba cloud
aws Manage credentials objects for AWS cloud
azure Manage credentials objects for Azure
gcp Manage credentials objects for Google cloud
help Help about any command
ibmcloud Manage credentials objects for IBM Cloud
nutanix Manage credentials objects for Nutanix

Flags:
-h, --help help for ccoctl

Use "ccoctl [command] --help" for more information about a command.

6.4.8.2.2. Creating AWS resources with the Cloud Credential Operator utility

You have the following options when creating AWS resources:

- You can use the ccoctl aws create-all command to create the AWS resources automatically. This is the quickest way to create the resources. See Creating AWS resources with a single command.
• If you need to review the JSON files that the `ccoctl` tool creates before modifying AWS resources, or if the process the `ccoctl` tool uses to create AWS resources automatically does not meet the requirements of your organization, you can create the AWS resources individually. See Creating AWS resources individually.

### 6.4.8.2.2.1. Creating AWS resources with a single command

If the process the `ccoctl` tool uses to create AWS resources automatically meets the requirements of your organization, you can use the `ccoctl aws create-all` command to automate the creation of AWS resources.

Otherwise, you can create the AWS resources individually. For more information, see "Creating AWS resources individually".

**NOTE**

By default, `ccoctl` creates objects in the directory in which the commands are run. To create the objects in a different directory, use the `--output-dir` flag. This procedure uses `<path_to_ccoctl_output_dir>` to refer to this directory.

### Prerequisites

You must have:

• Extracted and prepared the `ccoctl` binary.

### Procedure

1. Set a `$RELEASE_IMAGE` variable with the release image from your installation file by running the following command:

   ```bash
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/{print $3}')
   ```

2. Extract the list of `CredentialsRequest` objects from the OpenShift Container Platform release image by running the following command:

   ```bash
   $ oc adm release extract \n   --from=$RELEASE_IMAGE \n   --credentials-requests \n   --included \n   --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \n   --to=<path_to_directory_for_credentials_requests>  
   ```

   1. The `--included` parameter includes only the manifests that your specific cluster configuration requires.
   2. Specify the location of the `install-config.yaml` file.
   3. Specify the path to the directory where you want to store the `CredentialsRequest` objects. If the specified directory does not exist, this command creates it.
3. Use the `ccoctl` tool to process all `CredentialsRequest` objects by running the following command:

```
$ ccoctl aws create-all \
  --name=<name> \  1
  --region=<aws_region> \    2
  --credentials-requests-dir=<path_to_credentials_requests_directory> \  3
  --output-dir=<path_to_ccoctl_output_dir> \  4
  --create-private-s3-bucket  5
```

1. Specify the name used to tag any cloud resources that are created for tracking.
2. Specify the AWS region in which cloud resources will be created.
3. Specify the directory containing the files for the component `CredentialsRequest` objects.
4. Optional: Specify the directory in which you want the `ccoctl` utility to create objects. By default, the utility creates objects in the directory in which the commands are run.
5. Optional: By default, the `ccoctl` utility stores the OpenID Connect (OIDC) configuration files in a public S3 bucket and uses the S3 URL as the public OIDC endpoint. To store the OIDC configuration in a private S3 bucket that is accessed by the IAM identity provider through a public CloudFront distribution URL instead, use the `--create-private-s3-bucket` parameter.

**NOTE**

If your cluster uses Technology Preview features that are enabled by the `TechPreviewNoUpgrade` feature set, you must include the `--enable-tech-preview` parameter.

**Verification**

- To verify that the OpenShift Container Platform secrets are created, list the files in the `<path_to_ccoctl_output_dir>/manifests` directory:

```
$ ls <path_to_ccoctl_output_dir>/manifests
```

**Example output**

```
cluster-authentication-02-config.yaml
openshift-cloud-credential-operator-cloud-credential-operator-iam-ro-creds-credentials.yaml
openshift-cloud-network-config-controller-cloud-credentials-credentials.yaml
openshift-cluster-api-capa-manager-bootstrap-credentials-credentials.yaml
openshift-cluster-csi-drivers-ebs-cloud-credentials-credentials.yaml
openshift-image-registry-installer-cloud-credentials-credentials.yaml
openshift-ingress-operator-cloud-credentials-credentials.yaml
openshift-machine-api-aws-cloud-credentials-credentials.yaml
```
You can verify that the IAM roles are created by querying AWS. For more information, refer to AWS documentation on listing IAM roles.

### 6.4.8.2.2.2. Creating AWS resources individually

You can use the `ccoctl` tool to create AWS resources individually. This option might be useful for an organization that shares the responsibility for creating these resources among different users or departments.

Otherwise, you can use the `ccoctl aws create-all` command to create the AWS resources automatically. For more information, see "Creating AWS resources with a single command".

**NOTE**

By default, `ccoctl` creates objects in the directory in which the commands are run. To create the objects in a different directory, use the `--output-dir` flag. This procedure uses `<path_to_ccoctl_output_dir>` to refer to this directory.

Some `ccoctl` commands make AWS API calls to create or modify AWS resources. You can use the `--dry-run` flag to avoid making API calls. Using this flag creates JSON files on the local file system instead. You can review and modify the JSON files and then apply them with the AWS CLI tool using the `--cli-input-json` parameters.

**Prerequisites**

- Extract and prepare the `ccoctl` binary.

**Procedure**

1. Generate the public and private RSA key files that are used to set up the OpenID Connect provider for the cluster by running the following command:

   ```bash
   $ ccoctl aws create-key-pair
   ```

   **Example output**

   ```text
   2021/04/13 11:01:02 Generating RSA keypair
   2021/04/13 11:01:03 Writing private key to /<path_to_ccoctl_output_dir>/serviceaccount-signer.private
   2021/04/13 11:01:03 Writing public key to /<path_to_ccoctl_output_dir>/serviceaccount-signer.public
   2021/04/13 11:01:03 Copying signing key for use by installer
   ```

   where `serviceaccount-signer.private` and `serviceaccount-signer.public` are the generated key files.

   This command also creates a private key that the cluster requires during installation in `<path_to_ccoctl_output_dir>/tls/bound-service-account-signing-key.key`.

2. Create an OpenID Connect identity provider and S3 bucket on AWS by running the following command:

   ```bash
   $ ccoctl aws create-identity-provider \
   --name=<name>
   ```
--region=<aws_region> \  
--public-key-file=<path_to_ccoctl_output_dir>/serviceaccount-signer.public  

1. <name> is the name used to tag any cloud resources that are created for tracking.
2. <aws-region> is the AWS region in which cloud resources will be created.
3. <path_to_ccoctl_output_dir> is the path to the public key file that the ccoctl aws create-key-pair command generated.

Example output

2021/04/13 11:16:09 Bucket <name>-oidc created
2021/04/13 11:16:10 OpenID Connect discovery document in the S3 bucket <name>-oidc at .well-known/openid-configuration updated
2021/04/13 11:16:10 Reading public key
2021/04/13 11:16:10 JSON web key set (JWKS) in the S3 bucket <name>-oidc at keys.json updated

where openid-configuration is a discovery document and keys.json is a JSON web key set file.

This command also creates a YAML configuration file in /<path_to_ccoctl_output_dir>/manifests/cluster-authentication-02-config.yaml. This file sets the issuer URL field for the service account tokens that the cluster generates, so that the AWS IAM identity provider trusts the tokens.

3. Create IAM roles for each component in the cluster:

a. Set a $RELEASE_IMAGE variable with the release image from your installation file by running the following command:

   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')

b. Extract the list of CredentialsRequest objects from the OpenShift Container Platform release image:

   $ oc adm release extract \
   --from=$RELEASE_IMAGE \ 
   --credentials-requests \ 
   --included \  
   --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \ 
   --to=<path_to_directory_for_credentials_requests>  

1. The --included parameter includes only the manifests that your specific cluster configuration requires.
2. Specify the location of the install-config.yaml file.
3. Specify the path to the directory where you want to store the CredentialsRequest objects. If the specified directory does not exist, this command creates it.
c. Use the `ccoctl` tool to process all `CredentialsRequest` objects by running the following command:

```bash
$ ccoctl aws create-iam-roles \
  --name=<name> \
  --region=<aws_region> \
  --credentials-requests-dir=<path_to_credentials_requests_directory> \
```

**NOTE**

For AWS environments that use alternative IAM API endpoints, such as GovCloud, you must also specify your region with the `--region` parameter.

If your cluster uses Technology Preview features that are enabled by the `TechPreviewNoUpgrade` feature set, you must include the `--enable-tech-preview` parameter.

For each `CredentialsRequest` object, `ccoctl` creates an IAM role with a trust policy that is tied to the specified OIDC identity provider, and a permissions policy as defined in each `CredentialsRequest` object from the OpenShift Container Platform release image.

**Verification**

- To verify that the OpenShift Container Platform secrets are created, list the files in the `<path_to_ccoctl_output_dir>/manifests` directory:

```bash
$ ls <path_to_ccoctl_output_dir>/manifests
```

**Example output**

```
cluster-authentication-02-config.yaml
openshift-cloud-credential-operator-cloud-credential-operator-iam-ro-creds-credentials.yaml
openshift-cloud-network-config-controller-cloud-credentials-credentials.yaml
openshift-cluster-api-capa-manager-bootstrap-credentials-credentials.yaml
openshift-cluster-csi-drivers-ebs-cloud-credentials-credentials.yaml
openshift-image-registry-installer-cloud-credentials-credentials.yaml
openshift-ingress-operator-cloud-credentials-credentials.yaml
openshift-machine-api-aws-cloud-credentials-credentials.yaml
```

You can verify that the IAM roles are created by querying AWS. For more information, refer to AWS documentation on listing IAM roles.

**6.4.8.2.3. Incorporating the Cloud Credential Operator utility manifests**

To implement short-term security credentials managed outside the cluster for individual components, you must move the manifest files that the Cloud Credential Operator utility (`ccoctl`) created to the correct directories for the installation program.

**Prerequisites**

- You have configured an account with the cloud platform that hosts your cluster.
You have configured the Cloud Credential Operator utility (`ccoctl`).

You have created the cloud provider resources that are required for your cluster with the `ccoctl` utility.

**Procedure**

1. If you did not set the `credentialsMode` parameter in the `install-config.yaml` configuration file to `Manual`, modify the value as shown:

   **Sample configuration file snippet**

   ```yaml
   apiVersion: v1
   baseDomain: example.com
   credentialsMode: Manual
   # ...
   ```

2. If you have not previously created installation manifest files, do so by running the following command:

   ```sh
   $ openshift-install create manifests --dir <installation_directory>
   ```

   where `<installation_directory>` is the directory in which the installation program creates files.

3. Copy the manifests that the `ccoctl` utility generated to the `manifests` directory that the installation program created by running the following command:

   ```sh
   $ cp /<path_to_ccoctl_output_dir>/manifests/* ./manifests/
   ```

4. Copy the private key that the `ccoctl` utility generated in the `tls` directory to the installation directory by running the following command:

   ```sh
   $ cp -a /<path_to_ccoctl_output_dir>/tls .
   ```

**6.4.9. Deploying the cluster**

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

**Prerequisites**

- You have configured an account with the cloud platform that hosts your cluster.
- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.
Procedure

1. Change to the directory that contains the installation program and initialize the cluster deployment:

   $ ./openshift-install create cluster --dir <installation_directory> \ 1
   --log-level=info 2

   1 For `<installation_directory>`, specify the location of your customized `./install-config.yaml` file.
   2 To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

2. Optional: Remove or disable the `AdministratorAccess` policy from the IAM account that you used to install the cluster.

   **NOTE**
   The elevated permissions provided by the `AdministratorAccess` policy are required only during installation.

Verification

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the `kubeadmin` user.

- Credential information also outputs to `<installation_directory>/openshift_install.log`.

   **IMPORTANT**
   Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

Example output

...  
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

### 6.4.10. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

   ```
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```
   $ oc whoami
   ```

   **Example output**

   ```
   system:admin
   ```

### 6.4.11. Logging in to the cluster by using the web console

The `kubeadmin` user exists by default after an OpenShift Container Platform installation. You can log in to your cluster as the `kubeadmin` user by using the OpenShift Container Platform web console.

**Prerequisites**
- You have access to the installation host.
- You completed a cluster installation and all cluster Operators are available.

**Procedure**

1. Obtain the password for the `kubeadmin` user from the `kubeadmin-password` file on the installation host:

   ```
   $ cat <installation_directory>/auth/kubeadmin-password
   ```

   **NOTE**

   Alternatively, you can obtain the `kubeadmin` password from the `<installation_directory>/openshift_install.log` log file on the installation host.

2. List the OpenShift Container Platform web console route:

   ```
   $ oc get routes -n openshift-console | grep 'console-openshift'
   ```

   **NOTE**

   Alternatively, you can obtain the OpenShift Container Platform route from the `<installation_directory>/openshift_install.log` log file on the installation host.

   **Example output**

   ```
   console console-openshift-console.apps.<cluster_name>.<base_domain> console
   https reencrypt/Redirect None
   ```

3. Navigate to the route detailed in the output of the preceding command in a web browser and log in as the `kubeadmin` user.

**Additional resources**

- See [Accessing the web console](#) for more details about accessing and understanding the OpenShift Container Platform web console.

### 6.4.12. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager Hybrid Cloud Console](#).

After you confirm that your [OpenShift Cluster Manager Hybrid Cloud Console](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**
6.4.13. Next steps

- Validating an installation.
- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- If necessary, you can remove cloud provider credentials.

6.5. INSTALLING A CLUSTER ON AWS WITH NETWORK CUSTOMIZATIONS

In OpenShift Container Platform version 4.14, you can install a cluster on Amazon Web Services (AWS) with customized network configuration options. By customizing your network configuration, your cluster can coexist with existing IP address allocations in your environment and integrate with existing MTU and VXLAN configurations.

You must set most of the network configuration parameters during installation, and you can modify only `kubeProxy` configuration parameters in a running cluster.

6.5.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You configured an AWS account to host the cluster.

**IMPORTANT**

If you have an AWS profile stored on your computer, it must not use a temporary session token that you generated while using a multi-factor authentication device. The cluster continues to use your current AWS credentials to create AWS resources for the entire life of the cluster, so you must use key-based, long-term credentials. To generate appropriate keys, see Managing Access Keys for IAM Users in the AWS documentation. You can supply the keys when you run the installation program.

- If you use a firewall, you configured it to allow the sites that your cluster requires access to.

6.5.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager Hybrid Cloud Console to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 6.5.3. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the `core` user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user `core`. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>
   ```

   Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.
NOTE

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

$ cat /path/to/file.pub

For example, run the following to view the ~/.ssh/id_ed25519.pub public key:

$ cat ~/.ssh/id_ed25519.pub

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the ./openshift-install gather command.

NOTE

On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.

a. If the ssh-agent process is not already running for your local user, start it as a background task:

$ eval "$(ssh-agent -s)"

Example output

Agent pid 31874

NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the ssh-agent:

$ ssh-add /path/to/file

Specify the path and file name for your SSH private key, such as ~/.ssh/id_ed25519

Example output

Identity added: /home/<you>/path/to/file (<computer_name>)

Next steps
- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

6.5.4. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

**IMPORTANT**

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   `$ tar -xvf openshift-install-linux.tar.gz`

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

6.5.5. Network configuration phases

There are two phases prior to OpenShift Container Platform installation where you can customize the network configuration.

Phase 1
You can customize the following network-related fields in the `install-config.yaml` file before you create the manifest files:

- `networking.networkType`
- `networking.clusterNetwork`
- `networking.serviceNetwork`
- `networking.machineNetwork`

For more information on these fields, refer to `Installation configuration parameters`.

**NOTE**

Set the `networking.machineNetwork` to match the CIDR that the preferred NIC resides in.

**IMPORTANT**

The CIDR range `172.17.0.0/16` is reserved by libVirt. You cannot use this range or any range that overlaps with this range for any networks in your cluster.

**Phase 2**

After creating the manifest files by running `openshift-install create manifests`, you can define a customized Cluster Network Operator manifest with only the fields you want to modify. You can use the manifest to specify advanced network configuration.

You cannot override the values specified in phase 1 in the `install-config.yaml` file during phase 2. However, you can further customize the network plugin during phase 2.

### 6.5.6. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Amazon Web Services (AWS).

**Prerequisites**

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Create the `install-config.yaml` file.
   
   a. Change to the directory that contains the installation program and run the following command:

   ```bash
   $ ./openshift-install create install-config --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the directory name to store the files that the installation program creates.
When specifying the directory:

- Verify that the directory has the `execute` permission. This permission is required to run Terraform binaries under the installation directory.

- Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

**NOTE**

Always delete the `~/.powervs` directory to avoid reusing a stale configuration. Run the following command:

```
$ rm -rf ~/.powervs
```

b. At the prompts, provide the configuration details for your cloud:

i. Optional: Select an SSH key to use to access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

ii. Select AWS as the platform to target.

iii. If you do not have an Amazon Web Services (AWS) profile stored on your computer, enter the AWS access key ID and secret access key for the user that you configured to run the installation program.

iv. Select the AWS region to deploy the cluster to.

v. Select the base domain for the Route 53 service that you configured for your cluster.

vi. Enter a descriptive name for your cluster.

2. Modify the `install-config.yaml` file. You can find more information about the available parameters in the "Installation configuration parameters" section.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

**IMPORTANT**

The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

Additional resources

- Installation configuration parameters for AWS
6.5.6.1. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

### Table 6.2. Minimum resource requirements

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS, RHEL 8.6 and later [3]</td>
<td>2</td>
<td>8 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
</tbody>
</table>

1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or hyperthreading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: (threads per core × cores) × sockets = vCPUs.

2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.

3. As with all user-provisioned installations, if you choose to use RHEL compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and has been removed in OpenShift Container Platform 4.10 and later.

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

**Additional resources**

- Optimizing storage

6.5.6.2. Tested instance types for AWS

The following Amazon Web Services (AWS) instance types have been tested with OpenShift Container Platform.

**NOTE**

Use the machine types included in the following charts for your AWS instances. If you use an instance type that is not listed in the chart, ensure that the instance size you use matches the minimum resource requirements that are listed in "Minimum resource requirements for cluster installation".
Example 6.21. Machine types based on 64-bit x86 architecture

- c4.*
- c5.*
- c5a.*
- i3.*
- m4.*
- m5.*
- m5a.*
- m6i.*
- r4.*
- r5.*
- r5a.*
- r6i.*
- t3.*
- t3a.*

6.5.6.3. Tested instance types for AWS on 64-bit ARM infrastructures

The following Amazon Web Services (AWS) 64-bit ARM instance types have been tested with OpenShift Container Platform.

NOTE

Use the machine types included in the following charts for your AWS ARM instances. If you use an instance type that is not listed in the chart, ensure that the instance size you use matches the minimum resource requirements that are listed in "Minimum resource requirements for cluster installation".

Example 6.22. Machine types based on 64-bit ARM architecture

- c6g.*
- m6g.*

6.5.6.4. Sample customized install-config.yaml file for AWS

You can customize the installation configuration file (install-config.yaml) to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.
IMPORTANT

This sample YAML file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program and modify it.

```yaml
apiVersion: v1
baseDomain: example.com
credentialsMode: Mint
controlPlane:
  hyperthreading: Enabled
  name: master
  platform:
    aws:
      lbType: NLB
      zones:
        - us-west-2a
        - us-west-2b
      rootVolume:
        iops: 4000
        size: 500
        type: io1
      metadataService:
        authentication: Optional
        type: m6i.xlarge
      replicas: 3
      compute:
        - hyperthreading: Enabled
          name: worker
          platform:
            aws:
              rootVolume:
                iops: 2000
                size: 500
                type: io1
              metadataService:
                authentication: Optional
                type: c5.4xlarge
              zones:
                - us-west-2c
              replicas: 3
      metadata:
        name: test-cluster
        networking:
        clusterNetwork:
          - cidr: 10.128.0.0/14
            hostPrefix: 23
          machineNetwork:
            - cidr: 10.0.0.0/16
          networkType: OVNKubernetes
          serviceNetwork:
            - 172.30.0.0/16
        platform:
          aws:
            region: us-west-2
```
propagateUserTags: true 16
userTags:
  adminContact: jdoe
costCenter: 7536
amiID: ami-0c5d3e03c0ab9b19a 17
serviceEndpoints: 18
  - name: ec2
    url: https://vpce-id.ec2.us-west-2.vpce.amazonaws.com
fips: false 19
sshKey: ssh-ed25519 AAAA...
pullSecret: '{"auths": ...}' 20

1 12 15 21 Required. The installation program prompts you for this value.

2 Optional: Add this parameter to force the Cloud Credential Operator (CCO) to use the specified mode. By default, the CCO uses the root credentials in the kube-system namespace to dynamically try to determine the capabilities of the credentials. For details about CCO modes, see the "About the Cloud Credential Operator" section in the Authentication and authorization guide.

3 8 13 16 If you do not provide these parameters and values, the installation program provides the default value.

4 The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, -, and the first line of the controlPlane section must not. Only one control plane pool is used.

5 9 Whether to enable or disable simultaneous multithreading, or hyperthreading. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to Disabled. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

IMPORTANT

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger instance types, such as m4.2xlarge or m5.2xlarge, for your machines if you disable simultaneous multithreading.

6 10 To configure faster storage for etcd, especially for larger clusters, set the storage type as io1 and set iops to 2000.

7 11 Whether to require the Amazon EC2 Instance Metadata Service v2 (IMDSv2). To require IMDSv2, set the parameter value to Required. To allow the use of both IMDSv1 and IMDSv2, set the parameter value to Optional. If no value is specified, both IMDSv1 and IMDSv2 are allowed.

NOTE

The IMDS configuration for control plane machines that is set during cluster installation can only be changed by using the AWS CLI. The IMDS configuration for compute machines can be changed by using compute machine sets.

14 The cluster network plugin to install. The supported values are OVNKubernetes and OpenShiftSDN. The default value is OVNKubernetes.
The ID of the AMI used to boot machines for the cluster. If set, the AMI must belong to the same region as the cluster.

The AWS service endpoints. Custom endpoints are required when installing to an unknown AWS region. The endpoint URL must use the HTTPS protocol and the host must trust the certificate.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see Installing the system in FIPS mode. When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures.

You can optionally provide the **sshKey** value that you use to access the machines in your cluster.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

### 6.5.6.5. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

**Prerequisites**

- You have an existing **install-config.yaml** file.

- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object’s **spec.noProxy** field to bypass the proxy if necessary.
NOTE

The Proxy object status.noProxy field is populated with the values of the networking.machineNetwork[].cidr, networking.clusterNetwork[].cidr, and networking.serviceNetwork[] fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object status.noProxy field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your install-config.yaml file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
     httpProxy: http://<username>:<pswd>@<ip>:<port>  
     httpsProxy: https://<username>:<pswd>@<ip>:<port>  
   noProxy: ec2.<aws_region>.amazonaws.com,elasticloadbalancing.<aws_region>.amazonaws.com,s3.<aws_region>.amazonaws.com  
   additionalTrustBundle: |
   -----BEGIN CERTIFICATE-----
   <MY_TRUSTED_CA_CERT>
   -----END CERTIFICATE-----
   additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle>
   ```

   - **1** A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.
   - **2** A proxy URL to use for creating HTTPS connections outside the cluster.
   - **3** A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations. If you have added the Amazon EC2 Elastic Load Balancing and S3 VPC endpoints to your VPC, you must add these endpoints to the noProxy field.
   - **4** If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the trustedCA field of the Proxy object. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.
   - **5** Optional: The policy to determine the configuration of the Proxy object to reference the user-ca-bundle config map in the trustedCA field. The allowed values are Proxyonly and Always. Use Proxyonly to reference the user-ca-bundle config map only when http/https proxy is configured. Use Always to always reference the user-ca-bundle config map. The default value is Proxyonly.
NOTE

The installation program does not support the proxy `readinessEndpoints` field.

NOTE

If the installer times out, restart and then complete the deployment by using the `wait-for` command of the installer. For example:

```
$ ./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

NOTE

Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

6.5.7. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (`oc`) to interact with OpenShift Container Platform from a command-line interface. You can install `oc` on Linux, Windows, or macOS.

IMPORTANT

If you installed an earlier version of `oc`, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of `oc`.

Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (`oc`) binary on Linux by using the following procedure.

Procedure

2. Select the architecture from the `Product Variant` drop-down list.

3. Select the appropriate version from the `Version` drop-down list.

4. Click `Download Now` next to the `OpenShift v4.14 Linux Client` entry and save the file.

5. Unpack the archive:

   ```
   $ tar xvf <file>
   ```

6. Place the `oc` binary in a directory that is on your `PATH`.
   To check your `PATH`, execute the following command:
Installing the OpenShift CLI on Windows
You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

Procedure

2. Select the appropriate version from the Version drop-down list.
3. Click Download Now next to the OpenShift v4.14 Windows Client entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the oc binary to a directory that is on your PATH.
   To check your PATH, open the command prompt and execute the following command:

   $ echo $PATH

   C:> path

Verification

• After you install the OpenShift CLI, it is available using the oc command:

   $ oc <command>

Installing the OpenShift CLI on macOS
You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.

Procedure

2. Select the appropriate version from the Version drop-down list.
3. Click Download Now next to the OpenShift v4.14 macOS Client entry and save the file.
4. Unpack and unzip the archive.
5. Move the oc binary to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:

   $ echo $PATH
   $ oc <command>

   C:> path

Verification

• After you install the OpenShift CLI, it is available using the oc command:

   C:> oc <command>

NOTE

For macOS arm64, choose the OpenShift v4.14 macOS arm64 Client entry.
After you install the OpenShift CLI, it is available using the `oc` command:

```bash
$ oc <command>
```

**6.5.8. Alternatives to storing administrator-level secrets in the kube-system project**

By default, administrator secrets are stored in the `kube-system` project. If you configured the `credentialsMode` parameter in the `install-config.yaml` file to `Manual`, you must use one of the following alternatives:

- To manage long-term cloud credentials manually, follow the procedure in [Manually creating long-term credentials](#).
- To implement short-term credentials that are managed outside the cluster for individual components, follow the procedures in [Configuring an AWS cluster to use short-term credentials](#).

**6.5.8.1. Manually creating long-term credentials**

The Cloud Credential Operator (CCO) can be put into manual mode prior to installation in environments where the cloud identity and access management (IAM) APIs are not reachable, or the administrator prefers not to store an administrator-level credential secret in the cluster `kube-system` namespace.

**Procedure**

1. If you did not set the `credentialsMode` parameter in the `install-config.yaml` configuration file to `Manual`, modify the value as shown:

   ```yaml
   apiVersion: v1
   baseDomain: example.com
   credentialsMode: Manual
   # ...
   ```

2. If you have not previously created installation manifest files, do so by running the following command:

   ```bash
   $ openshift-install create manifests --dir <installation_directory>
   ```

   where `<installation_directory>` is the directory in which the installation program creates files.

3. Set a `$RELEASE_IMAGE` variable with the release image from your installation file by running the following command:

   ```bash
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
   ```
4. Extract the list of `CredentialsRequest` custom resources (CRs) from the OpenShift Container Platform release image by running the following command:

```bash
$ oc adm release extract \n  --from=$RELEASE_IMAGE \n  --credentials-requests \n  --included  \
  --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \n  --to=<path_to_directory_for_credentials_requests>
```

1. The `--included` parameter includes only the manifests that your specific cluster configuration requires.

2. Specify the location of the `install-config.yaml` file.

3. Specify the path to the directory where you want to store the `CredentialsRequest` objects. If the specified directory does not exist, this command creates it.

This command creates a YAML file for each `CredentialsRequest` object.

**Sample `CredentialsRequest` object**

```yaml
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
  name: <component_credentials_request>
  namespace: openshift-cloud-credential-operator
...
spec:
  providerSpec:
    apiVersion: cloudcredential.openshift.io/v1
    kind: AWSProviderSpec
    statementEntries:
      - effect: Allow
        action:
          - iam:GetUser
          - iam:GetUserPolicy
          - iam:ListAccessKeys
        resource: "*
...
```

5. Create YAML files for secrets in the `openshift-install` manifests directory that you generated previously. The secrets must be stored using the namespace and secret name defined in the `spec.secretRef` for each `CredentialsRequest` object.

**Sample `CredentialsRequest` object with secrets**

```yaml
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
  name: <component_credentials_request>
  namespace: openshift-cloud-credential-operator
...
spec:
```
Before upgrading a cluster that uses manually maintained credentials, you must ensure that the CCO is in an upgradeable state.

### 6.5.8.2. Configuring an AWS cluster to use short-term credentials

To install a cluster that is configured to use the AWS Security Token Service (STS), you must configure the CCO utility and create the required AWS resources for your cluster.

#### 6.5.8.2.1. Configuring the Cloud Credential Operator utility

To create and manage cloud credentials from outside of the cluster when the Cloud Credential Operator (CCO) is operating in manual mode, extract and prepare the CCO utility (**ccoctl**) binary.

#### NOTE

The **ccoctl** utility is a Linux binary that must run in a Linux environment.

**Prerequisites**

- You have access to an OpenShift Container Platform account with cluster administrator access.
- You have installed the OpenShift CLI (**oc**).
- You have created an AWS account for the **ccoctl** utility to use with the following permissions:

```yaml
Example 6.23. Required AWS permissions
```

```yaml
providerSpec:
  apiVersion: cloudcredential.openshift.io/v1
  kind: AWSProviderSpec
  statementEntries:
    - effect: Allow
      action:
        - s3:CreateBucket
        - s3:DeleteBucket
      resource: "*"
    ...
secretRef:
  name: <component_secret>
  namespace: <component_namespace>
  ...
```

**Sample Secret object**

```yaml
apiVersion: v1
kind: Secret
metadata:
  name: <component_secret>
  namespace: <component_namespace>
data:
  aws_access_key_id: <base64_encoded_aws_access_key_id>
  aws_secret_access_key: <base64_encoded_aws_secret_access_key>
Required `iam` permissions

- `iam:CreateOpenIDConnectProvider`
- `iam:CreateRole`
- `iam:DeleteOpenIDConnectProvider`
- `iam:DeleteRole`
- `iam:DeleteRolePolicy`
- `iam:GetOpenIDConnectProvider`
- `iam:GetRole`
- `iam:GetUser`
- `iam:ListOpenIDConnectProviders`
- `iam:ListRolePolicies`
- `iam:ListRoles`
- `iam:PutRolePolicy`
- `iam:TagOpenIDConnectProvider`
- `iam:TagRole`

Required `s3` permissions

- `s3:CreateBucket`
- `s3:DeleteBucket`
- `s3:DeleteObject`
- `s3:GetBucketAcl`
- `s3:GetBucketTagging`
- `s3:GetObject`
- `s3:GetObjectAcl`
- `s3:GetObjectTagging`
- `s3:ListBucket`
- `s3:PutBucketAcl`
- `s3:PutBucketPolicy`
- `s3:PutBucketPublicAccessBlock`
- `s3:PutBucketTagging`
If you plan to store the OIDC configuration in a private S3 bucket that is accessed by the IAM identity provider through a public CloudFront distribution URL, the AWS account that runs the `ccoctl` utility requires the following additional permissions:

**Example 6.24. Additional permissions for a private S3 bucket with CloudFront**

- `cloudfront:CreateCloudFrontOriginAccessIdentity`
- `cloudfront:CreateDistribution`
- `cloudfront:DeleteCloudFrontOriginAccessIdentity`
- `cloudfront:DeleteDistribution`
- `cloudfront:GetCloudFrontOriginAccessIdentity`
- `cloudfront:GetCloudFrontOriginAccessIdentityConfig`
- `cloudfront:GetDistribution`
- `cloudfront:TagResource`
- `cloudfront:UpdateDistribution`

**NOTE**

These additional permissions support the use of the `--create-private-s3-bucket` option when processing credentials requests with the `ccoctl aws create-all` command.

**Procedure**

1. Obtain the OpenShift Container Platform release image by running the following command:

   ```bash
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
   ```

2. Obtain the CCO container image from the OpenShift Container Platform release image by running the following command:
$ CCO_IMAGE=$(oc adm release info --image-for="cloud-credential-operator"
$RELEASE_IMAGE -a ~/.pull-secret)

NOTE
Ensure that the architecture of the $RELEASE_IMAGE matches the architecture of the environment in which you will use the ccoctl tool.

3. Extract the ccoctl binary from the CCO container image within the OpenShift Container Platform release image by running the following command:

$ oc image extract $CCO_IMAGE --file="/usr/bin/ccoctl" -a ~/.pull-secret

4. Change the permissions to make ccoctl executable by running the following command:

$ chmod 775 ccoctl

Verification
- To verify that ccoctl is ready to use, display the help file by running the following command:

$ ccoctl --help

Output of ccoctl --help

OpenShift credentials provisioning tool

Usage:
ccoctl [command]

Available Commands:
alibabacloud Manage credentials objects for alibaba cloud
aws Manage credentials objects for AWS cloud
azure Manage credentials objects for Azure
gcp Manage credentials objects for Google cloud
help Help about any command
ibmcloud Manage credentials objects for IBM Cloud
nutanix Manage credentials objects for Nutanix

Flags:
-h, --help help for ccoctl

Use "ccoctl [command] --help" for more information about a command.

6.5.8.2.2. Creating AWS resources with the Cloud Credential Operator utility

You have the following options when creating AWS resources:

- You can use the ccoctl aws create-all command to create the AWS resources automatically. This is the quickest way to create the resources. See Creating AWS resources with a single command.
If you need to review the JSON files that the `ccoctl` tool creates before modifying AWS resources, or if the process the `ccoctl` tool uses to create AWS resources automatically does not meet the requirements of your organization, you can create the AWS resources individually. See Creating AWS resources individually.

### 6.5.8.2.2.1. Creating AWS resources with a single command

If the process the `ccoctl` tool uses to create AWS resources automatically meets the requirements of your organization, you can use the `ccoctl aws create-all` command to automate the creation of AWS resources.

Otherwise, you can create the AWS resources individually. For more information, see "Creating AWS resources individually".

**NOTE**

By default, `ccoctl` creates objects in the directory in which the commands are run. To create the objects in a different directory, use the `--output-dir` flag. This procedure uses `<path_to_ccoctl_output_dir>` to refer to this directory.

### Prerequisites

You must have:

- Extracted and prepared the `ccoctl` binary.

### Procedure

1. Set a `$RELEASE_IMAGE` variable with the release image from your installation file by running the following command:

   ```bash
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
   ```

2. Extract the list of `CredentialsRequest` objects from the OpenShift Container Platform release image by running the following command:

   ```bash
   $ oc adm release extract \
     --from=$RELEASE_IMAGE \
     --credentials-requests \
     --included \
     --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \
     --to=<path_to_directory_for_credentials_requests>
   ```

   **1** The `--included` parameter includes only the manifests that your specific cluster configuration requires.

   **2** Specify the location of the `install-config.yaml` file.

   **3** Specify the path to the directory where you want to store the `CredentialsRequest` objects. If the specified directory does not exist, this command creates it.
3. Use the `ccoctl` tool to process all `CredentialsRequest` objects by running the following command:

```
$ ccoctl aws create-all  
  --name=<name>  
  --region=<aws_region>  
  --credentials-requests-dir=<path_to_credentials_requests_directory>  
  --output-dir=<path_to_ccoctl_output_dir>  
  --create-private-s3-bucket
```

1. Specify the name used to tag any cloud resources that are created for tracking.
2. Specify the AWS region in which cloud resources will be created.
3. Specify the directory containing the files for the component `CredentialsRequest` objects.
4. Optional: Specify the directory in which you want the `ccoctl` utility to create objects. By default, the utility creates objects in the directory in which the commands are run.
5. Optional: By default, the `ccoctl` utility stores the OpenID Connect (OIDC) configuration files in a public S3 bucket and uses the S3 URL as the public OIDC endpoint. To store the OIDC configuration in a private S3 bucket that is accessed by the IAM identity provider through a public CloudFront distribution URL instead, use the `--create-private-s3-bucket` parameter.

**NOTE**

If your cluster uses Technology Preview features that are enabled by the `TechPreviewNoUpgrade` feature set, you must include the `--enable-tech-preview` parameter.

**Verification**

- To verify that the OpenShift Container Platform secrets are created, list the files in the `<path_to_ccoctl_output_dir>/manifests` directory:

```
$ ls <path_to_ccoctl_output_dir>/manifests
```

**Example output**

```
cluster-authentication-02-config.yaml
openshift-cloud-credential-operator-cloud-credential-operator-iam-ro-creds-credentials.yaml
openshift-cloud-network-config-controller-cloud-credentials-credentials.yaml
openshift-cluster-api-capa-manager-bootstrap-credentials-credentials.yaml
openshift-cluster-csi-drivers-ebs-cloud-credentials-credentials.yaml
openshift-image-registry-installer-cloud-credentials-credentials.yaml
openshift-ingress-operator-cloud-credentials-credentials.yaml
openshift-machine-api-aws-cloud-credentials-credentials.yaml
```
You can verify that the IAM roles are created by querying AWS. For more information, refer to AWS documentation on listing IAM roles.

6.5.8.2.2.2. Creating AWS resources individually

You can use the ccoctl tool to create AWS resources individually. This option might be useful for an organization that shares the responsibility for creating these resources among different users or departments.

Otherwise, you can use the ccoctl aws create-all command to create the AWS resources automatically. For more information, see "Creating AWS resources with a single command".

NOTE

By default, ccoctl creates objects in the directory in which the commands are run. To create the objects in a different directory, use the --output-dir flag. This procedure uses <path_to_ccoctl_output_dir> to refer to this directory.

Some ccoctl commands make AWS API calls to create or modify AWS resources. You can use the --dry-run flag to avoid making API calls. Using this flag creates JSON files on the local file system instead. You can review and modify the JSON files and then apply them with the AWS CLI tool using the --cli-input-json parameters.

Prerequisites

- Extract and prepare the ccoctl binary.

Procedure

1. Generate the public and private RSA key files that are used to set up the OpenID Connect provider for the cluster by running the following command:

   ```
   $ ccoctl aws create-key-pair
   ```

   Example output

   ```
   2021/04/13 11:01:02 Generating RSA keypair
   2021/04/13 11:01:03 Writing private key to /<path_to_ccoctl_output_dir>/serviceaccount-signer.private
   2021/04/13 11:01:03 Writing public key to /<path_to_ccoctl_output_dir>/serviceaccount-signer.public
   2021/04/13 11:01:03 Copying signing key for use by installer
   ```

   where serviceaccount-signer.private and serviceaccount-signer.public are the generated key files.

   This command also creates a private key that the cluster requires during installation in /<path_to_ccoctl_output_dir>/tls/bound-service-account-signing-key.key.

2. Create an OpenID Connect identity provider and S3 bucket on AWS by running the following command:

   ```
   $ ccoctl aws create-identity-provider \
   --name=<name>
   ```
<name> is the name used to tag any cloud resources that are created for tracking.

/aws-region> is the AWS region in which cloud resources will be created.

/path_to_ccoctl_output_dir> is the path to the public key file that the `ccoctl aws create-key-pair` command generated.

Example output

```
2021/04/13 11:16:09 Bucket <name>-oidc created
2021/04/13 11:16:10 OpenID Connect discovery document in the S3 bucket <name>-oidc at .well-known/openid-configuration updated
2021/04/13 11:16:10 Reading public key
2021/04/13 11:16:10 JSON web key set (JWKS) in the S3 bucket <name>-oidc at keys.json updated
```

where openid-configuration is a discovery document and keys.json is a JSON web key set file.

This command also creates a YAML configuration file in

`/path_to_ccoctl_output_dir>/manifests/cluster-authentication-02-config.yaml`. This file sets the issuer URL field for the service account tokens that the cluster generates, so that the AWS IAM identity provider trusts the tokens.

3. Create IAM roles for each component in the cluster:

   a. Set a `$RELEASE_IMAGE` variable with the release image from your installation file by running the following command:

   ```bash
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
   ```

   b. Extract the list of CredentialsRequest objects from the OpenShift Container Platform release image:

   ```bash
   $ oc adm release extract \ 
   --from=$RELEASE_IMAGE \ 
   --credentials-requests \ 
   --included \ 
   --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \ 
   --to=<path_to_directory_for_credentials_requests>
   ```

   The `--included` parameter includes only the manifests that your specific cluster configuration requires.

   Specify the location of the `install-config.yaml` file.

   Specify the path to the directory where you want to store the CredentialsRequest objects. If the specified directory does not exist, this command creates it.
c. Use the `ccoctl` tool to process all `CredentialsRequest` objects by running the following command:

```
$ ccoctl aws create-iam-roles \
  --name=<name> \
  --region=<aws_region> \
  --credentials-requests-dir=<path_to_credentials_requests_directory> \
```

**NOTE**

For AWS environments that use alternative IAM API endpoints, such as GovCloud, you must also specify your region with the `--region` parameter.

If your cluster uses Technology Preview features that are enabled by the `TechPreviewNoUpgrade` feature set, you must include the `--enable-tech-preview` parameter.

For each `CredentialsRequest` object, `ccoctl` creates an IAM role with a trust policy that is tied to the specified OIDC identity provider, and a permissions policy as defined in each `CredentialsRequest` object from the OpenShift Container Platform release image.

**Verification**

- To verify that the OpenShift Container Platform secrets are created, list the files in the `<path_to_ccoctl_output_dir>/manifests` directory:

  ```
  $ ls <path_to_ccoctl_output_dir>/manifests
  ```

**Example output**

- `cluster-authentication-02-config.yaml`
- `openshift-cloud-credential-operator-cloud-credential-operator-iam-ro-creds-credentials.yaml`
- `openshift-cloud-network-config-controller-cloud-credentials-credentials.yaml`
- `openshift-cluster-api-capa-manager-bootstrap-credentials-credentials.yaml`
- `openshift-cluster-csi-drivers-ebs-cloud-credentials-credentials.yaml`
- `openshift-image-registry-installer-cloud-credentials-credentials.yaml`
- `openshift-ingress-operator-cloud-credentials-credentials.yaml`
- `openshift-machine-api-aws-cloud-credentials-credentials.yaml`

You can verify that the IAM roles are created by querying AWS. For more information, refer to AWS documentation on listing IAM roles.

6.5.8.2.3. Incorporating the Cloud Credential Operator utility manifests

To implement short-term security credentials managed outside the cluster for individual components, you must move the manifest files that the Cloud Credential Operator utility (`ccoctl`) created to the correct directories for the installation program.

**Prerequisites**

- You have configured an account with the cloud platform that hosts your cluster.
• You have configured the Cloud Credential Operator utility (ccoctl).

• You have created the cloud provider resources that are required for your cluster with the ccoctl utility.

Procedure

1. If you did not set the `credentialsMode` parameter in the `install-config.yaml` configuration file to `Manual`, modify the value as shown:

Sample configuration file snippet

   ```yaml
   apiVersion: v1
   baseDomain: example.com
   credentialsMode: Manual
   # ...
   ```

2. If you have not previously created installation manifest files, do so by running the following command:

   ```bash
   $ openshift-install create manifests --dir <installation_directory>
   ```

   where `<installation_directory>` is the directory in which the installation program creates files.

3. Copy the manifests that the ccoctl utility generated to the `manifests` directory that the installation program created by running the following command:

   ```bash
   $ cp /<path_to_ccoctl_output_dir>/manifests/* ./manifests/
   ```

4. Copy the private key that the ccoctl utility generated in the `tls` directory to the installation directory by running the following command:

   ```bash
   $ cp -a /<path_to_ccoctl_output_dir>/tls ./
   ```

6.5.9. Cluster Network Operator configuration

The configuration for the cluster network is specified as part of the Cluster Network Operator (CNO) configuration and stored in a custom resource (CR) object that is named `cluster`. The CR specifies the fields for the `Network` API in the `operator.openshift.io` API group.

The CNO configuration inherits the following fields during cluster installation from the `Network` API in the `Network.config.openshift.io` API group and these fields cannot be changed:

- `clusterNetwork`
  - IP address pools from which pod IP addresses are allocated.

- `serviceNetwork`
  - IP address pool for services.

- `defaultNetwork.type`
  - Cluster network plugin, such as OpenShift SDN or OVN-Kubernetes.

You can specify the cluster network plugin configuration for your cluster by setting the fields for the `defaultNetwork` object in the CNO object named `cluster`. 
6.5.9.1. Cluster Network Operator configuration object

The fields for the Cluster Network Operator (CNO) are described in the following table:

Table 6.3. Cluster Network Operator configuration object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>metadata.name</td>
<td>string</td>
<td>The name of the CNO object. This name is always <code>cluster</code>.</td>
</tr>
</tbody>
</table>
| spec.clusterNetwork  | array | A list specifying the blocks of IP addresses from which pod IP addresses are allocated and the subnet prefix length assigned to each individual node in the cluster. For example:

```yaml
spec:
  clusterNetwork:
    - cidr: 10.128.0.0/19
      hostPrefix: 23
    - cidr: 10.128.32.0/19
      hostPrefix: 23
```

You can customize this field only in the `install-config.yaml` file before you create the manifests. The value is read-only in the manifest file.

| spec.serviceNetwork  | array | A block of IP addresses for services. The OpenShift SDN and OVN-Kubernetes network plugins support only a single IP address block for the service network. For example:

```yaml
spec:
  serviceNetwork:
    - 172.30.0.0/14
```

You can customize this field only in the `install-config.yaml` file before you create the manifests. The value is read-only in the manifest file.

| spec.defaultNetwork  | object| Configures the network plugin for the cluster network.                                                                                   |
| spec.kubeProxyConfig | object| The fields for this object specify the kube-proxy configuration. If you are using the OVN-Kubernetes cluster network plugin, the kube-proxy configuration has no effect. |

defaultNetwork object configuration

The values for the `defaultNetwork` object are defined in the following table:

Table 6.4. defaultNetwork object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
Either **OpenShiftSDN** or **OVNKubernetes**. The Red Hat OpenShift Networking network plugin is selected during installation. This value cannot be changed after cluster installation.

**NOTE**

OpenShift Container Platform uses the OVN-Kubernetes network plugin by default.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>string</td>
<td>Either <strong>OpenShiftSDN</strong> or <strong>OVNKubernetes</strong>. The Red Hat OpenShift Networking network plugin is selected during installation. This value cannot be changed after cluster installation.</td>
</tr>
</tbody>
</table>

**openShiftSDNConfig** object

This object is only valid for the OpenShift SDN network plugin.

**ovnKubernetesConfig** object

This object is only valid for the OVN-Kubernetes network plugin.

### Configuration for the OpenShift SDN network plugin

The following table describes the configuration fields for the OpenShift SDN network plugin:

**Table 6.5. openShiftSDNConfig object**

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mode</td>
<td>string</td>
<td>Configures the network isolation mode for OpenShift SDN. The default value is <strong>NetworkPolicy</strong>. The values <strong>Multitenant</strong> and <strong>Subnet</strong> are available for backwards compatibility with OpenShift Container Platform 3.x but are not recommended. This value cannot be changed after cluster installation.</td>
</tr>
</tbody>
</table>
The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.

If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.

If your cluster requires different MTU values for different nodes, you must set this value to 50 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1450.

This value cannot be changed after cluster installation.

The port to use for all VXLAN packets. The default value is 4789. This value cannot be changed after cluster installation.

If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number.

On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port 9000 and port 9999.

Example OpenShift SDN configuration

```
defaultNetwork:
  type: OpenShiftSDN
  openshiftSDNConfig:
    mode: NetworkPolicy
    mtu: 1450
    vxlanPort: 4789
```
The maximum transmission unit (MTU) for the Geneve (Generic Network Virtualization Encapsulation) overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.

If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.

If your cluster requires different MTU values for different nodes, you must set this value to 100 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1400.

The port to use for all Geneve packets. The default value is 6081. This value cannot be changed after cluster installation.

Specify an empty object to enable IPsec encryption.

Specify a configuration object for customizing network policy audit logging. If unset, the defaults audit log settings are used.

Optional: Specify a configuration object for customizing how egress traffic is sent to the node gateway.

NOTE
While migrating egress traffic, you can expect some disruption to workloads and service traffic until the Cluster Network Operator (CNO) successfully rolls out the changes.
If your existing network infrastructure overlaps with the 100.64.0.0/16 IPv4 subnet, you can specify a different IP address range for internal use by OVN-Kubernetes. You must ensure that the IP address range does not overlap with any other subnet used by your OpenShift Container Platform installation. The IP address range must be larger than the maximum number of nodes that can be added to the cluster. For example, if the `clusterNetwork.cidr` value is 10.128.0.0/14 and the `clusterNetwork.hostPrefix` value is /23, then the maximum number of nodes is $2^{(23-14)}=512$.

This field cannot be changed after installation.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>v4InternalSubnet</td>
<td>If your existing network infrastructure overlaps with the 100.64.0.0/16 IPv4 subnet, you can specify a different IP address range for internal use by OVN-Kubernetes. You must ensure that the IP address range does not overlap with any other subnet used by your OpenShift Container Platform installation. The IP address range must be larger than the maximum number of nodes that can be added to the cluster. For example, if the <code>clusterNetwork.cidr</code> value is 10.128.0.0/14 and the <code>clusterNetwork.hostPrefix</code> value is /23, then the maximum number of nodes is $2^{(23-14)}=512$. This field cannot be changed after installation.</td>
<td>The default value is 100.64.0.0/16.</td>
</tr>
</tbody>
</table>
If your existing network infrastructure overlaps with the fd98::/48 IPv6 subnet, you can specify a different IP address range for internal use by OVN-Kubernetes. You must ensure that the IP address range does not overlap with any other subnet used by your OpenShift Container Platform installation. The IP address range must be larger than the maximum number of nodes that can be added to the cluster. This field cannot be changed after installation.

The default value is fd98::/48.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>v6InternalSubnet</td>
<td>If your existing network infrastructure overlaps with the fd98::/48 IPv6 subnet, you can specify a different IP address range for internal use by OVN-Kubernetes. You must ensure that the IP address range does not overlap with any other subnet used by your OpenShift Container Platform installation. The IP address range must be larger than the maximum number of nodes that can be added to the cluster. This field cannot be changed after installation.</td>
<td>The default value is fd98::/48.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>

</thead>
<tbody>
<tr>
<td>rateLimit</td>
<td>integer</td>
<td>The maximum number of messages to generate every second per node. The default value is 20 messages per second.</td>
</tr>
<tr>
<td>maxFileSize</td>
<td>integer</td>
<td>The maximum size for the audit log in bytes. The default value is 50000000 or 50 MB.</td>
</tr>
</tbody>
</table>
One of the following additional audit log targets:

- **libc**
  - The libc `syslog()` function of the journald process on the host.
- **udp:<host>:<port>**
  - A syslog server. Replace `<host>:<port>` with the host and port of the syslog server.
- **unix:<file>**
  - A Unix Domain Socket file specified by `<file>`.
- **null**
  - Do not send the audit logs to any additional target.

The syslog facility, such as `kern`, as defined by RFC5424. The default value is `local0`.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>destination</strong></td>
<td>string</td>
<td>One of the following additional audit log targets:</td>

</thead>
<tbody>
<tr>
<td><strong>routingViaHost</strong></td>
<td>boolean</td>
<td>Set this field to <code>true</code> to send egress traffic from pods to the host networking stack. For highly-specialized installations and applications that rely on manually configured routes in the kernel routing table, you might want to route egress traffic to the host networking stack. By default, egress traffic is processed in OVN to exit the cluster and is not affected by specialized routes in the kernel routing table. The default value is <code>false</code>.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>This field has an interaction with the Open vSwitch hardware offloading feature. If you set this field to <code>true</code>, you do not receive the performance benefits of the offloading because egress traffic is processed by the host networking stack.</td>
</tr>
<tr>
<td><strong>ipForwarding</strong></td>
<td>object</td>
<td>You can control IP forwarding for all traffic on OVN-Kubernetes managed interfaces by using the <code>ipForwarding</code> specification in the <code>Network</code> resource. Specify <code>Restricted</code> to only allow IP forwarding for Kubernetes related traffic. Specify <code>Global</code> to allow forwarding of all IP traffic. For new installations, the default is <code>Restricted</code>. For updates to OpenShift Container Platform 4.14, the default is <code>Global</code>.</td>
</tr>
</tbody>
</table>

**Table 6.8. gatewayConfig object**

Example OVN-Kubernetes configuration with IPSec enabled

```yaml
defaultNetwork:
  type: OVNKubernetes
  ovnKubernetesConfig:
    mtu: 1400
    genevePort: 6081
    ipsecConfig: {}
```

349
kubeProxyConfig object configuration
The values for the kubeProxyConfig object are defined in the following table:

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>iptablesSyncPeriod</td>
<td>string</td>
<td>The refresh period for iptables rules. The default value is 30s. Valid suffixes include s, m, and h and are described in the Go time package documentation.</td>
</tr>
<tr>
<td>proxyArguments.iptables-min-sync-period</td>
<td>array</td>
<td>The minimum duration before refreshing iptables rules. This field ensures that the refresh does not happen too frequently. Valid suffixes include s, m, and h and are described in the Go time package. The default value is: kubeProxyConfig: proxyArguments: iptables-min-sync-period: - 0s</td>
</tr>
</tbody>
</table>

NOTE
Because of performance improvements introduced in OpenShift Container Platform 4.3 and greater, adjusting the iptablesSyncPeriod parameter is no longer necessary.

6.5.10. Specifying advanced network configuration
You can use advanced network configuration for your network plugin to integrate your cluster into your existing network environment. You can specify advanced network configuration only before you install the cluster.

IMPORTANT
Customizing your network configuration by modifying the OpenShift Container Platform manifest files created by the installation program is not supported. Applying a manifest file that you create, as in the following procedure, is supported.

Prerequisites
- You have created the install-config.yaml file and completed any modifications to it.

Procedure
1. Change to the directory that contains the installation program and create the manifests:
$ ./openshift-install create manifests --dir <installation_directory>  

<installation_directory> specifies the name of the directory that contains the install-config.yaml file for your cluster.

2. Create a stub manifest file for the advanced network configuration that is named cluster-network-03-config.yml in the <installation_directory>/manifests/ directory:

```yaml
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
  name: cluster
spec:
  defaultNetwork:
    openshiftSDNConfig:
      vxlanPort: 4800
```

3. Specify the advanced network configuration for your cluster in the cluster-network-03-config.yml file, such as in the following examples:

**Specify a different VXLAN port for the OpenShift SDN network provider**

```yaml
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
  name: cluster
spec:
  defaultNetwork:
    openshiftSDNConfig:
      vxlanPort: 4800
```

**Enable IPsec for the OVN-Kubernetes network provider**

```yaml
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
  name: cluster
spec:
  defaultNetwork:
    ovnKubernetesConfig:
      ipsecConfig: {}
```

4. Optional: Back up the manifests/cluster-network-03-config.yml file. The installation program consumes the manifests/ directory when you create the Ignition config files.

**NOTE**

For more information on using a Network Load Balancer (NLB) on AWS, see Configuring Ingress cluster traffic on AWS using a Network Load Balancer.

### 6.5.11. Configuring an Ingress Controller Network Load Balancer on a new AWS cluster

You can create an Ingress Controller backed by an AWS Network Load Balancer (NLB) on a new cluster.
Prerequisites

- Create the `install-config.yaml` file and complete any modifications to it.

Procedure

Create an Ingress Controller backed by an AWS NLB on a new cluster.

1. Change to the directory that contains the installation program and create the manifests:

   ```bash
   $ ./openshift-install create manifests --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the name of the directory that contains the `install-config.yaml` file for your cluster.

2. Create a file that is named `cluster-ingress-default-ingresscontroller.yaml` in the `<installation_directory>/manifests/` directory:

   ```bash
   $ touch <installation_directory>/manifests/cluster-ingress-default-ingresscontroller.yaml
   ```

   For `<installation_directory>`, specify the directory name that contains the `manifests/` directory for your cluster.

After creating the file, several network configuration files are in the `manifests/` directory, as shown:

```bash
$ ls <installation_directory>/manifests/cluster-ingress-default-ingresscontroller.yaml
```

Example output

```
cluster-ingress-default-ingresscontroller.yaml
```

3. Open the `cluster-ingress-default-ingresscontroller.yaml` file in an editor and enter a custom resource (CR) that describes the Operator configuration you want:

   ```yaml
   apiVersion: operator.openshift.io/v1
   kind: IngressController
   metadata:
     creationTimestamp: null
     name: default
     namespace: openshift-ingress-operator
   spec:
     endpointPublishingStrategy:
       loadBalancer:
         scope: External
         providerParameters:
           type: AWS
           aws:
             type: NLB
             type: LoadBalancerService
   ```

4. Save the `cluster-ingress-default-ingresscontroller.yaml` file and quit the text editor.
5. Optional: Back up the `manifests/cluster-ingress-default-ingresscontroller.yaml` file. The installation program deletes the `manifests/` directory when creating the cluster.

### 6.5.12. Configuring hybrid networking with OVN-Kubernetes

You can configure your cluster to use hybrid networking with the OVN-Kubernetes network plugin. This allows a hybrid cluster that supports different node networking configurations.

**NOTE**

This configuration is necessary to run both Linux and Windows nodes in the same cluster.

**Prerequisites**

- You defined `OVNKubernetes` for the `networking.networkType` parameter in the `install-config.yaml` file. See the installation documentation for configuring OpenShift Container Platform network customizations on your chosen cloud provider for more information.

**Procedure**

1. Change to the directory that contains the installation program and create the manifests:

   ```
   $ ./openshift-install create manifests --dir <installation_directory>
   ```

   where:

   `<installation_directory>`

   Specifies the name of the directory that contains the `install-config.yaml` file for your cluster.

2. Create a stub manifest file for the advanced network configuration that is named `cluster-network-03-config.yml` in the `<installation_directory>/manifests/` directory:

   ```
   $ cat <<EOF > <installation_directory>/manifests/cluster-network-03-config.yml
   apiVersion: operator.openshift.io/v1
   kind: Network
   metadata:
     name: cluster
   spec:
   EOF
   ```

   where:

   `<installation_directory>`

   Specifies the directory name that contains the `manifests/` directory for your cluster.

3. Open the `cluster-network-03-config.yml` file in an editor and configure OVN-Kubernetes with hybrid networking, such as in the following example:

**Specify a hybrid networking configuration**

```python
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
```
Specify the CIDR configuration used for nodes on the additional overlay network. The `hybridClusterNetwork` CIDR cannot overlap with the `clusterNetwork` CIDR.

Specify a custom VXLAN port for the additional overlay network. This is required for running Windows nodes in a cluster installed on vSphere, and must not be configured for any other cloud provider. The custom port can be any open port excluding the default 4789 port. For more information on this requirement, see the Microsoft documentation on Pod-to-pod connectivity between hosts is broken.

NOTE
Windows Server Long-Term Servicing Channel (LTSC): Windows Server 2019 is not supported on clusters with a custom `hybridOverlayVXLANPort` value because this Windows server version does not support selecting a custom VXLAN port.

4. Save the `cluster-network-03-config.yml` file and quit the text editor.

5. Optional: Back up the `manifests/cluster-network-03-config.yml` file. The installation program deletes the `manifests/` directory when creating the cluster.

NOTE
For more information on using Linux and Windows nodes in the same cluster, see Understanding Windows container workloads.

6.5.13. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

IMPORTANT
You can run the `create cluster` command of the installation program only once, during initial installation.

Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.
- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.

**Procedure**

1. Change to the directory that contains the installation program and initialize the cluster deployment:

```
$ ./openshift-install create cluster --dir <installation_directory> \  
--log-level=info
```

   1. For `<installation_directory>`, specify the location of your customized `.install-config.yaml` file.
   2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

2. Optional: Remove or disable the `AdministratorAccess` policy from the IAM account that you used to install the cluster.

   **NOTE**

   The elevated permissions provided by the `AdministratorAccess` policy are required only during installation.

**Verification**

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the `kubeadmin` user.

- Credential information also outputs to `<installation_directory>/.openshift_install.log`.

**IMPORTANT**

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

**Example output**

```
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```
IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

6.5.14. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

Procedure

1. Export the `kubeadmin` credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   ``

   Example output

   ```
   system:admin
   ```

6.5.15. Logging in to the cluster by using the web console

The `kubeadmin` user exists by default after an OpenShift Container Platform installation. You can log in to your cluster as the `kubeadmin` user by using the OpenShift Container Platform web console.

Prerequisites
• You have access to the installation host.
• You completed a cluster installation and all cluster Operators are available.

Procedure

1. Obtain the password for the **kubeadmin** user from the **kubeadmin-password** file on the installation host:

   ```bash
   $ cat <installation_directory>/auth/kubeadmin-password
   ```

   **NOTE**
   Alternatively, you can obtain the **kubeadmin** password from the `<installation_directory>/openshift_install.log` log file on the installation host.

2. List the OpenShift Container Platform web console route:

   ```bash
   $ oc get routes -n openshift-console | grep 'console-openshift'
   ```

   **NOTE**
   Alternatively, you can obtain the OpenShift Container Platform route from the `<installation_directory>/openshift_install.log` log file on the installation host.

   **Example output**

   ```
   console     console-openshift-console.apps.<cluster_name>.<base_domain>            console
   https   reencrypt/Redirect   None
   ```

3. Navigate to the route detailed in the output of the preceding command in a web browser and log in as the **kubeadmin** user.

Additional resources

• See [Accessing the web console](#) for more details about accessing and understanding the OpenShift Container Platform web console.

6.5.16. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to **OpenShift Cluster Manager Hybrid Cloud Console**.

After you confirm that your **OpenShift Cluster Manager Hybrid Cloud Console** inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use **subscription watch** to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**
6.5.17. Next steps

- Validating an installation.
- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- If necessary, you can remove cloud provider credentials.

6.6. INSTALLING A CLUSTER ON AWS IN A RESTRICTED NETWORK

In OpenShift Container Platform version 4.14, you can install a cluster on Amazon Web Services (AWS) in a restricted network by creating an internal mirror of the installation release content on an existing Amazon Virtual Private Cloud (VPC).

6.6.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You mirrored the images for a disconnected installation to your registry and obtained the imageContentSources data for your version of OpenShift Container Platform.

**IMPORTANT**

Because the installation media is on the mirror host, you can use that computer to complete all installation steps.

- You have an existing VPC in AWS. When installing to a restricted network using installer-provisioned infrastructure, you cannot use the installer-provisioned VPC. You must use a user-provisioned VPC that satisfies one of the following requirements:
  - Contains the mirror registry
  - Has firewall rules or a peering connection to access the mirror registry hosted elsewhere
- You configured an AWS account to host the cluster.

**IMPORTANT**

If you have an AWS profile stored on your computer, it must not use a temporary session token that you generated while using a multi-factor authentication device. The cluster continues to use your current AWS credentials to create AWS resources for the entire life of the cluster, so you must use key-based, long-term credentials. To generate appropriate keys, see Managing Access Keys for IAM Users in the AWS documentation. You can supply the keys when you run the installation program.
You downloaded the AWS CLI and installed it on your computer. See Install the AWS CLI Using the Bundled Installer (Linux, macOS, or Unix) in the AWS documentation.

If you use a firewall and plan to use the Telemetry service, you configured the firewall to allow the sites that your cluster requires access to.

NOTE
If you are configuring a proxy, be sure to also review this site list.

6.6.2. About installations in restricted networks

In OpenShift Container Platform 4.14, you can perform an installation that does not require an active connection to the internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service’s Route 53 DNS and IAM services, require internet access. Depending on your network, you might require less internet access for an installation on bare metal hardware, Nutanix, or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift image registry and contains the installation media. You can create this registry on a mirror host, which can access both the internet and your closed network, or by using other methods that meet your restrictions.

6.6.2.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The ClusterVersion status includes an Unable to retrieve available updates error.
- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

6.6.3. About using a custom VPC

In OpenShift Container Platform 4.14, you can deploy a cluster into existing subnets in an existing Amazon Virtual Private Cloud (VPC) in Amazon Web Services (AWS). By deploying OpenShift Container Platform into an existing AWS VPC, you might be able to avoid limit constraints in new accounts or more easily abide by the operational constraints that your company’s guidelines set. If you cannot obtain the infrastructure creation permissions that are required to create the VPC yourself, use this installation option.

Because the installation program cannot know what other components are also in your existing subnets, it cannot choose subnet CIDRs and so forth on your behalf. You must configure networking for the subnets that you install your cluster to yourself.

6.6.3.1. Requirements for using your VPC

The installation program no longer creates the following components:

- Internet gateways
• NAT gateways
• Subnets
• Route tables
• VPCs
• VPC DHCP options
• VPC endpoints

NOTE
The installation program requires that you use the cloud-provided DNS server. Using a custom DNS server is not supported and causes the installation to fail.

If you use a custom VPC, you must correctly configure it and its subnets for the installation program and the cluster to use. See Amazon VPC console wizard configurations and Work with VPCs and subnets in the AWS documentation for more information on creating and managing an AWS VPC.

The installation program cannot:

• Subdivide network ranges for the cluster to use.
• Set route tables for the subnets.
• Set VPC options like DHCP.

You must complete these tasks before you install the cluster. See VPC networking components and Route tables for your VPC for more information on configuring networking in an AWS VPC.

Your VPC must meet the following characteristics:

• The VPC must not use the kubernetes.io/cluster/.*: owned, Name, and openshift.io/cluster tags.
  The installation program modifies your subnets to add the kubernetes.io/cluster/.*: shared tag, so your subnets must have at least one free tag slot available for it. See Tag Restrictions in the AWS documentation to confirm that the installation program can add a tag to each subnet that you specify. You cannot use a Name tag, because it overlaps with the EC2 Name field and the installation fails.

• You must enable the enableDnsSupport and enableDnsHostnames attributes in your VPC, so that the cluster can use the Route 53 zones that are attached to the VPC to resolve cluster’s internal DNS records. See DNS Support in Your VPC in the AWS documentation.
  If you prefer to use your own Route 53 hosted private zone, you must associate the existing hosted zone with your VPC prior to installing a cluster. You can define your hosted zone using the platform.aws.hostedZone and platform.aws.hostedZoneRole fields in the install-config.yaml file. You can use a private hosted zone from another account by sharing it with the account where you install the cluster. If you use a private hosted zone from another account, you must use the Passthrough or Manual credentials mode.

If you are working in a disconnected environment, you are unable to reach the public IP addresses for EC2, ELB, and S3 endpoints. Depending on the level to which you want to restrict internet traffic during the installation, the following configuration options are available:
Option 1: Create VPC endpoints
Create a VPC endpoint and attach it to the subnets that the clusters are using. Name the endpoints as follows:

- ec2.<aws_region>.amazonaws.com
- elasticloadbalancing.<aws_region>.amazonaws.com
- s3.<aws_region>.amazonaws.com

With this option, network traffic remains private between your VPC and the required AWS services.

Option 2: Create a proxy without VPC endpoints
As part of the installation process, you can configure an HTTP or HTTPS proxy. With this option, internet traffic goes through the proxy to reach the required AWS services.

Option 3: Create a proxy with VPC endpoints
As part of the installation process, you can configure an HTTP or HTTPS proxy with VPC endpoints. Create a VPC endpoint and attach it to the subnets that the clusters are using. Name the endpoints as follows:

- ec2.<aws_region>.amazonaws.com
- elasticloadbalancing.<aws_region>.amazonaws.com
- s3.<aws_region>.amazonaws.com

When configuring the proxy in the `install-config.yaml` file, add these endpoints to the `noProxy` field. With this option, the proxy prevents the cluster from accessing the internet directly. However, network traffic remains private between your VPC and the required AWS services.

Required VPC components
You must provide a suitable VPC and subnets that allow communication to your machines.

<table>
<thead>
<tr>
<th>Component</th>
<th>AWS type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VPC</td>
<td><strong>AWS::EC2::VPC</strong></td>
<td>You must provide a public VPC for the cluster to use. The VPC uses an endpoint that references the route tables for each subnet to improve communication with the registry that is hosted in S3.</td>
</tr>
<tr>
<td></td>
<td><strong>AWS::EC2::VPC Endpoint</strong></td>
<td></td>
</tr>
<tr>
<td>Public subnets</td>
<td><strong>AWS::EC2::Subnet</strong></td>
<td>Your VPC must have public subnets for between 1 and 3 availability zones and associate them with appropriate Ingress rules.</td>
</tr>
<tr>

</tr>
</tbody>
</table>
| Internet gateway   | • AWS::EC2::InternetGateway  
|                    | • AWS::EC2::VPCGatewayAttachment  
|                    | • AWS::EC2::RouteTable  
|                    | • AWS::EC2::Route  
|                    | • AWS::EC2::SubnetRouteTableAssociation  
|                    | • AWS::EC2::NatGateway  
|                    | • AWS::EC2::EIP  | You must have a public internet gateway, with public routes, attached to the VPC. In the provided templates, each public subnet has a NAT gateway with an EIP address. These NAT gateways allow cluster resources, like private subnet instances, to reach the internet and are not required for some restricted network or proxy scenarios. |
| Network access     | • AWS::EC2::NetworkAcl  
| control            | • AWS::EC2::NetworkAclEntry  | You must allow the VPC to access the following ports:                                                                                   |
|                    | Port | Reason                                      |
|                    | 80   | Inbound HTTP traffic                       |
|                    | 443  | Inbound HTTPS traffic                      |
|                    | 22   | Inbound SSH traffic                        |
|                    | 1024 - 65535 | Inbound ephemeral traffic          |
|                    | 0 - 65535 | Outbound ephemeral traffic          |
| Private subnets    | • AWS::EC2::Subnet  
|                    | • AWS::EC2::RouteTable  
|                    | • AWS::EC2::SubnetRouteTableAssociation  | Your VPC can have private subnets. The provided CloudFormation templates can create private subnets for between 1 and 3 availability zones. If you use private subnets, you must provide appropriate routes and tables for them. |

**6.6.3.2. VPC validation**

To ensure that the subnets that you provide are suitable, the installation program confirms the following data:
• All the subnets that you specify exist.

• You provide private subnets.

• The subnet CIDRs belong to the machine CIDR that you specified.

• You provide subnets for each availability zone. Each availability zone contains no more than one public and one private subnet. If you use a private cluster, provide only a private subnet for each availability zone. Otherwise, provide exactly one public and private subnet for each availability zone.

• You provide a public subnet for each private subnet availability zone. Machines are not provisioned in availability zones that you do not provide private subnets for.

If you destroy a cluster that uses an existing VPC, the VPC is not deleted. When you remove the OpenShift Container Platform cluster from a VPC, the `kubernetes.io/cluster/.*: shared` tag is removed from the subnets that it used.

6.6.3.3. Division of permissions

Starting with OpenShift Container Platform 4.3, you do not need all of the permissions that are required for an installation program-provisioned infrastructure cluster to deploy a cluster. This change mimics the division of permissions that you might have at your company: some individuals can create different resource in your clouds than others. For example, you might be able to create application-specific items, like instances, buckets, and load balancers, but not networking-related components such as VPCs, subnets, or ingress rules.

The AWS credentials that you use when you create your cluster do not need the networking permissions that are required to make VPCs and core networking components within the VPC, such as subnets, routing tables, internet gateways, NAT, and VPN. You still need permission to make the application resources that the machines within the cluster require, such as ELBs, security groups, S3 buckets, and nodes.

6.6.3.4. Isolation between clusters

If you deploy OpenShift Container Platform to an existing network, the isolation of cluster services is reduced in the following ways:

• You can install multiple OpenShift Container Platform clusters in the same VPC.

• ICMP ingress is allowed from the entire network.

• TCP 22 ingress (SSH) is allowed to the entire network.

• Control plane TCP 6443 ingress (Kubernetes API) is allowed to the entire network.

• Control plane TCP 22623 ingress (MCS) is allowed to the entire network.

6.6.4. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to obtain the images that are necessary to install your cluster.

You must have internet access to:
• Access OpenShift Cluster Manager Hybrid Cloud Console to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

• Access Quay.io to obtain the packages that are required to install your cluster.

• Obtain the packages that are required to perform cluster updates.

### 6.6.5. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The ./openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N " -f <path>/<file_name>
   ```

   Specify the path and file name, such as ~/.ssh/id_ed25519, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

**NOTE**

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.
2. View the public SSH key:

```
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

```
$ cat ~/.ssh/id_ed25519.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

   **NOTE**

   On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

   a. If the `ssh-agent` process is not already running for your local user, start it as a background task:

   ```
   $ eval "$(ssh-agent -s)"
   ```

   **Example output**

   ```
   Agent pid 31874
   ```

   **NOTE**

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the `ssh-agent`:

```
$ ssh-add <path>/<file_name>
```

   Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

   **Example output**

   ```
   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
   ```

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

**6.6.6. Creating the installation configuration file**

You can customize the OpenShift Container Platform cluster you install on Amazon Web Services (AWS).
Prerequisites

- You have the OpenShift Container Platform installation program and the pull secret for your cluster. For a restricted network installation, these files are on your mirror host.

- You have the `imageContentSources` values that were generated during mirror registry creation.

- You have obtained the contents of the certificate for your mirror registry.

Procedure

1. Create the `install-config.yaml` file.
   
a. Change to the directory that contains the installation program and run the following command:

   ```
   $ ./openshift-install create install-config --dir <installation_directory>  
   ```

   For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

   When specifying the directory:

   - Verify that the directory has the `execute` permission. This permission is required to run Terraform binaries under the installation directory.

   - Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

   **NOTE**

   Always delete the `~/.powervs` directory to avoid reusing a stale configuration. Run the following command:

   ```
   $ rm -rf ~/.powervs
   ```

   b. At the prompts, provide the configuration details for your cloud:

   i. Optional: Select an SSH key to use to access your cluster machines.

   **NOTE**

   For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

   ii. Select **AWS** as the platform to target.
iii. If you do not have an Amazon Web Services (AWS) profile stored on your computer, enter the AWS access key ID and secret access key for the user that you configured to run the installation program.

iv. Select the AWS region to deploy the cluster to.

v. Select the base domain for the Route 53 service that you configured for your cluster.

vi. Enter a descriptive name for your cluster.

2. Edit the `install-config.yaml` file to give the additional information that is required for an installation in a restricted network.

   a. Update the `pullSecret` value to contain the authentication information for your registry:

   ```yaml
   pullSecret: '{"auths":{"<mirror_host_name>:5000": {"auth": "<credentials>"}},"email": "you@example.com"}}
   ```

   For `<mirror_host_name>`, specify the registry domain name that you specified in the certificate for your mirror registry, and for `<credentials>`, specify the base64-encoded user name and password for your mirror registry.

   b. Add the `additionalTrustBundle` parameter and value.

   ```yaml
   additionalTrustBundle: |
   -----BEGIN CERTIFICATE-----
   ZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZ
   -----END CERTIFICATE-----
   ```

   The value must be the contents of the certificate file that you used for your mirror registry. The certificate file can be an existing, trusted certificate authority, or the self-signed certificate that you generated for the mirror registry.

   c. Define the subnets for the VPC to install the cluster in:

   ```yaml
   subnets:
   - subnet-1
   - subnet-2
   - subnet-3
   ```

   d. Add the image content resources, which resemble the following YAML excerpt:

   ```yaml
   imageContentSources:
   - mirrors:
     - `<mirror_host_name>:5000/<repo_name>/release` source: quay.io/openshift-release-dev/ocp-release
     - mirrors:
       - `<mirror_host_name>:5000/<repo_name>/release` source: registry.redhat.io/ocp/release
   ```

   For these values, use the `imageContentSources` that you recorded during mirror registry creation.

   e. Optional: Set the publishing strategy to `Internal`: 
By setting this option, you create an internal Ingress Controller and a private load balancer.

**IMPORTANT**

Azure Firewall does not work seamlessly with Azure Public Load balancers. Thus, when using Azure Firewall for restricting internet access, the `publish` field in `install-config.yaml` should be set to `Internal`.

3. Make any other modifications to the `install-config.yaml` file that you require. You can find more information about the available parameters in the Installation configuration parameters section.

4. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

**IMPORTANT**

The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

- Installation configuration parameters for AWS

### 6.6.6.1. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

**Table 6.10. Minimum resource requirements**

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS, RHEL 8.6 and later [3]</td>
<td>2</td>
<td>8 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
</tbody>
</table>

1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or hyperthreading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: (threads per core × cores) × sockets = vCPUs.

2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.
3. As with all user-provisioned installations, if you choose to use RHEL compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and has been removed in OpenShift Container Platform 4.10 and later.

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

**Additional resources**

- Optimizing storage

### 6.6.6.2. Sample customized install-config.yaml file for AWS

You can customize the installation configuration file (`install-config.yaml`) to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

**IMPORTANT**

This sample YAML file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program and modify it.

```yaml
apiVersion: v1
baseDomain: example.com
credentialsMode: Mint
controlPlane:
  hyperthreading: Enabled
  name: master
platform:
  aws:
    lbType: NLB
    zones:
      - us-west-2a
      - us-west-2b
    rootVolume:
      iops: 4000
      size: 500
      type: io1
metadataService:
  authentication: Optional
  type: m6i.xlarge
replicas: 3
compute:
  - hyperthreading: Enabled
    name: worker
    platform:
      aws:
        rootVolume:
          iops: 2000
          size: 500
          type: io1
metadataService:
```
authentication: Optional  
  type: c5.4xlarge  
  zones:  
    - us-west-2c
replicas: 3
metadata:  
  name: test-cluster
networking:  
  clusterNetwork:  
    - cidr: 10.128.0.0/14  
    hostPrefix: 23
machineNetwork:  
    - cidr: 10.0.0.0/16
networkType: OVNKubernetes
serviceNetwork:  
  - 172.30.0.0/16
platform:  
  aws:  
    region: us-west-2
    propagateUserTags: true
    userTags:  
      adminContact: jdoe
      costCenter: 7536
    subnets:  
      - subnet-1
      - subnet-2
      - subnet-3
    amiID: ami-0c5d3e03c0ab9b19a
    serviceEndpoints:  
      - name: ec2
        url: https://vpce-id.ec2.us-west-2.vpce.amazonaws.com
    hostedZone: Z3URY6TWQ91KV
fips: false
sshKey: ssh-ed25519 AAAA...
pullSecret: {'"auths":{"<local_registry>":{"auth": "<credentials>","email": "you@example.com"}}'}
additionalTrustBundle: |
  -----BEGIN CERTIFICATE-----
  <MY_TRUSTED_CA_CERT>
  -----END CERTIFICATE-----
imageContentSources:  
  - mirrors:  
    - <local_registry>/<local_repository_name>/release
      source: quay.io/openshift-release-dev/ocp-release
    - mirrors:  
      - <local_registry>/<local_repository_name>/release
        source: quay.io/openshift-release-dev/ocp-v4.0-art-dev

1 2 14 Required. The installation program prompts you for this value.

2 Optional: Add this parameter to force the Cloud Credential Operator (CCO) to use the specified mode. By default, the CCO uses the root credentials in the kube-system namespace to dynamically try to determine the capabilities of the credentials. For details about CCO modes, see the "About the Cloud Credential Operator" section in the Authentication and authorization guide.
If you do not provide these parameters and values, the installation program provides the default value.

The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, *, and the first line of the controlPlane section must not. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading, or hyperthreading. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to Disabled. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

IMPORTANT

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger instance types, such as m4.2xlarge or m5.2xlarge, for your machines if you disable simultaneous multithreading.

To configure faster storage for etcd, especially for larger clusters, set the storage type as io1 and set iops to 2000.

Whether to require the Amazon EC2 Instance Metadata Service v2 (IMDSv2). To require IMDSv2, set the parameter value to Required. To allow the use of both IMDSv1 and IMDSv2, set the parameter value to Optional. If no value is specified, both IMDSv1 and IMDSv2 are allowed.

NOTE

The IMDS configuration for control plane machines that is set during cluster installation can only be changed by using the AWS CLI. The IMDS configuration for compute machines can be changed by using compute machine sets.

The cluster network plugin to install. The supported values are OVNKubernetes and OpenShiftSDN. The default value is OVNKubernetes.

If you provide your own VPC, specify subnets for each availability zone that your cluster uses.

The ID of the AMI used to boot machines for the cluster. If set, the AMI must belong to the same region as the cluster.

The AWS service endpoints. Custom endpoints are required when installing to an unknown AWS region. The endpoint URL must use the https protocol and the host must trust the certificate.

The ID of your existing Route 53 private hosted zone. Providing an existing hosted zone requires that you supply your own VPC and the hosted zone is already associated with the VPC prior to installing your cluster. If undefined, the installation program creates a new hosted zone.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.
IMPORTANT

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see Installing the system in FIPS mode. When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures.

You can optionally provide the sshKey value that you use to access the machines in your cluster.

NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

For `<local_registry>`, specify the registry domain name, and optionally the port, that your mirror registry uses to serve content. For example `registry.example.com` or `registry.example.com:5000`. For `<credentials>`, specify the base64-encoded user name and password for your mirror registry.

Provide the contents of the certificate file that you used for your mirror registry.

Provide the `imageContentSources` section from the output of the command to mirror the repository.

6.6.6.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

Prerequisites

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

NOTE

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).
**Procedure**

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
      httpProxy: http://<username>:<pswd>@<ip>:<port>
      httpsProxy: https://<username>:<pswd>@<ip>:<port>
   noProxy: ec2.<aws_region>.amazonaws.com,elasticloadbalancing.<aws_region>.amazonaws.com,s3.<aws_region>.amazonaws.com
   additionalTrustBundle:
      -----BEGIN CERTIFICATE-----
      <MY_TRUSTED_CA_CERT>
      -----END CERTIFICATE-----
   additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle>
   
   A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.

   A proxy URL to use for creating HTTPS connections outside the cluster.

   A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations. If you have added the Amazon EC2 Elastic Load Balancing, and S3 VPC endpoints to your VPC, you must add these endpoints to the noProxy field.

   If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the trustedCA field of the Proxy object. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

   Optional: The policy to determine the configuration of the Proxy object to reference the user-ca-bundle config map in the trustedCA field. The allowed values are Proxyonly and Always. Use Proxyonly to reference the user-ca-bundle config map only when http/https proxy is configured. Use Always to always reference the user-ca-bundle config map. The default value is Proxyonly.

   **NOTE**

   The installation program does not support the proxy readinessEndpoints field.

   **NOTE**

   If the installer times out, restart and then complete the deployment by using the wait-for command of the installer. For example:

   ```bash
   $ ./openshift-install wait-for install-complete --log-level debug
   ```
2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

**NOTE**

Only the Proxy object named `cluster` is supported, and no additional proxies can be created.

### 6.6.7. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (`oc`) to interact with OpenShift Container Platform from a command-line interface. You can install `oc` on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of `oc`, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of `oc`.

**Installing the OpenShift CLI on Linux**

You can install the OpenShift CLI (`oc`) binary on Linux by using the following procedure.

**Procedure**

2. Select the architecture from the Product Variant drop-down list.
3. Select the appropriate version from the Version drop-down list.
4. Click Download Now next to the OpenShift v4.14 Linux Client entry and save the file.
5. Unpack the archive:

   ```
   $ tar xvf <file>
   ```

6. Place the `oc` binary in a directory that is on your PATH.
   To check your PATH, execute the following command:

   ```
   $ echo $PATH
   ```

**Verification**

- After you install the OpenShift CLI, it is available using the `oc` command:

  ```
  $ oc <command>
  ```

**Installing the OpenShift CLI on Windows**

You can install the OpenShift CLI (`oc`) binary on Windows by using the following procedure.
Procedure

2. Select the appropriate version from the Version drop-down list.

3. Click Download Now next to the OpenShift v4.14 Windows Client entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the oc binary to a directory that is on your PATH.

   To check your PATH, open the command prompt and execute the following command:

   ```
   C:\> path
   ```

Verification

- After you install the OpenShift CLI, it is available using the oc command:

  ```
  C:\> oc <command>
  ```

Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.

Procedure

2. Select the appropriate version from the Version drop-down list.

3. Click Download Now next to the OpenShift v4.14 macOS Client entry and save the file.

   **NOTE**

   For macOS arm64, choose the OpenShift v4.14 macOS arm64 Client entry.

4. Unpack and unzip the archive.

5. Move the oc binary to a directory on your PATH.

   To check your PATH, open a terminal and execute the following command:

   ```
   $ echo $PATH
   ```

Verification

- After you install the OpenShift CLI, it is available using the oc command:

  ```
  $ oc <command>
  ```

6.6.8. Alternatives to storing administrator-level secrets in the kube-system project
By default, administrator secrets are stored in the `kube-system` project. If you configured the `credentialsMode` parameter in the `install-config.yaml` file to `Manual`, you must use one of the following alternatives:

- To manage long-term cloud credentials manually, follow the procedure in Manually creating long-term credentials.

- To implement short-term credentials that are managed outside the cluster for individual components, follow the procedures in Configuring an AWS cluster to use short-term credentials.

### 6.6.8.1. Manually creating long-term credentials

The Cloud Credential Operator (CCO) can be put into manual mode prior to installation in environments where the cloud identity and access management (IAM) APIs are not reachable, or the administrator prefers not to store an administrator-level credential secret in the cluster `kube-system` namespace.

**Procedure**

1. If you did not set the `credentialsMode` parameter in the `install-config.yaml` configuration file to `Manual`, modify the value as shown:

   **Sample configuration file snippet**
   
   ```yaml
   apiVersion: v1
   baseDomain: example.com
   credentialsMode: Manual
   # ...
   ```

2. If you have not previously created installation manifest files, do so by running the following command:

   ```bash
   $ openshift-install create manifests --dir <installation_directory>
   ```

   where `<installation_directory>` is the directory in which the installation program creates files.

3. Set a `$RELEASE_IMAGE` variable with the release image from your installation file by running the following command:

   ```bash
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
   ```

4. Extract the list of `CredentialsRequest` custom resources (CRs) from the OpenShift Container Platform release image by running the following command:

   ```bash
   $ oc adm release extract \ 
   --from=$RELEASE_IMAGE \ 
   --credentials-requests \ 
   --included \ 1
   --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \ 2
   --to=<path_to_directory_for_credentials_requests> \ 3
   ```

   1. The `--included` parameter includes only the manifests that your specific cluster configuration requires.
2 Specify the location of the `install-config.yaml` file.

3 Specify the path to the directory where you want to store the `CredentialsRequest` objects. If the specified directory does not exist, this command creates it.

This command creates a YAML file for each `CredentialsRequest` object.

**Sample CredentialsRequest object**

```yaml
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
  name: <component_credentials_request>
  namespace: openshift-cloud-credential-operator
...
spec:
  providerSpec:
    apiVersion: cloudcredential.openshift.io/v1
    kind: AWSProviderSpec
    statementEntries:
    - effect: Allow
      action:
      - iam:GetUser
      - iam:GetUserPolicy
      - iam:ListAccessKeys
      resource: "*"
...
```

5. Create YAML files for secrets in the `openshift-install` manifests directory that you generated previously. The secrets must be stored using the namespace and secret name defined in the `spec.secretRef` for each `CredentialsRequest` object.

**Sample CredentialsRequest object with secrets**

```yaml
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
  name: <component_credentials_request>
  namespace: openshift-cloud-credential-operator
...
spec:
  providerSpec:
    apiVersion: cloudcredential.openshift.io/v1
    kind: AWSProviderSpec
    statementEntries:
    - effect: Allow
      action:
      - s3:CreateBucket
      - s3:DeleteBucket
      resource: "*"
...
secretRef:
```
IMPORTANT Before upgrading a cluster that uses manually maintained credentials, you must ensure that the CCO is in an upgradeable state.

6.6.8.2. Configuring an AWS cluster to use short-term credentials

To install a cluster that is configured to use the AWS Security Token Service (STS), you must configure the CCO utility and create the required AWS resources for your cluster.

6.6.8.2.1. Configuring the Cloud Credential Operator utility

To create and manage cloud credentials from outside of the cluster when the Cloud Credential Operator (CCO) is operating in manual mode, extract and prepare the CCO utility (`ccoctl`) binary.

NOTE

The `ccoctl` utility is a Linux binary that must run in a Linux environment.

Prerequisites

- You have access to an OpenShift Container Platform account with cluster administrator access.
- You have installed the OpenShift CLI (`oc`).
- You have created an AWS account for the `ccoctl` utility to use with the following permissions:

Example 6.25. Required AWS permissions

Required `iam` permissions

- `iam:CreateOpenIDConnectProvider`
- `iam:CreateRole`
- `iam:DeleteOpenIDConnectProvider`
- `iam:DeleteRole`
- `iam:DeleteRolePolicy`
- `iam:GetOpenIDConnectProvider`
- `iam:GetRole`
- `iam:GetUser`
- `iam:GetOpenIDConnectProviders`
- `iam:GetRolePolicies`
- `iam:GetRoles`
- `iam:PutRolePolicy`
- `iam:TagOpenIDConnectProvider`
- `iam:TagRole`

**Required s3 permissions**

- `s3:CreateBucket`
- `s3:DeleteBucket`
- `s3:DeleteObject`
- `s3:GetBucketAcl`
- `s3:GetBucketTagging`
- `s3:GetObject`
- `s3:GetObjectAcl`
- `s3:GetObjectTagging`
- `s3:ListBucket`
- `s3:PutBucketAcl`
- `s3:PutBucketPolicy`
- `s3:PutBucketPublicAccessBlock`
- `s3:PutBucketTagging`
- `s3:PutObject`
- `s3:PutObjectAcl`
- `s3:PutObjectTagging`

**Required cloudfront permissions**

- `cloudfront:ListCloudFrontOriginAccessIdentities`
- `cloudfront:ListDistributions`
If you plan to store the OIDC configuration in a private S3 bucket that is accessed by the IAM identity provider through a public CloudFront distribution URL, the AWS account that runs the ccoctI utility requires the following additional permissions:

Example 6.26. Additional permissions for a private S3 bucket with CloudFront

- cloudfront:ListTagsForResource
- cloudfront:CreateCloudFrontOriginAccessIdentity
- cloudfront:CreateDistribution
- cloudfront:DeleteCloudFrontOriginAccessIdentity
- cloudfront:DeleteDistribution
- cloudfront:GetCloudFrontOriginAccessIdentity
- cloudfront:GetCloudFrontOriginAccessIdentityConfig
- cloudfront:GetDistribution
- cloudfront:TagResource
- cloudfront:UpdateDistribution

**NOTE**

These additional permissions support the use of the --create-private-s3-bucket option when processing credentials requests with the ccoctI aws create-all command.

**Procedure**

1. Obtain the OpenShift Container Platform release image by running the following command:

   ```bash
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
   ```

2. Obtain the CCO container image from the OpenShift Container Platform release image by running the following command:

   ```bash
   $ CCO_IMAGE=$(oc adm release info --image-for='cloud-credential-operator' $RELEASE_IMAGE -a ~/.pull-secret)
   ```

   **NOTE**

   Ensure that the architecture of the $RELEASE_IMAGE matches the architecture of the environment in which you will use the ccoctI tool.

3. Extract the ccoctI binary from the CCO container image within the OpenShift Container Platform release image by running the following command:
4. Change the permissions to make `ccoctl` executable by running the following command:

```bash
$ chmod 775 ccoctl
```

**Verification**

- To verify that `ccoctl` is ready to use, display the help file by running the following command:

```bash
$ ccoctl --help
```

**Output of `ccoctl` --help**

OpenShift credentials provisioning tool

Usage:

```bash
ccoctl [command]
```

Available Commands:

- `alibabacloud` Manage credentials objects for alibaba cloud
- `aws` Manage credentials objects for AWS cloud
- `azure` Manage credentials objects for Azure
- `gcp` Manage credentials objects for Google cloud
- `help` Help about any command
- `ibmcloud` Manage credentials objects for IBM Cloud
- `nutanix` Manage credentials objects for Nutanix

Flags:

- `-h, --help` help for ccoctl

Use "ccoctl [command] --help" for more information about a command.

### 6.6.8.2.2. Creating AWS resources with the Cloud Credential Operator utility

You have the following options when creating AWS resources:

- You can use the `ccoctl aws create-all` command to create the AWS resources automatically. This is the quickest way to create the resources. See Creating AWS resources with a single command.

- If you need to review the JSON files that the `ccoctl` tool creates before modifying AWS resources, or if the process the `ccoctl` tool uses to create AWS resources automatically does not meet the requirements of your organization, you can create the AWS resources individually. See Creating AWS resources individually.

#### 6.6.8.2.2.1. Creating AWS resources with a single command

If the process the `ccoctl` tool uses to create AWS resources automatically meets the requirements of your organization, you can use the `ccoctl aws create-all` command to automate the creation of AWS resources.
Otherwise, you can create the AWS resources individually. For more information, see "Creating AWS resources individually".

**NOTE**

By default, `ccoctl` creates objects in the directory in which the commands are run. To create the objects in a different directory, use the `--output-dir` flag. This procedure uses `<path_to_ccoctl_output_dir>` to refer to this directory.

**Prerequisites**

You must have:

- Extracted and prepared the `ccoctl` binary.

**Procedure**

1. Set a `$RELEASE_IMAGE` variable with the release image from your installation file by running the following command:

   ```
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
   ```

2. Extract the list of `CredentialsRequest` objects from the OpenShift Container Platform release image by running the following command:

   ```
   $ oc adm release extract \
   --from=$RELEASE_IMAGE \
   --credentials-requests \
   --included \
   --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \
   --to=<path_to_directory_for_credentials_requests>
   ```

   1. The `--included` parameter includes only the manifests that your specific cluster configuration requires.
   2. Specify the location of the `install-config.yaml` file.
   3. Specify the path to the directory where you want to store the `CredentialsRequest` objects. If the specified directory does not exist, this command creates it.

   **NOTE**

   This command might take a few moments to run.

3. Use the `ccoctl` tool to process all `CredentialsRequest` objects by running the following command:

   ```
   $ ccoctl aws create-all \
   --name=<name> \
   --region=<aws_region>
   ```

   1. Specify the object name.
   2. Specify the AWS region.
Specify the name used to tag any cloud resources that are created for tracking.

Specify the AWS region in which cloud resources will be created.

Specify the directory containing the files for the component `CredentialsRequest` objects.

Optional: Specify the directory in which you want the `ccoctl` utility to create objects. By default, the utility creates objects in the directory in which the commands are run.

Optional: By default, the `ccoctl` utility stores the OpenID Connect (OIDC) configuration files in a public S3 bucket and uses the S3 URL as the public OIDC endpoint. To store the OIDC configuration in a private S3 bucket that is accessed by the IAM identity provider through a public CloudFront distribution URL instead, use the `--create-private-s3-bucket` parameter.

**NOTE**
If your cluster uses Technology Preview features that are enabled by the `TechPreviewNoUpgrade` feature set, you must include the `--enable-tech-preview` parameter.

**Verification**
- To verify that the OpenShift Container Platform secrets are created, list the files in the `<path_to_ccoctl_output_dir>/manifests` directory:

  ```bash
  $ ls <path_to_ccoctl_output_dir>/manifests
  ```

**Example output**
- `cluster-authentication-02-config.yaml`
- `openshift-cloud-credential-operator-cloud-credential-operator-iam-ro-creds-credentials.yaml`
- `openshift-cloud-network-config-controller-cloud-credentials-credentials.yaml`
- `openshift-cluster-api-capa-manager-bootstrap-credentials-credentials.yaml`
- `openshift-cluster-csi-drivers-ebs-cloud-credentials-credentials.yaml`
- `openshift-image-registry-installer-cloud-credentials-credentials.yaml`
- `openshift-ingress-operator-cloud-credentials-credentials.yaml`
- `openshift-machine-api-aws-cloud-credentials-credentials.yaml`

You can verify that the IAM roles are created by querying AWS. For more information, refer to AWS documentation on listing IAM roles.

### 6.6.8.2.2.2. Creating AWS resources individually

You can use the `ccoctl` tool to create AWS resources individually. This option might be useful for an organization that shares the responsibility for creating these resources among different users or departments.
Otherwise, you can use the `ccoctl aws create-all` command to create the AWS resources automatically. For more information, see "Creating AWS resources with a single command".

**NOTE**

By default, `ccoctl` creates objects in the directory in which the commands are run. To create the objects in a different directory, use the `--output-dir` flag. This procedure uses `<path_to_ccoctl_output_dir>` to refer to this directory.

Some `ccoctl` commands make AWS API calls to create or modify AWS resources. You can use the `--dry-run` flag to avoid making API calls. Using this flag creates JSON files on the local file system instead. You can review and modify the JSON files and then apply them with the AWS CLI tool using the `--cli-input-json` parameters.

### Prerequisites

- Extract and prepare the `ccoctl` binary.

### Procedure

1. Generate the public and private RSA key files that are used to set up the OpenID Connect provider for the cluster by running the following command:

   ```bash
   $ ccoctl aws create-key-pair
   ```

   **Example output**

   2021/04/13 11:01:02 Generating RSA keypair
   2021/04/13 11:01:03 Writing private key to /<path_to_ccoctl_output_dir>/serviceaccount-signer.private
   2021/04/13 11:01:03 Writing public key to /<path_to_ccoctl_output_dir>/serviceaccount-signer.public
   2021/04/13 11:01:03 Copying signing key for use by installer

   where `serviceaccount-signer.private` and `serviceaccount-signer.public` are the generated key files.

   This command also creates a private key that the cluster requires during installation in `/<path_to_ccoctl_output_dir>/tls/bound-service-account-signing-key.key`.

2. Create an OpenID Connect identity provider and S3 bucket on AWS by running the following command:

   ```bash
   $ ccoctl aws create-identity-provider \
   --name=<name> \1
   --region=<aws_region> \2
   --public-key-file=<path_to_ccoctl_output_dir>/serviceaccount-signer.public \3
   ```

   **Example output**

   ```
   
   ```

   where `<name>` is the name used to tag any cloud resources that are created for tracking.

   `<aws-region>` is the AWS region in which cloud resources will be created.

   `<path_to_ccoctl_output_dir>` is the path to the public key file that the `ccoctl aws create-key-pair` command generated.
Example output

2021/04/13 11:16:09 Bucket <name>-oidc created
2021/04/13 11:16:10 OpenID Connect discovery document in the S3 bucket <name>-oidc at .well-known/openid-configuration updated
2021/04/13 11:16:10 Reading public key
2021/04/13 11:16:10 JSON web key set (JWKS) in the S3 bucket <name>-oidc at keys.json updated

where openid-configuration is a discovery document and keys.json is a JSON web key set file.

This command also creates a YAML configuration file in /<path_to_ccocctl_output_dir>/manifests/cluster-authentication-02-config.yaml. This file sets the issuer URL field for the service account tokens that the cluster generates, so that the AWS IAM identity provider trusts the tokens.

3. Create IAM roles for each component in the cluster:
   
a. Set a $RELEASE_IMAGE variable with the release image from your installation file by running the following command:

   ```
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
   ```

b. Extract the list of CredentialsRequest objects from the OpenShift Container Platform release image:

   ```
   $ oc adm release extract --from=$RELEASE_IMAGE --credentials-requests --included 1 --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml 2 --to=<path_to_directory_for_credentials_requests> 3
   ```

   1 The --included parameter includes only the manifests that your specific cluster configuration requires.
   
   2 Specify the location of the install-config.yaml file.
   
   3 Specify the path to the directory where you want to store the CredentialsRequest objects. If the specified directory does not exist, this command creates it.

c. Use the ccoctl tool to process all CredentialsRequest objects by running the following command:

   ```
   $ ccoctl aws create-iam-roles --name=<name> --region=<aws_region> --credentials-requests-dir=<path_to_credentials_requests_directory> --identity-provider-arn=arn:aws:iam::<aws_account_id>:oidc-provider/<name>-oidc.s3.<aws_region>.amazonaws.com
   ```
NOTE

For AWS environments that use alternative IAM API endpoints, such as GovCloud, you must also specify your region with the --region parameter.

If your cluster uses Technology Preview features that are enabled by the TechPreviewNoUpgrade feature set, you must include the --enable-tech-preview parameter.

For each CredentialsRequest object, ccoctl creates an IAM role with a trust policy that is tied to the specified OIDC identity provider, and a permissions policy as defined in each CredentialsRequest object from the OpenShift Container Platform release image.

Verification

- To verify that the OpenShift Container Platform secrets are created, list the files in the <path_to_ccoctl_output_dir>/manifests directory:

  $ ls <path_to_ccoctl_output_dir>/manifests

Example output

  cluster-authentication-02-config.yaml
  openshift-cloud-credential-operator-cloud-credential-operator-iam-ro-creds-credentials.yaml
  openshift-cloud-network-config-controller-cloud-credentials-credentials.yaml
  openshift-cluster-api-capa-manager-bootstrap-credentials-credentials.yaml
  openshift-cluster-csi-drivers-ebs-cloud-credentials-credentials.yaml
  openshift-image-registry-installer-cloud-credentials-credentials.yaml
  openshift-ingress-operator-cloud-credentials-credentials.yaml
  openshift-machine-api-aws-cloud-credentials-credentials.yaml

You can verify that the IAM roles are created by querying AWS. For more information, refer to AWS documentation on listing IAM roles.

6.6.8.2.3. Incorporating the Cloud Credential Operator utility manifests

To implement short-term security credentials managed outside the cluster for individual components, you must move the manifest files that the Cloud Credential Operator utility (ccoctl) created to the correct directories for the installation program.

Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.

- You have configured the Cloud Credential Operator utility (ccoctl).

- You have created the cloud provider resources that are required for your cluster with the ccoctl utility.

Procedure

1. If you did not set the credentialsMode parameter in the install-config.yaml configuration file to Manual, modify the value as shown:
Sample configuration file snippet

```
apiVersion: v1
baseDomain: example.com
credentialsMode: Manual
# ...
```

2. If you have not previously created installation manifest files, do so by running the following command:

```
$ openshift-install create manifests --dir <installation_directory>
```

where `<installation_directory>` is the directory in which the installation program creates files.

3. Copy the manifests that the `ccoctl` utility generated to the `manifests` directory that the installation program created by running the following command:

```
$ cp /<path_to_ccoctl_output_dir>/manifests/* ./manifests/
```

4. Copy the private key that the `ccoctl` utility generated in the `tls` directory to the installation directory by running the following command:

```
$ cp -a /<path_to_ccoctl_output_dir>/tls .
```

6.6.9. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

**Prerequisites**

- You have configured an account with the cloud platform that hosts your cluster.
- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.

**Procedure**

1. Change to the directory that contains the installation program and initialize the cluster deployment:

```
$ ./openshift-install create cluster --dir <installation_directory> \
   --log-level=info
```

---

1. [ ]
2. [ ]
1. For `<installation_directory>`, specify the location of your customized `.install-config.yaml` file.

2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

2. Optional: Remove or disable the **AdministratorAccess** policy from the IAM account that you used to install the cluster.

   **NOTE**

   The elevated permissions provided by the **AdministratorAccess** policy are required only during installation.

**Verification**

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the **kubeadmin** user.

- Credential information also outputs to `<installation_directory>/.openshift_install.log`.

**IMPORTANT**

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

**Example output**

```plaintext
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for **Recovering from expired control plane certificates** for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.
### 6.6.10. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster kubeconfig file. The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the oc CLI.

**Procedure**

1. Export the kubeadmin credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run oc commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   ```

   **Example output**

   ```
   system:admin
   ```

### 6.6.11. Disabling the default OperatorHub catalog sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

**Procedure**

- Disable the sources for the default catalogs by adding `disableAllDefaultSources: true` to the OperatorHub object:

  ```bash
  $ oc patch OperatorHub cluster --type json
  -p '[{"op": "add", "path": "/spec/disableAllDefaultSources", "value": true}]'
  ```

**TIP**

Alternatively, you can use the web console to manage catalog sources. From the **Administration → Cluster Settings → Configuration → OperatorHub** page, click the **Sources** tab, where you can create, update, delete, disable, and enable individual sources.

### 6.6.12. Telemetry access for OpenShift Container Platform
In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager Hybrid Cloud Console.

After you confirm that your OpenShift Cluster Manager Hybrid Cloud Console inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service

6.6.13. Next steps

- Validate an installation.
- Customize your cluster.
- Configure image streams for the Cluster Samples Operator and the must-gather tool.
- Learn how to use Operator Lifecycle Manager (OLM) on restricted networks.
- If the mirror registry that you used to install your cluster has a trusted CA, add it to the cluster by configuring additional trust stores.
- If necessary, you can opt out of remote health reporting.

6.7. INSTALLING A CLUSTER ON AWS INTO AN EXISTING VPC

In OpenShift Container Platform version 4.14, you can install a cluster into an existing Amazon Virtual Private Cloud (VPC) on Amazon Web Services (AWS). The installation program provisions the rest of the required infrastructure, which you can further customize. To customize the installation, you modify parameters in the install-config.yaml file before you install the cluster.

6.7.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You configured an AWS account to host the cluster.
- If the existing VPC is owned by a different account than the cluster, you shared the VPC between accounts.
IMPORTANT

If you have an AWS profile stored on your computer, it must not use a temporary session token that you generated while using a multi-factor authentication device. The cluster continues to use your current AWS credentials to create AWS resources for the entire life of the cluster, so you must use long-term credentials. To generate appropriate keys, see Managing Access Keys for IAM Users in the AWS documentation. You can supply the keys when you run the installation program.

- If you use a firewall, you configured it to allow the sites that your cluster requires access to.

6.7.2. About using a custom VPC

In OpenShift Container Platform 4.14, you can deploy a cluster into existing subnets in an existing Amazon Virtual Private Cloud (VPC) in Amazon Web Services (AWS). By deploying OpenShift Container Platform into an existing AWS VPC, you might be able to avoid limit constraints in new accounts or more easily abide by the operational constraints that your company’s guidelines set. If you cannot obtain the infrastructure creation permissions that are required to create the VPC yourself, use this installation option.

Because the installation program cannot know what other components are also in your existing subnets, it cannot choose subnet CIDRs and so forth on your behalf. You must configure networking for the subnets that you install your cluster to yourself.

6.7.2.1. Requirements for using your VPC

The installation program no longer creates the following components:

- Internet gateways
- NAT gateways
- Subnets
- Route tables
- VPCs
- VPC DHCP options
- VPC endpoints

NOTE

The installation program requires that you use the cloud-provided DNS server. Using a custom DNS server is not supported and causes the installation to fail.

If you use a custom VPC, you must correctly configure it and its subnets for the installation program and the cluster to use. See Amazon VPC console wizard configurations and Work with VPCs and subnets in the AWS documentation for more information on creating and managing an AWS VPC.

The installation program cannot:

- Subdivide network ranges for the cluster to use.
- Set route tables for the subnets.
- Set VPC options like DHCP.

You must complete these tasks before you install the cluster. See VPC networking components and Route tables for your VPC for more information on configuring networking in an AWS VPC.

Your VPC must meet the following characteristics:

- Create a public and private subnet for each availability zone that your cluster uses. Each availability zone can contain no more than one public and one private subnet. For an example of this type of configuration, see VPC with public and private subnets (NAT) in the AWS documentation.
  Record each subnet ID. Completing the installation requires that you enter these values in the platform section of the install-config.yaml file. See Finding a subnet ID in the AWS documentation.
- The VPC’s CIDR block must contain the Networking.MachineCIDR range, which is the IP address pool for cluster machines. The subnet CIDR blocks must belong to the machine CIDR that you specify.
- The VPC must have a public internet gateway attached to it. For each availability zone:
  - The public subnet requires a route to the internet gateway.
  - The public subnet requires a NAT gateway with an EIP address.
  - The private subnet requires a route to the NAT gateway in public subnet.
- The VPC must not use the kubernetes.io/cluster/.*: owned, Name, and openshift.io/cluster tags.
  The installation program modifies your subnets to add the kubernetes.io/cluster/.*: shared tag, so your subnets must have at least one free tag slot available for it. See Tag Restrictions in the AWS documentation to confirm that the installation program can add a tag to each subnet that you specify. You cannot use a Name tag, because it overlaps with the EC2 Name field and the installation fails.
- You must enable the enableDnsSupport and enableDnsHostnames attributes in your VPC, so that the cluster can use the Route 53 zones that are attached to the VPC to resolve cluster’s internal DNS records. See DNS Support in Your VPC in the AWS documentation.
  If you prefer to use your own Route 53 hosted private zone, you must associate the existing hosted zone with your VPC prior to installing a cluster. You can define your hosted zone using the platform.aws.hostedZone and platform.aws.hostedZoneRole fields in the install-config.yaml file. You can use a private hosted zone from another account by sharing it with the account where you install the cluster. If you use a private hosted zone from another account, you must use the Passthrough or Manual credentials mode.

If you are working in a disconnected environment, you are unable to reach the public IP addresses for EC2, ELB, and S3 endpoints. Depending on the level to which you want to restrict internet traffic during the installation, the following configuration options are available:

**Option 1: Create VPC endpoints**
Create a VPC endpoint and attach it to the subnets that the clusters are using. Name the endpoints as follows:

- ec2.<aws_region>.amazonaws.com
- elasticloadbalancing.<aws_region>.amazonaws.com
- s3.<aws_region>.amazonaws.com

With this option, network traffic remains private between your VPC and the required AWS services.

Option 2: Create a proxy without VPC endpoints
As part of the installation process, you can configure an HTTP or HTTPS proxy. With this option, internet traffic goes through the proxy to reach the required AWS services.

Option 3: Create a proxy with VPC endpoints
As part of the installation process, you can configure an HTTP or HTTPS proxy with VPC endpoints. Create a VPC endpoint and attach it to the subnets that the clusters are using. Name the endpoints as follows:

- ec2.<aws_region>.amazonaws.com
- elasticloadbalancing.<aws_region>.amazonaws.com
- s3.<aws_region>.amazonaws.com

When configuring the proxy in the `install-config.yaml` file, add these endpoints to the `noProxy` field. With this option, the proxy prevents the cluster from accessing the internet directly. However, network traffic remains private between your VPC and the required AWS services.

Required VPC components
You must provide a suitable VPC and subnets that allow communication to your machines.

<table>
<thead>
<tr>
<th>Component</th>
<th>AWS type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VPC</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>AWS::EC2::VPC</td>
<td>You must provide a public VPC for the cluster to use. The VPC uses an endpoint that references the route tables for each subnet to improve communication with the registry that is hosted in S3.</td>
</tr>
<tr>
<td></td>
<td>AWS::EC2::VPCEndpoint</td>
<td></td>
</tr>
<tr>
<td>Public subnets</td>
<td>AWS::EC2::Subnet</td>
<td>Your VPC must have public subnets for between 1 and 3 availability zones and associate them with appropriate Ingress rules.</td>
</tr>
<tr>
<td></td>
<td>AWS::EC2::SubnetNetworkAclAssociation</td>
<td></td>
</tr>
</tbody>
</table>
### Internet gateway

- **AWS::EC2::InternetGateway**
- **AWS::EC2::VPCGatewayAttachment**
- **AWS::EC2::RouteTable**
- **AWS::EC2::Route**
- **AWS::EC2::SubnetRouteTableAssociation**
- **AWS::EC2::NatGateway**
- **AWS::EC2::EIP**

You must have a public internet gateway, with public routes, attached to the VPC. In the provided templates, each public subnet has a NAT gateway with an EIP address. These NAT gateways allow cluster resources, like private subnet instances, to reach the internet and are not required for some restricted network or proxy scenarios.

### Network access control

- **AWS::EC2::NetworkAcl**
- **AWS::EC2::NetworkAclEntry**

You must allow the VPC to access the following ports:

<table>
<thead>
<tr>
<th>Port</th>
<th>Reason</th>
</tr>
</thead>
<tbody>
<tr>
<td>80</td>
<td>Inbound HTTP traffic</td>
</tr>
<tr>
<td>443</td>
<td>Inbound HTTPS traffic</td>
</tr>
<tr>
<td>22</td>
<td>Inbound SSH traffic</td>
</tr>
<tr>
<td>1024 - 65535</td>
<td>Inbound ephemeral traffic</td>
</tr>
<tr>
<td>0 - 65535</td>
<td>Outbound ephemeral traffic</td>
</tr>
</tbody>
</table>

### Private subnets

- **AWS::EC2::Subnet**
- **AWS::EC2::RouteTable**
- **AWS::EC2::SubnetRouteTableAssociation**

Your VPC can have private subnets. The provided CloudFormation templates can create private subnets for between 1 and 3 availability zones. If you use private subnets, you must provide appropriate routes and tables for them.

### 6.7.2.2. VPC validation

To ensure that the subnets that you provide are suitable, the installation program confirms the following data:

- All the subnets that you specify exist.
You provide private subnets.

The subnet CIDRs belong to the machine CIDR that you specified.

You provide subnets for each availability zone. Each availability zone contains no more than one public and one private subnet. If you use a private cluster, provide only a private subnet for each availability zone. Otherwise, provide exactly one public and private subnet for each availability zone.

You provide a public subnet for each private subnet availability zone. Machines are not provisioned in availability zones that you do not provide private subnets for.

If you destroy a cluster that uses an existing VPC, the VPC is not deleted. When you remove the OpenShift Container Platform cluster from a VPC, the `kubernetes.io/cluster/*: shared` tag is removed from the subnets that it used.

### 6.7.2.3. Division of permissions

Starting with OpenShift Container Platform 4.3, you do not need all of the permissions that are required for an installation program-provisioned infrastructure cluster to deploy a cluster. This change mimics the division of permissions that you might have at your company: some individuals can create different resource in your clouds than others. For example, you might be able to create application-specific items, like instances, buckets, and load balancers, but not networking-related components such as VPCs, subnets, or ingress rules.

The AWS credentials that you use when you create your cluster do not need the networking permissions that are required to make VPCs and core networking components within the VPC, such as subnets, routing tables, internet gateways, NAT, and VPN. You still need permission to make the application resources that the machines within the cluster require, such as ELBs, security groups, S3 buckets, and nodes.

### 6.7.2.4. Isolation between clusters

If you deploy OpenShift Container Platform to an existing network, the isolation of cluster services is reduced in the following ways:

- You can install multiple OpenShift Container Platform clusters in the same VPC.
- ICMP ingress is allowed from the entire network.
- TCP 22 ingress (SSH) is allowed to the entire network.
- Control plane TCP 6443 ingress (Kubernetes API) is allowed to the entire network.
- Control plane TCP 22623 ingress (MCS) is allowed to the entire network.

### 6.7.2.5. AWS security groups

By default, the installation program creates and attaches security groups to control plane and compute machines. The rules associated with the default security groups cannot be modified.

However, you can apply additional existing AWS security groups, which are associated with your existing VPC, to control plane and compute machines. Applying custom security groups can help you meet the security needs of your organization, in such cases where you need to control the incoming or outgoing traffic of these machines.
As part of the installation process, you apply custom security groups by modifying the `install-config.yaml` file before deploying the cluster.

For more information, see "Applying existing AWS security groups to the cluster".

### 6.7.2.6. Modifying trust policy when installing into a shared VPC

If you install your cluster using a shared VPC, you can use the Passthrough or Manual credentials mode. You must add the IAM role used to install the cluster as a principal in the trust policy of the account that owns the VPC.

If you use Passthrough mode, add the Amazon Resource Name (ARN) of the account that creates the cluster, such as `arn:aws:iam::123456789012:user/clustercreator`, to the trust policy as a principal.

If you use Manual mode, add the ARN of the account that creates the cluster as well as the ARN of the ingress operator role in the cluster owner account, such as `arn:aws:iam::123456789012:role/<cluster-name>-openshift-ingress-operator-cloud-credentials`, to the trust policy as principals.

You must add the following actions to the policy:

```plaintext
route53:ChangeResourceRecordSets
route53:ListHostedZones
route53:ListHostedZonesByName
route53:ListResourceRecordSets
route53:ChangeTagsForResource
route53:GetAccountLimit
route53:GetChange
route53:GetHostedZone
route53:GetTagsForResource
route53:UpdateHostedZoneComment
tag:GetResources
tag:UntagResources
```

### 6.7.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager Hybrid Cloud Console to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
• Access Quay.io to obtain the packages that are required to install your cluster.

• Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 6.7.4. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the `core` user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user `core`. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `/openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> 1
   ```

   1 Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.
NOTE

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the **x86_64**, **ppc64le**, and **s390x** architectures, do not create a key that uses the **ed25519** algorithm. Instead, create a key that uses the **rsa** or **ecdsa** algorithm.

2. View the public SSH key:

   ```
   $ cat <path>/<file_name>.pub
   ```

   For example, run the following to view the ~/.ssh/id_ed25519.pub public key:

   ```
   $ cat ~/.ssh/id_ed25519.pub
   ```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

   **NOTE**

   On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.

   a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

      ```
      $ eval "$(ssh-agent -s)"
      ```

      **Example output**

      ```
      Agent pid 31874
      ```

   **NOTE**

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

   ```
   $ ssh-add <path>/<file_name>  
   ```

   **Specify the path and file name for your SSH private key, such as ~/.ssh/id_ed25519**

   **Example output**

   ```
   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
   ```

Next steps
• When you install OpenShift Container Platform, provide the SSH public key to the installation program.

6.7.5. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

Prerequisites

• You have a computer that runs Linux or macOS, with 500 MB of local disk space.

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

   **IMPORTANT**

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   **IMPORTANT**

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ tar -xvf openshift-install-linux.tar.gz
   ```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

6.7.6. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Amazon Web Services (AWS).

Prerequisites
• You have the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Create the install-config.yaml file.
   
a. Change to the directory that contains the installation program and run the following command:

   ```bash
   $ ./openshift-install create install-config --dir <installation_directory>
   ```
   
   For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

   When specifying the directory:

   • Verify that the directory has the execute permission. This permission is required to run Terraform binaries under the installation directory.

   • Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

   **NOTE**
   
   Always delete the ~/.powervs directory to avoid reusing a stale configuration. Run the following command:

   ```bash
   $ rm -rf ~/.powervs
   ```

   b. At the prompts, provide the configuration details for your cloud:

      i. Optional: Select an SSH key to use to access your cluster machines.

      **NOTE**
      
      For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

      ii. Select AWS as the platform to target.

      iii. If you do not have an Amazon Web Services (AWS) profile stored on your computer, enter the AWS access key ID and secret access key for the user that you configured to run the installation program.

      iv. Select the AWS region to deploy the cluster to.

      v. Select the base domain for the Route 53 service that you configured for your cluster.
vi. Enter a descriptive name for your cluster.

2. Modify the `install-config.yaml` file. You can find more information about the available parameters in the "Installation configuration parameters" section.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

**IMPORTANT**

The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

---

### Additional resources

- Installation configuration parameters for AWS

---

#### 6.7.6.1. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

### Table 6.11. Minimum resource requirements

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS, RHEL 8.6 and later [3]</td>
<td>2</td>
<td>8 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
</tbody>
</table>

1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or hyperthreading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: (threads per core × cores) × sockets = vCPUs.

2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.

3. As with all user-provisioned installations, if you choose to use RHEL compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and has been removed in OpenShift Container Platform 4.10 and later.

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

---

### Additional resources
6.7.6.2. Tested instance types for AWS

The following Amazon Web Services (AWS) instance types have been tested with OpenShift Container Platform.

NOTE

Use the machine types included in the following charts for your AWS instances. If you use an instance type that is not listed in the chart, ensure that the instance size you use matches the minimum resource requirements that are listed in "Minimum resource requirements for cluster installation".

Example 6.28. Machine types based on 64-bit x86 architecture

- c4.*
- c5.*
- c5a.*
- i3.*
- m4.*
- m5.*
- m5a.*
- m6i.*
- r4.*
- r5.*
- r5a.*
- r6i.*
- t3.*
- t3a.*

6.7.6.3. Tested instance types for AWS on 64-bit ARM infrastructures

The following Amazon Web Services (AWS) 64-bit ARM instance types have been tested with OpenShift Container Platform.
NOTE

Use the machine types included in the following charts for your AWS ARM instances. If you use an instance type that is not listed in the chart, ensure that the instance size you use matches the minimum resource requirements that are listed in "Minimum resource requirements for cluster installation".

Example 6.29. Machine types based on 64-bit ARM architecture

- c6g.*
- m6g.*

6.7.6.4. Sample customized install-config.yaml file for AWS

You can customize the installation configuration file (install-config.yaml) to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

IMPORTANT

This sample YAML file is provided for reference only. You must obtain your install-config.yaml file by using the installation program and modify it.

```yaml
apiVersion: v1
baseDomain: example.com
credentialsMode: Mint
controlPlane:
  hyperthreading: Enabled
  name: master
platform:
  aws:
    lbType: NLB
    zones:
    - us-west-2a
    - us-west-2b
    rootVolume:
      iops: 4000
      size: 500
      type: io1
    metadataService:
      authentication: Optional
      type: m6i.xlarge
replicas: 3
compute:
  - hyperthreading: Enabled
  name: worker
platform:
  aws:
    rootVolume:
      iops: 2000
      size: 500
      type: io1
```
metadataService:
  authentication: Optional
  type: c5.4xlarge
  zones:
    - us-west-2c
  replicas: 3
metadata:
  name: test-cluster
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
    hostPrefix: 23
  machineNetwork:
    - cidr: 10.0.0.0/16
  networkType: OVNKubernetes
  serviceNetwork:
    - 172.30.0.0/16
platform:
  aws:
    region: us-west-2
    propagateUserTags: true
    userTags:
      adminContact: jdoe
      costCenter: 7536
  subnets:
    - subnet-1
    - subnet-2
    - subnet-3
  amiID: ami-0c5d3e03c0ab9b19a
  serviceEndpoints:
    - name: ec2
      url: https://vpce-id.ec2.us-west-2.vpce.amazonaws.com
      hostedZone: Z3URY6TWQ91KV
  fips: false
  sshKey: ssh-ed25519 AAAA...
pullSecret: '{"auths": ...}'

---

1 Required. The installation program prompts you for this value.
2 Optional: Add this parameter to force the Cloud Credential Operator (CCO) to use the specified mode. By default, the CCO uses the root credentials in the kube-system namespace to dynamically try to determine the capabilities of the credentials. For details about CCO modes, see the "About the Cloud Credential Operator" section in the Authentication and authorization guide.
3 If you do not provide these parameters and values, the installation program provides the default value.
4 The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, -, and the first line of the controlPlane section must not. Only one control plane pool is used.
5 Whether to enable or disable simultaneous multithreading, or hyperthreading. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to Disabled. If you disable simultaneous
multithreading in some cluster machines, you must disable it in all cluster machines.

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger instance types, such as `m4.2xlarge` or `m5.2xlarge`, for your machines if you disable simultaneous multithreading.

To configure faster storage for etcd, especially for larger clusters, set the storage type as `io1` and set `iops` to `2000`.

Whether to require the Amazon EC2 Instance Metadata Service v2 (IMDSv2). To require IMDSv2, set the parameter value to `Required`. To allow the use of both IMDSv1 and IMDSv2, set the parameter value to `Optional`. If no value is specified, both IMDSv1 and IMDSv2 are allowed.

**NOTE**

The IMDS configuration for control plane machines that is set during cluster installation can only be changed by using the AWS CLI. The IMDS configuration for compute machines can be changed by using compute machine sets.

The cluster network plugin to install. The supported values are `OVNKubernetes` and `OpenShiftSDN`. The default value is `OVNKubernetes`.

If you provide your own VPC, specify subnets for each availability zone that your cluster uses.

The ID of the AMI used to boot machines for the cluster. If set, the AMI must belong to the same region as the cluster.

The AWS service endpoints. Custom endpoints are required when installing to an unknown AWS region. The endpoint URL must use the `https` protocol and the host must trust the certificate.

The ID of your existing Route 53 private hosted zone. Providing an existing hosted zone requires that you supply your own VPC and the hosted zone is already associated with the VPC prior to installing your cluster. If undefined, the installation program creates a new hosted zone.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see *Installing the system in FIPS mode*. When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures.

You can optionally provide the `sshKey` value that you use to access the machines in your cluster.
NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

6.7.6.5. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

Prerequisites

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

NOTE

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port> 1
  httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
  noProxy: ec2.<aws_region>.amazonaws.com,elasticloadbalancing.<aws_region>.amazonaws.com,s3.<aws_region>.amazonaws.com 3
additionalTrustBundle:
  -----BEGIN CERTIFICATE-----
  <MY_TRUSTED_CA_CERT>
  -----END CERTIFICATE-----
additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> 5
```

1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.
2. A proxy URL to use for creating HTTPS connections outside the cluster.
A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For

If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the trustedCA field of the Proxy object. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

Optional: The policy to determine the configuration of the Proxy object to reference the user-ca-bundle config map in the trustedCA field. The allowed values are Proxyonly and Always. Use Proxyonly to reference the user-ca-bundle config map only when http/https proxy is configured. Use Always to always reference the user-ca-bundle config map. The default value is Proxyonly.

NOTE
The installation program does not support the proxy readinessEndpoints field.

NOTE
If the installer times out, restart and then complete the deployment by using the wait-for command of the installer. For example:

```
$ ./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

NOTE
Only the Proxy object named cluster is supported, and no additional proxies can be created.

6.7.6.6. Applying existing AWS security groups to the cluster

Applying existing AWS security groups to your control plane and compute machines can help you meet the security needs of your organization, in such cases where you need to control the incoming or outgoing traffic of these machines.

Prerequisites

- You have created the security groups in AWS. For more information, see the AWS documentation about working with security groups.
- The security groups must be associated with the existing VPC that you are deploying the cluster to. The security groups cannot be associated with another VPC.
You have an existing `install-config.yaml` file.

**Procedure**

1. In the `install-config.yaml` file, edit the `compute.platform.aws.additionalSecurityGroupIDs` parameter to specify one or more custom security groups for your compute machines.

2. Edit the `controlPlane.platform.aws.additionalSecurityGroupIDs` parameter to specify one or more custom security groups for your control plane machines.

3. Save the file and reference it when deploying the cluster.

**Sample install-config.yaml file that specifies custom security groups**

```
# ...
compute:
- hyperthreading: Enabled
  name: worker
  platform:
    aws:
      additionalSecurityGroupIDs:
        - sg-1
        - sg-2
      replicas: 3
  controlPlane:
    hyperthreading: Enabled
    name: master
    platform:
      aws:
        additionalSecurityGroupIDs:
          - sg-3
          - sg-4
        replicas: 3
      platform:
        aws:
          region: us-east-1
          subnets: 2
          - subnet-1
          - subnet-2
          - subnet-3
```

1. Specify the name of the security group as it appears in the Amazon EC2 console, including the `sg` prefix.

2. Specify subnets for each availability zone that your cluster uses.

**6.7.7. Installing the OpenShift CLI by downloading the binary**

You can install the OpenShift CLI (`oc`) to interact with OpenShift Container Platform from a command-line interface. You can install `oc` on Linux, Windows, or macOS.
IMPORTANT

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of oc.

Installing the OpenShift CLI on Linux
You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure

2. Select the architecture from the Product Variant drop-down list.

3. Select the appropriate version from the Version drop-down list.

4. Click Download Now next to the OpenShift v4.14 Linux Client entry and save the file.

5. Unpack the archive:

   $ tar xvf <file>

6. Place the oc binary in a directory that is on your PATH. To check your PATH, execute the following command:

   $ echo $PATH

Verification

- After you install the OpenShift CLI, it is available using the oc command:

   $ oc <command>

Installing the OpenShift CLI on Windows
You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

Procedure

2. Select the appropriate version from the Version drop-down list.

3. Click Download Now next to the OpenShift v4.14 Windows Client entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the oc binary to a directory that is on your PATH. To check your PATH, open the command prompt and execute the following command:

   C:\> path

Verification
Verification

- After you install the OpenShift CLI, it is available using the `oc` command:

  C:> oc <command>

Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (`oc`) binary on macOS by using the following procedure.

Procedure

2. Select the appropriate version from the Version drop-down list.

3. Click Download Now next to the OpenShift v4.14 macOS Client entry and save the file.

   NOTE

   For macOS arm64, choose the OpenShift v4.14 macOS arm64 Client entry.

4. Unpack and unzip the archive.

5. Move the `oc` binary to a directory on your PATH.

   To check your PATH, open a terminal and execute the following command:

   `$ echo $PATH`

Verification

- After you install the OpenShift CLI, it is available using the `oc` command:

  `$ oc <command>`

6.7.8. Alternatives to storing administrator-level secrets in the kube-system project

By default, administrator secrets are stored in the `kube-system` project. If you configured the `credentialsMode` parameter in the `install-config.yaml` file to `Manual`, you must use one of the following alternatives:

- To manage long-term cloud credentials manually, follow the procedure in Manually creating long-term credentials.

- To implement short-term credentials that are managed outside the cluster for individual components, follow the procedures in Configuring an AWS cluster to use short-term credentials.

6.7.8.1. Manually creating long-term credentials

The Cloud Credential Operator (CCO) can be put into manual mode prior to installation in environments where the cloud identity and access management (IAM) APIs are not reachable, or the administrator prefers not to store an administrator-level credential secret in the cluster `kube-system` namespace.
Procedure

1. If you did not set the `credentialsMode` parameter in the `install-config.yaml` configuration file to Manual, modify the value as shown:

   **Sample configuration file snippet**
   ```yaml
   apiVersion: v1
   baseDomain: example.com
   credentialsMode: Manual
   # ...
   ```

2. If you have not previously created installation manifest files, do so by running the following command:

   ```
   $ openshift-install create manifests --dir <installation_directory>
   ```

   where `<installation_directory>` is the directory in which the installation program creates files.

3. Set a `$RELEASE_IMAGE` variable with the release image from your installation file by running the following command:

   ```
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
   ```

4. Extract the list of `CredentialsRequest` custom resources (CRs) from the OpenShift Container Platform release image by running the following command:

   ```
   $ oc adm release extract \ 
   --from=$RELEASE_IMAGE \ 
   --credentials-requests \ 
   --included \ 
   --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \ 
   --to=<path_to_directory_for_credentials_requests>
   ```

   The `--included` parameter includes only the manifests that your specific cluster configuration requires.

   Specify the location of the `install-config.yaml` file.

   Specify the path to the directory where you want to store the `CredentialsRequest` objects. If the specified directory does not exist, this command creates it.

   This command creates a YAML file for each `CredentialsRequest` object.

   **Sample `CredentialsRequest` object**
   ```yaml
   apiVersion: cloudcredential.openshift.io/v1
   kind: CredentialsRequest
   metadata:
     name: <component_credentials_request>
     namespace: openshift-cloud-credential-operator
   ...
   spec:
   ```
providerSpec:
  apiVersion: cloudcredential.openshift.io/v1
  kind: AWSProviderSpec
  statementEntries:
  - effect: Allow
    action:
    - iam:GetUser
    - iam:GetUserPolicy
    - iam:ListAccessKeys
    resource: "***"

5. Create YAML files for secrets in the `openshift-install` manifests directory that you generated previously. The secrets must be stored using the namespace and secret name defined in the `spec.secretRef` for each `CredentialsRequest` object.

Sample `CredentialsRequest` object with secrets

```yaml
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
  name: <component_credentials_request>
  namespace: openshift-cloud-credential-operator
...
spec:
  providerSpec:
    apiVersion: cloudcredential.openshift.io/v1
    kind: AWSProviderSpec
    statementEntries:
    - effect: Allow
      action:
      - s3:CreateBucket
      - s3:DeleteBucket
      resource: "***"
    ...
  secretRef:
    name: <component_secret>
    namespace: <component_namespace>
...
```

Sample Secret object

```yaml
apiVersion: v1
kind: Secret
metadata:
  name: <component_secret>
  namespace: <component_namespace>
data:
  aws_access_key_id: <base64_encoded_aws_access_key_id>
  aws_secret_access_key: <base64_encoded_aws_secret_access_key>
```
IMPORTANT

Before upgrading a cluster that uses manually maintained credentials, you must ensure that the CCO is in an upgradeable state.

6.7.8.2. Configuring an AWS cluster to use short-term credentials

To install a cluster that is configured to use the AWS Security Token Service (STS), you must configure the CCO utility and create the required AWS resources for your cluster.

6.7.8.2.1. Configuring the Cloud Credential Operator utility

To create and manage cloud credentials from outside of the cluster when the Cloud Credential Operator (CCO) is operating in manual mode, extract and prepare the CCO utility (ccoctl) binary.

NOTE

The ccoctl utility is a Linux binary that must run in a Linux environment.

Prerequisites

- You have access to an OpenShift Container Platform account with cluster administrator access.
- You have installed the OpenShift CLI (oc).
- You have created an AWS account for the ccoctl utility to use with the following permissions:

Example 6.30. Required AWS permissions

Required iam permissions

- iam:CreateOpenIDConnectProvider
- iam:CreateRole
- iam:DeleteOpenIDConnectProvider
- iam:DeleteRole
- iam:DeleteRolePolicy
- iam:GetOpenIDConnectProvider
- iam:GetRole
- iam:GetUser
- iam:ListOpenIDConnectProviders
- iam:ListRolePolicies
- iam:ListRoles
- iam:PutRolePolicy
- iam:TagOpenIDConnectProvider
- **iam:TagRole**

  Required **s3 permissions**
  - s3:CreateBucket
  - s3:DeleteBucket
  - s3:DeleteObject
  - s3:GetBucketAcl
  - s3:GetBucketTagging
  - s3:GetObject
  - s3:GetObjectAcl
  - s3:GetObjectTagging
  - s3:ListBucket
  - s3:PutBucketAcl
  - s3:PutBucketPolicy
  - s3:PutBucketPublicAccessBlock
  - s3:PutBucketTagging
  - s3:PutObject
  - s3:PutObjectAcl
  - s3:PutObjectTagging

  Required **cloudfront permissions**
  - cloudfront:ListCloudFrontOriginAccessIdentities
  - cloudfront:ListDistributions
  - cloudfront:ListTagsForResource

If you plan to store the OIDC configuration in a private S3 bucket that is accessed by the IAM identity provider through a public CloudFront distribution URL, the AWS account that runs the `ccoctl` utility requires the following additional permissions:

**Example 6.31. Additional permissions for a private S3 bucket with CloudFront**

- cloudfront:CreateCloudFrontOriginAccessIdentity
- cloudfront:CreateDistribution
- cloudfront:DeleteCloudFrontOriginAccessIdentity
- cloudfront:DeleteDistribution
Procedure

1. Obtain the OpenShift Container Platform release image by running the following command:

   ```bash
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
   ```

2. Obtain the CCO container image from the OpenShift Container Platform release image by running the following command:

   ```bash
   $ CCO_IMAGE=$(oc adm release info --image-for='cloud-credential-operator' $RELEASE_IMAGE -a ~/.pull-secret)
   ```

   **NOTE**

   Ensure that the architecture of the $RELEASE_IMAGE matches the architecture of the environment in which you will use the ccoctl tool.

3. Extract the ccoctl binary from the CCO container image within the OpenShift Container Platform release image by running the following command:

   ```bash
   $ oc image extract $CCO_IMAGE --file="/usr/bin/ccoctl" -a ~/.pull-secret
   ```

4. Change the permissions to make ccoctl executable by running the following command:

   ```bash
   $ chmod 775 ccoctl
   ```

Verification

- To verify that ccoctl is ready to use, display the help file by running the following command:

  ```bash
  $ ccoctl --help
  ```

  **Output of ccoctl --help**

---

- cloudfront:GetCloudFrontOriginAccessIdentity
- cloudfront:GetCloudFrontOriginAccessIdentityConfig
- cloudfront:GetDistribution
- cloudfront:TagResource
- cloudfront:UpdateDistribution

**NOTE**

These additional permissions support the use of the `--create-private-s3-bucket` option when processing credentials requests with the ccoctl aws create-all command.
Creating AWS resources with the Cloud Credential Operator utility

You have the following options when creating AWS resources:

- You can use the `ccoctl aws create-all` command to create the AWS resources automatically. This is the quickest way to create the resources. See Creating AWS resources with a single command.

- If you need to review the JSON files that the `ccoctl` tool creates before modifying AWS resources, or if the process the `ccoctl` tool uses to create AWS resources automatically does not meet the requirements of your organization, you can create the AWS resources individually. See Creating AWS resources individually.

**NOTE**

By default, `ccoctl` creates objects in the directory in which the commands are run. To create the objects in a different directory, use the `--output-dir` flag. This procedure uses `<path_to_ccoctl_output_dir>` to refer to this directory.

Prerequisites

You must have:

- Extracted and prepared the `ccoctl` binary.

Procedure
1. Set a `$RELEASE_IMAGE` variable with the release image from your installation file by running the following command:

   ```bash
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
   ```

2. Extract the list of `CredentialsRequest` objects from the OpenShift Container Platform release image by running the following command:

   ```bash
   $ oc adm release extract \
      --from=$RELEASE_IMAGE \
      --credentials-requests \
      --included \
      --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \
      --to=<path_to_directory_for_credentials_requests>
   ```

   **Note**
   The `--included` parameter includes only the manifests that your specific cluster configuration requires.

   **Specifying a Location**
   - Specify the location of the `install-config.yaml` file.
   - Specify the path to the directory where you want to store the `CredentialsRequest` objects. If the specified directory does not exist, this command creates it.

   **Note**
   This command might take a few moments to run.

3. Use the `ccoctl` tool to process all `CredentialsRequest` objects by running the following command:

   ```bash
   $ ccoctl aws create-all \
      --name=<name> \
      --region=<aws_region> \
      --credentials-requests-dir=<path_to_credentials_requests_directory> \
      --output-dir=<path_to_ccoctl_output_dir> \
      --create-private-s3-bucket
   ```

   **Specifying a Name**
   - Specify the name used to tag any cloud resources that are created for tracking.

   **Specifying an AWS Region**
   - Specify the AWS region in which cloud resources will be created.

   **Specifying a Directory**
   - Specify the directory containing the files for the component `CredentialsRequest` objects.

   **Optional**
   - Specify the directory in which you want the `ccoctl` utility to create objects. By default, the utility creates objects in the directory in which the commands are run.

   **Optional**
   - By default, the `ccoctl` utility stores the OpenID Connect (OIDC) configuration files in a public S3 bucket and uses the S3 URL as the public OIDC endpoint. To store the OIDC configuration in a private S3 bucket that is accessed by the IAM identity provider through a public CloudFront distribution URL instead, use the `--create-private-s3-bucket` parameter.
NOTE

If your cluster uses Technology Preview features that are enabled by the `TechPreviewNoUpgrade` feature set, you must include the `--enable-tech-preview` parameter.

Verification

- To verify that the OpenShift Container Platform secrets are created, list the files in the `<path_to_ccoclt_output_dir>/manifests` directory:

  ```
  $ ls <path_to_ccoclt_output_dir>/manifests
  ```

Example output

- `cluster-authentication-02-config.yaml`
- `openshift-cloud-credential-operator-cloud-credential-operator-iam-ro-creds-credentials.yaml`
- `openshift-cloud-network-config-controller-cloud-credentials-credentials.yaml`
- `openshift-cluster-api-capa-manager-bootstrap-credentials-credentials.yaml`
- `openshift-cluster-csi-drivers-ebs-cloud-credentials-credentials.yaml`
- `openshift-image-registry-installer-cloud-credentials-credentials.yaml`
- `openshift-ingress-operator-cloud-credentials-credentials.yaml`
- `openshift-machine-api-aws-cloud-credentials-credentials.yaml`

You can verify that the IAM roles are created by querying AWS. For more information, refer to AWS documentation on listing IAM roles.

6.7.8.2.2.2. Creating AWS resources individually

You can use the `ccoclt` tool to create AWS resources individually. This option might be useful for an organization that shares the responsibility for creating these resources among different users or departments.

Otherwise, you can use the `ccoclt aws create-all` command to create the AWS resources automatically. For more information, see "Creating AWS resources with a single command".

NOTE

By default, `ccoclt` creates objects in the directory in which the commands are run. To create the objects in a different directory, use the `--output-dir` flag. This procedure uses `<path_to_ccoclt_output_dir>` to refer to this directory.

Some `ccoclt` commands make AWS API calls to create or modify AWS resources. You can use the `--dry-run` flag to avoid making API calls. Using this flag creates JSON files on the local file system instead. You can review and modify the JSON files and then apply them with the AWS CLI tool using the `--cli-input-json` parameters.

Prerequisites

- Extract and prepare the `ccoclt` binary.

Procedure

1. Generate the `cluster-authentication-02-config` secret directly using the `ccoclt` command.
1. Generate the public and private RSA key files that are used to set up the OpenID Connect provider for the cluster by running the following command:

   ```bash
   $ ccoctl aws create-key-pair
   ``

   **Example output**

   ```
   2021/04/13 11:01:02 Generating RSA keypair
   2021/04/13 11:01:03 Writing private key to /<path_to_ccoctl_output_dir>/serviceaccount-signer.private
   2021/04/13 11:01:03 Writing public key to /<path_to_ccoctl_output_dir>/serviceaccount-signer.public
   2021/04/13 11:01:03 Copying signing key for use by installer
   ```

   where `serviceaccount-signer.private` and `serviceaccount-signer.public` are the generated key files.

   This command also creates a private key that the cluster requires during installation in `/<path_to_ccoctl_output_dir>/tls/bound-service-account-signing-key.key`.

2. Create an OpenID Connect identity provider and S3 bucket on AWS by running the following command:

   ```bash
   $ ccoctl aws create-identity-provider \
     --name=<name> \  
     --region=<aws_region> \ 
     --public-key-file=<path_to_ccoctl_output_dir>/serviceaccount-signer.public
   ```

   **Example output**

   ```
   2021/04/13 11:16:09 Bucket <name>-oidc created
   2021/04/13 11:16:10 OpenID Connect discovery document in the S3 bucket <name>-oidc at .well-known/openid-configuration updated
   2021/04/13 11:16:10 Reading public key
   2021/04/13 11:16:10 JSON web key set (JWKS) in the S3 bucket <name>-oidc at keys.json updated
   ```

   where `openid-configuration` is a discovery document and `keys.json` is a JSON web key set file.

   This command also creates a YAML configuration file in `/<path_to_ccoctl_output_dir>/manifests/cluster-authentication-02-config.yaml`. This file sets the issuer URL field for the service account tokens that the cluster generates, so that the AWS IAM identity provider trusts the tokens.

3. Create IAM roles for each component in the cluster:
a. Set a `$RELEASE_IMAGE` variable with the release image from your installation file by running the following command:

```bash
$ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
```

b. Extract the list of `CredentialsRequest` objects from the OpenShift Container Platform release image:

```bash
$ oc adm release extract \
   --from=$RELEASE_IMAGE \
   --credentials-requests \
   --included \n   --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \n   --to=<path_to_directory_for_credentials_requests>
```

1. The `--included` parameter includes only the manifests that your specific cluster configuration requires.

2. Specify the location of the `install-config.yaml` file.

3. Specify the path to the directory where you want to store the `CredentialsRequest` objects. If the specified directory does not exist, this command creates it.

c. Use the `ccoctl` tool to process all `CredentialsRequest` objects by running the following command:

```bash
$ ccoctl aws create-iam-roles \
   --name=<name> \
   --region=<aws_region> \
   --credentials-requests-dir=<path_to_credentials_requests_directory> \n   --identity-provider-arn=arn:aws:iam::<aws_account_id>:oidc-provider/<name>-oidc.s3.<aws_region>.amazonaws.com
```

**NOTE**

For AWS environments that use alternative IAM API endpoints, such as GovCloud, you must also specify your region with the `--region` parameter.

If your cluster uses Technology Preview features that are enabled by the `TechPreviewNoUpgrade` feature set, you must include the `--enable-tech-preview` parameter.

For each `CredentialsRequest` object, `ccoctl` creates an IAM role with a trust policy that is tied to the specified OIDC identity provider, and a permissions policy as defined in each `CredentialsRequest` object from the OpenShift Container Platform release image.

**Verification**

- To verify that the OpenShift Container Platform secrets are created, list the files in the `<path_to_ccoctl_output_dir>/manifests` directory:

  ```bash
  $ ls <path_to_ccoctl_output_dir>/manifests
  ```
Example output

You can verify that the IAM roles are created by querying AWS. For more information, refer to AWS documentation on listing IAM roles.

6.7.8.2.3. Incorporating the Cloud Credential Operator utility manifests

To implement short-term security credentials managed outside the cluster for individual components, you must move the manifest files that the Cloud Credential Operator utility (ccoctl) created to the correct directories for the installation program.

Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.
- You have configured the Cloud Credential Operator utility (ccoctl).
- You have created the cloud provider resources that are required for your cluster with the ccoctl utility.

Procedure

1. If you did not set the credentialsMode parameter in the install-config.yaml configuration file to Manual, modify the value as shown:

   Sample configuration file snippet

   ```yaml
   apiVersion: v1
   baseDomain: example.com
   credentialsMode: Manual
   # ...
   ```

2. If you have not previously created installation manifest files, do so by running the following command:

   ```bash
   $ openshift-install create manifests --dir <installation_directory>
   ```

   where `<installation_directory>` is the directory in which the installation program creates files.

3. Copy the manifests that the ccoctl utility generated to the manifests directory that the installation program created by running the following command:

   ```bash
   $ cp /<path_to_ccoctl_output_dir>/manifests/* ./manifests/
   ```
4. Copy the private key that the `ccoctl` utility generated in the `tls` directory to the installation directory by running the following command:

```
$ cp -a /<path_to_ccoctl_output_dir>/tls .
```

## 6.7.9. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

### IMPORTANT

You can run the `create cluster` command of the installation program only once, during initial installation.

### Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.
- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.

### Procedure

1. Change to the directory that contains the installation program and initialize the cluster deployment:

```
$ ./openshift-install create cluster --dir <installation_directory>  
--log-level=info
```

   **1** For `<installation_directory>`, specify the location of your customized `./install-config.yaml` file.

   **2** To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

2. Optional: Remove or disable the `AdministratorAccess` policy from the IAM account that you used to install the cluster.

   **NOTE**

   The elevated permissions provided by the `AdministratorAccess` policy are required only during installation.

### Verification

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the `kubeadmin` user.
Credential information also outputs to `<installation_directory>/openshift_install.log`.

**IMPORTANT**

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

**Example output**

```
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

**6.7.10. Logging in to the cluster by using the CLI**

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.

- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

   ```
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```
For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```
   $ oc whoami
   
   Example output
   
   system:admin
   ```

### 6.7.11. Logging in to the cluster by using the web console

The `kubeadmin` user exists by default after an OpenShift Container Platform installation. You can log in to your cluster as the `kubeadmin` user by using the OpenShift Container Platform web console.

**Prerequisites**

- You have access to the installation host.
- You completed a cluster installation and all cluster Operators are available.

**Procedure**

1. Obtain the password for the `kubeadmin` user from the `kubeadmin-password` file on the installation host:

   ```
   $ cat <installation_directory>/auth/kubeadmin-password
   
   NOTE
   
   Alternatively, you can obtain the `kubeadmin` password from the `<installation_directory>/.openshift_install.log` log file on the installation host.
   ```

2. List the OpenShift Container Platform web console route:

   ```
   $ oc get routes -n openshift-console | grep 'console-openshift'
   
   NOTE
   
   Alternatively, you can obtain the OpenShift Container Platform route from the `<installation_directory>/.openshift_install.log` log file on the installation host.
   ```

**Example output**

```console
console console-openshift-console.apps.<cluster_name>.<base_domain> console https reencrypt/Redirect None
```

3. Navigate to the route detailed in the output of the preceding command in a web browser and log in as the `kubeadmin` user.
Additional resources

- See Accessing the web console for more details about accessing and understanding the OpenShift Container Platform web console.

### 6.7.12. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager Hybrid Cloud Console.

After you confirm that your OpenShift Cluster Manager Hybrid Cloud Console inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service.

### 6.7.13. Next steps

- Validating an installation.
- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- If necessary, you can remove cloud provider credentials.

### 6.8. INSTALLING A PRIVATE CLUSTER ON AWS

In OpenShift Container Platform version 4.14, you can install a private cluster into an existing VPC on Amazon Web Services (AWS). The installation program provisions the rest of the required infrastructure, which you can further customize. To customize the installation, you modify parameters in the install-config.yaml file before you install the cluster.

### 6.8.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You configured an AWS account to host the cluster.
IMPORTANT

If you have an AWS profile stored on your computer, it must not use a temporary session token that you generated while using a multi-factor authentication device. The cluster continues to use your current AWS credentials to create AWS resources for the entire life of the cluster, so you must use long-term credentials. To generate appropriate keys, see Managing Access Keys for IAM Users in the AWS documentation. You can supply the keys when you run the installation program.

- If you use a firewall, you configured it to allow the sites that your cluster requires access to.

6.8.2. Private clusters

You can deploy a private OpenShift Container Platform cluster that does not expose external endpoints. Private clusters are accessible from only an internal network and are not visible to the internet.

By default, OpenShift Container Platform is provisioned to use publicly-accessible DNS and endpoints. A private cluster sets the DNS, Ingress Controller, and API server to private when you deploy your cluster. This means that the cluster resources are only accessible from your internal network and are not visible to the internet.

IMPORTANT

If the cluster has any public subnets, load balancer services created by administrators might be publicly accessible. To ensure cluster security, verify that these services are explicitly annotated as private.

To deploy a private cluster, you must:

- Use existing networking that meets your requirements. Your cluster resources might be shared between other clusters on the network.

- Deploy from a machine that has access to:
  - The API services for the cloud to which you provision.
  - The hosts on the network that you provision.
  - The internet to obtain installation media.

You can use any machine that meets these access requirements and follows your company’s guidelines. For example, this machine can be a bastion host on your cloud network or a machine that has access to the network through a VPN.

6.8.2.1. Private clusters in AWS

To create a private cluster on Amazon Web Services (AWS), you must provide an existing private VPC and subnets to host the cluster. The installation program must also be able to resolve the DNS records that the cluster requires. The installation program configures the Ingress Operator and API server for access from only the private network.

The cluster still requires access to internet to access the AWS APIs.
The following items are not required or created when you install a private cluster:

- Public subnets
- Public load balancers, which support public ingress
- A public Route 53 zone that matches the `baseDomain` for the cluster

The installation program does use the `baseDomain` that you specify to create a private Route 53 zone and the required records for the cluster. The cluster is configured so that the Operators do not create public records for the cluster and all cluster machines are placed in the private subnets that you specify.

### 6.8.2.1.1. Limitations

The ability to add public functionality to a private cluster is limited.

- You cannot make the Kubernetes API endpoints public after installation without taking additional actions, including creating public subnets in the VPC for each availability zone in use, creating a public load balancer, and configuring the control plane security groups to allow traffic from the internet on 6443 (Kubernetes API port).

- If you use a public Service type load balancer, you must tag a public subnet in each availability zone with `kubernetes.io/cluster/<cluster-infra-id>: shared` so that AWS can use them to create public load balancers.

### 6.8.3. About using a custom VPC

In OpenShift Container Platform 4.14, you can deploy a cluster into existing subnets in an existing Amazon Virtual Private Cloud (VPC) in Amazon Web Services (AWS). By deploying OpenShift Container Platform into an existing AWS VPC, you might be able to avoid limit constraints in new accounts or more easily abide by the operational constraints that your company’s guidelines set. If you cannot obtain the infrastructure creation permissions that are required to create the VPC yourself, use this installation option.

Because the installation program cannot know what other components are also in your existing subnets, it cannot choose subnet CIDRs and so forth on your behalf. You must configure networking for the subnets that you install your cluster to yourself.

### 6.8.3.1. Requirements for using your VPC

The installation program no longer creates the following components:

- Internet gateways
- NAT gateways
- Subnets
- Route tables
- VPCs
- VPC DHCP options
- VPC endpoints
The installation program requires that you use the cloud-provided DNS server. Using a custom DNS server is not supported and causes the installation to fail.

If you use a custom VPC, you must correctly configure it and its subnets for the installation program and the cluster to use. See Amazon VPC console wizard configurations and Work with VPCs and subnets in the AWS documentation for more information on creating and managing an AWS VPC.

The installation program cannot:

- Subdivide network ranges for the cluster to use.
- Set route tables for the subnets.
- Set VPC options like DHCP.

You must complete these tasks before you install the cluster. See VPC networking components and Route tables for your VPC for more information on configuring networking in an AWS VPC.

Your VPC must meet the following characteristics:

- The VPC must not use the `kubernetes.io/cluster/.*: owned`, `Name`, and `openshift.io/cluster` tags. The installation program modifies your subnets to add the `kubernetes.io/cluster/.*: shared` tag, so your subnets must have at least one free tag slot available for it. See Tag Restrictions in the AWS documentation to confirm that the installation program can add a tag to each subnet that you specify. You cannot use a `Name` tag, because it overlaps with the EC2 `Name` field and the installation fails.

- You must enable the `enableDnsSupport` and `enableDnsHostnames` attributes in your VPC, so that the cluster can use the Route 53 zones that are attached to the VPC to resolve cluster’s internal DNS records. See DNS Support in Your VPC in the AWS documentation. If you prefer to use your own Route 53 hosted private zone, you must associate the existing hosted zone with your VPC prior to installing a cluster. You can define your hosted zone using the `platform.aws.hostedZone` and `platform.aws.hostedZoneRole` fields in the `install-config.yaml` file. You can use a private hosted zone from another account by sharing it with the account where you install the cluster. If you use a private hosted zone from another account, you must use the Passthrough or Manual credentials mode.

If you are working in a disconnected environment, you are unable to reach the public IP addresses for EC2, ELB, and S3 endpoints. Depending on the level to which you want to restrict internet traffic during the installation, the following configuration options are available:

**Option 1: Create VPC endpoints**
Create a VPC endpoint and attach it to the subnets that the clusters are using. Name the endpoints as follows:

- `ec2.<aws_region>.amazonaws.com`
- `elasticloadbalancing.<aws_region>.amazonaws.com`
- `s3.<aws_region>.amazonaws.com`

With this option, network traffic remains private between your VPC and the required AWS services.

**Option 2: Create a proxy without VPC endpoints**
As part of the installation process, you can configure an HTTP or HTTPS proxy. With this option, internet traffic goes through the proxy to reach the required AWS services.

Option 3: Create a proxy with VPC endpoints
As part of the installation process, you can configure an HTTP or HTTPS proxy with VPC endpoints. Create a VPC endpoint and attach it to the subnets that the clusters are using. Name the endpoints as follows:

- ec2.<aws_region>.amazonaws.com
- elasticloadbalancing.<aws_region>.amazonaws.com
- s3.<aws_region>.amazonaws.com

When configuring the proxy in the `install-config.yaml` file, add these endpoints to the `noProxy` field. With this option, the proxy prevents the cluster from accessing the internet directly. However, network traffic remains private between your VPC and the required AWS services.

Required VPC components
You must provide a suitable VPC and subnets that allow communication to your machines.

<table>
<thead>
<tr>
<th>Component</th>
<th>AWS type</th>

<tr>
<td>22</td>
<td>Inbound SSH traffic</td>
</tr>
<tr>
<td>1024 - 65535</td>
<td>Inbound ephemeral traffic</td>
</tr>
<tr>
<td>0 - 65535</td>
<td>Outbound ephemeral traffic</td>
</tr>
</tbody>
</table>

**Private subnets**

- **AWS::EC2::Subnet**
- **AWS::EC2::RouteTable**
- **AWS::EC2::SubnetRouteTableAssociation**

**Description**

Your VPC can have private subnets. The provided CloudFormation templates can create private subnets for between 1 and 3 availability zones. If you use private subnets, you must provide appropriate routes and tables for them.

### 6.8.3.2. VPC validation

To ensure that the subnets that you provide are suitable, the installation program confirms the following data:

- All the subnets that you specify exist.
- You provide private subnets.
- The subnet CIDRs belong to the machine CIDR that you specified.
- You provide subnets for each availability zone. Each availability zone contains no more than one public and one private subnet. If you use a private cluster, provide only a private subnet for each availability zone. Otherwise, provide exactly one public and private subnet for each availability zone.
- You provide a public subnet for each private subnet availability zone. Machines are not provisioned in availability zones that you do not provide private subnets for.
If you destroy a cluster that uses an existing VPC, the VPC is not deleted. When you remove the OpenShift Container Platform cluster from a VPC, the `kubernetes.io/cluster/*/shared` tag is removed from the subnets that it used.

### 6.8.3.3. Division of permissions

Starting with OpenShift Container Platform 4.3, you do not need all of the permissions that are required for an installation program-provisioned infrastructure cluster to deploy a cluster. This change mimics the division of permissions that you might have at your company: some individuals can create different resource in your clouds than others. For example, you might be able to create application-specific items, like instances, buckets, and load balancers, but not networking-related components such as VPCs, subnets, or ingress rules.

The AWS credentials that you use when you create your cluster do not need the networking permissions that are required to make VPCs and core networking components within the VPC, such as subnets, routing tables, internet gateways, NAT, and VPN. You still need permission to make the application resources that the machines within the cluster require, such as ELBs, security groups, S3 buckets, and nodes.

### 6.8.3.4. Isolation between clusters

If you deploy OpenShift Container Platform to an existing network, the isolation of cluster services is reduced in the following ways:

- You can install multiple OpenShift Container Platform clusters in the same VPC.
- ICMP ingress is allowed from the entire network.
- TCP 22 ingress (SSH) is allowed to the entire network.
- Control plane TCP 6443 ingress (Kubernetes API) is allowed to the entire network.
- Control plane TCP 22623 ingress (MCS) is allowed to the entire network.

### 6.8.3.5. AWS security groups

By default, the installation program creates and attaches security groups to control plane and compute machines. The rules associated with the default security groups cannot be modified.

However, you can apply additional existing AWS security groups, which are associated with your existing VPC, to control plane and compute machines. Applying custom security groups can help you meet the security needs of your organization, in such cases where you need to control the incoming or outgoing traffic of these machines.

As part of the installation process, you apply custom security groups by modifying the `install-config.yaml` file before deploying the cluster.

For more information, see "Applying existing AWS security groups to the cluster".

### 6.8.4. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager Hybrid Cloud Console to download the installation program.
OpenShift Container Platform 4.14 Installing

- Access OpenShift Cluster Manager Hybrid Cloud Console to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- Access Quay.io to obtain the packages that are required to install your cluster.

- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

6.8.5. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The /openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N '' -f <path>/<file_name>  
   ```

   Specify the path and file name, such as ~/.ssh/id_ed25519, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.
NOTE

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

```bash
$ cat <path>/<file_name>.pub
```

For example, run the following to view the ~/.ssh/id_ed25519.pub public key:

```bash
$ cat ~/.ssh/id_ed25519.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the ./openshift-install gather command.

NOTE

On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.

a. If the ssh-agent process is not already running for your local user, start it as a background task:

```bash
$ eval "$(ssh-agent -s)"
```

Example output

```
Agent pid 31874
```

NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the ssh-agent:

```bash
$ ssh-add <path>/<file_name> 1
```

1 Specify the path and file name for your SSH private key, such as ~/.ssh/id_ed25519

Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

Next steps
- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

6.8.6. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

**IMPORTANT**

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

6.8.7. Manually creating the installation configuration file

When installing a private OpenShift Container Platform cluster, you must manually generate the installation configuration file.

Prerequisites
You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.

You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

### Procedure

1. Create an installation directory to store your required installation assets in:

   ```
   $ mkdir <installation_directory>
   ```

   **IMPORTANT**

   You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample `install-config.yaml` file template that is provided and save it in the `<installation_directory>`.

   **NOTE**

   You must name this configuration file `install-config.yaml`.

   **NOTE**

   For some platform types, you can alternatively run `./openshift-install create install-config --dir <installation_directory>` to generate an `install-config.yaml` file. You can provide details about your cluster configuration at the prompts.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

   **IMPORTANT**

   The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.

### Additional resources

- Installation configuration parameters for AWS

### 6.8.7.1. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

Table 6.12. Minimum resource requirements
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS, RHEL 8.6 and later [3]</td>
<td>2</td>
<td>8 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
</tbody>
</table>

1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or hyperthreading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: \((\text{threads per core} \times \text{cores}) \times \text{sockets} = \text{vCPUs}\).

2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.

3. As with all user-provisioned installations, if you choose to use RHEL compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and has been removed in OpenShift Container Platform 4.10 and later.

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

**Additional resources**

- Optimizing storage

**6.8.7.2. Tested instance types for AWS**

The following Amazon Web Services (AWS) instance types have been tested with OpenShift Container Platform.

**NOTE**

Use the machine types included in the following charts for your AWS instances. If you use an instance type that is not listed in the chart, ensure that the instance size you use matches the minimum resource requirements that are listed in "Minimum resource requirements for cluster installation".

**Example 6.32. Machine types based on 64-bit x86 architecture**

- c4.*
- c5.*
6.8.7.3. Tested instance types for AWS on 64-bit ARM infrastructures

The following Amazon Web Services (AWS) 64-bit ARM instance types have been tested with OpenShift Container Platform.

NOTE

Use the machine types included in the following charts for your AWS ARM instances. If you use an instance type that is not listed in the chart, ensure that the instance size you use matches the minimum resource requirements that are listed in "Minimum resource requirements for cluster installation".

Example 6.33. Machine types based on 64-bit ARM architecture

- c6g.*
- m6g.*

6.8.7.4. Sample customized install-config.yaml file for AWS

You can customize the installation configuration file (install-config.yaml) to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

IMPORTANT

This sample YAML file is provided for reference only. You must obtain your install-config.yaml file by using the installation program and modify it.
apiVersion: v1
baseDomain: example.com
credentialsMode: Mint
controlPlane:
  hyperthreading: Enabled
  name: master
  platform:
    aws:
      lbType: NLB
      zones:
      - us-west-2a
      - us-west-2b
      rootVolume:
        iops: 4000
        size: 500
        type: io1
      metadataService:
        authentication: Optional
        type: m6i.xlarge
      replicas: 3
      compute:
        - hyperthreading: Enabled
        name: worker
        platform:
          aws:
            rootVolume:
              iops: 2000
              size: 500
              type: io1
            metadataService:
              authentication: Optional
              type: c5.4xlarge
            zones:
            - us-west-2c
            replicas: 3
            metadata:
              name: test-cluster
networking:
  clusterNetwork:
  - cidr: 10.128.0.0/14
    hostPrefix: 23
  machineNetwork:
  - cidr: 10.0.0.0/16
  networkType: OVNKubernetes
  serviceNetwork:
  - 172.30.0.0/16
platform:
  aws:
    region: us-west-2
    propagateUserTags: true
    userTags:
      adminContact: jdoe
      costCenter: 7536
    subnets:
Required. The installation program prompts you for this value.

Optional: Add this parameter to force the Cloud Credential Operator (CCO) to use the specified mode. By default, the CCO uses the root credentials in the `kube-system` namespace to dynamically try to determine the capabilities of the credentials. For details about CCO modes, see the "About the Cloud Credential Operator" section in the Authentication and authorization guide.

If you do not provide these parameters and values, the installation program provides the default value.

The `controlPlane` section is a single mapping, but the `compute` section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the `compute` section must begin with a hyphen, `-`, and the first line of the `controlPlane` section must not. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading, or hyperthreading. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to `Disabled`. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

IMPORTANT

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger instance types, such as `m4.2xlarge` or `m5.2xlarge`, for your machines if you disable simultaneous multithreading.

To configure faster storage for etcd, especially for larger clusters, set the storage type as `io1` and set `iops` to 2000.

Whether to require the Amazon EC2 Instance Metadata Service v2 (IMDSv2). To require IMDSv2, set the parameter value to `Required`. To allow the use of both IMDSv1 and IMDSv2, set the parameter value to `Optional`. If no value is specified, both IMDSv1 and IMDSv2 are allowed.

NOTE

The IMDS configuration for control plane machines that is set during cluster installation can only be changed by using the AWS CLI. The IMDS configuration for compute machines can be changed by using compute machine sets.

The cluster network plugin to install. The supported values are `OVNKubernetes` and
If you provide your own VPC, specify subnets for each availability zone that your cluster uses.

The ID of the AMI used to boot machines for the cluster. If set, the AMI must belong to the same region as the cluster.

The AWS service endpoints. Custom endpoints are required when installing to an unknown AWS region. The endpoint URL must use the https protocol and the host must trust the certificate.

The ID of your existing Route 53 private hosted zone. Providing an existing hosted zone requires that you supply your own VPC and the hosted zone is already associated with the VPC prior to installing your cluster. If undefined, the installation program creates a new hosted zone.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see [Installing the system in FIPS mode](#). When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures.

You can optionally provide the *sshKey* value that you use to access the machines in your cluster.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your *ssh-agent* process uses.

How to publish the user-facing endpoints of your cluster. Set *publish* to *Internal* to deploy a private cluster, which cannot be accessed from the internet. The default value is *External*.

### 6.8.7.5. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the *install-config.yaml* file.

**Prerequisites**

- You have an existing *install-config.yaml* file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the *Proxy* object’s *spec.noProxy* field to bypass the proxy if necessary.
NOTE

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port>
  httpsProxy: https://<username>:<pswd>@<ip>:<port>
  noProxy: ec2.<aws_region>.amazonaws.com,elasticloadbalancing.<aws_region>.amazonaws.com,s3.<aws_region>.amazonaws.com
additionalTrustBundle: |
  -----BEGIN CERTIFICATE-----
  <MY_TRUSTED_CA_CERT>
  -----END CERTIFICATE-----
additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle>
```

1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.
2. A proxy URL to use for creating HTTPS connections outside the cluster.
3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations. If you have added the Amazon EC2 Elastic Load Balancing and S3 VPC endpoints to your VPC, you must add these endpoints to the `noProxy` field.
4. If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the `trustedCA` field of the `Proxy` object. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.
5. Optional: The policy to determine the configuration of the `Proxy` object to reference the `user-ca-bundle` config map in the `trustedCA` field. The allowed values are `Proxyonly` and `Always`. Use `Proxyonly` to reference the `user-ca-bundle` config map only when `http/https` proxy is configured. Use `Always` to always reference the `user-ca-bundle` config map. The default value is `Proxyonly`. 
NOTE
The installation program does not support the proxy `readinessEndpoints` field.

NOTE
If the installer times out, restart and then complete the deployment by using the `wait-for` command of the installer. For example:

```
$ ./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

NOTE
Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

6.8.7.6. Applying existing AWS security groups to the cluster

Applying existing AWS security groups to your control plane and compute machines can help you meet the security needs of your organization, in such cases where you need to control the incoming or outgoing traffic of these machines.

Prerequisites

- You have created the security groups in AWS. For more information, see the AWS documentation about working with security groups.
- The security groups must be associated with the existing VPC that you are deploying the cluster to. The security groups cannot be associated with another VPC.
- You have an existing `install-config.yaml` file.

Procedure

1. In the `install-config.yaml` file, edit the `compute.platform.aws.additionalSecurityGroupIDs` parameter to specify one or more custom security groups for your compute machines.

2. Edit the `controlPlane.platform.aws.additionalSecurityGroupIDs` parameter to specify one or more custom security groups for your control plane machines.

3. Save the file and reference it when deploying the cluster.

Sample `install-config.yaml` file that specifies custom security groups

```
# ...
compute:
  - hyperthreading: Enabled
  name: worker
```
6.8.8. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

IMPORTANT

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of oc.

Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure

2. Select the architecture from the Product Variant drop-down list.
3. Select the appropriate version from the Version drop-down list.
4. Click Download Now next to the OpenShift v4.14 Linux Client entry and save the file.
5. Unpack the archive:
6. Place the `oc` binary in a directory that is on your `PATH`. To check your `PATH`, execute the following command:

```
$ echo $PATH
```

**Verification**

- After you install the OpenShift CLI, it is available using the `oc` command:

```
$ oc <command>
```

**Installing the OpenShift CLI on Windows**

You can install the OpenShift CLI (`oc`) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version from the **Version** drop-down list.

3. Click **Download Now** next to the **OpenShift v4.14 Windows Client** entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the `oc` binary to a directory that is on your `PATH`. To check your `PATH`, open the command prompt and execute the following command:

```
C:\> path
```

**Verification**

- After you install the OpenShift CLI, it is available using the `oc` command:

```
C:\> oc <command>
```

**Installing the OpenShift CLI on macOS**

You can install the OpenShift CLI (`oc`) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version from the **Version** drop-down list.

3. Click **Download Now** next to the **OpenShift v4.14 macOS Client** entry and save the file.
NOTE

For macOS arm64, choose the OpenShift v4.14 macOS arm64 Client entry.

4. Unpack and unzip the archive.

5. Move the `oc` binary to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:

   ```
   $ echo $PATH
   ```

Verification

- After you install the OpenShift CLI, it is available using the `oc` command:

  ```
  $ oc <command>
  ```

6.8.9. Alternatives to storing administrator-level secrets in the kube-system project

By default, administrator secrets are stored in the `kube-system` project. If you configured the `credentialsMode` parameter in the `install-config.yaml` file to Manual, you must use one of the following alternatives:

- To manage long-term cloud credentials manually, follow the procedure in Manually creating long-term credentials.

- To implement short-term credentials that are managed outside the cluster for individual components, follow the procedures in Configuring an AWS cluster to use short-term credentials.

6.8.9.1. Manually creating long-term credentials

The Cloud Credential Operator (CCO) can be put into manual mode prior to installation in environments where the cloud identity and access management (IAM) APIs are not reachable, or the administrator prefers not to store an administrator-level credential secret in the cluster `kube-system` namespace.

Procedure

1. If you did not set the `credentialsMode` parameter in the `install-config.yaml` configuration file to Manual, modify the value as shown:

   Sample configuration file snippet

   ```yaml
   apiVersion: v1
   baseDomain: example.com
   credentialsMode: Manual
   # ...
   ```

2. If you have not previously created installation manifest files, do so by running the following command:

   ```
   $ openshift-install create manifests --dir <installation_directory>
   ```
where `<installation_directory>` is the directory in which the installation program creates files.

3. Set a `$RELEASE_IMAGE` variable with the release image from your installation file by running the following command:

```bash
$ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
```

4. Extract the list of `CredentialsRequest` custom resources (CRs) from the OpenShift Container Platform release image by running the following command:

```bash
$ oc adm release extract \\
--from=$RELEASE_IMAGE \\
--credentials-requests \\
--included \\
--install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \\
--to=<path_to_directory_for_credentials_requests>
```

1. The `--included` parameter includes only the manifests that your specific cluster configuration requires.

2. Specify the location of the `install-config.yaml` file.

3. Specify the path to the directory where you want to store the `CredentialsRequest` objects. If the specified directory does not exist, this command creates it.

This command creates a YAML file for each `CredentialsRequest` object.

**Sample CredentialsRequest object**

```yaml
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
  name: <component_credentials_request>
  namespace: openshift-cloud-credential-operator

spec:
  providerSpec:
    apiVersion: cloudcredential.openshift.io/v1
    kind: AWSProviderSpec
    statementEntries:
      - effect: Allow
        action:
          - iam:GetUser
          - iam:GetUserPolicy
          - iam:ListAccessKeys
        resource: "*"
```

5. Create YAML files for secrets in the `openshift-install` manifests directory that you generated previously. The secrets must be stored using the namespace and secret name defined in the `spec.secretRef` for each `CredentialsRequest` object.

**Sample CredentialsRequest object with secrets**

```yaml
```
Before upgrading a cluster that uses manually maintained credentials, you must ensure that the CCO is in an upgradeable state.

### 6.8.9.2. Configuring an AWS cluster to use short-term credentials

To install a cluster that is configured to use the AWS Security Token Service (STS), you must configure the CCO utility and create the required AWS resources for your cluster.

#### 6.8.9.2.1. Configuring the Cloud Credential Operator utility

To create and manage cloud credentials from outside of the cluster when the Cloud Credential Operator (CCO) is operating in manual mode, extract and prepare the CCO utility (`ccoctl`) binary.

**NOTE**

The `ccoctl` utility is a Linux binary that must run in a Linux environment.

**Prerequisites**
• You have access to an OpenShift Container Platform account with cluster administrator access.

• You have installed the OpenShift CLI (oc).

• You have created an AWS account for the ccoctl utility to use with the following permissions:

  Example 6.34. Required AWS permissions

  Required iam permissions
  ○ iam:CreateOpenIDConnectProvider
  ○ iam:CreateRole
  ○ iam:DeleteOpenIDConnectProvider
  ○ iam:DeleteRole
  ○ iam:DeleteRolePolicy
  ○ iam:GetOpenIDConnectProvider
  ○ iam:GetRole
  ○ iam:GetUser
  ○ iam:ListOpenIDConnectProviders
  ○ iam:ListRolePolicies
  ○ iam:ListRoles
  ○ iam:PutRolePolicy
  ○ iam:TagOpenIDConnectProvider
  ○ iam:TagRole

  Required s3 permissions
  ○ s3:CreateBucket
  ○ s3:DeleteBucket
  ○ s3:DeleteObject
  ○ s3:GetBucketAcl
  ○ s3:GetBucketTagging
  ○ s3:GetObject
  ○ s3:GetObjectAcl
  ○ s3:GetObjectTagging
  ○ s3:ListBucket
  ○ s3:PutBucketAcl
- s3:PutBucketPolicy
- s3:PutBucketPublicAccessBlock
- s3:PutBucketTagging
- s3:PutObject
- s3:PutObjectAcl
- s3:PutObjectTagging

Required `cloudfront` permissions

- cloudfront:ListCloudFrontOriginAccessIdentities
- cloudfront:ListDistributions
- cloudfront:ListTagsForResource

If you plan to store the OIDC configuration in a private S3 bucket that is accessed by the IAM identity provider through a public CloudFront distribution URL, the AWS account that runs the `ccoctl` utility requires the following additional permissions:

**Example 6.35. Additional permissions for a private S3 bucket with CloudFront**

- cloudfront:CreateCloudFrontOriginAccessIdentity
- cloudfront:CreateDistribution
- cloudfront:DeleteCloudFrontOriginAccessIdentity
- cloudfront:DeleteDistribution
- cloudfront:GetCloudFrontOriginAccessIdentity
- cloudfront:GetCloudFrontOriginAccessIdentityConfig
- cloudfront:GetDistribution
- cloudfront:TagResource
- cloudfront:UpdateDistribution

**NOTE**

These additional permissions support the use of the `--create-private-s3-bucket` option when processing credentials requests with the `ccoctl aws create-all` command.

**Procedure**

1. Obtain the OpenShift Container Platform release image by running the following command:
$ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')

2. Obtain the CCO container image from the OpenShift Container Platform release image by running the following command:

$ CCO_IMAGE=$(oc adm release info --image-for='cloud-credential-operator' $RELEASE_IMAGE -a ~/.pull-secret)

**NOTE**

Ensure that the architecture of the $RELEASE_IMAGE matches the architecture of the environment in which you will use the **ccoctl** tool.

3. Extract the **ccoctl** binary from the CCO container image within the OpenShift Container Platform release image by running the following command:

$ oc image extract $CCO_IMAGE --file="/usr/bin/ccoctl" -a ~/.pull-secret

4. Change the permissions to make **ccoctl** executable by running the following command:

$ chmod 775 ccoctl

**Verification**

- To verify that **ccoctl** is ready to use, display the help file by running the following command:

$ ccoctl --help

**Output of ccoctl --help**

OpenShift credentials provisioning tool

Usage:
ccoctl [command]

Available Commands:
alibabacloud Manage credentials objects for alibaba cloud
aws Manage credentials objects for AWS cloud
azure Manage credentials objects for Azure
gcp Manage credentials objects for Google cloud
help Help about any command
ibmcloud Manage credentials objects for IBM Cloud
nutanix Manage credentials objects for Nutanix

Flags:
-h, --help help for ccoctl

Use "ccoctl [command] --help" for more information about a command.

**6.8.9.2.2. Creating AWS resources with the Cloud Credential Operator utility**

You have the following options when creating AWS resources:
You can use the `ccoctl aws create-all` command to create the AWS resources automatically. This is the quickest way to create the resources. See Creating AWS resources with a single command.

If you need to review the JSON files that the `ccoctl` tool creates before modifying AWS resources, or if the process the `ccoctl` tool uses to create AWS resources automatically does not meet the requirements of your organization, you can create the AWS resources individually. See Creating AWS resources individually.

6.8.9.2.2.1. Creating AWS resources with a single command

If the process the `ccoctl` tool uses to create AWS resources automatically meets the requirements of your organization, you can use the `ccoctl aws create-all` command to automate the creation of AWS resources.

Otherwise, you can create the AWS resources individually. For more information, see "Creating AWS resources individually".

NOTE

By default, `ccoctl` creates objects in the directory in which the commands are run. To create the objects in a different directory, use the `--output-dir` flag. This procedure uses `<path_to_ccoctl_output_dir>` to refer to this directory.

Prerequisites

You must have:

- Extracted and prepared the `ccoctl` binary.

Procedure

1. Set a `$RELEASE_IMAGE` variable with the release image from your installation file by running the following command:

   ```
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3})
   ```

2. Extract the list of `CredentialsRequest` objects from the OpenShift Container Platform release image by running the following command:

   ```
   $ oc adm release extract
   --from=$RELEASE_IMAGE
   --credentials-requests
   --included
   --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml
   --to=<path_to_directory_for_credentials_requests>
   ```

   **1** The `--included` parameter includes only the manifests that your specific cluster configuration requires.

   **2** Specify the location of the `install-config.yaml` file.

   **3** Specify the path to the directory where you want to store the `CredentialsRequest` objects. If the specified directory does not exist, this command creates it.
NOTE

This command might take a few moments to run.

3. Use the `ccoctl` tool to process all `CredentialsRequest` objects by running the following command:

```bash
$ ccoctl aws create-all \     # 1
  --name=<name> \           # 2
  --region=<aws_region> \   # 3
  --credentials-requests-dir=<path_to_credentials_requests_directory> \ # 4
  --output-dir=<path_to_ccoctl_output_dir> \   # 5
  --create-private-s3-bucket
```

1. Specify the name used to tag any cloud resources that are created for tracking.
2. Specify the AWS region in which cloud resources will be created.
3. Specify the directory containing the files for the component `CredentialsRequest` objects.
4. Optional: Specify the directory in which you want the `ccoctl` utility to create objects. By default, the utility creates objects in the directory in which the commands are run.
5. Optional: By default, the `ccoctl` utility stores the OpenID Connect (OIDC) configuration files in a public S3 bucket and uses the S3 URL as the public OIDC endpoint. To store the OIDC configuration in a private S3 bucket that is accessed by the IAM identity provider through a public CloudFront distribution URL instead, use the `--create-private-s3-bucket` parameter.

NOTE

If your cluster uses Technology Preview features that are enabled by the `TechPreviewNoUpgrade` feature set, you must include the `--enable-tech-preview` parameter.

**Verification**

- To verify that the OpenShift Container Platform secrets are created, list the files in the `<path_to_ccoctl_output_dir>/manifests` directory:

  ```bash
  $ ls <path_to_ccoctl_output_dir>/manifests
  
  cluster-authentication-02-config.yaml
  openshift-cloud-credential-operator-cloud-credential-operator-iam-ro-creds-credentials.yaml
  openshift-cloud-network-config-controller-cloud-credentials-credentials.yaml
  openshift-cluster-api-capa-manager-bootstrap-credentials-credentials.yaml
  openshift-cluster-csi-drivers-ebs-cloud-credentials-credentials.yaml
  openshift-image-registry-installer-cloud-credentials-credentials.yaml
  openshift-ingress-operator-cloud-credentials-credentials.yaml
  openshift-machine-api-aws-cloud-credentials-credentials.yaml
  ```
You can verify that the IAM roles are created by querying AWS. For more information, refer to AWS documentation on listing IAM roles.

### 6.8.9.2.2.2. Creating AWS resources individually

You can use the `ccoctl` tool to create AWS resources individually. This option might be useful for an organization that shares the responsibility for creating these resources among different users or departments.

Otherwise, you can use the `ccoctl aws create-all` command to create the AWS resources automatically. For more information, see "Creating AWS resources with a single command".

**NOTE**

By default, `ccoctl` creates objects in the directory in which the commands are run. To create the objects in a different directory, use the `--output-dir` flag. This procedure uses `<path_to_ccoctl_output_dir>` to refer to this directory.

Some `ccoctl` commands make AWS API calls to create or modify AWS resources. You can use the `--dry-run` flag to avoid making API calls. Using this flag creates JSON files on the local file system instead. You can review and modify the JSON files and then apply them with the AWS CLI tool using the `--cli-input-json` parameters.

### Prerequisites

- Extract and prepare the `ccoctl` binary.

### Procedure

1. Generate the public and private RSA key files that are used to set up the OpenID Connect provider for the cluster by running the following command:
   
   ```bash
   $ ccoctl aws create-key-pair
   ```

   **Example output**

   ```plaintext
   2021/04/13 11:01:02 Generating RSA keypair
   2021/04/13 11:01:03 Writing private key to /<path_to_ccoctl_output_dir>/serviceaccount-signer.private
   2021/04/13 11:01:03 Writing public key to /<path_to_ccoctl_output_dir>/serviceaccount-signer.public
   2021/04/13 11:01:03 Copying signing key for use by installer
   ```

   where `serviceaccount-signer.private` and `serviceaccount-signer.public` are the generated key files.

   This command also creates a private key that the cluster requires during installation in `/<path_to_ccoctl_output_dir>/tls/bound-service-account-signing-key.key`

2. Create an OpenID Connect identity provider and S3 bucket on AWS by running the following command:

   ```bash
   $ ccoctl aws create-identity-provider \
   --name=<name> \
   ```
<name> is the name used to tag any cloud resources that are created for tracking.

/aws-region> is the AWS region in which cloud resources will be created.

/path_to_ccoctl_output_dir> is the path to the public key file that the ccoctl aws create-key-pair command generated.

Example output

2021/04/13 11:16:09 Bucket <name>-oidc created
2021/04/13 11:16:10 OpenID Connect discovery document in the S3 bucket <name>-oidc at .well-known/openid-configuration updated
2021/04/13 11:16:10 Reading public key
2021/04/13 11:16:10 JSON web key set (JWKS) in the S3 bucket <name>-oidc at keys.json updated

where openid-configuration is a discovery document and keys.json is a JSON web key set file.

This command also creates a YAML configuration file in /<path_to_ccoctl_output_dir>/manifests/cluster-authentication-02-config.yaml. This file sets the issuer URL field for the service account tokens that the cluster generates, so that the AWS IAM identity provider trusts the tokens.

3. Create IAM roles for each component in the cluster:

   a. Set a $RELEASE_IMAGE variable with the release image from your installation file by running the following command:

      ```bash
      $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
      ```

   b. Extract the list of CredentialsRequest objects from the OpenShift Container Platform release image:

      ```bash
      $ oc adm release extract \ 
      --from=$RELEASE_IMAGE \ 
      --credentials-requests \ 
      --included \ 
      --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \ 
      --to=<path_to_directory_for_credentials_requests>
      ```

      The --included parameter includes only the manifests that your specific cluster configuration requires.

      Specify the location of the install-config.yaml file.

      Specify the path to the directory where you want to store the CredentialsRequest objects. If the specified directory does not exist, this command creates it.
c. Use the `ccoctl` tool to process all `CredentialsRequest` objects by running the following command:

```bash
$ ccoctl aws create-iam-roles \
  --name=<name> \
  --region=<aws_region> \
  --credentials-requests-dir=<path_to_credentials_requests_directory> \
```

**NOTE**

For AWS environments that use alternative IAM API endpoints, such as GovCloud, you must also specify your region with the `--region` parameter.

If your cluster uses Technology Preview features that are enabled by the `TechPreviewNoUpgrade` feature set, you must include the `--enable-tech-preview` parameter.

For each `CredentialsRequest` object, `ccoctl` creates an IAM role with a trust policy that is tied to the specified OIDC identity provider, and a permissions policy as defined in each `CredentialsRequest` object from the OpenShift Container Platform release image.

**Verification**

- To verify that the OpenShift Container Platform secrets are created, list the files in the `<path_to_ccoctl_output_dir>/manifests` directory:

  ```bash
  $ ls <path_to_ccoctl_output_dir>/manifests
  ```

**Example output**

- `cluster-authentication-02-config.yaml`
- `openshift-cloud-credential-operator-cloud-credential-operator-iam-ro-creds-credentials.yaml`
- `openshift-cloud-network-config-controller-cloud-credentials-credentials.yaml`
- `openshift-cluster-api-capa-manager-bootstrap-credentials-credentials.yaml`
- `openshift-cluster-csi-drivers-ebs-cloud-credentials-credentials.yaml`
- `openshift-image-registry-installer-cloud-credentials-credentials.yaml`
- `openshift-ingress-operator-cloud-credentials-credentials.yaml`
- `openshift-machine-api-aws-cloud-credentials-credentials.yaml`

You can verify that the IAM roles are created by querying AWS. For more information, refer to AWS documentation on listing IAM roles.

### 6.8.9.2.3. Incorporating the Cloud Credential Operator utility manifests

To implement short-term security credentials managed outside the cluster for individual components, you must move the manifest files that the Cloud Credential Operator utility (`ccoctl`) created to the correct directories for the installation program.

**Prerequisites**

- You have configured an account with the cloud platform that hosts your cluster.
• You have configured the Cloud Credential Operator utility (ccoctl).

• You have created the cloud provider resources that are required for your cluster with the ccoctl utility.

Procedure

1. If you did not set the credentialsMode parameter in the install-config.yaml configuration file to Manual, modify the value as shown:

Sample configuration file snippet

```yaml
apiVersion: v1
baseDomain: example.com
credentialsMode: Manual
# ...
```

2. If you have not previously created installation manifest files, do so by running the following command:

   ```
   $ openshift-install create manifests --dir <installation_directory>
   ```

   where `<installation_directory>` is the directory in which the installation program creates files.

3. Copy the manifests that the ccoctl utility generated to the manifests directory that the installation program created by running the following command:

   ```
   $ cp /<path_to_ccoctl_output_dir>/manifests/* ./manifests/
   ```

4. Copy the private key that the ccoctl utility generated in the tls directory to the installation directory by running the following command:

   ```
   $ cp -a /<path_to_ccoctl_output_dir>/tls .
   ```

6.8.10. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the create cluster command of the installation program only once, during initial installation.

Prerequisites

• You have configured an account with the cloud platform that hosts your cluster.

• You have the OpenShift Container Platform installation program and the pull secret for your cluster.

• You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.
Procedure

1. Change to the directory that contains the installation program and initialize the cluster deployment:

```bash
$ ./openshift-install create cluster --dir <installation_directory> \ 1
--log-level=info 2
```

1. For `<installation_directory>`, specify the location of your customized `./install-config.yaml` file.

2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

2. Optional: Remove or disable the `AdministratorAccess` policy from the IAM account that you used to install the cluster.

```
NOTE
The elevated permissions provided by the `AdministratorAccess` policy are required only during installation.
```

Verification

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the `kubeadmin` user.

- Credential information also outputs to `<installation_directory>/openshift_install.log`.

```
IMPORTANT
Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.
```

Example output

```
... 
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```
IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

6.8.11. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   ```

   **Example output**

   ```
   system:admin
   ```

6.8.12. Logging in to the cluster by using the web console

The `kubeadmin` user exists by default after an OpenShift Container Platform installation. You can log in to your cluster as the `kubeadmin` user by using the OpenShift Container Platform web console.

**Prerequisites**
You have access to the installation host.

You completed a cluster installation and all cluster Operators are available.

Procedure

1. Obtain the password for the kubeadmin user from the kubeadmin-password file on the installation host:

   ```bash
   $ cat <installation_directory>/auth/kubeadmin-password
   ```

   **NOTE**
   Alternatively, you can obtain the kubeadmin password from the
   `<installation_directory>/openshift_install.log` log file on the installation host.

2. List the OpenShift Container Platform web console route:

   ```bash
   $ oc get routes -n openshift-console | grep 'console-openshift'
   ```

   **NOTE**
   Alternatively, you can obtain the OpenShift Container Platform route from the
   `<installation_directory>/openshift_install.log` log file on the installation host.

   **Example output**

   ```
   console   console-openshift-console.apps.<cluster_name>.<base_domain>       console
   https    reencrypt/Redirect  None
   ```

3. Navigate to the route detailed in the output of the preceding command in a web browser and log in as the kubeadmin user.

Additional resources

- See Accessing the web console for more details about accessing and understanding the OpenShift Container Platform web console.

### 6.8.13. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager Hybrid Cloud Console.

After you confirm that your OpenShift Cluster Manager Hybrid Cloud Console inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources
6.8.14. Next steps

- Validating an installation.
- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- If necessary, you can remove cloud provider credentials.

6.9. INSTALLING A CLUSTER ON AWS INTO A GOVERNMENT REGION

In OpenShift Container Platform version 4.14, you can install a cluster on Amazon Web Services (AWS) into a government region. To configure the region, modify parameters in the `install-config.yaml` file before you install the cluster.

6.9.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You configured an AWS account to host the cluster.

**IMPORTANT**

If you have an AWS profile stored on your computer, it must not use a temporary session token that you generated while using a multi-factor authentication device. The cluster continues to use your current AWS credentials to create AWS resources for the entire life of the cluster, so you must use long-term credentials. To generate appropriate keys, see Managing Access Keys for IAM Users in the AWS documentation. You can supply the keys when you run the installation program.

- If you use a firewall, you configured it to allow the sites that your cluster requires access to.

6.9.2. AWS government regions

OpenShift Container Platform supports deploying a cluster to an AWS GovCloud (US) region.

The following AWS GovCloud partitions are supported:

- `us-gov-east-1`
- `us-gov-west-1`

6.9.3. Installation requirements

Before you can install the cluster, you must:
6.9.4. Private clusters

You can deploy a private OpenShift Container Platform cluster that does not expose external endpoints. Private clusters are accessible from only an internal network and are not visible to the internet.

**NOTE**

Public zones are not supported in Route 53 in an AWS GovCloud Region. Therefore, clusters must be private if they are deployed to an AWS GovCloud Region.

By default, OpenShift Container Platform is provisioned to use publicly-accessible DNS and endpoints. A private cluster sets the DNS, Ingress Controller, and API server to private when you deploy your cluster. This means that the cluster resources are only accessible from your internal network and are not visible to the internet.

**IMPORTANT**

If the cluster has any public subnets, load balancer services created by administrators might be publicly accessible. To ensure cluster security, verify that these services are explicitly annotated as private.

To deploy a private cluster, you must:

- Use existing networking that meets your requirements. Your cluster resources might be shared between other clusters on the network.

- Deploy from a machine that has access to:
  - The API services for the cloud to which you provision.
  - The hosts on the network that you provision.
  - The internet to obtain installation media.

You can use any machine that meets these access requirements and follows your company’s guidelines. For example, this machine can be a bastion host on your cloud network or a machine that has access to the network through a VPN.

6.9.4.1. Private clusters in AWS

To create a private cluster on Amazon Web Services (AWS), you must provide an existing private VPC and subnets to host the cluster. The installation program must also be able to resolve the DNS records that the cluster requires. The installation program configures the Ingress Operator and API server for access from only the private network.

The cluster still requires access to internet to access the AWS APIs.

The following items are not required or created when you install a private cluster:
- Public subnets
- Public load balancers, which support public ingress
- A public Route 53 zone that matches the baseDomain for the cluster

The installation program does use the baseDomain that you specify to create a private Route 53 zone and the required records for the cluster. The cluster is configured so that the Operators do not create public records for the cluster and all cluster machines are placed in the private subnets that you specify.

6.9.4.1.1. Limitations

The ability to add public functionality to a private cluster is limited.

- You cannot make the Kubernetes API endpoints public after installation without taking additional actions, including creating public subnets in the VPC for each availability zone in use, creating a public load balancer, and configuring the control plane security groups to allow traffic from the internet on 6443 (Kubernetes API port).

- If you use a public Service type load balancer, you must tag a public subnet in each availability zone with kubernetes.io/cluster/<cluster-infra-id>: shared so that AWS can use them to create public load balancers.

6.9.5. About using a custom VPC

In OpenShift Container Platform 4.14, you can deploy a cluster into existing subnets in an existing Amazon Virtual Private Cloud (VPC) in Amazon Web Services (AWS). By deploying OpenShift Container Platform into an existing AWS VPC, you might be able to avoid limit constraints in new accounts or more easily abide by the operational constraints that your company’s guidelines set. If you cannot obtain the infrastructure creation permissions that are required to create the VPC yourself, use this installation option.

Because the installation program cannot know what other components are also in your existing subnets, it cannot choose subnet CIDRs and so forth on your behalf. You must configure networking for the subnets that you install your cluster to yourself.

6.9.5.1. Requirements for using your VPC

The installation program no longer creates the following components:

- Internet gateways
- NAT gateways
- Subnets
- Route tables
- VPCs
- VPC DHCP options
- VPC endpoints
NOTE

The installation program requires that you use the cloud-provided DNS server. Using a custom DNS server is not supported and causes the installation to fail.

If you use a custom VPC, you must correctly configure it and its subnets for the installation program and the cluster to use. See Amazon VPC console wizard configurations and Work with VPCs and subnets in the AWS documentation for more information on creating and managing an AWS VPC.

The installation program cannot:

- Subdivide network ranges for the cluster to use.
- Set route tables for the subnets.
- Set VPC options like DHCP.

You must complete these tasks before you install the cluster. See VPC networking components and Route tables for your VPC for more information on configuring networking in an AWS VPC.

Your VPC must meet the following characteristics:

- The VPC must not use the `kubernetes.io/cluster/.*: owned, Name, and openshift.io/cluster` tags.
  The installation program modifies your subnets to add the `kubernetes.io/cluster/.*: shared` tag, so your subnets must have at least one free tag slot available for it. See Tag Restrictions in the AWS documentation to confirm that the installation program can add a tag to each subnet that you specify. You cannot use a Name tag, because it overlaps with the EC2 Name field and the installation fails.

- You must enable the `enableDnsSupport` and `enableDnsHostnames` attributes in your VPC, so that the cluster can use the Route 53 zones that are attached to the VPC to resolve cluster’s internal DNS records. See DNS Support in Your VPC in the AWS documentation.
  If you prefer to use your own Route 53 hosted private zone, you must associate the existing hosted zone with your VPC prior to installing a cluster. You can define your hosted zone using the `platform.aws.hostedZone` and `platform.aws.hostedZoneRole` fields in the `install-config.yaml` file. You can use a private hosted zone from another account by sharing it with the account where you install the cluster. If you use a private hosted zone from another account, you must use the Passthrough or Manual credentials mode.

If you are working in a disconnected environment, you are unable to reach the public IP addresses for EC2, ELB, and S3 endpoints. Depending on the level to which you want to restrict internet traffic during the installation, the following configuration options are available:

Option 1: Create VPC endpoints
Create a VPC endpoint and attach it to the subnets that the clusters are using. Name the endpoints as follows:

- `ec2.<aws_region>.amazonaws.com`
- `elasticloadbalancing.<aws_region>.amazonaws.com`
- `s3.<aws_region>.amazonaws.com`

With this option, network traffic remains private between your VPC and the required AWS services.

Option 2: Create a proxy without VPC endpoints
As part of the installation process, you can configure an HTTP or HTTPS proxy. With this option, internet traffic goes through the proxy to reach the required AWS services.

**Option 3: Create a proxy with VPC endpoints**
As part of the installation process, you can configure an HTTP or HTTPS proxy with VPC endpoints. Create a VPC endpoint and attach it to the subnets that the clusters are using. Name the endpoints as follows:

- `ec2.<aws_region>.amazonaws.com`
- `elasticloadbalancing.<aws_region>.amazonaws.com`
- `s3.<aws_region>.amazonaws.com`

When configuring the proxy in the `install-config.yaml` file, add these endpoints to the `noProxy` field. With this option, the proxy prevents the cluster from accessing the internet directly. However, network traffic remains private between your VPC and the required AWS services.

**Required VPC components**
You must provide a suitable VPC and subnets that allow communication to your machines.

<table>
<thead>
<tr>
<th>Component</th>
<th>AWS type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>VPC</strong></td>
<td>- AWS::EC2::VPC</td>
<td>You must provide a public VPC for the cluster to use. The VPC uses an endpoint that references the route tables for each subnet to improve communication with the registry that is hosted in S3.</td>
</tr>
<tr>
<td></td>
<td>- AWS::EC2::VPCEndpoint</td>
<td></td>
</tr>
<tr>
<td><strong>Public subnets</strong></td>
<td>- AWS::EC2::Subnet</td>
<td>Your VPC must have public subnets for between 1 and 3 availability zones and associate them with appropriate Ingress rules.</td>
</tr>
<tr>
<td></td>
<td>- AWS::EC2::SubnetNetworkAclAssociation</td>
<td></td>
</tr>
<tr>
<td><strong>Internet gateway</strong></td>
<td>- AWS::EC2::InternetGateway</td>
<td>You must have a public internet gateway, with public routes, attached to the VPC. In the provided templates, each public subnet has a NAT gateway with an EIP address. These NAT gateways allow cluster resources, like private subnet instances, to reach the internet and are not required for some restricted network or proxy scenarios.</td>
</tr>
<tr>
<td></td>
<td>- AWS::EC2::VPCEndpointAttachment</td>
<td></td>
</tr>
<tr>
<td></td>
<td>- AWS::EC2::RouteTable</td>
<td></td>
</tr>
<tr>
<td></td>
<td>- AWS::EC2::Route</td>
<td></td>
</tr>
<tr>
<td></td>
<td>- AWS::EC2::SubnetRouteTableAssociation</td>
<td></td>
</tr>
<tr>
<td></td>
<td>- AWS::EC2::NatGateway</td>
<td></td>
</tr>
<tr>
<td></td>
<td>- AWS::EC2::EIP</td>
<td></td>
</tr>
</tbody>
</table>
Network access control

- AWS::EC2::NetworkAcl
- AWS::EC2::NetworkAclEntry

You must allow the VPC to access the following ports:

<table>
<thead>
<tr>
<th>Port</th>
<th>Reason</th>
</tr>
</thead>
<tbody>
<tr>
<td>80</td>
<td>Inbound HTTP traffic</td>
</tr>
<tr>
<td>443</td>
<td>Inbound HTTPS traffic</td>
</tr>
<tr>
<td>22</td>
<td>Inbound SSH traffic</td>
</tr>
<tr>
<td>1024 - 65535</td>
<td>Inbound ephemeral traffic</td>
</tr>
<tr>
<td>0 - 65535</td>
<td>Outbound ephemeral traffic</td>
</tr>
</tbody>
</table>

Private subnets

- AWS::EC2::Subnet
- AWS::EC2::RouteTable
- AWS::EC2::SubnetRouteTableAssociation

Your VPC can have private subnets. The provided CloudFormation templates can create private subnets for between 1 and 3 availability zones. If you use private subnets, you must provide appropriate routes and tables for them.

6.9.5.2. VPC validation

To ensure that the subnets that you provide are suitable, the installation program confirms the following data:

- All the subnets that you specify exist.
- You provide private subnets.
- The subnet CIDRs belong to the machine CIDR that you specified.
- You provide subnets for each availability zone. Each availability zone contains no more than one public and one private subnet. If you use a private cluster, provide only a private subnet for each availability zone. Otherwise, provide exactly one public and private subnet for each availability zone.
- You provide a public subnet for each private subnet availability zone. Machines are not provisioned in availability zones that you do not provide private subnets for.
If you destroy a cluster that uses an existing VPC, the VPC is not deleted. When you remove the OpenShift Container Platform cluster from a VPC, the `kubernetes.io/cluster/.*: shared` tag is removed from the subnets that it used.

### 6.9.5.3. Division of permissions

Starting with OpenShift Container Platform 4.3, you do not need all of the permissions that are required for an installation program-provisioned infrastructure cluster to deploy a cluster. This change mimics the division of permissions that you might have at your company: some individuals can create different resource in your clouds than others. For example, you might be able to create application-specific items, like instances, buckets, and load balancers, but not networking-related components such as VPCs, subnets, or ingress rules.

The AWS credentials that you use when you create your cluster do not need the networking permissions that are required to make VPCs and core networking components within the VPC, such as subnets, routing tables, internet gateways, NAT, and VPN. You still need permission to make the application resources that the machines within the cluster require, such as ELBs, security groups, S3 buckets, and nodes.

### 6.9.5.4. Isolation between clusters

If you deploy OpenShift Container Platform to an existing network, the isolation of cluster services is reduced in the following ways:

- You can install multiple OpenShift Container Platform clusters in the same VPC.
- ICMP ingress is allowed from the entire network.
- TCP 22 ingress (SSH) is allowed to the entire network.
- Control plane TCP 6443 ingress (Kubernetes API) is allowed to the entire network.
- Control plane TCP 22623 ingress (MCS) is allowed to the entire network.

### 6.9.5.5. AWS security groups

By default, the installation program creates and attaches security groups to control plane and compute machines. The rules associated with the default security groups cannot be modified.

However, you can apply additional existing AWS security groups, which are associated with your existing VPC, to control plane and compute machines. Applying custom security groups can help you meet the security needs of your organization, in such cases where you need to control the incoming or outgoing traffic of these machines.

As part of the installation process, you apply custom security groups by modifying the `install-config.yaml` file before deploying the cluster.

For more information, see "Applying existing AWS security groups to the cluster".

### 6.9.6. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager Hybrid Cloud Console to download the installation program
- Access OpenShift Container Platform 4.14 Installing

466
- Access OpenShift Cluster Manager Hybrid Cloud Console to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- Access Quay.io to obtain the packages that are required to install your cluster.

- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 6.9.7. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the `core` user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user `core`. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>
   ```

   Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.
NOTE

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   $ cat <path>/<file_name>.pub

   For example, run the following to view the ~/.ssh/id_ed25519.pub public key:

   $ cat ~/.ssh/id_ed25519.pub

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the ./openshift-install gather command.

   NOTE

   On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.

   a. If the ssh-agent process is not already running for your local user, start it as a background task:

      $ eval "$(ssh-agent -s)"

   Example output

      Agent pid 31874

      NOTE

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the ssh-agent:

   $ ssh-add <path>/<file_name>  

   Specify the path and file name for your SSH private key, such as ~/.ssh/id_ed25519

   Example output

   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

Next steps
When you install OpenShift Container Platform, provide the SSH public key to the installation program.

6.9.8. Obtaining an AWS Marketplace image

If you are deploying an OpenShift Container Platform cluster using an AWS Marketplace image, you must first subscribe through AWS. Subscribing to the offer provides you with the AMI ID that the installation program uses to deploy worker nodes.

Prerequisites

- You have an AWS account to purchase the offer. This account does not have to be the same account that is used to install the cluster.

Procedure

1. Complete the OpenShift Container Platform subscription from the AWS Marketplace.

2. Record the AMI ID for your specific region. As part of the installation process, you must update the `install-config.yaml` file with this value before deploying the cluster.

Sample `install-config.yaml` file with AWS Marketplace worker nodes

```yaml
apiVersion: v1
baseDomain: example.com
compute:
- hyperthreading: Enabled
  name: worker
  platform:
    aws:
      amiID: ami-06c4d345f7c207239
      type: m5.4xlarge
      replicas: 3
  metadata:
    name: test-cluster
  platform:
    aws:
      region: us-east-2
  sshKey: ssh-ed25519 AAAA...
pullSecret: '{"auths": ...}'
```

1. The AMI ID from your AWS Marketplace subscription.
2. Your AMI ID is associated with a specific AWS region. When creating the installation configuration file, ensure that you select the same AWS region that you specified when configuring your subscription.

6.9.9. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

Prerequisites
You have a computer that runs Linux or macOS, with 500 MB of local disk space.

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

   IMPORTANT

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   IMPORTANT

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   $ tar -xvf openshift-install-linux.tar.gz

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

6.9.10. Manually creating the installation configuration file

Installing the cluster requires that you manually generate the installation configuration file.

Prerequisites

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.

- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Create an installation directory to store your required installation assets in:
You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample `install-config.yaml` file template that is provided and save it in the `<installation_directory>`.  

   **NOTE**

   You must name this configuration file `install-config.yaml`.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

   **IMPORTANT**

   The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.

**Additional resources**

- Installation configuration parameters for AWS

**6.9.10.1. Minimum resource requirements for cluster installation**

Each cluster machine must meet the following minimum requirements:

**Table 6.13. Minimum resource requirements**

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS, RHEL 8.6 and later [3]</td>
<td>2</td>
<td>8 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
</tbody>
</table>

1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or hyperthreading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: (threads per core × cores) × sockets = vCPUs.
2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.

3. As with all user-provisioned installations, if you choose to use RHEL compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and has been removed in OpenShift Container Platform 4.10 and later.

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

Additional resources

- Optimizing storage

6.9.10.2. Tested instance types for AWS

The following Amazon Web Services (AWS) instance types have been tested with OpenShift Container Platform.

NOTE

Use the machine types included in the following charts for your AWS instances. If you use an instance type that is not listed in the chart, ensure that the instance size you use matches the minimum resource requirements that are listed in "Minimum resource requirements for cluster installation".

Example 6.36. Machine types based on 64-bit x86 architecture

- c4.*
- c5.*
- c5a.*
- i3.*
- m4.*
- m5.*
- m5a.*
- m6i.*
- r4.*
- r5.*
- r5a.*
- r6i.*
6.9.10.3. Tested instance types for AWS on 64-bit ARM infrastructures

The following Amazon Web Services (AWS) 64-bit ARM instance types have been tested with OpenShift Container Platform.

**NOTE**

Use the machine types included in the following charts for your AWS ARM instances. If you use an instance type that is not listed in the chart, ensure that the instance size you use matches the minimum resource requirements that are listed in "Minimum resource requirements for cluster installation".

Example 6.37. Machine types based on 64-bit ARM architecture

- c6g.*
- m6g.*

6.9.10.4. Sample customized install-config.yaml file for AWS

You can customize the installation configuration file (`install-config.yaml`) to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

**IMPORTANT**

This sample YAML file is provided for reference only. Use it as a resource to enter parameter values into the installation configuration file that you created manually.

```yaml
apiVersion: v1
baseDomain: example.com
credentialsMode: Mint
controlPlane:
  hyperthreading: Enabled
  name: master
platform:
  aws:
    lbType: NLB
    zones:
      - us-gov-west-1a
      - us-gov-west-1b
    rootVolume:
      iops: 4000
      size: 500
      type: io1
metadataService:
  authentication: Optional
```
type: m6i.xlarge
replicas: 3
compute: 8
- hyperthreading: Enabled 9
name: worker
platform:
  aws:
    rootVolume:
      iops: 2000
      size: 500
      type: io1 10
    metadataService:
      authentication: Optional 11
    type: c5.4xlarge
    zones:
      - us-gov-west-1c
    replicas: 3
metadata:
  name: test-cluster 12
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
    hostPrefix: 23
  machineNetwork:
    - cidr: 10.0.0.0/16
  networkType: OVNKubernetes 13
  serviceNetwork:
    - 172.30.0.0/16
platform:
  aws:
    region: us-gov-west-1 14
    propagateUserTags: true 15
    userTags:
      adminContact: jdoe
      costCenter: 7536
subnets: 16
- subnet-1
- subnet-2
- subnet-3
amiID: ami-0c5d3e03c0ab9b19a 17
serviceEndpoints: 18
  - name: ec2
    url: https://vpce-id.ec2.us-west-2.vpce.amazonaws.com
    hostedZone: Z3URY6TWQ91KV
fips: false 20
sshKey: ssh-ed25519 AAAA... 21
publish: Internal 22
pullSecret: {'"auths": ...'} 23

1 Required.
2 Optional: Add this parameter to force the Cloud Credential Operator (CCO) to use the specified mode. By default, the CCO uses the root credentials in the kube-system namespace to dynamically try to determine the capabilities of the credentials. For details about CCO modes, see
the "About the Cloud Credential Operator" section in the Authentication and authorization guide.

3. If you do not provide these parameters and values, the installation program provides the default value.

4. The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, -, and the first line of the controlPlane section must not. Only one control plane pool is used.

5. Whether to enable or disable simultaneous multithreading, or hyperthreading. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores. You can disable it by setting the parameter value to Disabled. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

   **IMPORTANT**

   If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger instance types, such as m4.2xlarge or m5.2xlarge, for your machines if you disable simultaneous multithreading.

6. To configure faster storage for etcd, especially for larger clusters, set the storage type as io1 and set iops to 2000.

7. Whether to require the Amazon EC2 Instance Metadata Service v2 (IMDSv2). To require IMDSv2, set the parameter value to Required. To allow the use of both IMDSv1 and IMDSv2, set the parameter value to Optional. If no value is specified, both IMDSv1 and IMDSv2 are allowed.

   **NOTE**

   The IMDS configuration for control plane machines that is set during cluster installation can only be changed by using the AWS CLI. The IMDS configuration for compute machines can be changed by using compute machine sets.

8. The cluster network plugin to install. The supported values are OVNKubernetes and OpenShiftSDN. The default value is OVNKubernetes.

9. If you provide your own VPC, specify subnets for each availability zone that your cluster uses.

10. The ID of the AMI used to boot machines for the cluster. If set, the AMI must belong to the same region as the cluster.

11. The AWS service endpoints. Custom endpoints are required when installing to an unknown AWS region. The endpoint URL must use the https protocol and the host must trust the certificate.

12. The ID of your existing Route 53 private hosted zone. Providing an existing hosted zone requires that you supply your own VPC and the hosted zone is already associated with the VPC prior to installing your cluster. If undefined, the installation program creates a new hosted zone.

13. Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.
IMPORTANT

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see Installing the system in FIPS mode. When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures.

You can optionally provide the sshKey value that you use to access the machines in your cluster.

NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

How to publish the user-facing endpoints of your cluster. Set publish to Internal to deploy a private cluster, which cannot be accessed from the internet. The default value is External.

6.9.10.5. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the install-config.yaml file.

Prerequisites

- You have an existing install-config.yaml file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the Proxy object’s spec.noProxy field to bypass the proxy if necessary.

NOTE

The Proxy object status.noProxy field is populated with the values of the networking.machineNetwork[].cidr, networking.clusterNetwork[].cidr, and networking.serviceNetwork[] fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object status.noProxy field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your install-config.yaml file and add the proxy settings. For example:

   apiVersion: v1
A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.

A proxy URL to use for creating HTTPS connections outside the cluster.

A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with `*` to match subdomains only. For example, `.y.com` matches `x.y.com`, but not `y.com`. Use `*` to bypass the proxy for all destinations. If you have added the Amazon EC2 Elastic Load Balancing, and S3 VPC endpoints to your VPC, you must add these endpoints to the `noProxy` field.

If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the `trustedCA` field of the `Proxy` object. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

Optional: The policy to determine the configuration of the `Proxy` object to reference the `user-ca-bundle` config map in the `trustedCA` field. The allowed values are `Proxyonly` and `Always`. Use `Proxyonly` to reference the `user-ca-bundle` config map only when `http/https` proxy is configured. Use `Always` to always reference the `user-ca-bundle` config map. The default value is `Proxyonly`.

**NOTE**
The installation program does not support the proxy `readinessEndpoints` field.

**NOTE**
If the installer times out, restart and then complete the deployment by using the `wait-for` command of the installer. For example:

```bash
$ ./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.
NOTE

Only the Proxy object named `cluster` is supported, and no additional proxies can be created.

6.9.10.6. Applying existing AWS security groups to the cluster

Applying existing AWS security groups to your control plane and compute machines can help you meet the security needs of your organization, in such cases where you need to control the incoming or outgoing traffic of these machines.

Prerequisites

- You have created the security groups in AWS. For more information, see the AWS documentation about working with security groups.
- The security groups must be associated with the existing VPC that you are deploying the cluster to. The security groups cannot be associated with another VPC.
- You have an existing `install-config.yaml` file.

Procedure

1. In the `install-config.yaml` file, edit the `compute.platform.aws.additionalSecurityGroupIDs` parameter to specify one or more custom security groups for your compute machines.

2. Edit the `controlPlane.platform.aws.additionalSecurityGroupIDs` parameter to specify one or more custom security groups for your control plane machines.

3. Save the file and reference it when deploying the cluster.

Sample `install-config.yaml` file that specifies custom security groups

```yaml
# ...
compute:
  - hyperthreading: Enabled
  name: worker
  platform:
    aws:
      additionalSecurityGroupIDs:
        - sg-1
        - sg-2
  replicas: 3
controlPlane:
  hyperthreading: Enabled
  name: master
  platform:
    aws:
      additionalSecurityGroupIDs:
        - sg-3
        - sg-4
  replicas: 3
platform:
  aws:
  region: us-east-1
```
1. Specify the name of the security group as it appears in the Amazon EC2 console, including the `sg` prefix.

2. Specify subnets for each availability zone that your cluster uses.

### 6.9.11. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (`oc`) to interact with OpenShift Container Platform from a command-line interface. You can install `oc` on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of `oc`, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of `oc`.

#### Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (`oc`) binary on Linux by using the following procedure.

**Procedure**

2. Select the architecture from the **Product Variant** drop-down list.

3. Select the appropriate version from the **Version** drop-down list.

4. Click **Download Now** next to the **OpenShift v4.14 Linux Client** entry and save the file.

5. Unpack the archive:

   ```
   $ tar xvf <file>
   ```

6. Place the `oc` binary in a directory that is on your **PATH**.

   To check your **PATH**, execute the following command:

   ```
   $ echo $PATH
   ```

**Verification**

- After you install the OpenShift CLI, it is available using the `oc` command:

  ```
  $ oc <command>
  ```

#### Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (`oc`) binary on Windows by using the following procedure.
Procedure

2. Select the appropriate version from the Version drop-down list.

3. Click Download Now next to the OpenShift v4.14 Windows Client entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the oc binary to a directory that is on your PATH. To check your PATH, open the command prompt and execute the following command:

```
C:\> path
```

Verification

- After you install the OpenShift CLI, it is available using the oc command:

```
C:\> oc <command>
```

Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.

Procedure

2. Select the appropriate version from the Version drop-down list.

3. Click Download Now next to the OpenShift v4.14 macOS Client entry and save the file.

   **NOTE**

   For macOS arm64, choose the OpenShift v4.14 macOS arm64 Client entry.

4. Unpack and unzip the archive.

5. Move the oc binary to a directory on your PATH. To check your PATH, open a terminal and execute the following command:

```
$ echo $PATH
```

Verification

- After you install the OpenShift CLI, it is available using the oc command:

```
$ oc <command>
```

6.9.12. Alternatives to storing administrator-level secrets in the kube-system project
By default, administrator secrets are stored in the `kube-system` project. If you configured the `credentialsMode` parameter in the `install-config.yaml` file to `Manual`, you must use one of the following alternatives:

- To manage long-term cloud credentials manually, follow the procedure in **Manually creating long-term credentials**.
- To implement short-term credentials that are managed outside the cluster for individual components, follow the procedures in **Incorporating the Cloud Credential Operator utility manifests**.

### 6.9.12.1. Manually creating long-term credentials

The Cloud Credential Operator (CCO) can be put into manual mode prior to installation in environments where the cloud identity and access management (IAM) APIs are not reachable, or the administrator prefers not to store an administrator-level credential secret in the cluster `kube-system` namespace.

**Procedure**

1. If you did not set the `credentialsMode` parameter in the `install-config.yaml` configuration file to `Manual`, modify the value as shown:

   **Sample configuration file snippet**

   ```yaml
   apiVersion: v1
   baseDomain: example.com
   credentialsMode: Manual
   # ...
   ```

2. If you have not previously created installation manifest files, do so by running the following command:

   ```bash
   $ openshift-install create manifests --dir <installation_directory>
   ```

   where `<installation_directory>` is the directory in which the installation program creates files.

3. Set a `$RELEASE_IMAGE` variable with the release image from your installation file by running the following command:

   ```bash
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
   ```

4. Extract the list of `CredentialsRequest` custom resources (CRs) from the OpenShift Container Platform release image by running the following command:

   ```bash
   $ oc adm release extract \
   --from=$RELEASE_IMAGE \
   --credentials-requests \
   --included \1
   --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \2
   --to=<path_to_directory_for_credentials_requests> \3
   ```

   1. The `--included` parameter includes only the manifests that your specific cluster configuration requires.
Specify the location of the `install-config.yaml` file.

Specify the path to the directory where you want to store the `CredentialsRequest` objects. If the specified directory does not exist, this command creates it.

This command creates a YAML file for each `CredentialsRequest` object.

Sample `CredentialsRequest` object

```yaml
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
  name: <component_credentials_request>
  namespace: openshift-cloud-credential-operator
...
spec:
  providerSpec:
    apiVersion: cloudcredential.openshift.io/v1
    kind: AWSProviderSpec
    statementEntries:
      - effect: Allow
        action:
          - iam:GetUser
          - iam:GetUserPolicy
          - iam:ListAccessKeys
        resource: "**"
...
```

5. Create YAML files for secrets in the `openshift-install` manifests directory that you generated previously. The secrets must be stored using the namespace and secret name defined in the `spec.secretRef` for each `CredentialsRequest` object.

Sample `CredentialsRequest` object with secrets

```yaml
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
  name: <component_credentials_request>
  namespace: openshift-cloud-credential-operator
...
spec:
  providerSpec:
    apiVersion: cloudcredential.openshift.io/v1
    kind: AWSProviderSpec
    statementEntries:
      - effect: Allow
        action:
          - s3:CreateBucket
          - s3:DeleteBucket
        resource: "**"
...
secretRef:
```
IMPORTANT

Before upgrading a cluster that uses manually maintained credentials, you must ensure that the CCO is in an upgradeable state.

6.9.12.2. Configuring an AWS cluster to use short-term credentials

To install a cluster that is configured to use the AWS Security Token Service (STS), you must configure the CCO utility and create the required AWS resources for your cluster.

6.9.12.2.1. Configuring the Cloud Credential Operator utility

To create and manage cloud credentials from outside of the cluster when the Cloud Credential Operator (CCO) is operating in manual mode, extract and prepare the CCO utility (`ccoctl`) binary.

NOTE

The `ccoctl` utility is a Linux binary that must run in a Linux environment.

Prerequisites

- You have access to an OpenShift Container Platform account with cluster administrator access.
- You have installed the OpenShift CLI (`oc`).
- You have created an AWS account for the `ccoctl` utility to use with the following permissions:

Example 6.38. Required AWS permissions

Required `iam` permissions

- `iam:CreateOpenIDConnectProvider`
- `iam:CreateRole`
- `iam:DeleteOpenIDConnectProvider`
- `iam:DeleteRole`
- `iam:DeleteRolePolicy`

Sample Secret object

```yaml
name: <component_secret>
namespace: <component_namespace>

apiVersion: v1
kind: Secret
metadata:
  name: <component_secret>
  namespace: <component_namespace>
data:
  aws_access_key_id: <base64_encoded_aws_access_key_id>
  aws_secret_access_key: <base64_encoded_aws_secret_access_key>
```
- iam:GetOpenIDConnectProvider
- iam:GetRole
- iam:GetUser
- iam:GetOpenIDConnectProviders
- iam:GetRolePolicies
- iam:GetRoles
- iam:PutRolePolicy
- iam:TagOpenIDConnectProvider
- iam:TagRole

Required s3 permissions
- s3:CreateBucket
- s3:DeleteBucket
- s3:DeleteObject
- s3:GetBucketAcl
- s3:GetBucketTagging
- s3:GetObject
- s3:GetObjectAcl
- s3:GetObjectTagging
- s3:ListBucket
- s3:PutBucketAcl
- s3:PutBucketPolicy
- s3:PutBucketPublicAccessBlock
- s3:PutBucketTagging
- s3:PutObject
- s3:PutObjectAcl
- s3:PutObjectTagging

Required cloudfront permissions
- cloudfront:ListCloudFrontOriginAccessIdentities
- cloudfront:ListDistributions
If you plan to store the OIDC configuration in a private S3 bucket that is accessed by the IAM identity provider through a public CloudFront distribution URL, the AWS account that runs the `ccoctl` utility requires the following additional permissions:

Example 6.39. Additional permissions for a private S3 bucket with CloudFront

- `cloudfront:ListTagsForResource`
- `cloudfront:CreateCloudFrontOriginAccessIdentity`
- `cloudfront:CreateDistribution`
- `cloudfront:DeleteCloudFrontOriginAccessIdentity`
- `cloudfront:DeleteDistribution`
- `cloudfront:GetCloudFrontOriginAccessIdentity`
- `cloudfront:GetCloudFrontOriginAccessIdentityConfig`
- `cloudfront:GetDistribution`
- `cloudfront:TagResource`
- `cloudfront:UpdateDistribution`

**NOTE**

These additional permissions support the use of the `--create-private-s3-bucket` option when processing credentials requests with the `ccoctl aws create-all` command.

**Procedure**

1. Obtain the OpenShift Container Platform release image by running the following command:

   ```
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
   ```

2. Obtain the CCO container image from the OpenShift Container Platform release image by running the following command:

   ```
   $ CCO_IMAGE=$(oc adm release info --image-for='cloud-credential-operator' $RELEASE_IMAGE -a ~/.pull-secret)
   ```

   **NOTE**

   Ensure that the architecture of the $RELEASE_IMAGE matches the architecture of the environment in which you will use the `ccoctl` tool.

3. Extract the `ccoctl` binary from the CCO container image within the OpenShift Container Platform release image by running the following command:

   ```
   # To be completed
   ```
4. Change the permissions to make `ccoctl` executable by running the following command:

```bash
$ chmod 775 ccoctl
```

**Verification**

- To verify that `ccoctl` is ready to use, display the help file by running the following command:

```bash
$ ccoctl --help
```

**Output of `ccoctl` --help**

OpenShift credentials provisioning tool

Usage:

`ccoctl [command]`

Available Commands:

- `alibabacloud` Manage credentials objects for alibaba cloud
- `aws` Manage credentials objects for AWS cloud
- `azure` Manage credentials objects for Azure
- `gcp` Manage credentials objects for Google cloud
- `help` Help about any command
- `ibmcloud` Manage credentials objects for IBM Cloud
- `nutanix` Manage credentials objects for Nutanix

Flags:

- `-h, --help` help for ccoctl

Use "ccoctl [command] --help" for more information about a command.

---

**6.9.12.2.2. Creating AWS resources with the Cloud Credential Operator utility**

You have the following options when creating AWS resources:

- You can use the `ccoctl aws create-all` command to create the AWS resources automatically. This is the quickest way to create the resources. See Creating AWS resources with a single command.

- If you need to review the JSON files that the `ccoctl` tool creates before modifying AWS resources, or if the process the `ccoctl` tool uses to create AWS resources automatically does not meet the requirements of your organization, you can create the AWS resources individually. See Creating AWS resources individually.

---

**6.9.12.2.2.1. Creating AWS resources with a single command**

If the process the `ccoctl` tool uses to create AWS resources automatically meets the requirements of your organization, you can use the `ccoctl aws create-all` command to automate the creation of AWS resources.
Otherwise, you can create the AWS resources individually. For more information, see "Creating AWS resources individually".

**NOTE**

By default, `ccoctl` creates objects in the directory in which the commands are run. To create the objects in a different directory, use the `--output-dir` flag. This procedure uses `<path_to_ccoctl_output_dir>` to refer to this directory.

**Prerequisites**

You must have:

- Extracted and prepared the `ccoctl` binary.

**Procedure**

1. Set a `$RELEASE_IMAGE` variable with the release image from your installation file by running the following command:

   ```bash
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
   ```

2. Extract the list of `CredentialsRequest` objects from the OpenShift Container Platform release image by running the following command:

   ```bash
   $ oc adm release extract 
   --from=$RELEASE_IMAGE 
   --credentials-requests 
   --included 1
   --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml 2
   --to=<path_to_directory_for_credentials_requests> 3
   ```

   **1** The `--included` parameter includes only the manifests that your specific cluster configuration requires.

   **2** Specify the location of the `install-config.yaml` file.

   **3** Specify the path to the directory where you want to store the `CredentialsRequest` objects. If the specified directory does not exist, this command creates it.

**NOTE**

This command might take a few moments to run.

3. Use the `ccoctl` tool to process all `CredentialsRequest` objects by running the following command:

   ```bash
   $ ccoctl aws create-all 
   --name=<name> 1
   --region=<aws_region> 2
   ```

   **1**

   **2**
Specify the name used to tag any cloud resources that are created for tracking.

Specify the AWS region in which cloud resources will be created.

Specify the directory containing the files for the component `CredentialsRequest` objects.

Optional: Specify the directory in which you want the `ccoctl` utility to create objects. By default, the utility creates objects in the directory in which the commands are run.

Optional: By default, the `ccoctl` utility stores the OpenID Connect (OIDC) configuration files in a public S3 bucket and uses the S3 URL as the public OIDC endpoint. To store the OIDC configuration in a private S3 bucket that is accessed by the IAM identity provider through a public CloudFront distribution URL instead, use the `--create-private-s3-bucket` parameter.

**NOTE**

If your cluster uses Technology Preview features that are enabled by the `TechPreviewNoUpgrade` feature set, you must include the `--enable-tech-preview` parameter.

**Verification**

- To verify that the OpenShift Container Platform secrets are created, list the files in the `<path_to_ccoctl_output_dir>/manifests` directory:

  ```bash
  $ ls <path_to_ccoctl_output_dir>/manifests
  ```

  Example output:

  ```
  cluster-authentication-02-config.yaml
  openshift-cloud-credential-operator-cloud-credential-operator-iam-ro-creds-credentials.yaml
  openshift-cloud-network-config-controller-cloud-credentials-credentials.yaml
  openshift-cluster-api-capa-manager-bootstrap-credentials-credentials.yaml
  openshift-cluster-csi-drivers-ebs-cloud-credentials-credentials.yaml
  openshift-image-registry-installer-cloud-credentials-credentials.yaml
  openshift-ingress-operator-cloud-credentials-credentials.yaml
  openshift-machine-api-aws-cloud-credentials-credentials.yaml
  ```

  You can verify that the IAM roles are created by querying AWS. For more information, refer to AWS documentation on listing IAM roles.

6.9.12.2.2.2. Creating AWS resources individually

You can use the `ccoctl` tool to create AWS resources individually. This option might be useful for an organization that shares the responsibility for creating these resources among different users or departments.
Otherwise, you can use the `ccoctl aws create-all` command to create the AWS resources automatically. For more information, see “Creating AWS resources with a single command”.

**NOTE**

By default, `ccoctl` creates objects in the directory in which the commands are run. To create the objects in a different directory, use the `--output-dir` flag. This procedure uses `<path_to_ccoctl_output_dir>` to refer to this directory.

Some `ccoctl` commands make AWS API calls to create or modify AWS resources. You can use the `--dry-run` flag to avoid making API calls. Using this flag creates JSON files on the local file system instead. You can review and modify the JSON files and then apply them with the AWS CLI tool using the `--cli-input-json` parameters.

Prerequisites

- Extract and prepare the `ccoctl` binary.

Procedure

1. Generate the public and private RSA key files that are used to set up the OpenID Connect provider for the cluster by running the following command:

   
   ```
   $ ccoctl aws create-key-pair
   
   2021/04/13 11:01:02 Generating RSA keypair
   2021/04/13 11:01:03 Writing private key to /<path_to_ccoctl_output_dir>/serviceaccount-signer.private
   2021/04/13 11:01:03 Writing public key to /<path_to_ccoctl_output_dir>/serviceaccount-signer.public
   2021/04/13 11:01:03 Copying signing key for use by installer
   ```

   where `serviceaccount-signer.private` and `serviceaccount-signer.public` are the generated key files.

   This command also creates a private key that the cluster requires during installation in `/<path_to_ccoctl_output_dir>/tls/bound-service-account-signing-key.key`

2. Create an OpenID Connect identity provider and S3 bucket on AWS by running the following command:

   ```
   $ ccoctl aws create-identity-provider
   --name=<name>  
   --region=<aws_region>  
   --public-key-file=<path_to_ccoctl_output_dir>/serviceaccount-signer.public
   ```

   where `<name>` is the name used to tag any cloud resources that are created for tracking.

   `<aws-region>` is the AWS region in which cloud resources will be created.

   `<path_to_ccoctl_output_dir>` is the path to the public key file that the `ccoctl aws create-key-pair` command generated.
Example output

2021/04/13 11:16:09 Bucket <name>-oidc created
2021/04/13 11:16:10 OpenID Connect discovery document in the S3 bucket <name>-oidc at .well-known/openid-configuration updated
2021/04/13 11:16:10 Reading public key
2021/04/13 11:16:10 JSON web key set (JWKS) in the S3 bucket <name>-oidc at keys.json updated

where openid-configuration is a discovery document and keys.json is a JSON web key set file.

This command also creates a YAML configuration file in 
/<path_to_ccoctl_output_dir>/manifests/cluster-authentication-02-config.yaml. This file sets the issuer URL field for the service account tokens that the cluster generates, so that the AWS IAM identity provider trusts the tokens.

3. Create IAM roles for each component in the cluster:

   a. Set a $RELEASE_IMAGE variable with the release image from your installation file by running the following command:

      ```
      $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
      ```

   b. Extract the list of CredentialsRequest objects from the OpenShift Container Platform release image:

      ```
      $ oc adm release extract 
      --from=$RELEASE_IMAGE 
      --credentials-requests 
      --included 
      --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml 
      --to=<path_to_directory_for_credentials_requests>
      ```

      The --included parameter includes only the manifests that your specific cluster configuration requires.

      Specify the location of the install-config.yaml file.

      Specify the path to the directory where you want to store the CredentialsRequest objects. If the specified directory does not exist, this command creates it.

   c. Use the ccoctl tool to process all CredentialsRequest objects by running the following command:

      ```
      $ ccoctl aws create-iam-roles 
      --name=<name> 
      --region=<aws_region> 
      --credentials-requests-dir=<path_to_credentials_requests_directory> 
      ```
NOTE

For AWS environments that use alternative IAM API endpoints, such as GovCloud, you must also specify your region with the `--region` parameter.

If your cluster uses Technology Preview features that are enabled by the `TechPreviewNoUpgrade` feature set, you must include the `--enable-tech-preview` parameter.

For each `CredentialsRequest` object, `ccoctl` creates an IAM role with a trust policy that is tied to the specified OIDC identity provider, and a permissions policy as defined in each `CredentialsRequest` object from the OpenShift Container Platform release image.

Verification

- To verify that the OpenShift Container Platform secrets are created, list the files in the `<path_to_ccoctl_output_dir>/manifests` directory:

  ```bash
  $ ls <path_to_ccoctl_output_dir>/manifests
  ```

  **Example output**

  ```
  cluster-authentication-02-config.yaml
  openshift-cloud-credential-operator-cloud-credential-operator-iam-ro-creds-credentials.yaml
  openshift-cloud-network-config-controller-cloud-credentials-credentials.yaml
  openshift-cluster-api-capa-manager-bootstrap-credentials-credentials.yaml
  openshift-cluster-csi-drivers-ebs-cloud-credentials-credentials.yaml
  openshift-image-registry-installer-cloud-credentials-credentials.yaml
  openshift-ingress-operator-cloud-credentials-credentials.yaml
  openshift-machine-api-aws-cloud-credentials-credentials.yaml
  ```

  You can verify that the IAM roles are created by querying AWS. For more information, refer to AWS documentation on listing IAM roles.

6.9.12.2.3. Incorporating the Cloud Credential Operator utility manifests

To implement short-term security credentials managed outside the cluster for individual components, you must move the manifest files that the Cloud Credential Operator utility (`ccoctl`) created to the correct directories for the installation program.

Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.
- You have configured the Cloud Credential Operator utility (`ccoctl`).
- You have created the cloud provider resources that are required for your cluster with the `ccoctl` utility.

Procedure

1. If you did not set the `credentialsMode` parameter in the `install-config.yaml` configuration file to `Manual`, modify the value as shown:
Sample configuration file snippet

```yaml
apiVersion: v1
baseDomain: example.com
credentialsMode: Manual
# ...
```

2. If you have not previously created installation manifest files, do so by running the following command:

```bash
$ openshift-install create manifests --dir <installation_directory>
```

where `<installation_directory>` is the directory in which the installation program creates files.

3. Copy the manifests that the `ccoctl` utility generated to the manifests directory that the installation program created by running the following command:

```bash
$ cp /<path_to_ccoctl_output_dir>/manifests/* ./manifests/
```

4. Copy the private key that the `ccoctl` utility generated in the tls directory to the installation directory by running the following command:

```bash
$ cp -a /<path_to_ccoctl_output_dir>/tls .
```

### 6.9.13. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

**Prerequisites**

- You have configured an account with the cloud platform that hosts your cluster.
- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.

**Procedure**

1. Change to the directory that contains the installation program and initialize the cluster deployment:

```bash
$ ./openshift-install create cluster --dir <installation_directory> \
   --log-level=info
```
1. For `<installation_directory>`, specify the location of your customized `./install-config.yaml` file.

2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

2. Optional: Remove or disable the `AdministratorAccess` policy from the IAM account that you used to install the cluster.

**NOTE**

The elevated permissions provided by the `AdministratorAccess` policy are required only during installation.

**Verification**

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the `kubeadmin` user.

- Credential information also outputs to `<installation_directory>/.openshift_install.log`.

**IMPORTANT**

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

**Example output**

```
...  
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for `Recovering from expired control plane certificates` for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.
6.9.14. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   
   ```

   1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   
   system:admin
   ```

6.9.15. Logging in to the cluster by using the web console

The `kubeadmin` user exists by default after an OpenShift Container Platform installation. You can log in to your cluster as the `kubeadmin` user by using the OpenShift Container Platform web console.

**Prerequisites**

- You have access to the installation host.
- You completed a cluster installation and all cluster Operators are available.

**Procedure**

1. Obtain the password for the `kubeadmin` user from the `kubeadmin-password` file on the installation host:

   ```bash
   $ cat <installation_directory>/auth/kubeadmin-password
   ```

   **NOTE**

   Alternatively, you can obtain the `kubeadmin` password from the `<installation_directory>/openshift_install.log` log file on the installation host.
2. List the OpenShift Container Platform web console route:

```
$ oc get routes -n openshift-console | grep 'console-openshift'
```

**NOTE**
Alternatively, you can obtain the OpenShift Container Platform route from the `<installation_directory>/openshift_install.log` log file on the installation host.

**Example output**

```
<table>
<thead>
<tr>
<th>Route</th>
<th>DNS Name</th>
<th>Protocol</th>
<th>Scheme</th>
<th>Hostname</th>
<th>Port</th>
<th>Path</th>
</tr>
</thead>
<tbody>
<tr>
<td>console-openshift-console</td>
<td>console-openshift-console.apps.</td>
<td>https</td>
<td>console</td>
<td><code>cluster_name</code></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>&lt;base_domain&gt;</code></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

3. Navigate to the route detailed in the output of the preceding command in a web browser and log in as the `kubeadmin` user.

**Additional resources**
- See [Accessing the web console](#) for more details about accessing and understanding the OpenShift Container Platform web console.

### 6.9.16. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager Hybrid Cloud Console.

After you confirm that your OpenShift Cluster Manager Hybrid Cloud Console inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use `subscription watch` to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**
- See [About remote health monitoring](#) for more information about the Telemetry service.

### 6.9.17. Next steps

- Validating an installation.
- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- If necessary, you can remove cloud provider credentials.

### 6.10. INSTALLING A CLUSTER ON AWS INTO A SECRET OR TOP SECRET REGION
In OpenShift Container Platform version 4.14, you can install a cluster on Amazon Web Services (AWS) into the following secret regions:

- Secret Commercial Cloud Services (SC2S)
- Commercial Cloud Services (C2S)

To configure a cluster in either region, you change parameters in the `install config.yaml` file before you install the cluster.

### 6.10.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You configured an AWS account to host the cluster.

**IMPORTANT**

If you have an AWS profile stored on your computer, it must not use a temporary session token that you generated while using a multifactor authentication device. The cluster continues to use your current AWS credentials to create AWS resources for the entire life of the cluster, so you must use long-term credentials. To generate appropriate keys, see Managing Access Keys for IAM Users in the AWS documentation. You can supply the keys when you run the installation program.

- If you use a firewall, you configured it to allow the sites that your cluster requires access to.

### 6.10.2. AWS secret regions

The following AWS secret partitions are supported:

- **us-isob-east-1** (SC2S)
- **us-iso-east-1** (C2S)

**NOTE**

The maximum supported MTU in an AWS SC2S and C2S Regions is not the same as AWS commercial. For more information about configuring MTU during installation, see the Cluster Network Operator configuration object section in Installing a cluster on AWS with network customizations

### 6.10.3. Installation requirements

Red Hat does not publish a Red Hat Enterprise Linux CoreOS (RHCOS) Amazon Machine Image for the AWS Secret and Top Secret Regions.

Before you can install the cluster, you must:

- Upload a custom RHCOS AMI.
• Manually create the installation configuration file (`install-config.yaml`).
• Specify the AWS region, and the accompanying custom AMI, in the installation configuration file.

You cannot use the OpenShift Container Platform installation program to create the installation configuration file. The installer does not list an AWS region without native support for an RHCOS AMI.

**IMPORTANT**

You must also define a custom CA certificate in the `additionalTrustBundle` field of the `install-config.yaml` file because the AWS API requires a custom CA trust bundle. To allow the installation program to access the AWS API, the CA certificates must also be defined on the machine that runs the installation program. You must add the CA bundle to the trust store on the machine, use the `AWS_CA_BUNDLE` environment variable, or define the CA bundle in the `ca_bundle` field of the AWS config file.

### 6.10.4. Private clusters

You can deploy a private OpenShift Container Platform cluster that does not expose external endpoints. Private clusters are accessible from only an internal network and are not visible to the internet.

**NOTE**

Public zones are not supported in Route 53 in an AWS Top Secret Region. Therefore, clusters must be private if they are deployed to an AWS Top Secret Region.

By default, OpenShift Container Platform is provisioned to use publicly-accessible DNS and endpoints. A private cluster sets the DNS, Ingress Controller, and API server to private when you deploy your cluster. This means that the cluster resources are only accessible from your internal network and are not visible to the internet.

**IMPORTANT**

If the cluster has any public subnets, load balancer services created by administrators might be publicly accessible. To ensure cluster security, verify that these services are explicitly annotated as private.

To deploy a private cluster, you must:

• Use existing networking that meets your requirements. Your cluster resources might be shared between other clusters on the network.

• Deploy from a machine that has access to:
  • The API services for the cloud to which you provision.
  • The hosts on the network that you provision.
  • The internet to obtain installation media.

You can use any machine that meets these access requirements and follows your company’s guidelines. For example, this machine can be a bastion host on your cloud network or a machine that has access to the network through a VPN.
6.10.4.1. Private clusters in AWS

To create a private cluster on Amazon Web Services (AWS), you must provide an existing private VPC and subnets to host the cluster. The installation program must also be able to resolve the DNS records that the cluster requires. The installation program configures the Ingress Operator and API server for access from only the private network.

The cluster still requires access to internet to access the AWS APIs.

The following items are not required or created when you install a private cluster:

- Public subnets
- Public load balancers, which support public ingress
- A public Route 53 zone that matches the `baseDomain` for the cluster

The installation program does use the `baseDomain` that you specify to create a private Route 53 zone and the required records for the cluster. The cluster is configured so that the Operators do not create public records for the cluster and all cluster machines are placed in the private subnets that you specify.

6.10.4.1.1. Limitations

The ability to add public functionality to a private cluster is limited.

- You cannot make the Kubernetes API endpoints public after installation without taking additional actions, including creating public subnets in the VPC for each availability zone in use, creating a public load balancer, and configuring the control plane security groups to allow traffic from the internet on 6443 (Kubernetes API port).

- If you use a public Service type load balancer, you must tag a public subnet in each availability zone with `kubernetes.io/cluster/<cluster-infra-id>: shared` so that AWS can use them to create public load balancers.

6.10.5. About using a custom VPC

In OpenShift Container Platform 4.14, you can deploy a cluster into existing subnets in an existing Amazon Virtual Private Cloud (VPC) in Amazon Web Services (AWS). By deploying OpenShift Container Platform into an existing AWS VPC, you might be able to avoid limit constraints in new accounts or more easily abide by the operational constraints that your company’s guidelines set. If you cannot obtain the infrastructure creation permissions that are required to create the VPC yourself, use this installation option.

Because the installation program cannot know what other components are also in your existing subnets, it cannot choose subnet CIDRs and so forth on your behalf. You must configure networking for the subnets that you install your cluster to yourself.

6.10.5.1. Requirements for using your VPC

The installation program no longer creates the following components:

- Internet gateways
- NAT gateways
- Subnets
• Route tables
• VPCs
• VPC DHCP options
• VPC endpoints

**NOTE**

The installation program requires that you use the cloud-provided DNS server. Using a custom DNS server is not supported and causes the installation to fail.

If you use a custom VPC, you must correctly configure it and its subnets for the installation program and the cluster to use. See Amazon VPC console wizard configurations and Work with VPCs and subnets in the AWS documentation for more information on creating and managing an AWS VPC.

The installation program cannot:

• Subdivide network ranges for the cluster to use.
• Set route tables for the subnets.
• Set VPC options like DHCP.

You must complete these tasks before you install the cluster. See VPC networking components and Route tables for your VPC for more information on configuring networking in an AWS VPC.

Your VPC must meet the following characteristics:

• The VPC must not use the `kubernetes.io/cluster/.*: owned, Name, and openshift.io/cluster` tags.
  The installation program modifies your subnets to add the `kubernetes.io/cluster/.*: shared` tag, so your subnets must have at least one free tag slot available for it. See Tag Restrictions in the AWS documentation to confirm that the installation program can add a tag to each subnet that you specify. You cannot use a Name tag, because it overlaps with the EC2 Name field and the installation fails.

• You must enable the `enableDnsSupport` and `enableDnsHostnames` attributes in your VPC, so that the cluster can use the Route 53 zones that are attached to the VPC to resolve cluster’s internal DNS records. See DNS Support in Your VPC in the AWS documentation.
  If you prefer to use your own Route 53 hosted private zone, you must associate the existing hosted zone with your VPC prior to installing a cluster. You can define your hosted zone using the `platform.aws.hostedZone` and `platform.aws.hostedZoneRole` fields in the `install-config.yaml` file. You can use a private hosted zone from another account by sharing it with the account where you install the cluster. If you use a private hosted zone from another account, you must use the Passthrough or Manual credentials mode.

A cluster in an SC2S or C2S Region is unable to reach the public IP addresses for the EC2, ELB, and S3 endpoints. Depending on the level to which you want to restrict internet traffic during the installation, the following configuration options are available:

**Option 1: Create VPC endpoints**
Create a VPC endpoint and attach it to the subnets that the clusters are using. Name the endpoints as follows:
With this option, network traffic remains private between your VPC and the required AWS services.

**Option 2: Create a proxy without VPC endpoints**
As part of the installation process, you can configure an HTTP or HTTPS proxy. With this option, internet traffic goes through the proxy to reach the required AWS services.

**Option 3: Create a proxy with VPC endpoints**
As part of the installation process, you can configure an HTTP or HTTPS proxy with VPC endpoints. Create a VPC endpoint and attach it to the subnets that the clusters are using. Name the endpoints as follows:

**SC2S**
- elasticloadbalancing.<aws_region>.sc2s.sgov.gov
- ec2.<aws_region>.sc2s.sgov.gov
- s3.<aws_region>.sc2s.sgov.gov

**C2S**
- elasticloadbalancing.<aws_region>.c2s.ic.gov
- ec2.<aws_region>.c2s.ic.gov
- s3.<aws_region>.c2s.ic.gov

When configuring the proxy in the `install-config.yaml` file, add these endpoints to the `noProxy` field. With this option, the proxy prevents the cluster from accessing the internet directly. However, network traffic remains private between your VPC and the required AWS services.

**Required VPC components**
You must provide a suitable VPC and subnets that allow communication to your machines.
<table>
<thead>
<tr>
<th>Component</th>
<th>AWS type</th>
<th>Description</th>
</tr>
</thead>
</table>
| VPC                | - AWS::EC2::VPC  
                   | - AWS::EC2::VPCEndpoint                        | You must provide a public VPC for the cluster to use. The VPC uses an endpoint that references the route tables for each subnet to improve communication with the registry that is hosted in S3. |
| Public subnets     | - AWS::EC2::Subnet                           | Your VPC must have public subnets for between 1 and 3 availability zones and associate them with appropriate Ingress rules.                                               |
|                    | - AWS::EC2::SubnetNetworkAclAssociation       |                                                                                                                                                                      |
| Internet gateway   | - AWS::EC2::InternetGateway                  | You must have a public internet gateway, with public routes, attached to the VPC. In the provided templates, each public subnet has a NAT gateway with an EIP address. These NAT gateways allow cluster resources, like private subnet instances, to reach the internet and are not required for some restricted network or proxy scenarios. |
|                    | - AWS::EC2::VPCGatewayAttachment              |                                                                                                                                                                      |
|                    | - AWS::EC2::RouteTable                        |                                                                                                                                                                      |

|                    | - AWS::EC2::SubnetRouteTableAssociation       |                                                                                                                                                                      |
|                    | - AWS::EC2::NatGateway                        |                                                                                                                                                                      |
|                    | - AWS::EC2::EIP                              |                                                                                                                                                                      |
| Network access     | - AWS::EC2::NetworkAcl                        | You must allow the VPC to access the following ports:                                                                                                                                 |
| control            | - AWS::EC2::NetworkAclEntry                   | Port | Reason                                                                                                           |
|                    |                                               | 80   | Inbound HTTP traffic                                                                                             |
|                    |                                               | 443  | Inbound HTTPS traffic                                                                                             |
|                    |                                               | 22   | Inbound SSH traffic                                                                                               |
|                    |                                               | 1024 - 65535 | Inbound ephemeral traffic                                                                                      |
|                    |                                               | 0 - 65535 | Outbound ephemeral traffic                                                                                      |
### Private subnets

- **AWS::EC2::Subnet**
- **AWS::EC2::RouteTable**
- **AWS::EC2::SubnetRouteTableAssociation**

Your VPC can have private subnets. The provided CloudFormation templates can create private subnets for between 1 and 3 availability zones. If you use private subnets, you must provide appropriate routes and tables for them.

### 6.10.5.2. VPC validation

To ensure that the subnets that you provide are suitable, the installation program confirms the following data:

- All the subnets that you specify exist.
- You provide private subnets.
- The subnet CIDRs belong to the machine CIDR that you specified.
- You provide subnets for each availability zone. Each availability zone contains no more than one public and one private subnet. If you use a private cluster, provide only a private subnet for each availability zone. Otherwise, provide exactly one public and private subnet for each availability zone.
- You provide a public subnet for each private subnet availability zone. Machines are not provisioned in availability zones that you do not provide private subnets for.

If you destroy a cluster that uses an existing VPC, the VPC is not deleted. When you remove the OpenShift Container Platform cluster from a VPC, the `kubernetes.io/cluster/.*: shared` tag is removed from the subnets that it used.

### 6.10.5.3. Division of permissions

Starting with OpenShift Container Platform 4.3, you do not need all of the permissions that are required for an installation program-provisioned infrastructure cluster to deploy a cluster. This change mimics the division of permissions that you might have at your company: some individuals can create different resource in your clouds than others. For example, you might be able to create application-specific items, like instances, buckets, and load balancers, but not networking-related components such as VPCs, subnets, or ingress rules.

The AWS credentials that you use when you create your cluster do not need the networking permissions that are required to make VPCs and core networking components within the VPC, such as subnets, routing tables, internet gateways, NAT, and VPN. You still need permission to make the application resources that the machines within the cluster require, such as ELBs, security groups, S3 buckets, and nodes.

### 6.10.5.4. Isolation between clusters

If you deploy OpenShift Container Platform to an existing network, the isolation of cluster services is reduced in the following ways:
You can install multiple OpenShift Container Platform clusters in the same VPC.

- ICMP ingress is allowed from the entire network.
- TCP 22 ingress (SSH) is allowed to the entire network.
- Control plane TCP 6443 ingress (Kubernetes API) is allowed to the entire network.
- Control plane TCP 22623 ingress (MCS) is allowed to the entire network.

### 6.10.5.5. AWS security groups

By default, the installation program creates and attaches security groups to control plane and compute machines. The rules associated with the default security groups cannot be modified.

However, you can apply additional existing AWS security groups, which are associated with your existing VPC, to control plane and compute machines. Applying custom security groups can help you meet the security needs of your organization, in such cases where you need to control the incoming or outgoing traffic of these machines.

As part of the installation process, you apply custom security groups by modifying the `install-config.yaml` file before deploying the cluster.

For more information, see "Applying existing AWS security groups to the cluster".

### 6.10.6. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager Hybrid Cloud Console](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- Access [Quay.io](#) to obtain the packages that are required to install your cluster.

- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 6.10.7. Uploading a custom RHCOS AMI in AWS

If you are deploying to a custom Amazon Web Services (AWS) region, you must upload a custom Red Hat Enterprise Linux CoreOS (RHCOS) Amazon Machine Image (AMI) that belongs to that region.

Prerequisites
You configured an AWS account.

You created an Amazon S3 bucket with the required IAM service role.

You uploaded your RHCOS VMDK file to Amazon S3. The RHCOS VMDK file must be the highest version that is less than or equal to the OpenShift Container Platform version you are installing.

You downloaded the AWS CLI and installed it on your computer. See Install the AWS CLI Using the Bundled Installer.

Procedure

1. Export your AWS profile as an environment variable:

   ```bash
   $ export AWS_PROFILE=<aws_profile>
   ```

2. Export the region to associate with your custom AMI as an environment variable:

   ```bash
   $ export AWS_DEFAULT_REGION=<aws_region>
   ```

3. Export the version of RHCOS you uploaded to Amazon S3 as an environment variable:

   ```bash
   $ export RHCOS_VERSION=<version>
   ```

   The RHCOS VMDK version, like **4.14.0**.

4. Export the Amazon S3 bucket name as an environment variable:

   ```bash
   $ export VMIMPORT_BUCKET_NAME=<s3_bucket_name>
   ```

5. Create the `containers.json` file and define your RHCOS VMDK file:

   ```bash
   $ cat <<EOF > containers.json
   {
     "Description": "rhcos-${RHCOS_VERSION}-x86_64-aws.x86_64",
     "Format": "vmdk",
     "UserBucket": {
       "S3Bucket": "${VMIMPORT_BUCKET_NAME}",
       "S3Key": "rhcos-${RHCOS_VERSION}-x86_64-aws.x86_64.vmdk"
     }
   }
   EOF
   ```

6. Import the RHCOS disk as an Amazon EBS snapshot:

   ```bash
   $ aws ec2 import-snapshot --region $(AWS_DEFAULT_REGION) \
     --description "<description>" \
     --disk-container "file://<file_path>/containers.json"
   ```

   The description of your RHCOS disk being imported, like **rhcos-${RHCOS_VERSION}-x86_64-aws.x86_64**.
2 The file path to the JSON file describing your RHCOS disk. The JSON file should contain your Amazon S3 bucket name and key.

7. Check the status of the image import:

   $ watch -n 5 aws ec2 describe-import-snapshot-tasks --region ${AWS_DEFAULT_REGION}

**Example output**

```json
{
   "ImportSnapshotTasks": [
      {
         "Description": "rhcos-4.7.0-x86_64-aws.x86_64",
         "ImportTaskId": "import-snap-fh6i8uil",
         "SnapshotTaskDetail": {
            "Description": "rhcos-4.7.0-x86_64-aws.x86_64",
            "DiskImageSize": 819056640.0,
            "Format": "VMDK",
            "SnapshotId": "snap-06331325870076318",
            "Status": "completed",
            "UserBucket": {
              "S3Bucket": "external-images",
              "S3Key": "rhcos-4.7.0-x86_64-aws.x86_64.vmdk"
            }
         }
      }
   ]
}
```

Copy the **SnapshotId** to register the image.

8. Create a custom RHCOS AMI from the RHCOS snapshot:

   $ aws ec2 register-image
   --region ${AWS_DEFAULT_REGION} 
   --architecture x86_64 \  
   --description "rhcos-$(RHCOS_VERSION)-x86_64-aws.x86_64" \  
   --ena-support \  
   --name "rhcos-$(RHCOS_VERSION)-x86_64-aws.x86_64" \  
   --virtualization-type hvm \  
   --root-device-name '/dev/xvda' \  
   --block-device-mappings 'DeviceName=/dev/xvda,Ebs={DeleteOnTermination=true,SnapshotId=<snapshot_ID>}'

   1 The RHCOS VMDK architecture type, like x86_64, aarch64, s390x, or ppc64le.
   2 The **Description** from the imported snapshot.
   3 The name of the RHCOS AMI.
   4 The **SnapshotId** from the imported snapshot.
To learn more about these APIs, see the AWS documentation for importing snapshots and creating EBS-backed AMIs.

6.10.8. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>
   ```

   Specify the path and file name, such as ~/.ssh/id_ed25519, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

2. View the public SSH key:

   ```
   $ cat <path>/<file_name>.pub
   ```

   For example, run the following to view the ~/.ssh/id_ed25519.pub public key:
3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the ./openshift-install gather command.

NOTE
On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.

a. If the ssh-agent process is not already running for your local user, start it as a background task:

   $ eval "$(ssh-agent -s)"

   **Example output**

   Agent pid 31874

   **NOTE**
   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the ssh-agent:

   $ ssh-add <path>/<file_name>

   **Example output**

   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

Next steps
- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

6.10.9. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

**Prerequisites**
- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

**Procedure**
1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

**IMPORTANT**

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
$ mkdir <installation_directory>
```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 6.10.10. Manually creating the installation configuration file

Installing the cluster requires that you manually generate the installation configuration file.

**Prerequisites**

- You have uploaded a custom RHCOS AMI.
- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.
- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Create an installation directory to store your required installation assets in:

```
$ mkdir <installation_directory>
```
IMPORTANT

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample `install-config.yaml` file template that is provided and save it in the `<installation_directory>`.

NOTE

You must name this configuration file `install-config.yaml`.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

IMPORTANT

The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.

Additional resources

- Installation configuration parameters for AWS

6.10.10.1. Tested instance types for AWS

The following Amazon Web Services (AWS) instance types have been tested with OpenShift Container Platform.

NOTE

Use the machine types included in the following charts for your AWS instances. If you use an instance type that is not listed in the chart, ensure that the instance size you use matches the minimum resource requirements that are listed in "Minimum resource requirements for cluster installation".

Example 6.40. Machine types based on 64-bit x86 architecture for secret regions

- c4.*
- c5.*
- i3.*
- m4.*
- m5.*
- r4.*
- r5.*
6.10.10.2. Sample customized install-config.yaml file for AWS

You can customize the installation configuration file (install-config.yaml) to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

```
apiVersion: v1
baseDomain: example.com
credentialsMode: Mint
controlPlane:
  hyperthreading: Enabled
  name: master
  platform:
    aws:
      lbType: NLB
      zones:
      - us-iso-east-1a
      - us-iso-east-1b
      rootVolume:
        iops: 4000
        size: 500
        type: io1
      metadataService:
        authentication: Optional
        type: m6i.xlarge
      replicas: 3
    compute:
      - hyperthreading: Enabled
        name: worker
        platform:
          aws:
            rootVolume:
              iops: 2000
              size: 500
              type: io1
            metadataService:
              authentication: Optional
              type: c5.4xlarge
            zones:
            - us-iso-east-1a
            - us-iso-east-1b
            replicas: 3
          metadata:
            name: test-cluster
      networking:
        clusterNetwork:
```

**IMPORTANT**

This sample YAML file is provided for reference only. Use it as a resource to enter parameter values into the installation configuration file that you created manually.
Required.

Optional: Add this parameter to force the Cloud Credential Operator (CCO) to use the specified mode. By default, the CCO uses the root credentials in the `kube-system` namespace to dynamically try to determine the capabilities of the credentials. For details about CCO modes, see the "About the Cloud Credential Operator" section in the Authentication and authorization guide.

If you do not provide these parameters and values, the installation program provides the default value.

The `controlPlane` section is a single mapping, but the `compute` section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the `compute` section must begin with a hyphen, `-`, and the first line of the `controlPlane` section must not. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading, or hyperthreading. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to Disabled. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.
IMPORTANT

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger instance types, such as m4.2xlarge or m5.2xlarge, for your machines if you disable simultaneous multithreading.

To configure faster storage for etcd, especially for larger clusters, set the storage type as io1 and set iops to 2000.

Whether to require the Amazon EC2 Instance Metadata Service v2 (IMDSv2). To require IMDSv2, set the parameter value to Required. To allow the use of both IMDSv1 and IMDSv2, set the parameter value to Optional. If no value is specified, both IMDSv1 and IMDSv2 are allowed.

NOTE

The IMDS configuration for control plane machines that is set during cluster installation can only be changed by using the AWS CLI. The IMDS configuration for compute machines can be changed by using compute machine sets.

The cluster network plugin to install. The supported values are OVNKubernetes and OpenShiftSDN. The default value is OVNKubernetes.

If you provide your own VPC, specify subnets for each availability zone that your cluster uses.

The ID of the AMI used to boot machines for the cluster. If set, the AMI must belong to the same region as the cluster.

The AWS service endpoints. Custom endpoints are required when installing to an unknown AWS region. The endpoint URL must use the https protocol and the host must trust the certificate.

The ID of your existing Route 53 private hosted zone. Providing an existing hosted zone requires that you supply your own VPC and the hosted zone is already associated with the VPC prior to installing your cluster. If undefined, the installation program creates a new hosted zone.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

IMPORTANT

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see Installing the system in FIPS mode. When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures.

You can optionally provide the sshKey value that you use to access the machines in your cluster.
NOTE
For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

How to publish the user-facing endpoints of your cluster. Set publish to Internal to deploy a private cluster, which cannot be accessed from the internet. The default value is External.

The custom CA certificate. This is required when deploying to the SC2S or C2S Regions because the AWS API requires a custom CA trust bundle.

6.10.10.3. Configuring the cluster-wide proxy during installation
Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the install-config.yaml file.

Prerequisites

- You have an existing install-config.yaml file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the Proxy object’s spec.noProxy field to bypass the proxy if necessary.

NOTE
The Proxy object status.noProxy field is populated with the values of the networking.machineNetwork[].cidr, networking.clusterNetwork[].cidr, and networking.serviceNetwork[] fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object status.noProxy field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your install-config.yaml file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port> 1
  httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
  noProxy: ec2.<aws_region>.amazonaws.com,elasticloadbalancing.<aws_region>.amazonaws.com,s3.<aws_region>.amazonaws.com 3
additionalTrustBundle: | 4
-----BEGIN CERTIFICATE-----
```
A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.

A proxy URL to use for creating HTTPS connections outside the cluster.

A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with `.`, to match subdomains only. For example, `.y.com` matches `x.y.com`, but not `y.com`. Use `*` to bypass the proxy for all destinations. If you have added the Amazon EC2 Elastic Load Balancing, and S3 VPC endpoints to your VPC, you must add these endpoints to the `noProxy` field.

If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the `trustedCA` field of the `Proxy` object. The `additionalTrustBundle` field is required unless the proxy's identity certificate is signed by an authority from the RHCOS trust bundle.

Optional: The policy to determine the configuration of the `Proxy` object to reference the `user-ca-bundle` config map in the `trustedCA` field. The allowed values are `Proxyonly` and `Always`. Use `Proxyonly` to reference the `user-ca-bundle` config map only when `http/https` proxy is configured. Use `Always` to always reference the `user-ca-bundle` config map. The default value is `Proxyonly`.

NOTE
The installation program does not support the proxy `readinessEndpoints` field.

NOTE
If the installer times out, restart and then complete the deployment by using the `wait-for` command of the installer. For example:

```
$ ./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

NOTE
Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

6.10.10.4. Applying existing AWS security groups to the cluster
Applying existing AWS security groups to your control plane and compute machines can help you meet the security needs of your organization, in such cases where you need to control the incoming or outgoing traffic of these machines.

**Prerequisites**

- You have created the security groups in AWS. For more information, see the AWS documentation about working with security groups.
- The security groups must be associated with the existing VPC that you are deploying the cluster to. The security groups cannot be associated with another VPC.
- You have an existing `install-config.yaml` file.

**Procedure**

1. In the `install-config.yaml` file, edit the `compute.platform.aws.additionalSecurityGroupIDs` parameter to specify one or more custom security groups for your compute machines.

2. Edit the `controlPlane.platform.aws.additionalSecurityGroupIDs` parameter to specify one or more custom security groups for your control plane machines.

3. Save the file and reference it when deploying the cluster.

**Sample install-config.yaml file that specifies custom security groups**

```yaml
```

1 Specify the name of the security group as it appears in the Amazon EC2 console, including the `sg` prefix.
Specify subnets for each availability zone that your cluster uses.

6.10.11. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of oc.

Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

**Procedure**

2. Select the architecture from the **Product Variant** drop-down list.

3. Select the appropriate version from the **Version** drop-down list.

4. Click **Download Now** next to the **OpenShift v4.14 Linux Client** entry and save the file.

5. Unpack the archive:

   $ tar xvf <file>

6. Place the oc binary in a directory that is on your **PATH**.
   To check your **PATH**, execute the following command:

   $ echo $PATH

**Verification**

- After you install the OpenShift CLI, it is available using the oc command:

  $ oc <command>

Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version from the **Version** drop-down list.

3. Click **Download Now** next to the **OpenShift v4.14 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.

5. Move the `oc` binary to a directory that is on your `PATH`.
   To check your `PATH`, open the command prompt and execute the following command:

   ```
   C:\> path
   ```

**Verification**

- After you install the OpenShift CLI, it is available using the `oc` command:

  ```
  C:\> oc <command>
  ```

**Installing the OpenShift CLI on macOS**

You can install the OpenShift CLI (`oc`) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version from the Version drop-down list.

3. Click **Download Now** next to the **OpenShift v4.14 macOS Client** entry and save the file.

   **NOTE**
   
   For macOS arm64, choose the **OpenShift v4.14 macOS arm64 Client** entry.

4. Unpack and unzip the archive.

5. Move the `oc` binary to a directory on your `PATH`.
   To check your `PATH`, open a terminal and execute the following command:

   ```
   $ echo $PATH
   ```

**Verification**

- After you install the OpenShift CLI, it is available using the `oc` command:

  ```
  $ oc <command>
  ```

**6.10.12. Alternatives to storing administrator-level secrets in the kube-system project**

By default, administrator secrets are stored in the `kube-system` project. If you configured the `credentialsMode` parameter in the `install-config.yaml` file to **Manual**, you must use one of the following alternatives:

- To manage long-term cloud credentials manually, follow the procedure in Manually creating long-term credentials.
To implement short-term credentials that are managed outside the cluster for individual components, follow the procedures in Configuring an AWS cluster to use short-term credentials.

6.10.12.1. Manually creating long-term credentials

The Cloud Credential Operator (CCO) can be put into manual mode prior to installation in environments where the cloud identity and access management (IAM) APIs are not reachable, or the administrator prefers not to store an administrator-level credential secret in the cluster kube-system namespace.

Procedure

1. If you did not set the credentialsMode parameter in the install-config.yaml configuration file to Manual, modify the value as shown:

Sample configuration file snippet

```yaml
apiVersion: v1
baseDomain: example.com
credentialsMode: Manual
# ...
```

2. If you have not previously created installation manifest files, do so by running the following command:

   ```bash
   $ openshift-install create manifests --dir <installation_directory>
   ```

   where `<installation_directory>` is the directory in which the installation program creates files.

3. Set a $RELEASE_IMAGE variable with the release image from your installation file by running the following command:

   ```bash
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
   ```

4. Extract the list of CredentialsRequest custom resources (CRs) from the OpenShift Container Platform release image by running the following command:

   ```bash
   $ oc adm release extract \ 
   --from=$RELEASE_IMAGE \ 
   --credentials-requests \ 
   --included \ 
   --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \ 
   --to=<path_to_directory_for_credentials_requests>
   ```

   1. The --included parameter includes only the manifests that your specific cluster configuration requires.

   2. Specify the location of the install-config.yaml file.

   3. Specify the path to the directory where you want to store the CredentialsRequest objects. If the specified directory does not exist, this command creates it.
This command creates a YAML file for each `CredentialsRequest` object.

**Sample CredentialsRequest object**

```yaml
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
  name: <component_credentials_request>
  namespace: openshift-cloud-credential-operator
...  
spec:
  providerSpec:
    apiVersion: cloudcredential.openshift.io/v1
    kind: AWSProviderSpec
    statementEntries:
      - effect: Allow
        action:
          - iam:GetUser
          - iam:GetUserPolicy
          - iam:ListAccessKeys
        resource: "*"
      ...

apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
  name: <component_credentials_request>
  namespace: openshift-cloud-credential-operator
...  
spec:
  providerSpec:
    apiVersion: cloudcredential.openshift.io/v1
    kind: AWSProviderSpec
    statementEntries:
      - effect: Allow
        action:
          - s3:CreateBucket
          - s3:DeleteBucket
        resource: "*"
      ...

secretRef:
  name: <component_secret>
  namespace: <component_namespace>
...
```

5. Create YAML files for secrets in the `openshift-install` manifests directory that you generated previously. The secrets must be stored using the namespace and secret name defined in the `spec.secretRef` for each `CredentialsRequest` object.

**Sample CredentialsRequest object with secrets**

```yaml
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
  name: <component_credentials_request>
  namespace: openshift-cloud-credential-operator
...  
spec:
  providerSpec:
    apiVersion: cloudcredential.openshift.io/v1
    kind: AWSProviderSpec
    statementEntries:
      - effect: Allow
        action:
          - s3:CreateBucket
          - s3:DeleteBucket
        resource: "*"
      ...

secretRef:
  name: <component_secret>
  namespace: <component_namespace>
...
```

**Sample Secret object**

```yaml
apiVersion: v1
```
IMPORTANT

Before upgrading a cluster that uses manually maintained credentials, you must ensure that the CCO is in an upgradeable state.

6.10.12.2. Configuring an AWS cluster to use short-term credentials

To install a cluster that is configured to use the AWS Security Token Service (STS), you must configure the CCO utility and create the required AWS resources for your cluster.

6.10.12.2.1. Configuring the Cloud Credential Operator utility

To create and manage cloud credentials from outside of the cluster when the Cloud Credential Operator (CCO) is operating in manual mode, extract and prepare the CCO utility (ccoctl) binary.

NOTE

The ccoctl utility is a Linux binary that must run in a Linux environment.

Prerequisites

- You have access to an OpenShift Container Platform account with cluster administrator access.
- You have installed the OpenShift CLI (oc).
- You have created an AWS account for the ccoctl utility to use with the following permissions:

  Example 6.41. Required AWS permissions

  Required iam permissions

  ○ iam:CreateOpenIDConnectProvider
  ○ iam:CreateRole
  ○ iam:DeleteOpenIDConnectProvider
  ○ iam:DeleteRole
  ○ iam:DeleteRolePolicy
  ○ iam:GetOpenIDConnectProvider
  ○ iam:GetRole
  ○ iam:GetUser
  ○ iam:ListOpenIDConnectProviders
Required s3 permissions
- s3:CreateBucket
- s3:DeleteBucket
- s3:DeleteObject
- s3:GetBucketAcl
- s3:GetBucketTagging
- s3:GetObject
- s3:GetObjectAcl
- s3:GetObjectTagging
- s3:ListBucket
- s3:PutBucketAcl
- s3:PutBucketPolicy
- s3:PutBucketPublicAccessBlock
- s3:PutBucketTagging
- s3:PutObject
- s3:PutObjectAcl
- s3:PutObjectTagging

Required cloudfront permissions
- cloudfront:ListCloudFrontOriginAccessIdentities
- cloudfront:ListDistributions
- cloudfront:ListTagsForResource

If you plan to store the OIDC configuration in a private S3 bucket that is accessed by the IAM identity provider through a public CloudFront distribution URL, the AWS account that runs the ccoctl utility requires the following additional permissions:
Example 6.42. Additional permissions for a private S3 bucket with CloudFront

- cloudfront:CreateCloudFrontOriginAccessIdentity
- cloudfront:CreateDistribution
- cloudfront:DeleteCloudFrontOriginAccessIdentity
- cloudfront:DeleteDistribution
- cloudfront:GetCloudFrontOriginAccessIdentity
- cloudfront:GetCloudFrontOriginAccessIdentityConfig
- cloudfront:GetDistribution
- cloudfront:TagResource
- cloudfront:UpdateDistribution

NOTE

These additional permissions support the use of the `--create-private-s3-bucket` option when processing credentials requests with the `ccoctl aws create-all` command.

Procedure

1. Obtain the OpenShift Container Platform release image by running the following command:

```
$ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
```

2. Obtain the CCO container image from the OpenShift Container Platform release image by running the following command:

```
$ CCO_IMAGE=$(oc adm release info --image-for='cloud-credential-operator' $RELEASE_IMAGE -a ~/.pull-secret)
```

NOTE

Ensure that the architecture of the `$RELEASE_IMAGE` matches the architecture of the environment in which you will use the `ccoctl` tool.

3. Extract the `ccoctl` binary from the CCO container image within the OpenShift Container Platform release image by running the following command:

```
$ oc image extract $CCO_IMAGE --file="/usr/bin/ccoctl" -a ~/.pull-secret
```

4. Change the permissions to make `ccoctl` executable by running the following command:

```
$ chmod 775 ccoctl
```
Verification

- To verify that `ccoctl` is ready to use, display the help file by running the following command:

```
$ ccoctl --help
```

**Output of ccoctl --help**

OpenShift credentials provisioning tool

Usage:

`ccoctl [command]`

Available Commands:

- `alibabacloud` Manage credentials objects for alibaba cloud
- `aws` Manage credentials objects for AWS cloud
- `azure` Manage credentials objects for Azure
- `gcp` Manage credentials objects for Google cloud
- `help` Help about any command
- `ibmcloud` Manage credentials objects for IBM Cloud
- `nutanix` Manage credentials objects for Nutanix

Flags:

- `-h`, `--help` help for ccoctl

Use "ccoctl [command] --help" for more information about a command.

6.10.12.2.2. Creating AWS resources with the Cloud Credential Operator utility

You have the following options when creating AWS resources:

- You can use the `ccoctl aws create-all` command to create the AWS resources automatically. This is the quickest way to create the resources. See Creating AWS resources with a single command.

- If you need to review the JSON files that the `ccoctl` tool creates before modifying AWS resources, or if the process the `ccoctl` tool uses to create AWS resources automatically does not meet the requirements of your organization, you can create the AWS resources individually. See Creating AWS resources individually.

6.10.12.2.2.1. Creating AWS resources with a single command

If the process the `ccoctl` tool uses to create AWS resources automatically meets the requirements of your organization, you can use the `ccoctl aws create-all` command to automate the creation of AWS resources.

Otherwise, you can create the AWS resources individually. For more information, see "Creating AWS resources individually".

**NOTE**

By default, `ccoctl` creates objects in the directory in which the commands are run. To create the objects in a different directory, use the `--output-dir` flag. This procedure uses `<path_to_ccoctl_output_dir>` to refer to this directory.
Prerequisites

You must have:

- Extracted and prepared the `ccoctl` binary.

Procedure

1. Set a `$RELEASE_IMAGE` variable with the release image from your installation file by running the following command:

   ```bash
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
   ```

2. Extract the list of `CredentialsRequest` objects from the OpenShift Container Platform release image by running the following command:

   ```bash
   $ oc adm release extract \
   --from=$RELEASE_IMAGE \
   --credentials-requests \
   --included \
   --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \
   --to=<path_to_directory_for_credentials_requests>
   ```

   - The `--included` parameter includes only the manifests that your specific cluster configuration requires.
   - Specify the location of the `install-config.yaml` file.
   - Specify the path to the directory where you want to store the `CredentialsRequest` objects. If the specified directory does not exist, this command creates it.

   **NOTE**
   
   This command might take a few moments to run.

3. Use the `ccoctl` tool to process all `CredentialsRequest` objects by running the following command:

   ```bash
   $ ccoctl aws create-all \
   --name=<name> \
   --region=<aws_region> \
   --credentials-requests-dir=<path_to_credentials_requests_directory> \
   --output-dir=<path_to_ccoctl_output_dir> \
   --create-private-s3-bucket
   ```

   - Specify the name used to tag any cloud resources that are created for tracking.
   - Specify the AWS region in which cloud resources will be created.
   - Specify the directory containing the files for the component `CredentialsRequest` objects.
   - Optional: Specify the directory in which you want the `ccoctl` utility to create objects. By default, the utility creates objects in the directory in which the commands are run.
Optional: By default, the `ccoctl` utility stores the OpenID Connect (OIDC) configuration files in a public S3 bucket and uses the S3 URL as the public OIDC endpoint. To store the

**NOTE**

If your cluster uses Technology Preview features that are enabled by the `TechPreviewNoUpgrade` feature set, you must include the `--enable-tech-preview` parameter.

**Verification**

- To verify that the OpenShift Container Platform secrets are created, list the files in the `<path_to_ccoctl_output_dir>/manifests` directory:

  ```bash
  $ ls <path_to_ccoctl_output_dir>/manifests
  ```

**Example output**

- `cluster-authentication-02-config.yaml`
- `openshift-cloud-credential-operator-cloud-credential-operator-iam-ro-creds-credentials.yaml`
- `openshift-cloud-network-config-controller-cloud-credentials-credentials.yaml`
- `openshift-cluster-api-capa-manager-bootstrap-credentials-credentials.yaml`
- `openshift-cluster-csi-drivers-ebs-cloud-credentials-credentials.yaml`
- `openshift-image-registry-installer-cloud-credentials-credentials.yaml`
- `openshift-ingress-operator-cloud-credentials-credentials.yaml`
- `openshift-machine-api-aws-cloud-credentials-credentials.yaml`

You can verify that the IAM roles are created by querying AWS. For more information, refer to AWS documentation on listing IAM roles.

### 6.10.12.2.2. Creating AWS resources individually

You can use the `ccoctl` tool to create AWS resources individually. This option might be useful for an organization that shares the responsibility for creating these resources among different users or departments.

Otherwise, you can use the `ccoctl aws create-all` command to create the AWS resources automatically. For more information, see “Creating AWS resources with a single command”.

**NOTE**

By default, `ccoctl` creates objects in the directory in which the commands are run. To create the objects in a different directory, use the `--output-dir` flag. This procedure uses `<path_to_ccoctl_output_dir>` to refer to this directory.

Some `ccoctl` commands make AWS API calls to create or modify AWS resources. You can use the `--dry-run` flag to avoid making API calls. Using this flag creates JSON files on the local file system instead. You can review and modify the JSON files and then apply them with the AWS CLI tool using the `--cli-input-json` parameters.

**Prerequisites**

- Extract and prepare the `ccoctl` binary.
Procedure

1. Generate the public and private RSA key files that are used to set up the OpenID Connect provider for the cluster by running the following command:

   ```
   $ ccoctl aws create-key-pair
   ```

   **Example output**

   2021/04/13 11:01:02 Generating RSA keypair
   2021/04/13 11:01:03 Writing private key to /<path_to_ccoctl_output_dir>/serviceaccount-signer.private
   2021/04/13 11:01:03 Writing public key to /<path_to_ccoctl_output_dir>/serviceaccount-signer.public
   2021/04/13 11:01:03 Copying signing key for use by installer

   where `serviceaccount-signer.private` and `serviceaccount-signer.public` are the generated key files.

   This command also creates a private key that the cluster requires during installation in `<path_to_ccoctl_output_dir>/tls/bound-service-account-signing-key.key`.

2. Create an OpenID Connect identity provider and S3 bucket on AWS by running the following command:

   ```
   $ ccoctl aws create-identity-provider \
   --name=<name> \1
   --region=<aws_region> \2
   --public-key-file=<path_to_ccoctl_output_dir>/serviceaccount-signer.public \3
   ```

   **Example output**

   2021/04/13 11:16:09 Bucket <name>-oidc created
   2021/04/13 11:16:10 OpenID Connect discovery document in the S3 bucket <name>-oidc at .well-known/openid-configuration updated
   2021/04/13 11:16:10 Reading public key
   2021/04/13 11:16:10 JSON web key set (JWKS) in the S3 bucket <name>-oidc at keys.json updated

   where `openid-configuration` is a discovery document and `keys.json` is a JSON web key set file.

   This command also creates a YAML configuration file in `<path_to_ccoctl_output_dir>/manifests/cluster-authentication-02-config.yaml`. This file sets the issuer URL field for the service account tokens that the cluster generates, so that the
AWS IAM identity provider trusts the tokens.

3. Create IAM roles for each component in the cluster:
   a. Set a `$RELEASE_IMAGE` variable with the release image from your installation file by running the following command:

   ```
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
   ```

   b. Extract the list of `CredentialsRequest` objects from the OpenShift Container Platform release image:

   ```
   $ oc adm release extract \
   --from=$RELEASE_IMAGE \
   --credentials-requests \
   --included \
   --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \
   --to=<path_to_directory_for_credentials_requests>
   ```

   1 The `--included` parameter includes only the manifests that your specific cluster configuration requires.

   2 Specify the location of the `install-config.yaml` file.

   3 Specify the path to the directory where you want to store the `CredentialsRequest` objects. If the specified directory does not exist, this command creates it.

   c. Use the `ccoctl` tool to process all `CredentialsRequest` objects by running the following command:

   ```
   $ ccoctl aws create-iam-roles \
   --name=<name> \
   --region=<aws_region> \
   --credentials-requests-dir=<path_to_credentials_requests_directory> \
   ```

   **NOTE**

   For AWS environments that use alternative IAM API endpoints, such as GovCloud, you must also specify your region with the `--region` parameter.

   If your cluster uses Technology Preview features that are enabled by the `TechPreviewNoUpgrade` feature set, you must include the `--enable-tech-preview` parameter.

   For each `CredentialsRequest` object, `ccoctl` creates an IAM role with a trust policy that is tied to the specified OIDC identity provider, and a permissions policy as defined in each `CredentialsRequest` object from the OpenShift Container Platform release image.

**Verification**
To verify that the OpenShift Container Platform secrets are created, list the files in the `<path_to_ccoctl_output_dir>/manifests` directory:

```
$ ls <path_to_ccoctl_output_dir>/manifests
```

Example output

```
cluster-authentication-02-config.yaml
openshift-cloud-credential-operator-cloud-credential-operator-iam-ro-creds-credentials.yaml
openshift-cloud-network-config-controller-cloud-credentials-credentials.yaml
openshift-cluster-api-capacity-manager-bootstrap-credentials-credentials.yaml
openshift-cluster-csi-drivers-ebs-cloud-credentials-credentials.yaml
openshift-image-registry-installer-cloud-credentials-credentials.yaml
openshift-ingress-operator-cloud-credentials-credentials.yaml
openshift-machine-api-aws-cloud-credentials-credentials.yaml
```

You can verify that the IAM roles are created by querying AWS. For more information, refer to AWS documentation on listing IAM roles.

6.10.12.2.3. Incorporating the Cloud Credential Operator utility manifests

To implement short-term security credentials managed outside the cluster for individual components, you must move the manifest files that the Cloud Credential Operator utility (ccoctl) created to the correct directories for the installation program.

Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.
- You have configured the Cloud Credential Operator utility (ccoctl).
- You have created the cloud provider resources that are required for your cluster with the ccoctl utility.

Procedure

1. If you did not set the `credentialsMode` parameter in the `install-config.yaml` configuration file to `Manual`, modify the value as shown:

   Sample configuration file snippet

   ```
   apiVersion: v1
   baseDomain: example.com
   credentialsMode: Manual
   # ...
   ```

2. If you have not previously created installation manifest files, do so by running the following command:

   ```
   $ openshift-install create manifests --dir <installation_directory>
   ```

   where `<installation_directory>` is the directory in which the installation program creates files.
3. Copy the manifests that the `ccoctl` utility generated to the `manifests` directory that the installation program created by running the following command:

   ```bash
   $ cp <path_to_ccoctl_output_dir>/manifests/* ./manifests/
   ```

4. Copy the private key that the `ccoctl` utility generated in the `tls` directory to the installation directory by running the following command:

   ```bash
   $ cp -a <path_to_ccoctl_output_dir>/tls .
   ```

### 6.10.13. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

**Prerequisites**

- You have configured an account with the cloud platform that hosts your cluster.
- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.

**Procedure**

1. Change to the directory that contains the installation program and initialize the cluster deployment:

   ```bash
   $ ./openshift-install create cluster --dir <installation_directory> \
   --log-level=info
   ```

   **1** For `<installation_directory>`, specify the location of your customized `./install-config.yaml` file.

   **2** To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

2. Optional: Remove or disable the `AdministratorAccess` policy from the IAM account that you used to install the cluster.

   **NOTE**

   The elevated permissions provided by the `AdministratorAccess` policy are required only during installation.

**Verification**
When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the **kubeadmin** user.

- Credential information also outputs to `<installation_directory>/.openshift_install.log`.

**IMPORTANT**

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

### Example output

```plaintext
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

### 6.10.14. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.

- You installed the **oc** CLI.

**Procedure**
1. Export the `kubeadmin` credentials:

```bash
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

```bash
$ oc whoami
```

Example output

```
system:admin
```

### 6.10.15. Logging in to the cluster by using the web console

The `kubeadmin` user exists by default after an OpenShift Container Platform installation. You can log in to your cluster as the `kubeadmin` user by using the OpenShift Container Platform web console.

**Prerequisites**

- You have access to the installation host.
- You completed a cluster installation and all cluster Operators are available.

**Procedure**

1. Obtain the password for the `kubeadmin` user from the `kubeadmin-password` file on the installation host:

```bash
$ cat <installation_directory>/auth/kubeadmin-password
```

**NOTE**

Alternatively, you can obtain the `kubeadmin` password from the `<installation_directory>/openshift_install.log` log file on the installation host.

2. List the OpenShift Container Platform web console route:

```bash
$ oc get routes -n openshift-console | grep 'console-openshift'
```

**NOTE**

Alternatively, you can obtain the OpenShift Container Platform route from the `<installation_directory>/openshift_install.log` log file on the installation host.

**Example output**
3. Navigate to the route detailed in the output of the preceding command in a web browser and log in as the **kubeadmin** user.

### Additional resources

- Accessing the web console

#### 6.10.16. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to **OpenShift Cluster Manager Hybrid Cloud Console**.

After you confirm that your **OpenShift Cluster Manager Hybrid Cloud Console** inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use **subscription watch** to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

### Additional resources

- About remote health monitoring

#### 6.10.17. Next steps

- Validating an installation.
- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- If necessary, you can remove cloud provider credentials.

### 6.11. INSTALLING A CLUSTER ON AWS CHINA

In OpenShift Container Platform version 4.14, you can install a cluster to the following Amazon Web Services (AWS) China regions:

- **cn-north-1** (Beijing)
- **cn-northwest-1** (Ningxia)

#### 6.11.1. Prerequisites

- You have an Internet Content Provider (ICP) license.
- You reviewed details about the **OpenShift Container Platform installation and update processes**.
- You read the documentation on **selecting a cluster installation method and preparing it for users**.
You configured an AWS account to host the cluster.

If you use a firewall, you configured it to allow the sites that your cluster requires access to.

**IMPORTANT**

If you have an AWS profile stored on your computer, it must not use a temporary session token that you generated while using a multi-factor authentication device. The cluster continues to use your current AWS credentials to create AWS resources for the entire life of the cluster, so you must use long-term credentials. To generate appropriate keys, see Managing Access Keys for IAM Users in the AWS documentation. You can supply the keys when you run the installation program.

### 6.11.2. Installation requirements

Red Hat does not publish a Red Hat Enterprise Linux CoreOS (RHCOS) Amazon Machine Image (AMI) for the AWS China regions.

Before you can install the cluster, you must:

- Upload a custom RHCOS AMI.
- Manually create the installation configuration file (*install-config.yaml*).
- Specify the AWS region, and the accompanying custom AMI, in the installation configuration file.

You cannot use the OpenShift Container Platform installation program to create the installation configuration file. The installer does not list an AWS region without native support for an RHCOS AMI.

### 6.11.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager Hybrid Cloud Console to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 6.11.4. Private clusters
You can deploy a private OpenShift Container Platform cluster that does not expose external endpoints. Private clusters are accessible from only an internal network and are not visible to the internet.

By default, OpenShift Container Platform is provisioned to use publicly-accessible DNS and endpoints. A private cluster sets the DNS, Ingress Controller, and API server to private when you deploy your cluster. This means that the cluster resources are only accessible from your internal network and are not visible to the internet.

**IMPORTANT**

If the cluster has any public subnets, load balancer services created by administrators might be publicly accessible. To ensure cluster security, verify that these services are explicitly annotated as private.

To deploy a private cluster, you must:

- Use existing networking that meets your requirements. Your cluster resources might be shared between other clusters on the network.
- Deploy from a machine that has access to:
  - The API services for the cloud to which you provision.
  - The hosts on the network that you provision.
  - The internet to obtain installation media.

You can use any machine that meets these access requirements and follows your company’s guidelines. For example, this machine can be a bastion host on your cloud network.

**NOTE**

AWS China does not support a VPN connection between the VPC and your network. For more information about the Amazon VPC service in the Beijing and Ningxia regions, see Amazon Virtual Private Cloud in the AWS China documentation.

### 6.11.4.1. Private clusters in AWS

To create a private cluster on Amazon Web Services (AWS), you must provide an existing private VPC and subnets to host the cluster. The installation program must also be able to resolve the DNS records that the cluster requires. The installation program configures the Ingress Operator and API server for access from only the private network.

The cluster still requires access to internet to access the AWS APIs.

The following items are not required or created when you install a private cluster:

- Public subnets
- Public load balancers, which support public ingress
- A public Route 53 zone that matches the `baseDomain` for the cluster
The installation program does use the **baseDomain** that you specify to create a private Route 53 zone and the required records for the cluster. The cluster is configured so that the Operators do not create public records for the cluster and all cluster machines are placed in the private subnets that you specify.

### 6.11.4.1.1. Limitations

The ability to add public functionality to a private cluster is limited.

- You cannot make the Kubernetes API endpoints public after installation without taking additional actions, including creating public subnets in the VPC for each availability zone in use, creating a public load balancer, and configuring the control plane security groups to allow traffic from the internet on 6443 (Kubernetes API port).

- If you use a public Service type load balancer, you must tag a public subnet in each availability zone with `kubernetes.io/cluster/<cluster-infra-id>: shared` so that AWS can use them to create public load balancers.

### 6.11.5. About using a custom VPC

In OpenShift Container Platform 4.14, you can deploy a cluster into existing subnets in an existing Amazon Virtual Private Cloud (VPC) in Amazon Web Services (AWS). By deploying OpenShift Container Platform into an existing AWS VPC, you might be able to avoid limit constraints in new accounts or more easily abide by the operational constraints that your company’s guidelines set. If you cannot obtain the infrastructure creation permissions that are required to create the VPC yourself, use this installation option.

Because the installation program cannot know what other components are also in your existing subnets, it cannot choose subnet CIDRs and so forth on your behalf. You must configure networking for the subnets that you install your cluster to yourself.

### 6.11.5.1. Requirements for using your VPC

The installation program no longer creates the following components:

- Internet gateways
- NAT gateways
- Subnets
- Route tables
- VPCs
- VPC DHCP options
- VPC endpoints

**NOTE**

The installation program requires that you use the cloud-provided DNS server. Using a custom DNS server is not supported and causes the installation to fail.
If you use a custom VPC, you must correctly configure it and its subnets for the installation program and the cluster to use. See Amazon VPC console wizard configurations and Work with VPCs and subnets in the AWS documentation for more information on creating and managing an AWS VPC.

The installation program cannot:

- Subdivide network ranges for the cluster to use.
- Set route tables for the subnets.
- Set VPC options like DHCP.

You must complete these tasks before you install the cluster. See VPC networking components and Route tables for your VPC for more information on configuring networking in an AWS VPC.

Your VPC must meet the following characteristics:

- The VPC must not use the `kubernetes.io/cluster/.*: owned, Name, and openshift.io/cluster` tags.
  The installation program modifies your subnets to add the `kubernetes.io/cluster/.*: shared` tag, so your subnets must have at least one free tag slot available for it. See Tag Restrictions in the AWS documentation to confirm that the installation program can add a tag to each subnet that you specify. You cannot use a `Name` tag, because it overlaps with the EC2 `Name` field and the installation fails.

- You must enable the `enableDnsSupport` and `enableDnsHostnames` attributes in your VPC, so that the cluster can use the Route 53 zones that are attached to the VPC to resolve cluster’s internal DNS records. See DNS Support in Your VPC in the AWS documentation.
  If you prefer to use your own Route 53 hosted private zone, you must associate the existing hosted zone with your VPC prior to installing a cluster. You can define your hosted zone using the `platform.aws.hostedZone` and `platform.aws.hostedZoneRole` fields in the `install-config.yaml` file. You can use a private hosted zone from another account by sharing it with the account where you install the cluster. If you use a private hosted zone from another account, you must use the Passthrough or Manual credentials mode.

If you are working in a disconnected environment, you are unable to reach the public IP addresses for EC2, ELB, and S3 endpoints. Depending on the level to which you want to restrict internet traffic during the installation, the following configuration options are available:

**Option 1: Create VPC endpoints**
Create a VPC endpoint and attach it to the subnets that the clusters are using. Name the endpoints as follows:

- `ec2.<aws_region>.amazonaws.com.cn`
- `elasticloadbalancing.<aws_region>.amazonaws.com`
- `s3.<aws_region>.amazonaws.com`

With this option, network traffic remains private between your VPC and the required AWS services.

**Option 2: Create a proxy without VPC endpoints**
As part of the installation process, you can configure an HTTP or HTTPS proxy. With this option, internet traffic goes through the proxy to reach the required AWS services.

**Option 3: Create a proxy with VPC endpoints**
As part of the installation process, you can configure an HTTP or HTTPS proxy with VPC endpoints. Create a VPC endpoint and attach it to the subnets that the clusters are using. Name the endpoints as follows:

- ec2.<aws_region>.amazonaws.com.cn
- elasticloadbalancing.<aws_region>.amazonaws.com
- s3.<aws_region>.amazonaws.com

When configuring the proxy in the `install-config.yaml` file, add these endpoints to the `noProxy` field. With this option, the proxy prevents the cluster from accessing the internet directly. However, network traffic remains private between your VPC and the required AWS services.

### Required VPC components

You must provide a suitable VPC and subnets that allow communication to your machines.

<table>
<thead>
<tr>
<th>Component</th>
<th>AWS type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VPC</td>
<td><a href="https://docs.aws.amazon.com/AWSCloudFormation/latest/UserGuide/aws-resource-ec2-vpc.html">AWS::EC2::VPC</a></td>
<td>You must provide a public VPC for the cluster to use. The VPC uses an endpoint that references the route tables for each subnet to improve communication with the registry that is hosted in S3.</td>
</tr>
<tr>
<td></td>

### 6.11.5.2. VPC validation

To ensure that the subnets that you provide are suitable, the installation program confirms the following data:

- All the subnets that you specify exist.
- You provide private subnets.
- The subnet CIDRs belong to the machine CIDR that you specified.
- You provide subnets for each availability zone. Each availability zone contains no more than one public and one private subnet. If you use a private cluster, provide only a private subnet for each availability zone. Otherwise, provide exactly one public and private subnet for each availability zone.
- You provide a public subnet for each private subnet availability zone. Machines are not provisioned in availability zones that you do not provide private subnets for.

If you destroy a cluster that uses an existing VPC, the VPC is not deleted. When you remove the OpenShift Container Platform cluster from a VPC, the `kubernetes.io/cluster/.*: shared` tag is removed from the subnets that it used.

### 6.11.5.3. Division of permissions

Starting with OpenShift Container Platform 4.3, you do not need all of the permissions that are required...
for an installation program-provisioned infrastructure cluster to deploy a cluster. This change mimics the division of permissions that you might have at your company: some individuals can create different resource in your clouds than others. For example, you might be able to create application-specific items, like instances, buckets, and load balancers, but not networking-related components such as VPCs, subnets, or ingress rules.

The AWS credentials that you use when you create your cluster do not need the networking permissions that are required to make VPCs and core networking components within the VPC, such as subnets, routing tables, internet gateways, NAT, and VPN. You still need permission to make the application resources that the machines within the cluster require, such as ELBs, security groups, S3 buckets, and nodes.

6.11.5.4. Isolation between clusters
If you deploy OpenShift Container Platform to an existing network, the isolation of cluster services is reduced in the following ways:

- You can install multiple OpenShift Container Platform clusters in the same VPC.
- ICMP ingress is allowed from the entire network.
- TCP 22 ingress (SSH) is allowed to the entire network.
- Control plane TCP 6443 ingress (Kubernetes API) is allowed to the entire network.
- Control plane TCP 22623 ingress (MCS) is allowed to the entire network.

6.11.5.5. AWS security groups
By default, the installation program creates and attaches security groups to control plane and compute machines. The rules associated with the default security groups cannot be modified.

However, you can apply additional existing AWS security groups, which are associated with your existing VPC, to control plane and compute machines. Applying custom security groups can help you meet the security needs of your organization, in such cases where you need to control the incoming or outgoing traffic of these machines.

As part of the installation process, you apply custom security groups by modifying the `install-config.yaml` file before deploying the cluster.

For more information, see "Applying existing AWS security groups to the cluster".

6.11.6. Generating a key pair for cluster node SSH access
During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the `core` user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user `core`. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.
If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   `ssh-keygen -t ed25519 -N "" -f <path>/<file_name>`

   Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

   **NOTE**

   On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

2. View the public SSH key:

   `$ cat <path>/<file_name>.pub`

   For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

   `$ cat ~/.ssh/id_ed25519.pub`

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `openshift-install gather` command.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the `x86_64`, `ppc64le`, and `s390x` architectures, do not create a key that uses the `ed25519` algorithm. Instead, create a key that uses the `rsa` or `ecdsa` algorithm.
a. If the `ssh-agent` process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

**Example output**

```
Agent pid 31874
```

**NOTE**

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the `ssh-agent`:

```
$ ssh-add <path>/<file_name>
```

1. Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

**Example output**

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

### 6.11.7. Uploading a custom RHCOS AMI in AWS

If you are deploying to a custom Amazon Web Services (AWS) region, you must upload a custom Red Hat Enterprise Linux CoreOS (RHCOS) Amazon Machine Image (AMI) that belongs to that region.

**Prerequisites**

- You configured an AWS account.
- You created an Amazon S3 bucket with the required IAM service role.
- You uploaded your RHCOS VMDK file to Amazon S3. The RHCOS VMDK file must be the highest version that is less than or equal to the OpenShift Container Platform version you are installing.
- You downloaded the AWS CLI and installed it on your computer. See Install the AWS CLI Using the Bundled Installer.

**Procedure**

1. Export your AWS profile as an environment variable:
$ export AWS_PROFILE=<aws_profile>  
1  The AWS profile name that holds your AWS credentials, like beijingadmin.

2. Export the region to associate with your custom AMI as an environment variable:

   $ export AWS_DEFAULT_REGION=<aws_region>  
1  The AWS region, like cn-north-1.

3. Export the version of RHCOS you uploaded to Amazon S3 as an environment variable:

   $ export RHCOS_VERSION=<version>  
1  The RHCOS VMDK version, like 4.14.0.

4. Export the Amazon S3 bucket name as an environment variable:

   $ export VMIMPORT_BUCKET_NAME=<s3_bucket_name>

5. Create the containers.json file and define your RHCOS VMDK file:

   $ cat <<EOF > containers.json
   
   {  
   "Description": "rhcos-${RHCOS_VERSION}-x86_64-aws.x86_64",
   "Format": "vmdk",
   "UserBucket": {  
   "S3Bucket": "${VMIMPORT_BUCKET_NAME}",
   "S3Key": "rhcos-${RHCOS_VERSION}-x86_64-aws.x86_64.vmdk"
   }  
   }  
EOF

6. Import the RHCOS disk as an Amazon EBS snapshot:

   $ aws ec2 import-snapshot --region ${AWS_DEFAULT_REGION}  
   --description "<description>"  
   --disk-container "file://<file_path>/containers.json"  
1  The description of your RHCOS disk being imported, like rhcos-${RHCOS_VERSION}-x86_64-aws.x86_64.
   
2  The file path to the JSON file describing your RHCOS disk. The JSON file should contain your Amazon S3 bucket name and key.

7. Check the status of the image import:

   $ watch -n 5 aws ec2 describe-import-snapshot-tasks --region ${AWS_DEFAULT_REGION}
Example output

```json
{
  "ImportSnapshotTasks": [
    {
      "Description": "rhcos-4.7.0-x86_64-aws.x86_64",
      "ImportTaskId": "import-snap-fh6i8uil",
      "SnapshotTaskDetail": {
        "Description": "rhcos-4.7.0-x86_64-aws.x86_64",
        "DiskImageSize": 819056640.0,
        "Format": "VMDK",
        "SnapshotId": "snap-06331325870076318",
        "Status": "completed",
        "UserBucket": {
          "S3Bucket": "external-images",
          "S3Key": "rhcos-4.7.0-x86_64-aws.x86_64.vmdk"
        }
      }
    }
  ]
}
```

Copy the **SnapshotId** to register the image.

8. Create a custom RHCOS AMI from the RHCOS snapshot:

```
$ aws ec2 register-image \
   --region ${AWS_DEFAULT_REGION} \  
   --architecture x86_64 \ 1  
   --description "rhcos-$(RHCOS_VERSION)-x86_64-aws.x86_64" \ 2  
   --ena-support \  
   --name "rhcos-$(RHCOS_VERSION)-x86_64-aws.x86_64" \ 3  
   --virtualization-type hvm \  
   --root-device-name '/dev/xvda' \  
   --block-device-mappings 'DeviceName=/dev/xvda,Ebs={DeleteOnTermination=true,SnapshotId=<snapshot_ID>]' \ 4
```

1. The RHCOS VMDK architecture type, like **x86_64, aarch64, s390x, or ppc64le**.
2. The **Description** from the imported snapshot.
3. The name of the RHCOS AMI.
4. The **SnapshotId** from the imported snapshot.

To learn more about these APIs, see the AWS documentation for [importing snapshots](#) and [creating EBS-backed AMIs](#).

**6.11.8. Obtaining the installation program**

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.
Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

   IMPORTANT

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   IMPORTANT

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   $ tar -xvf openshift-install-linux.tar.gz

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

6.11.9. Manually creating the installation configuration file

Installing the cluster requires that you manually generate the installation configuration file.

Prerequisites

- You have uploaded a custom RHCOS AMI.

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.

- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.
Procedure

1. Create an installation directory to store your required installation assets in:

   $ mkdir <installation_directory>

   **IMPORTANT**
   
   You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample `install-config.yaml` file template that is provided and save it in the `<installation_directory>`.

   **NOTE**
   
   You must name this configuration file `install-config.yaml`.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

   **IMPORTANT**
   
   The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.

Additional resources

- Installation configuration parameters for AWS

6.11.9.1. Sample customized install-config.yaml file for AWS

You can customize the installation configuration file (`install-config.yaml`) to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

   **IMPORTANT**
   
   This sample YAML file is provided for reference only. Use it as a resource to enter parameter values into the installation configuration file that you created manually.

```yaml
apiVersion: v1
baseDomain: example.com
credentialsMode: Mint
controlPlane:
  hypethreading: Enabled
  name: master
  platform:
    aws:
      lbType: NLB
```
OpenShift Container Platform 4.14 Installing

amiID: ami-96c6f8f7
serviceEndpoints:
  - name: ec2
    url: https://vpce-id.ec2.cn-north-1.vpce.amazonaws.com.cn
hostedZone: Z3URY6TWQ91KVY
fips: false
sshKey: ssh-ed25519 AAAA...
publish: Internal
pullSecret: {'"auths": ...'}

1 12 14 17 24 Required.

Optional: Add this parameter to force the Cloud Credential Operator (CCO) to use the specified mode. By default, the CCO uses the root credentials in the `kube-system` namespace to dynamically try to determine the capabilities of the credentials. For details about CCO modes, see the "About the Cloud Credential Operator" section in the Authentication and authorization guide.

If you do not provide these parameters and values, the installation program provides the default value.

The `controlPlane` section is a single mapping, but the `compute` section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the `compute` section must begin with a hyphen, `-`, and the first line of the `controlPlane` section must not. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading, or hyperthreading. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores. You can disable it by setting the parameter value to `Disabled`. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger instance types, such as `m4.2xlarge` or `m5.2xlarge`, for your machines if you disable simultaneous multithreading.

To configure faster storage for etcd, especially for larger clusters, set the storage type as `io1` and set `iops` to `2000`.

Whether to require the Amazon EC2 Instance Metadata Service v2 (IMDSv2). To require IMDSv2, set the parameter value to `Required`. To allow the use of both IMDSv1 and IMDSv2, set the parameter value to `Optional`. If no value is specified, both IMDSv1 and IMDSv2 are allowed.

The IMDS configuration for control plane machines that is set during cluster installation can only be changed by using the AWS CLI. The IMDS configuration for compute machines can be changed by using compute machine sets.

The cluster network plugin to install. The supported values are `OVNKubernetes` and `OpenShiftSDN`. The default value is `OVNKubernetes`.

If you provide your own VPC, specify subnets for each availability zone that your cluster uses.

The ID of the AMI used to boot machines for the cluster. If set, the AMI must belong to the same region as the cluster.

The AWS service endpoints. Custom endpoints are required when installing to an unknown AWS region. The endpoint URL must use the `https` protocol and the host must trust the certificate.
The ID of your existing Route 53 private hosted zone. Providing an existing hosted zone requires that you supply your own VPC and the hosted zone is already associated with the VPC prior to

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see [Installing the system in FIPS mode](#). When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures.

You can optionally provide the `sshKey` value that you use to access the machines in your cluster.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

How to publish the user-facing endpoints of your cluster. Set `publish` to **Internal** to deploy a private cluster, which cannot be accessed from the internet. The default value is **External**.

### 6.11.9.2. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

#### Table 6.14. Minimum resource requirements

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS, RHEL 8.6 and later [3]</td>
<td>2</td>
<td>8 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
</tbody>
</table>

1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or hyperthreading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: \(\text{threads per core} \times \text{cores} \times \text{sockets} = \text{vCPUs}\).
2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.

3. As with all user-provisioned installations, if you choose to use RHEL compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and has been removed in OpenShift Container Platform 4.10 and later.

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

Additional resources

- Optimizing storage

6.11.9.3. Tested instance types for AWS

The following Amazon Web Services (AWS) instance types have been tested with OpenShift Container Platform.

**NOTE**

Use the machine types included in the following charts for your AWS instances. If you use an instance type that is not listed in the chart, ensure that the instance size you use matches the minimum resource requirements that are listed in "Minimum resource requirements for cluster installation".

**Example 6.43. Machine types based on 64-bit x86 architecture**

- c4.*
- c5.*
- c5a.*
- i3.*
- m4.*
- m5.*
- m5a.*
- m6i.*
- r4.*
- r5.*
- r5a.*
- r6i.*
6.11.9.4. Tested instance types for AWS on 64-bit ARM infrastructures

The following Amazon Web Services (AWS) 64-bit ARM instance types have been tested with OpenShift Container Platform.

NOTE

Use the machine types included in the following charts for your AWS ARM instances. If you use an instance type that is not listed in the chart, ensure that the instance size you use matches the minimum resource requirements that are listed in "Minimum resource requirements for cluster installation".

Example 6.44. Machine types based on 64-bit ARM architecture

- c6g.*
- m6g.*

6.11.9.5. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

Prerequisites

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the Proxy object’s `spec.noProxy` field to bypass the proxy if necessary.

NOTE

The Proxy object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your `install-config.yaml` file and add the proxy settings. For example:
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:@<ip>:<port> ①
  httpsProxy: https://<username>:@<ip>:<port> ②
noProxy: ec2.<aws_region>.amazonaws.com,elasticloadbalancing.<aws_region>.amazonaws.com,s3.<aws_region>.amazonaws.com ③
additionalTrustBundle: | ④
-----BEGIN CERTIFICATE-----
<MY_TRUSTED_CA_CERT>
-----END CERTIFICATE-----
additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> ⑤

① A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.

② A proxy URL to use for creating HTTPS connections outside the cluster.

③ A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations. If you have added the Amazon EC2, Elastic Load Balancing, and S3 VPC endpoints to your VPC, you must add these endpoints to the noProxy field.

④ If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the trustedCA field of the Proxy object. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

⑤ Optional: The policy to determine the configuration of the Proxy object to reference the user-ca-bundle config map in the trustedCA field. The allowed values are Proxyonly and Always. Use Proxyonly to reference the user-ca-bundle config map only when http/https proxy is configured. Use Always to always reference the user-ca-bundle config map. The default value is Proxyonly.

NOTE
The installation program does not support the proxy readinessEndpoints field.

NOTE
If the installer times out, restart and then complete the deployment by using the wait-for command of the installer. For example:

```
$ ./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.
The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

**NOTE**

Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

6.11.9.6. Applying existing AWS security groups to the cluster

Applying existing AWS security groups to your control plane and compute machines can help you meet the security needs of your organization, in such cases where you need to control the incoming or outgoing traffic of these machines.

**Prerequisites**

- You have created the security groups in AWS. For more information, see the AWS documentation about working with security groups.
- The security groups must be associated with the existing VPC that you are deploying the cluster to. The security groups cannot be associated with another VPC.
- You have an existing `install-config.yaml` file.

**Procedure**

1. In the `install-config.yaml` file, edit the `compute.platform.aws.additionalSecurityGroupIDs` parameter to specify one or more custom security groups for your compute machines.

2. Edit the `controlPlane.platform.aws.additionalSecurityGroupIDs` parameter to specify one or more custom security groups for your control plane machines.

3. Save the file and reference it when deploying the cluster.

**Sample `install-config.yaml` file that specifies custom security groups**

```yaml
# ...
compute:
  - hyperthreading: Enabled
    name: worker
    platform:
      aws:
        additionalSecurityGroupIDs:
          - sg-1
          - sg-2
    replicas: 3
controlPlane:
  hyperthreading: Enabled
  name: master
  platform:
    aws:
      additionalSecurityGroupIDs:
        - sg-3
        - sg-4
```

OpenShift Container Platform 4.14 Installing
Specify the name of the security group as it appears in the Amazon EC2 console, including the `sg` prefix.

Specify subnets for each availability zone that your cluster uses.

### 6.11.10. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI ([oc](https://github.com/openshift/quickstart#installation)) to interact with OpenShift Container Platform from a command-line interface. You can install [oc](https://github.com/openshift/quickstart#installation) on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of [oc](https://github.com/openshift/quickstart#installation), you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of [oc](https://github.com/openshift/quickstart#installation).

#### Installing the OpenShift CLI on Linux

You can install the OpenShift CLI ([oc](https://github.com/openshift/quickstart#installation)) binary on Linux by using the following procedure.

**Procedure**

2. Select the architecture from the **Product Variant** drop-down list.

3. Select the appropriate version from the **Version** drop-down list.

4. Click **Download Now** next to the **OpenShift v4.14 Linux Client** entry and save the file.

5. Unpack the archive:

   ```bash
   $ tar xvf <file>
   ```

6. Place the `oc` binary in a directory that is on your `PATH`.

   To check your `PATH`, execute the following command:

   ```bash
   $ echo $PATH
   ```

**Verification**

- After you install the OpenShift CLI, it is available using the `oc` command:

  ```bash
  $ oc <command>
  ```
Installing the OpenShift CLI on Windows
You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

Procedure
2. Select the appropriate version from the Version drop-down list.
3. Click Download Now next to the OpenShift v4.14 Windows Client entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the oc binary to a directory that is on your PATH.
   To check your PATH, open the command prompt and execute the following command:

C:\> path

Verification
- After you install the OpenShift CLI, it is available using the oc command:

C:\> oc <command>

Installing the OpenShift CLI on macOS
You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.

Procedure
2. Select the appropriate version from the Version drop-down list.
3. Click Download Now next to the OpenShift v4.14 macOS Client entry and save the file.
   
   NOTE
   For macOS arm64, choose the OpenShift v4.14 macOS arm64 Client entry.

4. Unpack and unzip the archive.
5. Move the oc binary to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:

$ echo $PATH

Verification
- After you install the OpenShift CLI, it is available using the oc command:

$ oc <command>
6.11.11. Alternatives to storing administrator-level secrets in the kube-system project

By default, administrator secrets are stored in the `kube-system` project. If you configured the `credentialsMode` parameter in the `install-config.yaml` file to **Manual**, you must use one of the following alternatives:

- To manage long-term cloud credentials manually, follow the procedure in [Manually creating long-term credentials](#).
- To implement short-term credentials that are managed outside the cluster for individual components, follow the procedures in [Configuring an AWS cluster to use short-term credentials](#).

6.11.11.1. Manually creating long-term credentials

The Cloud Credential Operator (CCO) can be put into manual mode prior to installation in environments where the cloud identity and access management (IAM) APIs are not reachable, or the administrator prefers not to store an administrator-level credential secret in the cluster `kube-system` namespace.

**Procedure**

1. If you did not set the `credentialsMode` parameter in the `install-config.yaml` configuration file to **Manual**, modify the value as shown:

   **Sample configuration file snippet**

   ```yaml
   apiVersion: v1
   baseDomain: example.com
   credentialsMode: Manual
   # ...
   ```

2. If you have not previously created installation manifest files, do so by running the following command:

   ```bash
   $ openshift-install create manifests --dir <installation_directory>
   ```
   
   where `<installation_directory>` is the directory in which the installation program creates files.

3. Set a `$RELEASE_IMAGE` variable with the release image from your installation file by running the following command:

   ```bash
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
   ```

4. Extract the list of `CredentialsRequest` custom resources (CRs) from the OpenShift Container Platform release image by running the following command:

   ```bash
   $ oc adm release extract \ 
   --from=$RELEASE_IMAGE \ 
   --credentials-requests \ 
   --included \ 
   --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \ 
   --to=<path_to_directory_for_credentials_requests>
   ```
1. The \texttt{--included} parameter includes only the manifests that your specific cluster configuration requires.

2. Specify the location of the \texttt{install-config.yaml} file.

3. Specify the path to the directory where you want to store the \texttt{CredentialsRequest} objects. If the specified directory does not exist, this command creates it.

This command creates a YAML file for each \texttt{CredentialsRequest} object.

**Sample \texttt{CredentialsRequest} object**

```yaml
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
  name: <component_credentials_request>
  namespace: openshift-cloud-credential-operator
...
spec:
  providerSpec:
    apiVersion: cloudcredential.openshift.io/v1
    kind: AWSProviderSpec
    statementEntries:
      - effect: Allow
        action:
          - iam:GetUser
          - iam:GetUserPolicy
          - iam:ListAccessKeys
          resource: "*"
    ...
```

4. Create YAML files for secrets in the \texttt{openshift-install} manifests directory that you generated previously. The secrets must be stored using the namespace and secret name defined in the \texttt{spec.secretRef} for each \texttt{CredentialsRequest} object.

**Sample \texttt{CredentialsRequest} object with secrets**

```yaml
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
  name: <component_credentials_request>
  namespace: openshift-cloud-credential-operator
...
spec:
  providerSpec:
    apiVersion: cloudcredential.openshift.io/v1
    kind: AWSProviderSpec
    statementEntries:
      - effect: Allow
        action:
          - s3:CreateBucket
          - s3:DeleteBucket
        resource: "*"
    ...
  secretRef:
```

5. Create YAML files for secrets in the \texttt{openshift-install} manifests directory that you generated previously. The secrets must be stored using the namespace and secret name defined in the \texttt{spec.secretRef} for each \texttt{CredentialsRequest} object.
IMPORTANT

Before upgrading a cluster that uses manually maintained credentials, you must ensure that the CCO is in an upgradeable state.

6.11.11.2. Configuring an AWS cluster to use short-term credentials

To install a cluster that is configured to use the AWS Security Token Service (STS), you must configure the CCO utility and create the required AWS resources for your cluster.

6.11.11.2.1. Configuring the Cloud Credential Operator utility

To create and manage cloud credentials from outside of the cluster when the Cloud Credential Operator (CCO) is operating in manual mode, extract and prepare the CCO utility (ccoctl) binary.

NOTE

The ccoctl utility is a Linux binary that must run in a Linux environment.

Prerequisites

- You have access to an OpenShift Container Platform account with cluster administrator access.
- You have installed the OpenShift CLI (oc).
- You have created an AWS account for the ccoctl utility to use with the following permissions:

Example 6.45. Required AWS permissions

Required iam permissions

- iam:CreateOpenIDConnectProvider
- iam:CreateRole
- iam:DeleteOpenIDConnectProvider
- iam:DeleteRole
- iam:DeleteRolePolicy
- `iam:GetOpenIDConnectProvider`
- `iam:GetRole`
- `iam:GetUser`
- `iam:ListOpenIDConnectProviders`
- `iam:ListRolePolicies`
- `iam:ListRoles`
- `iam:PutRolePolicy`
- `iam:TagOpenIDConnectProvider`
- `iam:TagRole`

Required `s3` permissions

- `s3:CreateBucket`
- `s3:DeleteBucket`
- `s3:DeleteObject`
- `s3:GetBucketAcl`
- `s3:GetBucketTagging`
- `s3:GetObject`
- `s3:GetObjectAcl`
- `s3:GetObjectTagging`
- `s3:ListBucket`
- `s3:PutBucketAcl`
- `s3:PutBucketPolicy`
- `s3:PutBucketPublicAccessBlock`
- `s3:PutBucketTagging`
- `s3:PutObject`
- `s3:PutObjectAcl`
- `s3:PutObjectTagging`

Required `cloudfront` permissions

- `cloudfront:ListCloudFrontOriginAccessIdentities`
- `cloudfront:ListDistributions`
If you plan to store the OIDC configuration in a private S3 bucket that is accessed by the IAM identity provider through a public CloudFront distribution URL, the AWS account that runs the ccoctl utility requires the following additional permissions:

Example 6.46. Additional permissions for a private S3 bucket with CloudFront

- cloudfront:ListTagsForResource
- cloudfront:CreateCloudFrontOriginAccessIdentity
- cloudfront:CreateDistribution
- cloudfront:DeleteCloudFrontOriginAccessIdentity
- cloudfront:DeleteDistribution
- cloudfront:GetCloudFrontOriginAccessIdentity
- cloudfront:GetCloudFrontOriginAccessIdentityConfig
- cloudfront:GetDistribution
- cloudfront:TagResource
- cloudfront:UpdateDistribution

**NOTE**

These additional permissions support the use of the `--create-private-s3-bucket` option when processing credentials requests with the `ccoctl aws create-all` command.

**Procedure**

1. Obtain the OpenShift Container Platform release image by running the following command:

   ```sh
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
   
   $ CCO_IMAGE=$(oc adm release info --image-for='cloud-credential-operator' $RELEASE_IMAGE -a ~/.pull-secret)
   
   **NOTE**

   Ensure that the architecture of the $RELEASE_IMAGE matches the architecture of the environment in which you will use the ccoctl tool.

2. Obtain the CCO container image from the OpenShift Container Platform release image by running the following command:

3. Extract the ccoctl binary from the CCO container image within the OpenShift Container Platform release image by running the following command:
$ oc image extract $CCO_IMAGE --file="/usr/bin/ccocctl" -a ~/.pull-secret

4. Change the permissions to make ccoctl executable by running the following command:

$ chmod 775 ccoctl

Verification

- To verify that ccoctl is ready to use, display the help file by running the following command:

$ ccoctl --help

Output of ccoctl --help

OpenShift credentials provisioning tool

Usage:
ccocctl [command]

Available Commands:
alibabacloud Manage credentials objects for alibaba cloud
aws Manage credentials objects for AWS cloud
azure Manage credentials objects for Azure
gcp Manage credentials objects for Google cloud
help Help about any command
ibmcloud Manage credentials objects for IBM Cloud
nutanix Manage credentials objects for Nutanix

Flags:
-h, --help help for ccoctl

Use "ccoctl [command] --help" for more information about a command.

6.11.2.2. Creating AWS resources with the Cloud Credential Operator utility

You have the following options when creating AWS resources:

- You can use the ccoctl aws create-all command to create the AWS resources automatically. This is the quickest way to create the resources. See Creating AWS resources with a single command.

- If you need to review the JSON files that the ccoctl tool creates before modifying AWS resources, or if the process the ccoctl tool uses to create AWS resources automatically does not meet the requirements of your organization, you can create the AWS resources individually. See Creating AWS resources individually.

6.11.2.2.1. Creating AWS resources with a single command

If the process the ccoctl tool uses to create AWS resources automatically meets the requirements of your organization, you can use the ccoctl aws create-all command to automate the creation of AWS resources.
Otherwise, you can create the AWS resources individually. For more information, see "Creating AWS resources individually".

**NOTE**

By default, `ccoctl` creates objects in the directory in which the commands are run. To create the objects in a different directory, use the `--output-dir` flag. This procedure uses `<path_to_ccoctl_output_dir>` to refer to this directory.

**Prerequisites**

You must have:

- Extracted and prepared the `ccoctl` binary.

**Procedure**

1. Set a `$RELEASE_IMAGE` variable with the release image from your installation file by running the following command:

   ```bash
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
   ```

2. Extract the list of `CredentialsRequest` objects from the OpenShift Container Platform release image by running the following command:

   ```bash
   $ oc adm release extract \
   --from=$RELEASE_IMAGE \
   --credentials-requests \
   --included \1
   --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \2
   --to=<path_to_directory_for_credentials_requests> \3
   ```

   The `--included` parameter includes only the manifests that your specific cluster configuration requires.

   Specify the location of the `install-config.yaml` file.

   Specify the path to the directory where you want to store the `CredentialsRequest` objects. If the specified directory does not exist, this command creates it.

   **NOTE**

   This command might take a few moments to run.

3. Use the `ccoctl` tool to process all `CredentialsRequest` objects by running the following command:

   ```bash
   $ ccoctl aws create-all \
   --name=<name> \1
   --region=<aws_region> \2
   ```
Specify the name used to tag any cloud resources that are created for tracking.

Specify the AWS region in which cloud resources will be created.

Specify the directory containing the files for the component CredentialsRequest objects.

Optional: Specify the directory in which you want the ccoctl utility to create objects. By default, the utility creates objects in the directory in which the commands are run.

Optional: By default, the ccoctl utility stores the OpenID Connect (OIDC) configuration files in a public S3 bucket and uses the S3 URL as the public OIDC endpoint. To store the OIDC configuration in a private S3 bucket that is accessed by the IAM identity provider through a public CloudFront distribution URL instead, use the --create-private-s3-bucket parameter.

NOTE
If your cluster uses Technology Preview features that are enabled by the TechPreviewNoUpgrade feature set, you must include the --enable-tech-preview parameter.

Verification

- To verify that the OpenShift Container Platform secrets are created, list the files in the <path_to_ccoctl_output_dir>/manifests directory:

  $ ls <path_to_ccoctl_output_dir>/manifests

Example output

```
cluster-authentication-02-config.yaml
openshift-cloud-credential-operator-cloud-credential-operator-iam-ro-creds-credentials.yaml
openshift-cloud-network-config-controller-cloud-credentials-credentials.yaml
openshift-cluster-api-capa-manager-bootstrap-credentials-credentials.yaml
openshift-cluster-csi-drivers-ebs-cloud-credentials-credentials.yaml
openshift-image-registry-installer-cloud-credentials-credentials.yaml
openshift-ingress-operator-cloud-credentials-credentials.yaml
openshift-machine-api-aws-cloud-credentials-credentials.yaml
```

You can verify that the IAM roles are created by querying AWS. For more information, refer to AWS documentation on listing IAM roles.

6.11.11.2.2.2. Creating AWS resources individually

You can use the ccoctl tool to create AWS resources individually. This option might be useful for an organization that shares the responsibility for creating these resources among different users or departments.
Otherwise, you can use the **ccoctl aws create-all** command to create the AWS resources automatically. For more information, see "Creating AWS resources with a single command".

**NOTE**

By default, **ccoctl** creates objects in the directory in which the commands are run. To create the objects in a different directory, use the **--output-dir** flag. This procedure uses `<path_to_ccoctl_output_dir>` to refer to this directory.

Some **ccoctl** commands make AWS API calls to create or modify AWS resources. You can use the **--dry-run** flag to avoid making API calls. Using this flag creates JSON files on the local file system instead. You can review and modify the JSON files and then apply them with the AWS CLI tool using the **--cli-input-json** parameters.

**Prerequisites**

- Extract and prepare the **ccoctl** binary.

**Procedure**

1. Generate the public and private RSA key files that are used to set up the OpenID Connect provider for the cluster by running the following command:

   ```bash
   $ ccoctl aws create-key-pair
   ```

   **Example output**

   ```
   2021/04/13 11:01:02 Generating RSA keypair
   2021/04/13 11:01:03 Writing private key to /<path_to_ccoctl_output_dir>/serviceaccount-signer.private
   2021/04/13 11:01:03 Writing public key to /<path_to_ccoctl_output_dir>/serviceaccount-signer.public
   2021/04/13 11:01:03 Copying signing key for use by installer
   ```

   where **serviceaccount-signer.private** and **serviceaccount-signer.public** are the generated key files.

   This command also creates a private key that the cluster requires during installation in `/<path_to_ccoctl_output_dir>/tls/bound-service-account-signing-key.key`.

2. Create an OpenID Connect identity provider and S3 bucket on AWS by running the following command:

   ```bash
   $ ccoctl aws create-identity-provider \
   --name=<name> \[1\] \
   --region=<aws_region> \[2\] \
   --public-key-file=<path_to_ccoctl_output_dir>/serviceaccount-signer.public \[3\]
   ```

   **Example**

   ```bash
   $ ccoctl aws create-identity-provider
   --name=example
   --region=localhost
   --public-key-file=/path/to/keyfile
   ```

   **Example output**

   ```bash
   2021/04/13 11:01:03 Writing private key to /<path_to_ccoctl_output_dir>/serviceaccount-signer.private
   2021/04/13 11:01:03 Writing public key to /<path_to_ccoctl_output_dir>/serviceaccount-signer.public
   2021/04/13 11:01:03 Copying signing key for use by installer
   ```

   where **serviceaccount-signer.private** and **serviceaccount-signer.public** are the generated key files.

   This command also creates a private key that the cluster requires during installation in `/<path_to_ccoctl_output_dir>/tls/bound-service-account-signing-key.key`.

   **Prerequisites**

   - Extract and prepare the **ccoctl** binary.

   **Procedure**

   1. Generate the public and private RSA key files that are used to set up the OpenID Connect provider for the cluster by running the following command:

      ```bash
      $ ccoctl aws create-key-pair
      ```

      **Example output**

      ```bash
      2021/04/13 11:01:02 Generating RSA keypair
      2021/04/13 11:01:03 Writing private key to /<path_to_ccoctl_output_dir>/serviceaccount-signer.private
      2021/04/13 11:01:03 Writing public key to /<path_to_ccoctl_output_dir>/serviceaccount-signer.public
      2021/04/13 11:01:03 Copying signing key for use by installer
      ```

      where **serviceaccount-signer.private** and **serviceaccount-signer.public** are the generated key files.

      This command also creates a private key that the cluster requires during installation in `/<path_to_ccoctl_output_dir>/tls/bound-service-account-signing-key.key`.

   2. Create an OpenID Connect identity provider and S3 bucket on AWS by running the following command:

      ```bash
      $ ccoctl aws create-identity-provider \
      --name=<name> \[1\] \
      --region=<aws_region> \[2\] \
      --public-key-file=<path_to_ccoctl_output_dir>/serviceaccount-signer.public \[3\]
      ```

      **Example**

      ```bash
      $ ccoctl aws create-identity-provider
      --name=example
      --region=localhost
      --public-key-file=/path/to/keyfile
      ```

      **Example output**

      ```bash
      2021/04/13 11:01:03 Writing private key to /<path_to_ccoctl_output_dir>/serviceaccount-signer.private
      2021/04/13 11:01:03 Writing public key to /<path_to_ccoctl_output_dir>/serviceaccount-signer.public
      2021/04/13 11:01:03 Copying signing key for use by installer
      ```

      where **serviceaccount-signer.private** and **serviceaccount-signer.public** are the generated key files.

      This command also creates a private key that the cluster requires during installation in `/<path_to_ccoctl_output_dir>/tls/bound-service-account-signing-key.key`.
Example output

2021/04/13 11:16:09 Bucket <name>-oidc created
2021/04/13 11:16:10 OpenID Connect discovery document in the S3 bucket <name>-oidc at
.well-known/openid-configuration updated
2021/04/13 11:16:10 Reading public key
2021/04/13 11:16:10 JSON web key set (JWKS) in the S3 bucket <name>-oidc at keys.json
updated
2021/04/13 11:16:18 Identity Provider created with ARN: arn:aws:iam::
<aws_account_id>:oidc-provider/<name>-oidc.s3.<aws_region>.amazonaws.com

where openid-configuration is a discovery document and keys.json is a JSON web key set file.

This command also creates a YAML configuration file in
/</path_to_ccoctl_output_dir>/manifests/cluster-authentication-02-config.yaml. This file
sets the issuer URL field for the service account tokens that the cluster generates, so that the
AWS IAM identity provider trusts the tokens.

3. Create IAM roles for each component in the cluster:

   a. Set a $RELEASE_IMAGE variable with the release image from your installation file by
      running the following command:

      ```
      $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
      ```

   b. Extract the list of CredentialsRequest objects from the OpenShift Container Platform
      release image:

      ```
      $ oc adm release extract \
          --from=$RELEASE_IMAGE \
          --credentials-requests \
          --included \1
          --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \
          --to=<path_to_directory_for_credentials_requests> \2
      ```

      1 The --included parameter includes only the manifests that your specific cluster
         configuration requires.

      2 Specify the location of the install-config.yaml file.

      3 Specify the path to the directory where you want to store the CredentialsRequest
         objects. If the specified directory does not exist, this command creates it.

   c. Use the ccoctl tool to process all CredentialsRequest objects by running the following
      command:

      ```
      $ ccoctl aws create-iam-roles \
          --name=<name> \ 
          --region=<aws_region> \ 
          --credentials-requests-dir=<path_to_credentials_requests_directory> \ 
          --identity-provider-arn=arn:aws:iam::<aws_account_id>:oidc-provider/<name>-oidc.s3. \
          <aws_region>.amazonaws.com
      ```
NOTE

For AWS environments that use alternative IAM API endpoints, such as GovCloud, you must also specify your region with the
\texttt{--region} parameter.

If your cluster uses Technology Preview features that are enabled by the
\texttt{TechPreviewNoUpgrade} feature set, you must include the \texttt{--enable-tech-preview} parameter.

For each \texttt{CredentialsRequest} object, \texttt{ccoctl} creates an IAM role with a trust policy that is
tied to the specified OIDC identity provider, and a permissions policy as defined in each
\texttt{CredentialsRequest} object from the OpenShift Container Platform release image.

Verification

- To verify that the OpenShift Container Platform secrets are created, list the files in the
\texttt{<path_to_ccoctl_output_dir>/manifests} directory:

  \begin{verbatim}
  $ ls <path_to_ccoctl_output_dir>/manifests
  \end{verbatim}

**Example output**

```
cluster-authentication-02-config.yaml
openshift-cloud-credential-operator-cloud-credential-operator-iam-ro-creds-credentials.yaml
openshift-cloud-network-config-controller-cloud-credentials-credentials.yaml
openshift-cluster-api-capacities-management-bootstrap-credentials-credentials.yaml
openshift-cluster-csi-drivers-ebs-cloud-credentials-credentials.yaml
openshift-image-registry-installer-cloud-credentials-credentials.yaml
openshift-ingress-operator-cloud-credentials-credentials.yaml
openshift-machine-api-aws-cloud-credentials-credentials.yaml
```

You can verify that the IAM roles are created by querying AWS. For more information, refer to
AWS documentation on listing IAM roles.

6.11.11.2.3. Incorporating the Cloud Credential Operator utility manifests

To implement short-term security credentials managed outside the cluster for individual components,
you must move the manifest files that the Cloud Credential Operator utility (\texttt{ccoctl}) created to the
correct directories for the installation program.

Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.

- You have configured the Cloud Credential Operator utility (\texttt{ccoctl}).

- You have created the cloud provider resources that are required for your cluster with the \texttt{ccoctl}
  utility.

Procedure

1. If you did not set the \texttt{credentialsMode} parameter in the \texttt{install-config.yaml} configuration file
to \texttt{Manual}, modify the value as shown:
Sample configuration file snippet

```yaml
apiVersion: v1
baseDomain: example.com
credentialsMode: Manual
# ...
```

2. If you have not previously created installation manifest files, do so by running the following command:

```
$ openshift-install create manifests --dir <installation_directory>
```

where `<installation_directory>` is the directory in which the installation program creates files.

3. Copy the manifests that the `ccoctl` utility generated to the `manifests` directory that the installation program created by running the following command:

```
$ cp /<path_to_ccoctl_output_dir>/manifests/* ./manifests/
```

4. Copy the private key that the `ccoctl` utility generated in the `tls` directory to the installation directory by running the following command:

```
$ cp -a /<path_to_ccoctl_output_dir>/tls ./
```

6.11.12. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

**Prerequisites**

- You have configured an account with the cloud platform that hosts your cluster.

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.

- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.

**Procedure**

1. Change to the directory that contains the installation program and initialize the cluster deployment:

```
$ ./openshift-install create cluster --dir <installation_directory> \  
  --log-level=info
```

For `<installation_directory>`, specify the location of your customized "/install-config.yaml" file.

To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

2. Optional: Remove or disable the `AdministratorAccess` policy from the IAM account that you used to install the cluster.

**NOTE**

The elevated permissions provided by the `AdministratorAccess` policy are required only during installation.

**Verification**

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the `kubeadmin` user.
- Credential information also outputs to `<installation_directory>/.openshift_install.log`.

**IMPORTANT**

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

**Example output**

```
...  
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.
6.11.13. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   
   1 For `<installation_directory>`, specify the path to the directory that you stored the installation files in.
   
   2. Verify you can run `oc` commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   
   Example output
   
   system:admin
   ```

6.11.14. Logging in to the cluster by using the web console

The `kubeadmin` user exists by default after an OpenShift Container Platform installation. You can log in to your cluster as the `kubeadmin` user by using the OpenShift Container Platform web console.

**Prerequisites**

- You have access to the installation host.
- You completed a cluster installation and all cluster Operators are available.

**Procedure**

1. Obtain the password for the `kubeadmin` user from the `kubeadmin-password` file on the installation host:

   ```bash
   $ cat <installation_directory>/auth/kubeadmin-password
   ```

   **NOTE**

   Alternatively, you can obtain the `kubeadmin` password from the
   `<installation_directory>/openshift_install.log` log file on the installation host.
2. List the OpenShift Container Platform web console route:

   ```bash
   $ oc get routes -n openshift-console | grep 'console-openshift'
   ```

   **NOTE**

   Alternatively, you can obtain the OpenShift Container Platform route from the `<installation_directory>/openshift_install.log` log file on the installation host.

   **Example output**

   ```
   console console-openshift-console.apps.<cluster_name>.<base_domain> console
   https reencrypt/Redirect None
   ```

3. Navigate to the route detailed in the output of the preceding command in a web browser and log in as the `kubeadmin` user.

### 6.11.15. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager Hybrid Cloud Console.

After you confirm that your OpenShift Cluster Manager Hybrid Cloud Console inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use `subscription watch` to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- See [Accessing the web console](#) for more details about accessing and understanding the OpenShift Container Platform web console.
- See [About remote health monitoring](#) for more information about the Telemetry service.

### 6.11.16. Next steps

- Validating an installation.
- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- If necessary, you can remove cloud provider credentials.

### 6.12. INSTALLING A CLUSTER ON USER-PROVISIONED INFRASTRUCTURE IN AWS BY USING CLOUDFORMATION TEMPLATES

In OpenShift Container Platform version 4.14, you can install a cluster on Amazon Web Services (AWS) that uses infrastructure that you provide.
One way to create this infrastructure is to use the provided CloudFormation templates. You can modify the templates to customize your infrastructure or use the information that they contain to create AWS objects according to your company’s policies.

**IMPORTANT**

The steps for performing a user-provisioned infrastructure installation are provided as an example only. Installing a cluster with infrastructure you provide requires knowledge of the cloud provider and the installation process of OpenShift Container Platform. Several CloudFormation templates are provided to assist in completing these steps or to help model your own. You are also free to create the required resources through other methods; the templates are just an example.

### 6.12.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You configured an AWS account to host the cluster.

**IMPORTANT**

If you have an AWS profile stored on your computer, it must not use a temporary session token that you generated while using a multi-factor authentication device. The cluster continues to use your current AWS credentials to create AWS resources for the entire life of the cluster, so you must use key-based, long-term credentials. To generate appropriate keys, see Managing Access Keys for IAM Users in the AWS documentation. You can supply the keys when you run the installation program.

- You downloaded the AWS CLI and installed it on your computer. See Install the AWS CLI Using the Bundled Installer (Linux, macOS, or UNIX) in the AWS documentation.
- If you use a firewall, you configured it to allow the sites that your cluster requires access to.

**NOTE**

Be sure to also review this site list if you are configuring a proxy.

- If the cloud identity and access management (IAM) APIs are not accessible in your environment, or if you do not want to store an administrator-level credential secret in the `kube-system` namespace, you can manually create and maintain long-term credentials.

### 6.12.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager Hybrid Cloud Console to download the installation program.
• Access OpenShift Cluster Manager Hybrid Cloud Console to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

• Access Quay.io to obtain the packages that are required to install your cluster.

• Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

6.12.3. Requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

This section describes the requirements for deploying OpenShift Container Platform on user-provisioned infrastructure.

6.12.3.1. Required machines for cluster installation

The smallest OpenShift Container Platform clusters require the following hosts:

**Table 6.15. Minimum required hosts**

<table>
<thead>
<tr>
<th>Hosts</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>One temporary bootstrap machine</td>
<td>The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.</td>
</tr>
<tr>
<td>Three control plane machines</td>
<td>The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.</td>
</tr>
<tr>
<td>At least two compute machines, which are also known as worker machines.</td>
<td>The workloads requested by OpenShift Container Platform users run on the compute machines.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

To maintain high availability of your cluster, use separate physical hosts for these cluster machines.

The bootstrap and control plane machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system. However, the compute machines can choose between Red Hat Enterprise Linux CoreOS (RHCOS), Red Hat Enterprise Linux (RHEL) 8.6 and later.
Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 9.2 and inherits all of its hardware certifications and requirements. See Red Hat Enterprise Linux technology capabilities and limits.

### 6.12.3.2. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

**Table 6.16. Minimum resource requirements**

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS, RHEL 8.6 and later [3]</td>
<td>2</td>
<td>8 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
</tbody>
</table>

1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or hyperthreading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: (threads per core × cores) × sockets = vCPUs.

2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.

3. As with all user-provisioned installations, if you choose to use RHEL compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and has been removed in OpenShift Container Platform 4.10 and later.

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

**Additional resources**

- Optimizing storage

### 6.12.3.3. Tested instance types for AWS

The following Amazon Web Services (AWS) instance types have been tested with OpenShift Container Platform.
NOTE
Use the machine types included in the following charts for your AWS instances. If you use an instance type that is not listed in the chart, ensure that the instance size you use matches the minimum resource requirements that are listed in "Minimum resource requirements for cluster installation".

Example 6.47. Machine types based on 64-bit x86 architecture

- c4.*
- c5.*
- c5a.*
- i3.*
- m4.*
- m5.*
- m5a.*
- m6i.*
- r4.*
- r5.*
- r5a.*
- r6i.*
- t3.*
- t3a.*

6.12.3.4. Tested instance types for AWS on 64-bit ARM infrastructures

The following Amazon Web Services (AWS) 64-bit ARM instance types have been tested with OpenShift Container Platform.

NOTE
Use the machine types included in the following charts for your AWS ARM instances. If you use an instance type that is not listed in the chart, ensure that the instance size you use matches the minimum resource requirements that are listed in "Minimum resource requirements for cluster installation".

Example 6.48. Machine types based on 64-bit ARM architecture

- c6g.*
- m6g.*
6.12.3.5. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The kube-controller-manager only approves the kubelet client CSRs. The machine approver cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

6.12.4. Required AWS infrastructure components

To install OpenShift Container Platform on user-provisioned infrastructure in Amazon Web Services (AWS), you must manually create both the machines and their supporting infrastructure.

For more information about the integration testing for different platforms, see the OpenShift Container Platform 4.x Tested Integrations page.

By using the provided CloudFormation templates, you can create stacks of AWS resources that represent the following components:

- An AWS Virtual Private Cloud (VPC)
- Networking and load balancing components
- Security groups and roles
- An OpenShift Container Platform bootstrap node
- OpenShift Container Platform control plane nodes
- An OpenShift Container Platform compute node

Alternatively, you can manually create the components or you can reuse existing infrastructure that meets the cluster requirements. Review the CloudFormation templates for more details about how the components interrelate.

6.12.4.1. Other infrastructure components

- A VPC
- DNS entries
- Load balancers (classic or network) and listeners
- A public and a private Route 53 zone
- Security groups
- IAM roles
- S3 buckets
If you are working in a disconnected environment, you are unable to reach the public IP addresses for EC2, ELB, and S3 endpoints. Depending on the level to which you want to restrict internet traffic during the installation, the following configuration options are available:

**Option 1: Create VPC endpoints**
Create a VPC endpoint and attach it to the subnets that the clusters are using. Name the endpoints as follows:

- `ec2.<aws_region>.amazonaws.com`
- `elasticloadbalancing.<aws_region>.amazonaws.com`
- `s3.<aws_region>.amazonaws.com`

With this option, network traffic remains private between your VPC and the required AWS services.

**Option 2: Create a proxy without VPC endpoints**
As part of the installation process, you can configure an HTTP or HTTPS proxy. With this option, internet traffic goes through the proxy to reach the required AWS services.

**Option 3: Create a proxy with VPC endpoints**
As part of the installation process, you can configure an HTTP or HTTPS proxy with VPC endpoints. Create a VPC endpoint and attach it to the subnets that the clusters are using. Name the endpoints as follows:

- `ec2.<aws_region>.amazonaws.com`
- `elasticloadbalancing.<aws_region>.amazonaws.com`
- `s3.<aws_region>.amazonaws.com`

When configuring the proxy in the `install-config.yaml` file, add these endpoints to the `noProxy` field. With this option, the proxy prevents the cluster from accessing the internet directly. However, network traffic remains private between your VPC and the required AWS services.

**Required VPC components**
You must provide a suitable VPC and subnets that allow communication to your machines.

<table>
<thead>
<tr>
<th>Component</th>
<th>AWS type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VPC</td>
<td><code>AWS::EC2::VPC</code></td>
<td>You must provide a public VPC for the cluster to use. The VPC uses an endpoint that references the route tables for each subnet to improve communication with the registry that is hosted in S3.</td>
</tr>
<tr>
<td></td>
<td><code>AWS::EC2::VPC Endpoint</code></td>
<td></td>
</tr>
<tr>
<td>Public subnets</td>
<td><code>AWS::EC2::Subnet</code></td>
<td>Your VPC must have public subnets for between 1 and 3 availability zones and associate them with appropriate Ingress rules.</td>
</tr>
<tr>
<td></td>
<td><code>AWS::EC2::SubnetNetworkAclAssociation</code></td>
<td></td>
</tr>
<tr>
<td>Component</td>
<td>AWS type</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>----------------------------------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Internet gateway</td>
<td>• AWS::EC2::InternetGateway&lt;br&gt;• AWS::EC2::VPCGatewayAttachment&lt;br&gt;• AWS::EC2::RouteTable&lt;br&gt;• AWS::EC2::Route&lt;br&gt;• AWS::EC2::SubnetRouteTableAssociation&lt;br&gt;• AWS::EC2::NatGateway&lt;br&gt;• AWS::EC2::EIP</td>
<td>You must have a public internet gateway, with public routes, attached to the VPC. In the provided templates, each public subnet has a NAT gateway with an EIP address. These NAT gateways allow cluster resources, like private subnet instances, to reach the internet and are not required for some restricted network or proxy scenarios.</td>
</tr>
<tr>
<td>Network access</td>
<td>• AWS::EC2::NetworkAcl&lt;br&gt;• AWS::EC2::NetworkAclEntry</td>
<td>You must allow the VPC to access the following ports:</td>
</tr>
<tr>
<td>control</td>
<td></td>
<td>Port</td>
</tr>
<tr>
<td></td>
<td></td>
<td>80</td>
</tr>
<tr>
<td></td>
<td></td>
<td>443</td>
</tr>
<tr>
<td></td>
<td></td>
<td>22</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1024 - 65535</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0 - 65535</td>
</tr>
<tr>
<td>Private subnets</td>
<td>• AWS::EC2::Subnet&lt;br&gt;• AWS::EC2::RouteTable&lt;br&gt;• AWS::EC2::SubnetRouteTableAssociation</td>
<td>Your VPC can have private subnets. The provided CloudFormation templates can create private subnets for between 1 and 3 availability zones. If you use private subnets, you must provide appropriate routes and tables for them.</td>
</tr>
</tbody>
</table>

**Required DNS and load balancing components**

Your DNS and load balancer configuration needs to use a public hosted zone and can use a private hosted zone similar to the one that the installation program uses if it provisions the cluster’s infrastructure. You must create a DNS entry that resolves to your load balancer. An entry for `api`. 
<cluster_name>.<domain> must point to the external load balancer, and an entry for api-int. <cluster_name>.<domain> must point to the internal load balancer.

The cluster also requires load balancers and listeners for port 6443, which are required for the Kubernetes API and its extensions, and port 22623, which are required for the Ignition config files for new machines. The targets will be the control plane nodes. Port 6443 must be accessible to both clients external to the cluster and nodes within the cluster. Port 22623 must be accessible to nodes within the cluster.

<table>
<thead>
<tr>
<th>Component</th>
<th>AWS type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DNS</td>
<td>AWS::Route53::HostedZone</td>
<td>The hosted zone for your internal DNS.</td>

</tr>
<tr>
<td>Internal target group</td>
<td>AWS::Elastic LoadBalancingV2::Target Group</td>
<td>The target group for the internal load balancer.</td>
</tr>
</tbody>
</table>

### Security groups

The control plane and worker machines require access to the following ports:

<table>
<thead>
<tr>
<th>Group</th>
<th>Type</th>
<th>IP Protocol</th>
<th>Port range</th>
</tr>
</thead>
<tbody>
<tr>
<td>MasterSecurityGroup</td>
<td>AWS::EC2::Security Group</td>
<td>icmp</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>tcp</td>
<td>22</td>
</tr>
<tr>
<td></td>
<td></td>
<td>tcp</td>
<td>6443</td>
</tr>
<tr>
<td></td>
<td></td>
<td>tcp</td>
<td>22623</td>
</tr>
<tr>
<td>WorkerSecurityGroup</td>
<td>AWS::EC2::Security Group</td>
<td>icmp</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>tcp</td>
<td>22</td>
</tr>
<tr>
<td>BootstrapSecurityGroup</td>
<td>AWS::EC2::Security Group</td>
<td>tcp</td>
<td>22</td>
</tr>
<tr>
<td></td>
<td></td>
<td>tcp</td>
<td>19531</td>
</tr>
</tbody>
</table>

### Control plane Ingress

The control plane machines require the following Ingress groups. Each Ingress group is a AWS::EC2::SecurityGroupIngress resource.

<table>
<thead>
<tr>
<th>Ingress group</th>
<th>Description</th>
<th>IP protocol</th>
<th>Port range</th>
</tr>
</thead>
<tbody>
<tr>
<td>MasterIngress Etcd</td>
<td>etcd</td>
<td>tcp</td>
<td>2379–2380</td>
</tr>
<tr>
<td>MasterIngress Vxlan</td>
<td>Vxlan packets</td>
<td>udp</td>
<td>4789</td>
</tr>
<tr>
<td>Ingress group</td>
<td>Description</td>
<td>IP protocol</td>
<td>Port range</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>------------------------------------------------------</td>
<td>-------------</td>
<td>----------------</td>
</tr>
<tr>

<td></td>
</tr>
</tbody>
</table>

**Roles and instance profiles**

You must grant the machines permissions in AWS. The provided CloudFormation templates grant the machines `Allow` permissions for the following `AWS::IAM::Role` objects and provide a `AWS::IAM::InstanceProfile` for each set of roles. If you do not use the templates, you can grant the machines the following broad permissions or the following individual permissions.

<table>
<thead>
<tr>
<th>Role</th>
<th>Effect</th>
<th>Action</th>
<th>Resource</th>
</tr>
</thead>
<tbody>
<tr>
<td>Master</td>
<td>Allow</td>
<td>ec2:*</td>
<td>*</td>

<td>ec2:AttachVolume</td>
<td>*</td>
</tr>
<tr>
<td></td>
<td>Allow</td>
<td>ec2:DetachVolume</td>
<td>*</td>
</tr>
</tbody>
</table>

### 6.12.4.2. Cluster machines

You need `AWS::EC2::Instance` objects for the following machines:

- A bootstrap machine. This machine is required during installation, but you can remove it after your cluster deploys.
- Three control plane machines. The control plane machines are not governed by a control plane machine set.
- Compute machines. You must create at least two compute machines, which are also known as worker machines, during installation. These machines are not governed by a compute machine set.

### 6.12.4.3. Required AWS permissions for the IAM user
NOTE

Your IAM user must have the permission `tag:GetResources` in the region `us-east-1` to delete the base cluster resources. As part of the AWS API requirement, the OpenShift Container Platform installation program performs various actions in this region.

When you attach the `AdministratorAccess` policy to the IAM user that you create in Amazon Web Services (AWS), you grant that user all of the required permissions. To deploy all components of an OpenShift Container Platform cluster, the IAM user requires the following permissions:

Example 6.49. Required EC2 permissions for installation

- `ec2:AuthorizeSecurityGroupEgress`
- `ec2:AuthorizeSecurityGroupIngress`
- `ec2:CopyImage`
- `ec2:CreateNetworkInterface`
- `ec2:AttachNetworkInterface`
- `ec2:CreateSecurityGroup`
- `ec2:CreateTags`
- `ec2:CreateVolume`
- `ec2:DeleteSecurityGroup`
- `ec2:DeleteSnapshot`
- `ec2:DeleteTags`
- `ec2:DeregisterImage`
- `ec2:DescribeAccountAttributes`
- `ec2:DescribeAddresses`
- `ec2:DescribeAvailabilityZones`
- `ec2:DescribeDhcpOptions`
- `ec2:DescribeImages`
- `ec2:DescribeInstanceAttribute`
- `ec2:DescribeInstanceCreditSpecifications`
- `ec2:DescribeInstances`
- `ec2:DescribeInstanceTypes`
- `ec2:DescribeInternetGateways`
- `ec2:DescribeKeyPairs`
- ec2:DescribeNatGateways
- ec2:DescribeNetworkAcls
- ec2:DescribeNetworkInterfaces
- ec2:DescribePrefixLists
- ec2:DescribeRegions
- ec2:DescribeRouteTables
- ec2:DescribeSecurityGroups
- ec2:DescribeSubnets
- ec2:DescribeTags
- ec2:DescribeVolumes
- ec2:DescribeVpcAttribute
- ec2:DescribeVpcClassicLink
- ec2:DescribeVpcClassicLinkDnsSupport
- ec2:DescribeVpcEndpoints
- ec2:DescribeVpcs
- ec2:GetEbsDefaultKmsKeyId
- ec2:ModifyInstanceAttribute
- ec2:ModifyNetworkInterfaceAttribute
- ec2:RevokeSecurityGroupEgress
- ec2:RevokeSecurityGroupIngress
- ec2:RunInstances
- ec2:TerminateInstances

Example 6.50. Required permissions for creating network resources during installation

- ec2:AllocateAddress
- ec2:AssociateAddress
- ec2:AssociateDhcpOptions
- ec2:AssociateRouteTable
- ec2:AttachInternetGateway
- ec2:CreateDhcpOptions
• ec2:CreateInternetGateway
• ec2:CreateNatGateway
• ec2:CreateRoute
• ec2:CreateRouteTable
• ec2:CreateSubnet
• ec2:CreateVpc
• ec2:CreateVpcEndpoint
• ec2:ModifySubnetAttribute
• ec2:ModifyVpcAttribute

NOTE
If you use an existing VPC, your account does not require these permissions for creating network resources.

Example 6.51. Required Elastic Load Balancing permissions (ELB) for installation
• elasticloadbalancing:AddTags
• elasticloadbalancing:ApplySecurityGroupsToLoadBalancer
• elasticloadbalancing:AttachLoadBalancerToSubnets
• elasticloadbalancing:ConfigureHealthCheck
• elasticloadbalancing:CreateLoadBalancer
• elasticloadbalancing:CreateLoadBalancerListeners
• elasticloadbalancing:DeleteLoadBalancer
• elasticloadbalancing:DeregisterInstancesFromLoadBalancer
• elasticloadbalancing:DescribeInstanceHealth
• elasticloadbalancing:DescribeLoadBalancerAttributes
• elasticloadbalancing:DescribeLoadBalancers
• elasticloadbalancing:DescribeTags
• elasticloadbalancing:ModifyLoadBalancerAttributes
• elasticloadbalancing:RegisterInstancesWithLoadBalancer
• elasticloadbalancing:SetLoadBalancerPoliciesOfListener
Example 6.52. Required Elastic Load Balancing permissions (ELBv2) for installation

- `elasticloadbalancing:AddTags`
- `elasticloadbalancing:CreateListener`
- `elasticloadbalancing:CreateLoadBalancer`
- `elasticloadbalancing:CreateTargetGroup`
- `elasticloadbalancing:DeleteLoadBalancer`
- `elasticloadbalancing:DeregisterTargets`
- `elasticloadbalancing:DescribeListeners`
- `elasticloadbalancing:DescribeLoadBalancerAttributes`
- `elasticloadbalancing:DescribeLoadBalancers`
- `elasticloadbalancing:DescribeTargetGroupAttributes`
- `elasticloadbalancing:DescribeTargetHealth`
- `elasticloadbalancing:ModifyLoadBalancerAttributes`
- `elasticloadbalancing:ModifyTargetGroup`
- `elasticloadbalancing:ModifyTargetGroupAttributes`
- `elasticloadbalancing:RegisterTargets`

Example 6.53. Required IAM permissions for installation

- `iam:AddRoleToInstanceProfile`
- `iam:CreateInstanceProfile`
- `iam:CreateRole`
- `iam:DeleteInstanceProfile`
- `iam:DeleteRole`
- `iam:DeleteRolePolicy`
- `iam:GetInstanceProfile`
- `iam:GetRole`
- `iam:GetRolePolicy`
- `iam:GetUser`
- `iam:ListInstanceProfilesForRole`
• `iam:ListRoles`
• `iam:ListUsers`
• `iam:PassRole`
• `iam:PutRolePolicy`
• `iam:RemoveRoleFromInstanceProfile`
• `iam:SimulatePrincipalPolicy`
• `iam:TagRole`

**NOTE**

If you have not created a load balancer in your AWS account, the IAM user also requires the `iam:CreateServiceLinkedRole` permission.

Example 6.54. Required Route 53 permissions for installation

• `route53:ChangeResourceRecordSets`
• `route53:ChangeTagsForResource`
• `route53:CreateHostedZone`
• `route53:DeleteHostedZone`
• `route53:GetChange`
• `route53:GetHostedZone`
• `route53:ListHostedZones`
• `route53:ListHostedZonesByName`
• `route53:ListResourceRecordSets`
• `route53:ListTagsForResource`
• `route53:UpdateHostedZoneComment`

Example 6.55. Required S3 permissions for installation

• `s3:CreateBucket`
• `s3:DeleteBucket`
• `s3:GetAccelerateConfiguration`
• `s3:GetBucketAcl`
• `s3:GetBucketCors`
Example 6.56. S3 permissions that cluster Operators require

- s3:DeleteObject
- s3:GetObject
- s3:GetObjectAcl
- s3:GetObjectTagging
- s3:GetObjectVersion
- s3:PutObject
- s3:PutObjectAcl
- s3:PutObjectTagging

Example 6.57. Required permissions to delete base cluster resources

- autoscaling:DescribeAutoScalingGroups
- ec2:DeletePlacementGroup
Example 6.58. Required permissions to delete network resources

- ec2:DeleteDhcpOptions
- ec2:DeleteInternetGateway
- ec2:DeleteNatGateway
- ec2:DeleteRoute
- ec2:DeleteRouteTable
- ec2:DeleteSubnet
- ec2:DeleteVpc
- ec2:DeleteVpcEndpoints
- ec2:DetachInternetGateway
- ec2:DisassociateRouteTable
- ec2:ReleaseAddress
- ec2:ReplaceRouteTableAssociation
NOTE

If you use an existing VPC, your account does not require these permissions to delete network resources. Instead, your account only requires the `tag:UntagResources` permission to delete network resources.

Example 6.59. Required permissions to delete a cluster with shared instance roles

- `iam:UntagRole`

Example 6.60. Additional IAM and S3 permissions that are required to create manifests

- `iam:DeleteAccessKey`
- `iam:DeleteUser`
- `iam:DeleteUserPolicy`
- `iam:GetUserPolicy`
- `iam:ListAccessKeys`
- `iam:PutUserPolicy`
- `iam:TagUser`
- `s3:PutBucketPublicAccessBlock`
- `s3:GetBucketPublicAccessBlock`
- `s3:PutLifecycleConfiguration`
- `s3:HeadBucket`
- `s3:ListBucketMultipartUploads`
- `s3:AbortMultipartUpload`

NOTE

If you are managing your cloud provider credentials with mint mode, the IAM user also requires the `iam:CreateAccessKey` and ` iam:CreateUser` permissions.

Example 6.61. Optional permissions for instance and quota checks for installation

- `ec2:DescribeInstanceTypeOfferings`
- `servicequotas:ListAWSDefaultServiceQuotas`
Example 6.62. Optional permissions for the cluster owner account when installing a cluster on a shared VPC

- sts:AssumeRole

6.12.5. Obtaining an AWS Marketplace image

If you are deploying an OpenShift Container Platform cluster using an AWS Marketplace image, you must first subscribe through AWS. Subscribing to the offer provides you with the AMI ID that the installation program uses to deploy worker nodes.

Prerequisites

- You have an AWS account to purchase the offer. This account does not have to be the same account that is used to install the cluster.

Procedure

1. Complete the OpenShift Container Platform subscription from the AWS Marketplace.

2. Record the AMI ID for your specific region. If you use the CloudFormation template to deploy your worker nodes, you must update the worker0.type.properties.ImageID parameter with this value.

6.12.6. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.
IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```bash
$ tar -xvf openshift-install-linux.tar.gz
```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

6.12.7. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the `core` user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user `core`. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

NOTE

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

```bash
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> ①
```

① Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.
NOTE

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   $ cat <path>/<file_name>.pub

   For example, run the following to view the ~/.ssh/id_ed25519.pub public key:

   $ cat ~/.ssh/id_ed25519.pub

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the ./openshift-install gather command.

   NOTE

   On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.

   a. If the ssh-agent process is not already running for your local user, start it as a background task:

      $ eval "$(ssh-agent -s)"

      Example output

      Agent pid 31874

      NOTE

      If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the ssh-agent:

   $ ssh-add <path>/<file_name> 1

   1 Specify the path and file name for your SSH private key, such as ~/.ssh/id_ed25519

   Example output

   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

Next steps
When you install OpenShift Container Platform, provide the SSH public key to the installation program. If you install a cluster on infrastructure that you provision, you must provide the key to the installation program.

6.12.8. Creating the installation files for AWS

To install OpenShift Container Platform on Amazon Web Services (AWS) using user-provisioned infrastructure, you must generate the files that the installation program needs to deploy your cluster and modify them so that the cluster creates only the machines that it will use. You generate and customize the *install-config.yaml* file, Kubernetes manifests, and Ignition config files. You also have the option to first set up a separate *var* partition during the preparation phases of installation.

6.12.8.1. Optional: Creating a separate /var partition

It is recommended that disk partitioning for OpenShift Container Platform be left to the installer. However, there are cases where you might want to create separate partitions in a part of the filesystem that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the /var partition or a subdirectory of /var. For example:

- **/var/lib/containers**: Holds container-related content that can grow as more images and containers are added to a system.
- **/var/lib/etcd**: Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.
- **/var**: Holds data that you might want to keep separate for purposes such as auditing.

Storing the contents of a /var directory separately makes it easier to grow storage for those areas as needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

Because /var must be in place before a fresh installation of Red Hat Enterprise Linux CoreOS (RHCOS), the following procedure sets up the separate /var partition by creating a machine config manifest that is inserted during the openshift-install preparation phases of an OpenShift Container Platform installation.

**IMPORTANT**

If you follow the steps to create a separate /var partition in this procedure, it is not necessary to create the Kubernetes manifest and Ignition config files again as described later in this section.

**Procedure**

1. Create a directory to hold the OpenShift Container Platform installation files:

   `$ mkdir $HOME/clusterconfig`

2. Run openshift-install to create a set of files in the manifest and openshift subdirectories. Answer the system questions as you are prompted:

   `$ openshift-install create manifests --dir $HOME/clusterconfig`
Example output

? SSH Public Key ...
INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
INFO Consuming Install Config from target directory
INFO Manifests created in: $HOME/clusterconfig/manifests and
$HOME/clusterconfig/openshift

3. Optional: Confirm that the installation program created manifests in the
`clusterconfig/openshift` directory:

```bash
ls $HOME/clusterconfig/openshift/
```

Example output

```
99_kubeadmin-password-secret.yaml
99_openshift-cluster-api_master-machines-0.yaml
99_openshift-cluster-api_master-machines-1.yaml
99_openshift-cluster-api_master-machines-2.yaml
...
```

4. Create a Butane config that configures the additional partition. For example, name the file
`$HOME/clusterconfig/98-var-partition.bu`, change the disk device name to the name of the
storage device on the `worker` systems, and set the storage size as appropriate. This example
places the `/var` directory on a separate partition:

```yaml
variant: openshift
version: 4.14.0
metadata:
  labels:
    machineconfiguration.openshift.io/role: worker
name: 98-var-partition
storage:
  disks:
    - device: /dev/disk/by-id/<device_name> ¹
      partitions:
        - label: var
          start_mib: <partition_start_offset> ²
          size_mib: <partition_size> ³
      filesystems:
        - device: /dev/disk/by-partlabel/var
          path: /var
          format: xfs
          mount_options: [defaults, prjquota] ⁴
          with_mount_unit: true
```

¹ The storage device name of the disk that you want to partition.
² When adding a data partition to the boot disk, a minimum value of 25000 MiB (Mebibytes)
   is recommended. The root file system is automatically resized to fill all available space up
to the specified offset. If no value is specified, or if the specified value is smaller than the
recommended minimum, the resulting root file system will be too small, and future
reinstalls of RHCOS might overwrite the beginning of the data partition.
The size of the data partition in mebibytes.

The `prjquota` mount option must be enabled for filesystems used for container storage.

**NOTE**

When creating a separate `/var` partition, you cannot use different instance types for worker nodes, if the different instance types do not have the same device name.

5. Create a manifest from the Butane config and save it to the `clusterconfig/openshift` directory. For example, run the following command:

```bash
$ butane $HOME/clusterconfig/98-var-partition.bu -o $HOME/clusterconfig/openshift/98-var-partition.yaml
```

6. Run `openshift-install` again to create Ignition configs from a set of files in the `manifest` and `openshift` subdirectories:

```bash
$ openshift-install create ignition-configs --dir $HOME/clusterconfig
$ ls $HOME/clusterconfig/
auth bootstrap.ign master.ign metadata.json worker.ign
```

Now you can use the Ignition config files as input to the installation procedures to install Red Hat Enterprise Linux CoreOS (RHCOS) systems.

### 6.12.8.2. Creating the installation configuration file

Generate and customize the installation configuration file that the installation program needs to deploy your cluster.

**Prerequisites**

- You obtained the OpenShift Container Platform installation program for user-provisioned infrastructure and the pull secret for your cluster.

- You checked that you are deploying your cluster to a region with an accompanying Red Hat Enterprise Linux CoreOS (RHCOS) AMI published by Red Hat. If you are deploying to a region that requires a custom AMI, such as an AWS GovCloud region, you must create the `install-config.yaml` file manually.

**Procedure**

1. Create the `install-config.yaml` file.

   a. Change to the directory that contains the installation program and run the following command:

   ```bash
   $ ./openshift-install create install-config --dir <installation_directory>
   ```

   1. For `<installation_directory>`, specify the directory name to store the files that the installation program creates.
b. At the prompts, provide the configuration details for your cloud:

i. Optional: Select an SSH key to use to access your cluster machines.

**NOTE**
For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

ii. Select `aws` as the platform to target.

iii. If you do not have an AWS profile stored on your computer, enter the AWS access key ID and secret access key for the user that you configured to run the installation program.

**NOTE**
The AWS access key ID and secret access key are stored in `~/.aws/credentials` in the home directory of the current user on the installation host. You are prompted for the credentials by the installation program if the credentials for the exported profile are not present in the file. Any credentials that you provide to the installation program are stored in the file.

iv. Select the AWS region to deploy the cluster to.

v. Select the base domain for the Route 53 service that you configured for your cluster.

vi. Enter a descriptive name for your cluster.

vii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

2. If you are installing a three-node cluster, modify the `install-config.yaml` file by setting the `compute.replicas` parameter to 0. This ensures that the cluster’s control planes are schedulable. For more information, see "Installing a three-node cluster on AWS".

3. Optional: Back up the `install-config.yaml` file.

**IMPORTANT**
The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.
6.12.8.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**Prerequisites**

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

**Procedure**

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
     httpProxy: http://<username>:<pswd>@<ip>:<port> ¹
     httpsProxy: https://<username>:<pswd>@<ip>:<port> ²
     noProxy: ec2.<aws_region>.amazonaws.com,elasticloadbalancing.<aws_region>.amazonaws.com,s3.<aws_region>.amazonaws.com ³
   additionalTrustBundle: |
     -----BEGIN CERTIFICATE-----
     <MY_TRUSTED_CA_CERT>
     -----END CERTIFICATE-----
   additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> ⁵
   ```

   ¹ A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.
   ² A proxy URL to use for creating HTTPS connections outside the cluster.
   ³ A comma-separated list of destination domain names, IP addresses, or other network
If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace that contains one or more additional CA certificates.

Optional: The policy to determine the configuration of the `Proxy` object to reference the `user-ca-bundle` config map in the `trustedCA` field. The allowed values are `Proxyonly` and `Always`. Use `Proxyonly` to reference the `user-ca-bundle` config map only when `http/https` proxy is configured. Use `Always` to always reference the `user-ca-bundle` config map. The default value is `Proxyonly`.

**NOTE**

The installation program does not support the proxy `readinessEndpoints` field.

**NOTE**

If the installer times out, restart and then complete the deployment by using the `wait-for` command of the installer. For example:

```bash
$ ./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

**NOTE**

Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

### 6.12.8.4. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.
The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

**Prerequisites**

- You obtained the OpenShift Container Platform installation program.
- You created the `install-config.yaml` installation configuration file.

**Procedure**

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

   ```bash
   $ ./openshift-install create manifests --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.

2. Remove the Kubernetes manifest files that define the control plane machines:

   ```bash
   $ rm -f <installation_directory>/openshift/99_openshift-cluster-api_master-machines-*.yaml
   $ rm -f <installation_directory>/openshift/99_openshift-machine-api_master-control-plane-machine-set.yaml
   $ rm -f <installation_directory>/openshift/99_openshift-cluster-api_worker-machineset-*.yaml
   ```

   By removing these files, you prevent the cluster from automatically generating control plane machines.

3. Remove the Kubernetes manifest files that define the control plane machine set:

   ```bash
   $ rm -f <installation_directory>/openshift/99_openshift-machine-api_master-control-plane-machine-set.yaml
   ```

   **IMPORTANT**

   If you disabled the MachineAPI capability when installing a cluster on user-provisioned infrastructure, you must remove the Kubernetes manifest files that define the worker machines. Otherwise, your cluster fails to install.
Because you create and manage the worker machines yourself, you do not need to initialize these machines.

**WARNING**

If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.

**IMPORTANT**

When you configure control plane nodes from the default unschedulable to schedulable, additional subscriptions are required. This is because control plane nodes then become compute nodes.

4. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:
   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.
   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.
   c. Save and exit the file.

5. Optional: If you do not want the Ingress Operator to create DNS records on your behalf, remove the `privateZone` and `publicZone` sections from the `<installation_directory>/manifests/cluster-dns-02-config.yml` DNS configuration file:

   ```yaml
   apiVersion: config.openshift.io/v1
   kind: DNS
   metadata:
     creationTimestamp: null
     name: cluster
   spec:
     baseDomain: example.openshift.com
     privateZone: 1
       id: mycluster-100419-private-zone
     publicZone: 2
       id: example.openshift.com
   status: {}
   ```

   1 2 Remove this section completely.

   If you do so, you must add ingress DNS records manually in a later step.

6. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

   ```bash
   $ ./openshift-install create ignition-configs --dir <installation_directory> 1
   ```
For `<installation_directory>`, specify the same installation directory.

Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The `kubeadmin-password` and `kubeconfig` files are created in the `./<installation_directory>/auth` directory:

```
├── auth
│   ├── kubeadmin-password
│   └── kubeconfig
├── bootstrap.ign
├── master.ign
├── metadata.json
└── worker.ign
```

6.12.9. Extracting the infrastructure name

The Ignition config files contain a unique cluster identifier that you can use to uniquely identify your cluster in Amazon Web Services (AWS). The infrastructure name is also used to locate the appropriate AWS resources during an OpenShift Container Platform installation. The provided CloudFormation templates contain references to this infrastructure name, so you must extract it.

Prerequisites

- You obtained the OpenShift Container Platform installation program and the pull secret for your cluster.
- You generated the Ignition config files for your cluster.
- You installed the `jq` package.

Procedure

- To extract and view the infrastructure name from the Ignition config file metadata, run the following command:

  ```
  $ jq -r .infraID <installation_directory>/metadata.json
  ```

  1  For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

Example output

```
openshift-vw9j6
```

1  The output of this command is your cluster name and a random string.

6.12.10. Creating a VPC in AWS
You must create a Virtual Private Cloud (VPC) in Amazon Web Services (AWS) for your OpenShift Container Platform cluster to use. You can customize the VPC to meet your requirements, including VPN and route tables.

You can use the provided CloudFormation template and a custom parameter file to create a stack of AWS resources that represent the VPC.

NOTE

If you do not use the provided CloudFormation template to create your AWS infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

Prerequisites

- You configured an AWS account.
- You added your AWS keys and region to your local AWS profile by running `aws configure`.
- You generated the Ignition config files for your cluster.

Procedure

1. Create a JSON file that contains the parameter values that the template requires:

   ```json
   [
     {
       "ParameterKey": "VpcCidr", 1
       "ParameterValue": "10.0.0.0/16" 2
     },
     {
       "ParameterKey": "AvailabilityZoneCount", 3
       "ParameterValue": "1" 4
     },
     {
       "ParameterKey": "SubnetBits", 5
       "ParameterValue": "12" 6
     }
   ]
   
   1 The CIDR block for the VPC.
   2 Specify a CIDR block in the format `x.x.x.x/16-24`.
   3 The number of availability zones to deploy the VPC in.
   4 Specify an integer between 1 and 3.
   5 The size of each subnet in each availability zone.
   6 Specify an integer between 5 and 13, where 5 is /27 and 13 is /19.
   ```
2. Copy the template from the CloudFormation template for the VPC section of this topic and save it as a YAML file on your computer. This template describes the VPC that your cluster requires.

3. Launch the CloudFormation template to create a stack of AWS resources that represent the VPC:

   **IMPORTANT**

   You must enter the command on a single line.

   ```
   $ aws cloudformation create-stack --stack-name <name>  
   --template-body file://<template>.yaml  
   --parameters file://<parameters>.json
   ```

   - `<name>` is the name for the CloudFormation stack, such as `cluster-vpc`. You need the name of this stack if you remove the cluster.
   - `<template>` is the relative path to and name of the CloudFormation template YAML file that you saved.
   - `<parameters>` is the relative path to and name of the CloudFormation parameters JSON file.

4. Confirm that the template components exist:

   ```
   $ aws cloudformation describe-stacks --stack-name <name>
   ```

   After the StackStatus displays `CREATE_COMPLETE`, the output displays values for the following parameters. You must provide these parameter values to the other CloudFormation templates that you run to create your cluster:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VpcId</td>
<td>The ID of your VPC.</td>
</tr>
<tr>
<td>PublicSubnetIds</td>
<td>The IDs of the new public subnets.</td>
</tr>
<tr>
<td>PrivateSubnetIds</td>
<td>The IDs of the new private subnets.</td>
</tr>
</tbody>
</table>

6.12.10.1. CloudFormation template for the VPC

You can use the following CloudFormation template to deploy the VPC that you need for your OpenShift Container Platform cluster.

Example 6.63. CloudFormation template for the VPC
AWSTemplateFormatVersion: 2010-09-09
Description: Template for Best Practice VPC with 1-3 AZs

Parameters:
VpcCidr:
   AllowedPattern: ^((\[0-9]\][1-9][0-9]\]|0[1-9][0-9]\]|2[0-4][0-9]\]|25[0-5]\)]\[0-9]\]|0[1-9]\]|2[0-4]\]|25[0-5]\)\[0-9]\]|(\[0-9]\[1-9][0-9]\]|1[0-9][0-9]\]|2[0-4]\]|25[0-5]\)\[0-9]\]|0[1-9]\]|2[0-4]\]|25[0-5]\)\(/((\[6-9\]|2[0-4]\)))$
   ConstraintDescription: CIDR block parameter must be in the form x.x.x.x/16-24.
   Default: 10.0.0.0/16
   Description: CIDR block for VPC.
   Type: String
AvailabilityZoneCount:
   ConstraintDescription: "The number of availability zones. (Min: 1, Max: 3)"
   MinValue: 1
   MaxValue: 3
   Default: 1
   Description: "How many AZs to create VPC subnets for. (Min: 1, Max: 3)"
   Type: Number
SubnetBits:
   ConstraintDescription: CIDR block parameter must be in the form x.x.x.x/19-27.
   MinValue: 5
   MaxValue: 13
   Default: 12
   Description: "Size of each subnet to create within the availability zones. (Min: 5 = /27, Max: 13 = /19)"
   Type: Number

Metadata:
AWS::CloudFormation::Interface:
ParameterGroups:
- Label: default: "Network Configuration"
  Parameters:
  - VpcCidr
  - SubnetBits
- Label: default: "Availability Zones"
  Parameters:
  - AvailabilityZoneCount
ParameterLabels:
  AvailabilityZoneCount: default: "Availability Zone Count"
VpcCidr:
   default: "VPC CIDR"
SubnetBits:
   default: "Bits Per Subnet"

Conditions:

### 6.12.11. Creating networking and load balancing components in AWS

You must configure networking and classic or network load balancing in Amazon Web Services (AWS) that your OpenShift Container Platform cluster can use.

You can use the provided CloudFormation template and a custom parameter file to create a stack of AWS resources. The stack represents the networking and load balancing components that your OpenShift Container Platform cluster requires. The template also creates a hosted zone and subnet tags.

You can run the template multiple times within a single Virtual Private Cloud (VPC).

**NOTE**

If you do not use the provided CloudFormation template to create your AWS infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

**Prerequisites**

- You configured an AWS account.
- You added your AWS keys and region to your local AWS profile by running `aws configure`.
- You generated the Ignition config files for your cluster.
- You created and configured a VPC and associated subnets in AWS.

**Procedure**

```yaml
"",
[!Ref PublicSubnet, !If [DoAz2, !Ref PublicSubnet2, !Ref "AWS::NoValue"], !If [DoAz3, !Ref PublicSubnet3, !Ref "AWS::NoValue"]]
]
PrivateSubnetIds:
Description: Subnet IDs of the private subnets.
Value:
!Join [ "",
[!Ref PrivateSubnet, !If [DoAz2, !Ref PrivateSubnet2, !Ref "AWS::NoValue"], !If [DoAz3, !Ref PrivateSubnet3, !Ref "AWS::NoValue"]]
]
PublicRouteTableId:
Description: Public Route table ID
Value: !Ref PublicRouteTable

Additional resources

- You can view details about the CloudFormation stacks that you create by navigating to the AWS CloudFormation console.
```
1. Obtain the hosted zone ID for the Route 53 base domain that you specified in the `install-config.yaml` file for your cluster. You can obtain details about your hosted zone by running the following command:

```bash
$ aws route53 list-hosted-zones-by-name --dns-name <route53_domain>
```

For the `<route53_domain>`, specify the Route 53 base domain that you used when you generated the `install-config.yaml` file for the cluster.

**Example output**

```
mycluster.example.com. False 100
HOSTEDZONES 65F8F38E-2268-B835-E15C-AB55336FCBFA
/hostedzone/Z21IXYZABCZ2A4 mycluster.example.com. 10
```

In the example output, the hosted zone ID is `Z21IXYZABCZ2A4`.

2. Create a JSON file that contains the parameter values that the template requires:

```json
[
  {
    "ParameterKey": "ClusterName",  
    "ParameterValue": "mycluster"
  },
  {
    "ParameterKey": "InfrastructureName",
    "ParameterValue": "mycluster-<random_string>"
  },
  {
    "ParameterKey": "HostedZoneId",
    "ParameterValue": "<random_string>
  },
  {
    "ParameterKey": "HostedZoneName",
    "ParameterValue": "example.com"
  },
  {
    "ParameterKey": "PublicSubnets",
    "ParameterValue": "subnet-<random_string>
  },
  {
    "ParameterKey": "PrivateSubnets",
    "ParameterValue": "subnet-<random_string>
  },
  {
    "ParameterKey": "VpcId",
    "ParameterValue": "vpc-<random_string>
  }
]
```

1 A short, representative cluster name to use for hostnames, etc.
Specify the cluster name that you used when you generated the `install-config.yaml` file for the cluster.

The name for your cluster infrastructure that is encoded in your Ignition config files for the cluster.

Specify the infrastructure name that you extracted from the Ignition config file metadata, which has the format `<cluster-name>-<random-string>`.

The Route 53 public zone ID to register the targets with.

Specify the Route 53 public zone ID, which as a format similar to `Z21IXYZABCZ2A4`. You can obtain this value from the AWS console.

The Route 53 zone to register the targets with.

Specify the Route 53 base domain that you used when you generated the `install-config.yaml` file for the cluster. Do not include the trailing period (.) that is displayed in the AWS console.

The public subnets that you created for your VPC.

Specify the `PublicSubnetIds` value from the output of the CloudFormation template for the VPC.

The private subnets that you created for your VPC.

Specify the `PrivateSubnetIds` value from the output of the CloudFormation template for the VPC.

The VPC that you created for the cluster.

Specify the `VpcId` value from the output of the CloudFormation template for the VPC.

3. Copy the template from the CloudFormation template for the network and load balancers section of this topic and save it as a YAML file on your computer. This template describes the networking and load balancing objects that your cluster requires.

**IMPORTANT**

If you are deploying your cluster to an AWS government or secret region, you must update the `InternalApiServerRecord` in the CloudFormation template to use `CNAME` records. Records of type `ALIAS` are not supported for AWS government regions.

4. Launch the CloudFormation template to create a stack of AWS resources that provide the networking and load balancing components:

**IMPORTANT**

You must enter the command on a single line.

```
$ aws cloudformation create-stack --stack-name <name> 1
    --template-body file://<template>.yaml 2
```
<name> is the name for the CloudFormation stack, such as cluster-dns. You need the name of this stack if you remove the cluster.

$template> is the relative path to and name of the CloudFormation template YAML file that you saved.

<parameters> is the relative path to and name of the CloudFormation parameters JSON file.

You must explicitly declare the CAPABILITY_NAMED_IAM capability because the provided template creates some AWS::IAM::Role resources.

Example output

```
arn:aws:cloudformation:us-east-1:269333783861:stack/cluster-dns/cd3e5de0-2fd4-11eb-5cf0-12be5c33a183
```

5. Confirm that the template components exist:

```
$ aws cloudformation describe-stacks --stack-name <name>
```

After the StackStatus displays CREATE_COMPLETE, the output displays values for the following parameters. You must provide these parameter values to the other CloudFormation templates that you run to create your cluster:

<table>
<thead>
<tr>
<th>PrivateHostedZoneId</th>
<th>Hosted zone ID for the private DNS.</th>
</tr>
</thead>
<tbody>
<tr>
<td>ExternalApiLoadBalancerName</td>
<td>Full name of the external API load balancer.</td>
</tr>
<tr>
<td>InternalApiLoadBalancerName</td>
<td>Full name of the internal API load balancer.</td>
</tr>
<tr>
<td>ApiServerDnsName</td>
<td>Full hostname of the API server.</td>
</tr>
<tr>
<td>RegisterNlbIpTargetsLambda</td>
<td>Lambda ARN useful to help register/deregister IP targets for these load balancers.</td>
</tr>
</tbody>
</table>
6.12.11. CloudFormation template for the network and load balancers

You can use the following CloudFormation template to deploy the networking objects and load balancers that you need for your OpenShift Container Platform cluster.

Example 6.64. CloudFormation template for the network and load balancers

AWSTemplateFormatVersion: 2010-09-09
Description: Template for OpenShift Cluster Network Elements (Route53 & LBs)

Parameters:
ClusterName:
  AllowedPattern: ^([a-zA-Z][a-zA-Z0-9-]([a-zA-Z0-9-])$)
  MaxLength: 27
  MinLength: 1
  ConstraintDescription: Cluster name must be alphanumeric, start with a letter, and have a maximum of 27 characters.
  Description: A short, representative cluster name to use for host names and other identifying names.
  Type: String
InfrastructureName:
  AllowedPattern: ^([a-zA-Z][a-zA-Z0-9-]([a-zA-Z0-9-])$)
  MaxLength: 27
  MinLength: 1
  ConstraintDescription: Infrastructure name must be alphanumeric, start with a letter, and have a maximum of 27 characters.
  Description: A short, unique cluster ID used to tag cloud resources and identify items owned or used by the cluster.
  Type: String
HostedZoneId:
  Description: The Route53 public zone ID to register the targets with, such as Z21IXYZABCZ2AAA.
  Type: String
HostedZoneName:
  Description: The Route53 zone to register the targets with, such as example.com. Omit the trailing period.
  Type: String
  Default: "example.com"
PublicSubnets:
CHAPTER 6. INSTALLING ON AWS

Description: The internet-facing subnets.
Type: List<AWS::EC2::Subnet::Id>

PrivateSubnets:
Description: The internal subnets.
Type: List<AWS::EC2::Subnet::Id>

VpcId:
Description: The VPC-scoped resources will belong to this VPC.
Type: AWS::EC2::VPC::Id

Metadata:
AWS::CloudFormation::Interface:
ParameterGroups:
- Label:
  default: "Cluster Information"
Parameters:
  - ClusterName
  - InfrastructureName
- Label:
  default: "Network Configuration"
Parameters:
  - VpcId
  - PublicSubnets
  - PrivateSubnets
- Label:
  default: "DNS"
Parameters:
  - HostedZoneName
  - HostedZoneId

ParameterLabels:
ClusterName:
  default: "Cluster Name"
InfrastructureName:
  default: "Infrastructure Name"
VpcId:
  default: "VPC ID"

        if event['RequestType'] == 'Delete':
          for subnet_id in event['ResourceProperties']['Subnets']:
            ec2_client.delete_tags(Resources=[subnet_id], Tags=[{'Key': 'kubernetes.io/cluster/' + event['ResourceProperties']['InfrastructureName']},])
        else:
          for subnet_id in event['ResourceProperties']['Subnets']:
            ec2_client.create_tags(Resources=[subnet_id], Tags=[{'Key': 'kubernetes.io/cluster/' + event['ResourceProperties']['InfrastructureName'], 'Value': 'shared'}]);
          responseData = {}
IMPORTANT

If you are deploying your cluster to an AWS government or secret region, you must update the **InternalApiServerRecord** to use **CNAME** records. Records of type **ALIAS** are not supported for AWS government regions. For example:

```yaml
Type: CNAME
TTL: 10
ResourceRecords:
  - !GetAtt IntApiElb.DNSName
```
6.12.12. Creating security group and roles in AWS

You must create security groups and roles in Amazon Web Services (AWS) for your OpenShift Container Platform cluster to use.

You can use the provided CloudFormation template and a custom parameter file to create a stack of AWS resources. The stack represents the security groups and roles that your OpenShift Container Platform cluster requires.

NOTE

If you do not use the provided CloudFormation template to create your AWS infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

Prerequisites

- You configured an AWS account.
- You added your AWS keys and region to your local AWS profile by running `aws configure`.
- You generated the Ignition config files for your cluster.
- You created and configured a VPC and associated subnets in AWS.

Procedure

1. Create a JSON file that contains the parameter values that the template requires:

```json
[
  {
    "ParameterKey": "InfrastructureName", 1
    "ParameterValue": "mycluster-<random_string>" 2
  },
  {
    "ParameterKey": "VpcCidr", 3
    "ParameterValue": "10.0.0.0/16" 4
  },
  {
    "ParameterKey": "PrivateSubnets", 5
    "ParameterValue": "subnet-<random_string>" 6
  },
  {  
    "ParameterKey": "VpcId", 7
    "ParameterValue": "myvpc"
  }
]
```
The name for your cluster infrastructure that is encoded in your Ignition config files for the cluster.

Specify the infrastructure name that you extracted from the Ignition config file metadata, which has the format `<cluster-name>-<random-string>`.

The CIDR block for the VPC.

Specify the CIDR block parameter that you used for the VPC that you defined in the form `x.x.x.x/16-24`.

The private subnets that you created for your VPC.

Specify the `PrivateSubnetIds` value from the output of the CloudFormation template for the VPC.

The VPC that you created for the cluster.

Specify the `VpcId` value from the output of the CloudFormation template for the VPC.

2. Copy the template from the CloudFormation template for security objects section of this topic and save it as a YAML file on your computer. This template describes the security groups and roles that your cluster requires.

3. Launch the CloudFormation template to create a stack of AWS resources that represent the security groups and roles:

   **IMPORTANT**
   You must enter the command on a single line.

   ```bash
   $ aws cloudformation create-stack --stack-name <name> 1
   --template-body file://<template>.yaml 2
   --parameters file://<parameters>.json 3
   --capabilities CAPABILITY_NAMED_IAM 4
   ```

   1. `<name>` is the name for the CloudFormation stack, such as `cluster-sec`. You need the name of this stack if you remove the cluster.

   2. `<template>` is the relative path to and name of the CloudFormation template YAML file that you saved.

   3. `<parameters>` is the relative path to and name of the CloudFormation parameters JSON file.

   4. You must explicitly declare the `CAPABILITY_NAMED_IAM` capability because the provided template creates some `AWS::IAM::Role` and `AWS::IAM::InstanceProfile` resources.
Example output

```
arn:aws:cloudformation:us-east-1:269333783861:stack/cluster-sec/03bd4210-2ed7-11eb-6d7a-13fc0b61e9db
```

4. Confirm that the template components exist:

```
$ aws cloudformation describe-stacks --stack-name <name>
```

After the StackStatus displays CREATE_COMPLETE, the output displays values for the following parameters. You must provide these parameter values to the other CloudFormation templates that you run to create your cluster:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MasterSecurityGroupId</td>
<td>Master Security Group ID</td>
</tr>
<tr>
<td>WorkerSecurityGroupId</td>
<td>Worker Security Group ID</td>
</tr>
<tr>
<td>MasterInstanceProfile</td>
<td>Master IAM Instance Profile</td>
</tr>
<tr>
<td>WorkerInstanceProfile</td>
<td>Worker IAM Instance Profile</td>
</tr>
</tbody>
</table>

You can use the following CloudFormation template to deploy the security objects that you need for your OpenShift Container Platform cluster.

Example 6.65. CloudFormation template for security objects

```
AWSTemplateFormatVersion: 2010-09-09
Description: Template for OpenShift Cluster Security Elements (Security Groups & IAM)

Parameters:
  InfrastructureName:
    AllowedPattern: ^([a-zA-Z][a-zA-Z0-9-]0-26)$
    MaxLength: 27
    MinLength: 1
    ConstraintDescription: Infrastructure name must be alphanumeric, start with a letter, and have a maximum of 27 characters.
    Description: A short, unique cluster ID used to tag cloud resources and identify items owned or used by the cluster.
    Type: String
  VpcCidr:
    AllowedPattern: ^((0-9][1-9][0-9][0-9][1-9][0-9][2][0-4][0-9][25][0-5])\(3\)[0-9][1-9][0-9][1][0-9][2][0-4][0-9][25][0-5](\(6\)[0-9][2][0-4])$```
ConstraintDescription: CIDR block parameter must be in the form x.x.x.x/16-24.
Default: 10.0.0.0/16
Description: CIDR block for VPC.
Type: String
VpcId:
Description: The VPC-scoped resources will belong to this VPC.
Type: AWS::EC2::VPC::Id
PrivateSubnets:
Description: The internal subnets.
Type: List<AWS::EC2::Subnet::Id>

Metadata:
AWS::CloudFormation::Interface:
ParameterGroups:
- Label:
  default: "Cluster Information"
Parameters:
- InfrastructureName
- Label:
  default: "Network Configuration"
Parameters:
- VpcId
- VpcCidr
- PrivateSubnets
ParameterLabels:
  InfrastructureName:
    default: "Infrastructure Name"
VpcId:
  default: "VPC ID"
VpcCidr:
  default: "VPC CIDR"
PrivateSubnets:
  default: "Private Subnets"

6.12.13. Accessing RHCOS AMIs with stream metadata

In OpenShift Container Platform, *stream metadata* provides standardized metadata about RHCOS in the JSON format and injects the metadata into the cluster. Stream metadata is a stable format that supports multiple architectures and is intended to be self-documenting for maintaining automation.

You can use the `coreos print-stream-json` sub-command of `openshift-install` to access information about the boot images in the stream metadata format. This command provides a method for printing stream metadata in a scriptable, machine-readable format.

For user-provisioned installations, the `openshift-install` binary contains references to the version of RHCOS boot images that are tested for use with OpenShift Container Platform, such as the AWS AMI.

**Procedure**

To parse the stream metadata, use one of the following methods:

- From a Go program, use the official `stream-metadata-go` library at [https://github.com/coreos/stream-metadata-go](https://github.com/coreos/stream-metadata-go). You can also view example code in the library.

- From another programming language, such as Python or Ruby, use the JSON library of your preferred programming language.

- From a command-line utility that handles JSON data, such as `jq`:

```bash
- "ec2:DescribeRegions"
  Resource: ""

WorkerInstanceProfile:
  Type: "AWS::IAM::InstanceProfile"
  Properties:
    Roles:
    - Ref: "WorkerIamRole"

Outputs:
MasterSecurityGroupId:
  Description: Master Security Group ID
  Value: !GetAtt MasterSecurityGroup.GroupId

WorkerSecurityGroupId:
  Description: Worker Security Group ID
  Value: !GetAtt WorkerSecurityGroup.GroupId

MasterInstanceProfile:
  Description: Master IAM Instance Profile
  Value: !Ref MasterInstanceProfile

WorkerInstanceProfile:
  Description: Worker IAM Instance Profile
  Value: !Ref WorkerInstanceProfile

Additional resources

- You can view details about the CloudFormation stacks that you create by navigating to the AWS CloudFormation console.
Print the current `x86_64` or `aarch64` AMI for an AWS region, such as **us-west-1**:

For `x86_64`

```
$ openshift-install coreos print-stream-json | jq -r '.architectures.x86_64.images.aws.regions["us-west-1"].image'
```

**Example output**

`ami-0d3e625f84626bbda`

For `aarch64`

```
$ openshift-install coreos print-stream-json | jq -r '.architectures.aarch64.images.aws.regions["us-west-1"].image'
```

**Example output**

`ami-0af1d3b7fa5be2131`

The output of this command is the AWS AMI ID for your designated architecture and the **us-west-1** region. The AMI must belong to the same region as the cluster.

### 6.12.14. RHCOS AMIs for the AWS infrastructure

Red Hat provides Red Hat Enterprise Linux CoreOS (RHCOS) AMIs that are valid for the various AWS regions and instance architectures that you can manually specify for your OpenShift Container Platform nodes.

**NOTE**

By importing your own AMI, you can also install to regions that do not have a published RHCOS AMI.

### 6.12.14.1. AWS regions without a published RHCOS AMI

You can deploy an OpenShift Container Platform cluster to Amazon Web Services (AWS) regions without native support for a Red Hat Enterprise Linux CoreOS (RHCOS) Amazon Machine Image (AMI) or the AWS software development kit (SDK). If a published AMI is not available for an AWS region, you can upload a custom AMI prior to installing the cluster.

If you are deploying to a region not supported by the AWS SDK and you do not specify a custom AMI, the installation program copies the `us-east-1` AMI to the user account automatically. Then the installation program creates the control plane machines with encrypted EBS volumes using the default or user-specified Key Management Service (KMS) key. This allows the AMI to follow the same process workflow as published RHCOS AMIs.

A region without native support for an RHCOS AMI is not available to select from the terminal during cluster creation because it is not published. However, you can install to this region by configuring the custom AMI in the `install-config.yaml` file.

### 6.12.14.2. Uploading a custom RHCOS AMI in AWS

If you are deploying to a custom Amazon Web Services (AWS) region, you must upload a custom Red Hat Enterprise Linux CoreOS (RHCOS) Amazon Machine Image (AMI) that belongs to that region.

**Prerequisites**

- You configured an AWS account.
- You created an Amazon S3 bucket with the required IAM service role.

<table>
<thead>

</tr>
<tr>
<td>us-west-2</td>
<td>ami-0b189d89b44bdff2</td>
</tr>
</tbody>
</table>
You uploaded your RHCOS VMDK file to Amazon S3. The RHCOS VMDK file must be the highest version that is less than or equal to the OpenShift Container Platform version you are installing.

You downloaded the AWS CLI and installed it on your computer. See Install the AWS CLI Using the Bundled Installer.

Procedure

1. Export your AWS profile as an environment variable:

   ```bash
   $ export AWS_PROFILE=<aws_profile>
   ```

2. Export the region to associate with your custom AMI as an environment variable:

   ```bash
   $ export AWS_DEFAULT_REGION=<aws_region>
   ```

3. Export the version of RHCOS you uploaded to Amazon S3 as an environment variable:

   ```bash
   $ export RHCOS_VERSION=<version>
   ```

4. Export the Amazon S3 bucket name as an environment variable:

   ```bash
   $ export VMIMPORT_BUCKET_NAME=<s3_bucket_name>
   ```

5. Create the `containers.json` file and define your RHCOS VMDK file:

   ```bash
   $ cat <<EOF > containers.json
   {
   "Description": "rhcos-\${RHCOS_VERSION\}-x86_64-aws.x86_64",
   "Format": "vmdk",
   "UserBucket": {  
               "S3Bucket": "$\{VMIMPORT_BUCKET_NAME\}",
               "S3Key": "rhcos-\${RHCOS_VERSION\}-x86_64-aws.x86_64.vmdk"
   }
   }
   EOF
   ```

6. Import the RHCOS disk as an Amazon EBS snapshot:

   ```bash
   $ aws ec2 import-snapshot --region ${AWS_DEFAULT_REGION}  
   --description "<description>"  
   --disk-container "file://<file_path>/containers.json"
   ```

   The description of your RHCOS disk being imported, like `rhcos-\${RHCOS_VERSION\}-x86_64-aws.x86_64`.

   The file path to the JSON file describing your RHCOS disk. The JSON file should contain your Amazon S3 bucket name and key.
7. Check the status of the image import:

   $ watch -n 5 aws ec2 describe-import-snapshot-tasks --region ${AWS_DEFAULT_REGION}

Example output

```
{
   "ImportSnapshotTasks": [
      {
         "Description": "rhcos-4.7.0-x86_64-aws.x86_64",
         "ImportTaskId": "import-snap-fh6i8ui",
         "SnapshotTaskDetail": {
            "Description": "rhcos-4.7.0-x86_64-aws.x86_64",
            "DiskImageSize": 819056640.0,
            "Format": "VMDK",
            "SnapshotId": "snap-06331325870076318",
            "Status": "completed",
            "UserBucket": {
               "S3Bucket": "external-images",
               "S3Key": "rhcos-4.7.0-x86_64-aws.x86_64.vmdk"
            }
         }
      }
   ]
}
```

Copy the **SnapshotId** to register the image.

8. Create a custom RHCOS AMI from the RHCOS snapshot:

   $ aws ec2 register-image \
      --region ${AWS_DEFAULT_REGION} \
      --architecture x86_64 \
      --description "rhcos-${RHCOS_VERSION}-x86_64-aws.x86_64" \
      --ena-support \
      --name "rhcos-${RHCOS_VERSION}-x86_64-aws.x86_64" \
      --virtualization-type hvm \
      --root-device-name '/dev/xvda' \
      --block-device-mappings 'DeviceName=/dev/xvda,Ebs=\n      {DeleteOnTermination=true,SnapshotId=<snapshot_ID>}'

1. The RHCOS VMDK architecture type, like **x86_64**, **aarch64**, **s390x**, or **ppc64le**.
2. The **Description** from the imported snapshot.
3. The name of the RHCOS AMI.
4. The **SnapshotId** from the imported snapshot.

To learn more about these APIs, see the AWS documentation for importing snapshots and creating EBS-backed AMIs.

6.12.15. Creating the bootstrap node in AWS
You must create the bootstrap node in Amazon Web Services (AWS) to use during OpenShift Container Platform cluster initialization. You do this by:

- Providing a location to serve the `bootstrap.ign` Ignition config file to your cluster. This file is located in your installation directory. The provided CloudFormation Template assumes that the Ignition config files for your cluster are served from an S3 bucket. If you choose to serve the files from another location, you must modify the templates.

- Using the provided CloudFormation template and a custom parameter file to create a stack of AWS resources. The stack represents the bootstrap node that your OpenShift Container Platform installation requires.

**NOTE**

If you do not use the provided CloudFormation template to create your bootstrap node, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

**Prerequisites**

- You configured an AWS account.
- You added your AWS keys and region to your local AWS profile by running `aws configure`.
- You generated the Ignition config files for your cluster.
- You created and configured a VPC and associated subnets in AWS.
- You created and configured DNS, load balancers, and listeners in AWS.
- You created the security groups and roles required for your cluster in AWS.

**Procedure**

1. Create the bucket by running the following command:

   ```bash
   $ aws s3 mb s3://<cluster-name>-infra
   ```

   `<cluster-name>-infra` is the bucket name. When creating the `install-config.yaml` file, replace `<cluster-name>` with the name specified for the cluster.

   You must use a presigned URL for your S3 bucket, instead of the `s3://` schema, if you are:

   - Deploying to a region that has endpoints that differ from the AWS SDK.
   - Deploying a proxy.
   - Providing your own custom endpoints.

2. Upload the `bootstrap.ign` Ignition config file to the bucket by running the following command:

   ```bash
   $ aws s3 cp <installation_directory>/bootstrap.ign s3://<cluster-name>-infra/bootstrap.ign
   ```
1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

3. Verify that the file uploaded by running the following command:

   ```bash
   $ aws s3 ls s3://<cluster-name>-infra/
   ```

   Example output:

   ```
   2019-04-03 16:15:16     314878 bootstrap.ign
   ```

   **NOTE**

   The bootstrap Ignition config file does contain secrets, like X.509 keys. The following steps provide basic security for the S3 bucket. To provide additional security, you can enable an S3 bucket policy to allow only certain users, such as the OpenShift IAM user, to access objects that the bucket contains. You can avoid S3 entirely and serve your bootstrap Ignition config file from any address that the bootstrap machine can reach.

4. Create a JSON file that contains the parameter values that the template requires:

   ```json
   [
   {
     "ParameterKey": "InfrastructureName", 1
     "ParameterValue": "mycluster-<random_string>" 2
   },
   {
     "ParameterKey": "RhcosAmi", 3
     "ParameterValue": "ami-<random_string>" 4
   },
   {
     "ParameterKey": "AllowedBootstrapSshCidr", 5
     "ParameterValue": "0.0.0.0/0" 6
   },
   {
     "ParameterKey": "PublicSubnet", 7
     "ParameterValue": "subnet-<random_string>" 8
   },
   {
     "ParameterKey": "MasterSecurityGroupId", 9
     "ParameterValue": "sg-<random_string>" 10
   },
   {
     "ParameterKey": "VpcId", 11
     "ParameterValue": "vpc-<random_string>" 12
   },
   {
     "ParameterKey": "BootstrapIgnitionLocation", 13
     "ParameterValue": "s3://<bucket_name>/bootstrap.ign" 14
   },
   ]
   ```
The name for your cluster infrastructure that is encoded in your Ignition config files for the cluster.

Specify the infrastructure name that you extracted from the Ignition config file metadata, which has the format `<cluster-name>-<random-string>`. Current Red Hat Enterprise Linux CoreOS (RHCOS) AMI to use for the bootstrap node based on your selected architecture.

Specify a valid `AWS::EC2::Image::Id` value.

CIDR block to allow SSH access to the bootstrap node.

Specify a CIDR block in the format `x.x.x.x/16-24`.

The public subnet that is associated with your VPC to launch the bootstrap node into.

Specify the `PublicSubnetIds` value from the output of the CloudFormation template for the VPC.

The master security group ID (for registering temporary rules)

Specify the `MasterSecurityGroupId` value from the output of the CloudFormation template for the security group and roles.

The VPC created resources will belong to.

Specify the `VpcId` value from the output of the CloudFormation template for the VPC.

```json
{
  "ParameterKey": "AutoRegisterELB",
  "ParameterValue": "yes"
},
{
  "ParameterKey": "RegisterNlbIpTargetsLambdaArn",
  "ParameterValue": "arn:aws:lambda:<aws_region>:<account_number>:function:<dns_stack_name>-RegisterNlbIpTargets-<random_string>"
},
{
  "ParameterKey": "ExternalApiTargetGroupArn",
  "ParameterValue": "arn:aws:elasticloadbalancing:<aws_region>:<account_number>:targetgroup/<dns_stack_name>-Exter-<random_string>"
},
{
  "ParameterKey": "InternalApiTargetGroupArn",
  "ParameterValue": "arn:aws:elasticloadbalancing:<aws_region>:<account_number>:targetgroup/<dns_stack_name>-Inter-<random_string>"
},
{
  "ParameterKey": "InternalServiceTargetGroupArn",
  "ParameterValue": "arn:aws:elasticloadbalancing:<aws_region>:<account_number>:targetgroup/<dns_stack_name>-Inter-<random_string>"
}
}
```
Location to fetch bootstrap Ignition config file from.

Specify the S3 bucket and file name in the form `s3://<bucket_name>/bootstrap.ign`.

Whether or not to register a network load balancer (NLB).

Specify `yes` or `no`. If you specify `yes`, you must provide a Lambda Amazon Resource Name (ARN) value.

The ARN for NLB IP target registration lambda group.

Specify the `RegisterNlbIpTargetsLambda` value from the output of the CloudFormation template for DNS and load balancing. Use `arn:aws-us-gov` if deploying the cluster to an AWS GovCloud region.

The ARN for external API load balancer target group.

Specify the `ExternalApiTargetGroupArn` value from the output of the CloudFormation template for DNS and load balancing. Use `arn:aws-us-gov` if deploying the cluster to an AWS GovCloud region.

The ARN for internal API load balancer target group.

Specify the `InternalApiTargetGroupArn` value from the output of the CloudFormation template for DNS and load balancing. Use `arn:aws-us-gov` if deploying the cluster to an AWS GovCloud region.

The ARN for internal service load balancer target group.

Specify the `InternalServiceTargetGroupArn` value from the output of the CloudFormation template for DNS and load balancing. Use `arn:aws-us-gov` if deploying the cluster to an AWS GovCloud region.

5. Copy the template from the CloudFormation template for the bootstrap machine section of this topic and save it as a YAML file on your computer. This template describes the bootstrap machine that your cluster requires.

6. Optional: If you are deploying the cluster with a proxy, you must update the ignition in the template to add the `ignition.config.proxy` fields. Additionally, if you have added the Amazon EC2, Elastic Load Balancing, and S3 VPC endpoints to your VPC, you must add these endpoints to the `noProxy` field.

7. Launch the CloudFormation template to create a stack of AWS resources that represent the bootstrap node:

   IMPORTANT
   You must enter the command on a single line.

   ```
   $ aws cloudformation create-stack --stack-name <name> 1
   --template-body file://<template>.yaml 2
   --parameters file://<parameters>.json 3
   --capabilities CAPABILITY_NAMED_IAM 4
   ```
<name> is the name for the CloudFormation stack, such as cluster-bootstrap. You need the name of this stack if you remove the cluster.

<template> is the relative path to and name of the CloudFormation template YAML file that you saved.

<parameters> is the relative path to and name of the CloudFormation parameters JSON file.

You must explicitly declare the CAPABILITY_NAMED_IAM capability because the provided template creates some AWS::IAM::Role and AWS::IAM::InstanceProfile resources.

Example output

```
arn:aws:cloudformation:us-east-1:269333783861:stack/cluster-bootstrap/12944486-2add-11eb-9dee-12dace8e3a83
```

8. Confirm that the template components exist:

```
$ aws cloudformation describe-stacks --stack-name <name>
```

After the StackStatus displays CREATE_COMPLETE, the output displays values for the following parameters. You must provide these parameter values to the other CloudFormation templates that you run to create your cluster:

<table>
<thead>
<tr>
<th>Bootstrap InstanceId</th>
<th>The bootstrap Instance ID.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap PublicIp</td>
<td>The bootstrap node public IP address.</td>
</tr>
<tr>
<td>Bootstrap PrivateIp</td>
<td>The bootstrap node private IP address.</td>
</tr>
</tbody>
</table>

6.12.15.1. CloudFormation template for the bootstrap machine

You can use the following CloudFormation template to deploy the bootstrap machine that you need for your OpenShift Container Platform cluster.

Example 6.66. CloudFormation template for the bootstrap machine

```
AWSTemplateFormatVersion: 2010-09-09
Description: Template for OpenShift Cluster Bootstrap (EC2 Instance, Security Groups and IAM)

Parameters:
InfrastructureName:
    AllowedPattern: ^([a-zA-Z][a-zA-Z0-9-]{0,26})$
    MaxLength: 27
    MinLength: 1
    ConstraintDescription: Infrastructure name must be alphanumeric, start with a letter, and have a maximum of 27 characters.
```
Description: A short, unique cluster ID used to tag cloud resources and identify items owned or used by the cluster.
Type: String
RhcosAmi:
Description: Current Red Hat Enterprise Linux CoreOS AMI to use for bootstrap.
Type: AWS::EC2::Image::Id
AllowedBootstrapSshCidr:
Default: 0.0.0.0/0
Description: CIDR block to allow SSH access to the bootstrap node.
Type: String
PublicSubnet:
Description: The public subnet to launch the bootstrap node into.
Type: AWS::EC2::Subnet::Id
MasterSecurityGroupId:
Description: The master security group ID for registering temporary rules.
Type: AWS::EC2::SecurityGroup::Id
VpcId:
Description: The VPC-scoped resources will belong to this VPC.
Type: AWS::EC2::VPC::Id
BootstrapIgnitionLocation:
Default: s3://my-s3-bucket/bootstrap.ign
Description: Ignition config file location.
Type: String
AutoRegisterELB:
Default: "yes"
AllowedValues:
- "yes"
- "no"
Description: Do you want to invoke NLB registration, which requires a Lambda ARN parameter?
Type: String
RegisterNlbIpTargetsLambdaArn:
Description: ARN for NLB IP target registration lambda.
Type: String
ExternalApiTargetGroupArn:
Description: ARN for external API load balancer target group.
Type: String
InternalApiTargetGroupArn:
Description: ARN for internal API load balancer target group.
Type: String
InternalServiceTargetGroupArn:
Description: ARN for internal service load balancer target group.
Type: String
BootstrapInstanceType:
Description: Instance type for the bootstrap EC2 instance
Default: "i3.large"
Type: String
Metadata:
AWS::CloudFormation::Interface:
ParameterGroups:
- Label:
  default: "Cluster Information"
Parameters:
- InfrastructureName
- Label:
  - default: "Host Information"
Parameters:
- RhcosAmi
- BootstrapIgnitionLocation
- MasterSecurityGroupId
- Label:
  - default: "Network Configuration"
Parameters:
- VpcId
- AllowedBootstrapSshCidr
- PublicSubnet
- Label:
  - default: "Load Balancer Automation"
Parameters:
- AutoRegisterELB
- RegisterNlbIpTargetsLambdaArn
- ExternalApiTargetGroupArn
- InternalApiTargetGroupArn
- InternalServiceTargetGroupArn
ParameterLabels:
  InfrastructureName:
    - default: "Infrastructure Name"
VpcId:
    - default: "VPC ID"
AllowedBootstrapSshCidr:
    - default: "Allowed SSH Source"
PublicSubnet:
    - default: "Public Subnet"
RhcosAmi:
    - default: "Red Hat Enterprise Linux CoreOS AMI ID"
BootstrapIgnitionLocation:
    - default: "Bootstrap Ignition Source"
MasterSecurityGroupId:
    - default: "Master Security Group ID"
AutoRegisterELB:
    - default: "Use Provided ELB Automation"

Conditions:
DoRegistration: !Equals ["yes", !Ref AutoRegisterELB]

Resources:
BootstrapIamRole:
  Type: AWS::IAM::Role
Properties:
  AssumeRolePolicyDocument:
    Version: "2012-10-17"
    Statement:
    - Effect: "Allow"
      Principal:
        Service:
        - "ec2.amazonaws.com"
      Action:
      - "sts:AssumeRole"
    Path: "/"
Policies:
- PolicyName: !Join ["-", [!Ref InfrastructureName, "bootstrap", "policy"]]

PolicyDocument:
  Version: "2012-10-17"
  Statement:
  - Effect: "Allow"
    Action: "ec2:Describe*"
    Resource: "*"
  - Effect: "Allow"
    Action: "ec2:AttachVolume"
    Resource: "*"
  - Effect: "Allow"
    Action: "ec2:DetachVolume"
    Resource: "*"
  - Effect: "Allow"
    Action: "s3:GetObject"
    Resource: "*"

BootstrapInstanceProfile:
  Type: "AWS::IAM::InstanceProfile"
  Properties:
    Path: "/"
    Roles:
    - Ref: "BootstrapIamRole"

BootstrapSecurityGroup:
  Type: AWS::EC2::SecurityGroup
  Properties:
    GroupDescription: Cluster Bootstrap Security Group
    SecurityGroupIngress:
    - IpProtocol: tcp
      FromPort: 22
      ToPort: 22
      CidrIp: !Ref AllowedBootstrapSshCidr
    - IpProtocol: tcp
      FromPort: 19531
      ToPort: 19531
      CidrIp: 0.0.0.0/0
    VpcId: !Ref VpcId

BootstrapInstance:
  Type: AWS::EC2::Instance
  Properties:
    ImageId: !Ref RhcosAmi
    IamInstanceProfile: !Ref BootstrapInstanceProfile
    InstanceType: !Ref BootstrapInstanceType
    NetworkInterfaces:
    - AssociatePublicIpAddress: "true"
      DeviceIndex: "0"
      GroupSet:
      - !Ref "BootstrapSecurityGroup"
      - !Ref "MasterSecurityGroupId"
    SubnetId: !Ref "PublicSubnet"
  UserData:
    Fn::Base64: !Sub
    - '{"ignition":{"config":{"replace":{"source":"${S3Loc}"},"version":"3.1.0"}}}'
You can view details about the CloudFormation stacks that you create by navigating to the AWS CloudFormation console.

See RHCOS AMIs for the AWS infrastructure for details about the Red Hat Enterprise Linux CoreOS (RHCOS) AMIs for the AWS zones.

6.12.16. Creating the control plane machines in AWS

You must create the control plane machines in Amazon Web Services (AWS) that your cluster will use.
You can use the provided CloudFormation template and a custom parameter file to create a stack of AWS resources that represent the control plane nodes.

**IMPORTANT**

The CloudFormation template creates a stack that represents three control plane nodes.

**NOTE**

If you do not use the provided CloudFormation template to create your control plane nodes, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

**Prerequisites**

- You configured an AWS account.
- You added your AWS keys and region to your local AWS profile by running `aws configure`.
- You generated the Ignition config files for your cluster.
- You created and configured a VPC and associated subnets in AWS.
- You created and configured DNS, load balancers, and listeners in AWS.
- You created the security groups and roles required for your cluster in AWS.
- You created the bootstrap machine.

**Procedure**

1. Create a JSON file that contains the parameter values that the template requires:

```json
[
  {
    "ParameterKey": "InfrastructureName", 1
    "ParameterValue": "mycluster-<random_string>" 2
  },
  {
    "ParameterKey": "RhcosAmi", 3
    "ParameterValue": "ami-<random_string>" 4
  },
  {
    "ParameterKey": "AutoRegisterDNS", 5
    "ParameterValue": "yes" 6
  },
  {
    "ParameterKey": "PrivateHostedZoneId", 7
    "ParameterValue": "<random_string>" 8
  },
  {
    "ParameterKey": "PrivateHostedZoneName", 9
    "ParameterValue": "mycluster.example.com" 10
  }
]
```
{"ParameterKey": "Master0Subnet", "ParameterValue": "subnet-<random_string>"}

{"ParameterKey": "Master1Subnet", "ParameterValue": "subnet-<random_string>"}

{"ParameterKey": "Master2Subnet", "ParameterValue": "subnet-<random_string>"}

{"ParameterKey": "MasterSecurityGroupId", "ParameterValue": "sg-<random_string>"}

{"ParameterKey": "IgnitionLocation", "ParameterValue": "https://api-int.<cluster_name>.<domain_name>:22623/config/master"}

{"ParameterKey": "CertificateAuthorities", "ParameterValue": "data:text/plain;charset=utf-8;base64,ABC...xYz="}

{"ParameterKey": "MasterInstanceProfileName", "ParameterValue": "<roles_stack>-MasterInstanceProfile-<random_string>"}

{"ParameterKey": "MasterInstanceType", "ParameterValue": ""}

{"ParameterKey": "AutoRegisterELB", "ParameterValue": "yes"}

{"ParameterKey": "RegisterNlbIpTargetsLambdaArn", "ParameterValue": "arn:aws:lambda:<aws_region>:<account_number>:function:<dns_stack_name>-RegisterNlbIpTargets-<random_string>"}

{"ParameterKey": "InternalApiTargetGroupArn", "ParameterValue": "arn:aws:elasticloadbalancing:<aws_region>:<account_number>:targetgroup/<dns_stack_name>-Inter-<random_string>"}
CHAPTER 6. INSTALLING ON AWS

The name for your cluster infrastructure that is encoded in your Ignition config files for the cluster.

Specify the infrastructure name that you extracted from the Ignition config file metadata, which has the format `<cluster-name>-<random-string>`.

Current Red Hat Enterprise Linux CoreOS (RHCOS) AMI to use for the control plane machines based on your selected architecture.

Specify an `AWS::EC2::Image::Id` value.

Whether or not to perform DNS etcd registration.

Specify `yes` or `no`. If you specify `yes`, you must provide hosted zone information.

The Route 53 private zone ID to register the etcd targets with.

Specify the `PrivateHostedZoneId` value from the output of the CloudFormation template for DNS and load balancing.

The Route 53 zone to register the targets with.

Specify `<cluster_name>-<domain_name>` where `<domain_name>` is the Route 53 base domain that you used when you generated `install-config.yaml` file for the cluster. Do not include the trailing period (.) that is displayed in the AWS console.

A subnet, preferably private, to launch the control plane machines on.

Specify a subnet from the `PrivateSubnets` value from the output of the CloudFormation template for DNS and load balancing.

The master security group ID to associate with control plane nodes.

Specify the `MasterSecurityGroupId` value from the output of the CloudFormation template for the security group and roles.

The location to fetch control plane Ignition config file from.

Specify the generated Ignition config file location, `https://api-int.<cluster_name>.<domain_name>:22623/config/master`.

The base64 encoded certificate authority string to use.

Specify the value from the `master.ign` file that is in the installation directory. This value is the long string with the format `data:text/plain;charset=utf-8;base64,ABC…xYz==`

The IAM profile to associate with control plane nodes.

Specify the `MasterInstanceProfile` parameter value from the output of the CloudFormation template for the security group and roles.
The type of AWS instance to use for the control plane machines based on your selected architecture.

The instance type value corresponds to the minimum resource requirements for control plane machines. For example, **m6i.xlarge** is a type for AMD64 and **m6g.xlarge** is a type for ARM64.

Whether or not to register a network load balancer (NLB).

Specify **yes** or **no**. If you specify **yes**, you must provide a Lambda Amazon Resource Name (ARN) value.

The ARN for NLB IP target registration lambda group.

Specify the **RegisterNlbIpTargetsLambda** value from the output of the CloudFormation template for DNS and load balancing. Use **arn:aws-us-gov** if deploying the cluster to an AWS GovCloud region.

The ARN for external API load balancer target group.

Specify the **ExternalApiTargetGroupArn** value from the output of the CloudFormation template for DNS and load balancing. Use **arn:aws-us-gov** if deploying the cluster to an AWS GovCloud region.

The ARN for internal API load balancer target group.

Specify the **InternalApiTargetGroupArn** value from the output of the CloudFormation template for DNS and load balancing. Use **arn:aws-us-gov** if deploying the cluster to an AWS GovCloud region.

The ARN for internal service load balancer target group.

Specify the **InternalServiceTargetGroupArn** value from the output of the CloudFormation template for DNS and load balancing. Use **arn:aws-us-gov** if deploying the cluster to an AWS GovCloud region.

2. Copy the template from the CloudFormation template for control plane machines section of this topic and save it as a YAML file on your computer. This template describes the control plane machines that your cluster requires.

3. If you specified an **m5** instance type as the value for **MasterInstanceType**, add that instance type to the **MasterInstanceType.AllowedValues** parameter in the CloudFormation template.

4. Launch the CloudFormation template to create a stack of AWS resources that represent the control plane nodes:

   **IMPORTANT**

   You must enter the command on a single line.

   ```
   $ aws cloudformation create-stack --stack-name <name>  
   --template-body file://<template>.yaml  
   --parameters file://<parameters>.json
   ```
<name> is the name for the CloudFormation stack, such as `cluster-control-plane`. You need the name of this stack if you remove the cluster.

<template> is the relative path to and name of the CloudFormation template YAML file that you saved.

<parameters> is the relative path to and name of the CloudFormation parameters JSON file.

Example output

```
arn:aws:cloudformation:us-east-1:269333783861:stack/cluster-control-plane/21c7e2b0-2ee2-11eb-c6f6-0aa34627df4b
```

**NOTE**

The CloudFormation template creates a stack that represents three control plane nodes.

5. Confirm that the template components exist:

```
$ aws cloudformation describe-stacks --stack-name <name>
```

6.12.16.1. CloudFormation template for control plane machines

You can use the following CloudFormation template to deploy the control plane machines that you need for your OpenShift Container Platform cluster.

Example 6.67. CloudFormation template for control plane machines

```
AWSTemplateFormatVersion: 2010-09-09
Description: Template for OpenShift Cluster Node Launch (EC2 master instances)

Parameters:
InfrastructureName:
  AllowedPattern: ^([a-zA-Z][a-zA-Z0-9-]{0,26})$
  MaxLength: 27
  MinLength: 1
  ConstraintDescription: Infrastructure name must be alphanumeric, start with a letter, and have a maximum of 27 characters.
  Description: A short, unique cluster ID used to tag nodes for the kubelet cloud provider.
  Type: String
RhcosAmi:
  Description: Current Red Hat Enterprise Linux CoreOS AMI to use for bootstrap.
  Type: AWS::EC2::Image::Id
AutoRegisterDNS:
  Default: ""
  Description: unused
  Type: String
PrivateHostedZoneId:
  Default: ""
  Description: unused
  Type: String
```
PrivateHostedZoneName:
  Default: ""
  Description: unused
  Type: String
Master0Subnet:
  Description: The subnets, recommend private, to launch the master nodes into.
  Type: AWS::EC2::Subnet::Id
Master1Subnet:
  Description: The subnets, recommend private, to launch the master nodes into.
  Type: AWS::EC2::Subnet::Id
Master2Subnet:
  Description: The subnets, recommend private, to launch the master nodes into.
  Type: AWS::EC2::Subnet::Id
MasterSecurityGroupId:
  Description: The master security group ID to associate with master nodes.
  Type: AWS::EC2::SecurityGroup::Id
IgnitionLocation:
  Default: https://api-int.$CLUSTER_NAME.$DOMAIN:22623/config/master
  Description: Ignition config file location.
  Type: String
CertificateAuthorities:
  Default: data:text/plain;charset=utf-8;base64,ABC...xYz==
  Description: Base64 encoded certificate authority string to use.
  Type: String
MasterInstanceProfileName:
  Description: IAM profile to associate with master nodes.
  Type: String
MasterInstanceType:
  Default: m5.xlarge
  Type: String
AutoRegisterELB:
  Default: "yes"
  AllowedValues:
    - "yes"
    - "no"
  Description: Do you want to invoke NLB registration, which requires a Lambda ARN parameter?
  Type: String
RegisterNlbIpTargetsLambdaArn:
  Description: ARN for NLB IP target registration lambda. Supply the value from the cluster
  infrastructure or select "no" for AutoRegisterELB.
  Type: String
ExternalApiTargetGroupArn:
  Description: ARN for external API load balancer target group. Supply the value from the cluster
  infrastructure or select "no" for AutoRegisterELB.
  Type: String
InternalApiTargetGroupArn:
  Description: ARN for internal API load balancer target group. Supply the value from the cluster
  infrastructure or select "no" for AutoRegisterELB.
  Type: String
InternalServiceTargetGroupArn:
  Description: ARN for internal service load balancer target group. Supply the value from the
  cluster infrastructure or select "no" for AutoRegisterELB.
  Type: String

Metadata:
AWS::CloudFormation::Interface:
  ParameterGroups:
  - Label:
      default: "Cluster Information"
    Parameters:
    - InfrastructureName
  - Label:
      default: "Host Information"
    Parameters:
    - MasterInstanceType
    - RhcosAmi
    - IgnitionLocation
    - CertificateAuthorities
    - MasterSecurityGroupId
    - MasterInstanceProfileName
  - Label:
      default: "Network Configuration"
    Parameters:
    - VpcId
    - AllowedBootstrapSshCidr
    - Master0Subnet
    - Master1Subnet
    - Master2Subnet
  - Label:
      default: "Load Balancer Automation"
    Parameters:
    - AutoRegisterELB
    - RegisterNlbIpTargetsLambdaArn
    - ExternalApiTargetGroupArn
    - InternalApiTargetGroupArn
    - InternalServiceTargetGroupArn

ParameterLabels:
  - InfrastructureName:
      default: "Infrastructure Name"
  - VpcId:
      default: "VPC ID"
  - Master0Subnet:
      default: "Master-0 Subnet"
  - Master1Subnet:
      default: "Master-1 Subnet"
  - Master2Subnet:
      default: "Master-2 Subnet"
  - MasterInstanceType:
      default: "Master Instance Type"
  - MasterInstanceProfileName:
      default: "Master Instance Profile Name"
  - RhcosAmi:
      default: "Red Hat Enterprise Linux CoreOS AMI ID"
  - BootstrapIgnitionLocation:
      default: "Master Ignition Source"
  - CertificateAuthorities:
      default: "Ignition CA String"
  - MasterSecurityGroupId:
      default: "Master Security Group ID"
  - AutoRegisterELB:

    TargetIp: !GetAtt Master2.PrivateIp

Outputs:
PrivateIPs:
  Description: The control-plane node private IP addresses.
  Value:

660
Additional resources

- You can view details about the CloudFormation stacks that you create by navigating to the AWS CloudFormation console.

6.12.17. Creating the worker nodes in AWS

You can create worker nodes in Amazon Web Services (AWS) for your cluster to use.

NOTE

If you are installing a three-node cluster, skip this step. A three-node cluster consists of three control plane machines, which also act as compute machines.

You can use the provided CloudFormation template and a custom parameter file to create a stack of AWS resources that represent a worker node.

IMPORTANT

The CloudFormation template creates a stack that represents one worker node. You must create a stack for each worker node.

NOTE

If you do not use the provided CloudFormation template to create your worker nodes, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

Prerequisites

- You configured an AWS account.
- You added your AWS keys and region to your local AWS profile by running `aws configure`.
- You generated the Ignition config files for your cluster.
- You created and configured a VPC and associated subnets in AWS.
- You created and configured DNS, load balancers, and listeners in AWS.
- You created the security groups and roles required for your cluster in AWS.
- You created the bootstrap machine.
- You created the control plane machines.
Procedure

1. Create a JSON file that contains the parameter values that the CloudFormation template requires:

```json
[
  {
    "ParameterKey": "InfrastructureName",  
    "ParameterValue": "mycluster-<random_string>"  
  },
  {
    "ParameterKey": "RhcosAmi",  
    "ParameterValue": "ami-<random_string>"  
  },
  {
    "ParameterKey": "Subnet",  
    "ParameterValue": "subnet-<random_string>"  
  },
  {
    "ParameterKey": "WorkerSecurityGroupId",  
    "ParameterValue": "sg-<random_string>"  
  },
  {
    "ParameterKey": "IgnitionLocation",  
    "ParameterValue": "https://api-int.<cluster_name>.<domain_name>:22623/config/worker"  
  },
  {
    "ParameterKey": "CertificateAuthorities",  
    "ParameterValue": ""  
  },
  {
    "ParameterKey": "WorkerInstanceProfileName",  
    "ParameterValue": ""  
  },
  {
    "ParameterKey": "WorkerInstanceType",  
    "ParameterValue": ""  
  }
]
```

1. The name for your cluster infrastructure that is encoded in your Ignition config files for the cluster.
2. Specify the infrastructure name that you extracted from the Ignition config file metadata, which has the format `<cluster-name>-<random-string>`.
3. Current Red Hat Enterprise Linux CoreOS (RHCOS) AMI to use for the worker nodes based on your selected architecture.
4. Specify an `AWS::EC2::Image::Id` value.
5. A subnet, preferably private, to start the worker nodes on.
6. Specify a subnet from the **PrivateSubnets** value from the output of the CloudFormation template for DNS and load balancing.

7. The worker security group ID to associate with worker nodes.

8. Specify the **WorkerSecurityGroupId** value from the output of the CloudFormation template for the security group and roles.

9. The location to fetch the bootstrap Ignition config file from.

10. Specify the generated Ignition config location, **https://api-int.<cluster_name>.<domain_name>:22623/config/worker**.

11. Base64 encoded certificate authority string to use.

12. Specify the value from the **worker.ign** file that is in the installation directory. This value is the long string with the format **data:text/plain;charset=utf-8;base64,ABC…xYz==**.

13. The IAM profile to associate with worker nodes.

14. Specify the **WorkerInstanceProfile** parameter value from the output of the CloudFormation template for the security group and roles.

15. The type of AWS instance to use for the compute machines based on your selected architecture.

16. The instance type value corresponds to the minimum resource requirements for compute machines. For example **m6i.large** is a type for AMD64 and **m6g.large** is a type for ARM64.

2. Copy the template from the **CloudFormation template for worker machines** section of this topic and save it as a YAML file on your computer. This template describes the networking objects and load balancers that your cluster requires.

3. Optional: If you specified an **m5** instance type as the value for **WorkerInstanceType**, add that instance type to the **WorkerInstanceType.AllowedValues** parameter in the CloudFormation template.

4. Optional: If you are deploying with an AWS Marketplace image, update the **Worker0.type.properties.ImageID** parameter with the AMI ID that you obtained from your subscription.

5. Use the CloudFormation template to create a stack of AWS resources that represent a worker node:

   **IMPORTANT**

   You must enter the command on a single line.

   ```
   $ aws cloudformation create-stack --stack-name <name> 1
   --template-body file:///<template>.yaml \ 2
   --parameters file:///<parameters>.json 3
   ```

   1. `<name>` is the name for the CloudFormation stack, such as **cluster-worker-1**. You need the name of this stack if you remove the cluster.
2. `<template>` is the relative path to and name of the CloudFormation template YAML file that you saved.

3. `<parameters>` is the relative path to and name of the CloudFormation parameters JSON file.

Example output

```
```

**NOTE**

The CloudFormation template creates a stack that represents one worker node.

6. Confirm that the template components exist:

```
$ aws cloudformation describe-stacks --stack-name <name>
```

7. Continue to create worker stacks until you have created enough worker machines for your cluster. You can create additional worker stacks by referencing the same template and parameter files and specifying a different stack name.

**IMPORTANT**

You must create at least two worker machines, so you must create at least two stacks that use this CloudFormation template.

6.12.17.1. CloudFormation template for worker machines

You can use the following CloudFormation template to deploy the worker machines that you need for your OpenShift Container Platform cluster.

Example 6.68. CloudFormation template for worker machines

```
AWSTemplateFormatVersion: 2010-09-09
Description: Template for OpenShift Cluster Node Launch (EC2 worker instance)

Parameters:
InfrastructureName:
  AllowedPattern: ^([a-zA-Z][a-zA-Z0-9-]{0,26})$
  MaxLength: 27
  MinLength: 1
  ConstraintDescription: Infrastructure name must be alphanumeric, start with a letter, and have a maximum of 27 characters.
  Description: A short, unique cluster ID used to tag nodes for the kubelet cloud provider.
  Type: String
RhcosAmi:
  Description: Current Red Hat Enterprise Linux CoreOS AMI to use for bootstrap.
  Type: AWS::EC2::Image::Id
Subnet:
  Description: The subnets, recommend private, to launch the master nodes into.
```

```
Type: AWS::EC2::Subnet::Id
WorkerSecurityGroupId:
  Description: The master security group ID to associate with master nodes.
  Type: AWS::EC2::SecurityGroup::Id
IgnitionLocation:
  Default: https://api-int.$CLUSTER_NAME.$DOMAIN:22623/config/worker
  Description: Ignition config file location.
  Type: String
CertificateAuthorities:
  Default: data:text/plain;charset=utf-8;base64,ABC...xYz==
  Description: Base64 encoded certificate authority string to use.
  Type: String
WorkerInstanceProfileName:
  Description: IAM profile to associate with master nodes.
  Type: String
WorkerInstanceType:
  Default: m5.large
  Type: String

Metadata:
AWS::CloudFormation::Interface:
  ParameterGroups:
    - Label:
      default: "Cluster Information"
      Parameters:
        - InfrastructureName
    - Label:
      default: "Host Information"
      Parameters:
        - WorkerInstanceType
        - RhcosAmi
        - IgnitionLocation
        - CertificateAuthorities
        - WorkerSecurityGroupId
        - WorkerInstanceProfileName
    - Label:
      default: "Network Configuration"
      Parameters:
        - Subnet
  ParameterLabels:
    Subnet:
      default: "Subnet"
    InfrastructureName:
      default: "Infrastructure Name"
    WorkerInstanceType:
      default: "Worker Instance Type"
    WorkerInstanceProfileName:
      default: "Worker Instance Profile Name"
    RhcosAmi:
      default: "Red Hat Enterprise Linux CoreOS AMI ID"
    IgnitionLocation:
      default: "Worker Ignition Source"
    CertificateAuthorities:
      default: "Ignition CA String"
    WorkerSecurityGroupId:
      default: "Worker Security Group ID"
6.12.18. Initializing the bootstrap sequence on AWS with user-provisioned infrastructure

After you create all of the required infrastructure in Amazon Web Services (AWS), you can start the bootstrap sequence that initializes the OpenShift Container Platform control plane.

Prerequisites

- You configured an AWS account.
- You added your AWS keys and region to your local AWS profile by running `aws configure`.
- You generated the Ignition config files for your cluster.
You created and configured a VPC and associated subnets in AWS.

You created and configured DNS, load balancers, and listeners in AWS.

You created the security groups and roles required for your cluster in AWS.

You created the bootstrap machine.

You created the control plane machines.

You created the worker nodes.

**Procedure**

1. Change to the directory that contains the installation program and start the bootstrap process that initializes the OpenShift Container Platform control plane:

   ```bash
   $ ./openshift-install wait-for bootstrap-complete --dir <installation_directory> \  
   --log-level=info
   ```

   1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

**Example output**

```bash
INFO Waiting up to 20m0s for the Kubernetes API at https://api.mycluster.example.com:6443...
INFO API v1.27.3 up
INFO Waiting up to 30m0s for bootstrapping to complete...
INFO It is now safe to remove the bootstrap resources
INFO Time elapsed: 1s
```

If the command exits without a **FATAL** warning, your OpenShift Container Platform control plane has initialized.

**NOTE**

After the control plane initializes, it sets up the compute nodes and installs additional services in the form of Operators.

**Additional resources**

- See [Monitoring installation progress](#) for details about monitoring the installation, bootstrap, and control plane logs as an OpenShift Container Platform installation progresses.

- See [Gathering bootstrap node diagnostic data](#) for information about troubleshooting issues related to the bootstrap process.

- You can view details about the running instances that are created by using the [AWS EC2 console](#).
6.12.19. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of oc.

**Installing the OpenShift CLI on Linux**

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

**Procedure**

2. Select the architecture from the Product Variant drop-down list.
3. Select the appropriate version from the Version drop-down list.
4. Click Download Now next to the OpenShift v4.14 Linux Client entry and save the file.
5. Unpack the archive:
   
   ```
   $ tar xvf <file>
   ```
6. Place the oc binary in a directory that is on your PATH.
   To check your PATH, execute the following command:

   ```
   $ echo $PATH
   ```

**Verification**

- After you install the OpenShift CLI, it is available using the oc command:

   ```
   $ oc <command>
   ```

**Installing the OpenShift CLI on Windows**

You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version from the Version drop-down list.
3. Click Download Now next to the OpenShift v4.14 Windows Client entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the oc binary to a directory that is on your PATH.
To check your `PATH`, open the command prompt and execute the following command:

```
C:\> path
```

**Verification**

- After you install the OpenShift CLI, it is available using the `oc` command:

```
C:\> oc <command>
```

### Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (`oc`) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version from the **Version** drop-down list.

3. Click **Download Now** next to the **OpenShift v4.14 macOS Client** entry and save the file.

   **NOTE**

   For macOS arm64, choose the **OpenShift v4.14 macOS arm64 Client** entry.

4. Unpack and unzip the archive.

5. Move the `oc` binary to a directory on your `PATH`.

   To check your `PATH`, open a terminal and execute the following command:

   ```
   $ echo $PATH
   ```

**Verification**

- After you install the OpenShift CLI, it is available using the `oc` command:

```
$ oc <command>
```

### 6.12.20. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.

- You installed the `oc` CLI.
Procedure

1. Export the **kubeadmin** credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   system:admin
   ```

**Example output**

### 6.12.21. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

**Prerequisites**

- You added machines to your cluster.

**Procedure**

1. Confirm that the cluster recognizes the machines:

   ```bash
   $ oc get nodes
   ```

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>64m</td>
<td>v1.27.3</td>
</tr>
</tbody>
</table>

   The output lists all of the machines that you created.

   **NOTE**

   The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

   ```bash
   $ oc get csr
   ```
Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-8b2br</td>
<td>15m</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-8vnps</td>
<td>15m</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Pending</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in Pending status, approve the CSRs for your cluster machines:

NOTE

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the machine-approver if the Kubelet requests a new certificate with identical parameters.

NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the oc exec, oc rsh, and oc logs commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the node-bootstrapper service account in the system:node or system:admin groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

```bash
$ oc adm certificate approve <csr_name> 1
```

1. `<csr_name>` is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```bash
$ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs --no-run-if-empty oc adm certificate approve
```
Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

   $ oc get csr

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-c57lv</td>
<td>5m26s</td>
<td>system:node:ip-10-0-95-157.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

   - To approve them individually, run the following command for each valid CSR:

     ```shell
     $ oc adm certificate approve <csr_name>
     
     `<csr_name>` is the name of a CSR from the list of current CSRs.
     ```

   - To approve all pending CSRs, run the following command:

     ```shell
     $ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs oc adm certificate approve
     
     ```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

   $ oc get nodes

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>74m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>worker-0</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>worker-1</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.27.3</td>
</tr>
</tbody>
</table>

   **NOTE**

   It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.
Additional information

- For more information on CSRs, see Certificate Signing Requests.

6.12.22. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

Prerequisites

- Your control plane has initialized.

Procedure

1. Watch the cluster components come online:

```
$ watch -n5 oc get clusteroperators
```

Example output

<table>
<thead>
<tr>
<th>NAME</th>

2. Configure the Operators that are not available.

6.12.22.1. Image registry storage configuration

Amazon Web Services provides default storage, which means the Image Registry Operator is available after installation. However, if the Registry Operator cannot create an S3 bucket and automatically configure storage, you must manually configure registry storage.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the `Recreate` rollout strategy during upgrades.

You can configure registry storage for user-provisioned infrastructure in AWS to deploy OpenShift Container Platform to hidden regions. See Configuring the registry for AWS user-provisioned infrastructure for more information.

6.12.22.1.1. Configuring registry storage for AWS with user-provisioned infrastructure

During installation, your cloud credentials are sufficient to create an Amazon S3 bucket and the Registry Operator will automatically configure storage.

If the Registry Operator cannot create an S3 bucket and automatically configure storage, you can create an S3 bucket and configure storage with the following procedure.

Prerequisites

- You have a cluster on AWS with user-provisioned infrastructure.
- For Amazon S3 storage, the secret is expected to contain two keys:
  - `REGISTRY_STORAGE_S3_ACCESSKEY`
  - `REGISTRY_STORAGE_S3_SECRETKEY`

Procedure

Use the following procedure if the Registry Operator cannot create an S3 bucket and automatically configure storage.

1. Set up a Bucket Lifecycle Policy to abort incomplete multipart uploads that are one day old.

2. Fill in the storage configuration in `configs.imageregistry.operator.openshift.io/cluster`:

   ```bash
   $ oc edit configs.imageregistry.operator.openshift.io/cluster
   
   Example configuration
   ```

   ```yaml
   storage:
   s3:
     bucket: <bucket-name>
     region: <region-name>
   ```
To secure your registry images in AWS, block public access to the S3 bucket.

6.12.22.1.2. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

Procedure

- To set the image registry storage to an empty directory:

  $ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec": {"storage": {"emptyDir": {}}}}'

  **WARNING**
  Configure this option for only non-production clusters.

If you run this command before the Image Registry Operator initializes its components, the `oc patch` command fails with the following error:

  Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found

  Wait a few minutes and run the command again.

6.12.23. Deleting the bootstrap resources

After you complete the initial Operator configuration for the cluster, remove the bootstrap resources from Amazon Web Services (AWS).

Prerequisites

- You completed the initial Operator configuration for your cluster.

Procedure

1. Delete the bootstrap resources. If you used the CloudFormation template, delete its stack:

   $ aws cloudformation delete-stack --stack-name <name>

   ![1]
<name> is the name of your bootstrap stack.

- Delete the stack by using the AWS CloudFormation console.

If you removed the DNS Zone configuration, manually create DNS records that point to the Ingress load balancer. You can create either a wildcard record or specific records. While the following procedure uses A records, you can use other record types that you require, such as CNAME or alias.

Prerequisites

- You deployed an OpenShift Container Platform cluster on Amazon Web Services (AWS) that uses infrastructure that you provisioned.

- You installed the OpenShift CLI (oc).

- You installed the jq package.

- You downloaded the AWS CLI and installed it on your computer. See Install the AWS CLI Using the Bundled Installer (Linux, macOS, or Unix).

Procedure

1. Determine the routes to create.

   - To create a wildcard record, use *.apps.<cluster_name>.<domain_name>, where <cluster_name> is your cluster name, and <domain_name> is the Route 53 base domain for your OpenShift Container Platform cluster.

   - To create specific records, you must create a record for each route that your cluster uses, as shown in the output of the following command:

     ```
     $ oc get --all-namespaces -o jsonpath='{range .items[*]}{range .status.ingress[*]}{.host}
     {
     "\"n\"}{end}{end}' routes
     ``

     Example output

     ```
     oauth-openshift.apps.<cluster_name>.<domain_name>
     console-openshift-console.apps.<cluster_name>.<domain_name>
     downloads-openshift-console.apps.<cluster_name>.<domain_name>
     alertmanager-main-openshift-monitoring.apps.<cluster_name>.<domain_name>
     prometheus-k8s-openshift-monitoring.apps.<cluster_name>.<domain_name>
     ```

2. Retrieve the Ingress Operator load balancer status and note the value of the external IP address that it uses, which is shown in the EXTERNAL-IP column:

   ```
   $ oc -n openshift-ingress get service router-default
   ```

   Example output

   ```
   NAME TYPE CLUSTER-IP EXTERNAL-IP PORT(S)
   AGE
   ```
3. Locate the hosted zone ID for the load balancer:

```bash
$ aws elb describe-load-balancers | jq -r '.LoadBalancerDescriptions[] | select(.DNSName == "<external_ip>").CanonicalHostedZoneNameID'
```

For `<external_ip>`, specify the value of the external IP address of the Ingress Operator load balancer that you obtained.

**Example output**

```
Z3AADJGX6KTTL2
```

The output of this command is the load balancer hosted zone ID.

4. Obtain the public hosted zone ID for your cluster’s domain:

```bash
$ aws route53 list-hosted-zones-by-name \
  --dns-name "<domain_name>" \
  --query 'HostedZones[? Config.PrivateZone != `true` && Name == `<domain_name>.`].Id' \
  --output text
```

For `<domain_name>`, specify the Route 53 base domain for your OpenShift Container Platform cluster.

**Example output**

```
/hostedzone/Z3URY6TWQ91KVV
```

The public hosted zone ID for your domain is shown in the command output. In this example, it is `Z3URY6TWQ91KVV`.

5. Add the alias records to your private zone:

```bash
$ aws route53 change-resource-record-sets --hosted-zone-id "<private_hosted_zone_id>" --change-batch '{
  "Changes": [
    {
      "Action": "CREATE",
      "ResourceRecordSet": {
        "Name": "\052.apps.<cluster_domain>",
        "Type": "A",
        "AliasTarget": {
          "HostedZoneId": "<hosted_zone_id>",
          "DNSName": "<external_ip>",
          "EvaluateTargetHealth": false
        }
      }
    }
  ]
}
```

CHAPTER 6. INSTALLING ON AWS

677
For `<private_hosted_zone_id>`, specify the value from the output of the CloudFormation template for DNS and load balancing.

For `<cluster_domain>`, specify the domain or subdomain that you use with your OpenShift Container Platform cluster.

For `<hosted_zone_id>`, specify the public hosted zone ID for the load balancer that you obtained.

For `<external_ip>`, specify the value of the external IP address of the Ingress Operator load balancer. Ensure that you include the trailing period (.) in this parameter value.

6. Add the records to your public zone:

```bash
$ aws route53 change-resource-record-sets --hosted-zone-id "<public_hosted_zone_id>" --change-batch '{
  "Changes": [
    {
      "Action": "CREATE",
      "ResourceRecordSet": {
        "Name": "\052.apps.<cluster_domain>",
        "Type": "A",
        "AliasTarget": {
          "HostedZoneId": "<hosted_zone_id>",
          "DNSName": "<external_ip>",
          "EvaluateTargetHealth": false
        }
      }
    }
  ]
}'
```

For `<public_hosted_zone_id>`, specify the public hosted zone for your domain.

For `<cluster_domain>`, specify the domain or subdomain that you use with your OpenShift Container Platform cluster.

For `<hosted_zone_id>`, specify the public hosted zone ID for the load balancer that you obtained.

For `<external_ip>`, specify the value of the external IP address of the Ingress Operator load balancer. Ensure that you include the trailing period (.) in this parameter value.

6.12.25. Completing an AWS installation on user-provisioned infrastructure

After you start the OpenShift Container Platform installation on Amazon Web Service (AWS) user-provisioned infrastructure, monitor the deployment to completion.

**Prerequisites**
You removed the bootstrap node for an OpenShift Container Platform cluster on user-provisioned AWS infrastructure.

You installed the oc CLI.

Procedure

- From the directory that contains the installation program, complete the cluster installation:

```bash
$ ./openshift-install --dir <installation_directory> wait-for install-complete
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

Example output

```
INFO Waiting up to 40m0s for the cluster at https://api.mycluster.example.com:6443 to initialize...
INFO Waiting up to 10m0s for the openshift-console route to be created...
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 1s
```

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

6.12.26. Logging in to the cluster by using the web console

The kubeadmin user exists by default after an OpenShift Container Platform installation. You can log in to your cluster as the kubeadmin user by using the OpenShift Container Platform web console.

**Prerequisites**

- You have access to the installation host.
You completed a cluster installation and all cluster Operators are available.

Procedure

1. Obtain the password for the kubeadmin user from the kubeadmin-password file on the installation host:

   ```bash
   $ cat <installation_directory>/auth/kubeadmin-password
   ``

   **NOTE**
   Alternatively, you can obtain the kubeadmin password from the <installation_directory>/openshift_install.log log file on the installation host.

2. List the OpenShift Container Platform web console route:

   ```bash
   $ oc get routes -n openshift-console | grep 'console-openshift'
   ``

   **NOTE**
   Alternatively, you can obtain the OpenShift Container Platform route from the <installation_directory>/openshift_install.log log file on the installation host.

   **Example output**
   
   ```text
   console  console-openshift-console.apps.<cluster_name>.<base_domain>  console
   https  reencrypt/Redirect  None
   ```

3. Navigate to the route detailed in the output of the preceding command in a web browser and log in as the kubeadmin user.

Additional resources

- See Accessing the web console for more details about accessing and understanding the OpenShift Container Platform web console.

6.12.27. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager Hybrid Cloud Console.

After you confirm that your OpenShift Cluster Manager Hybrid Cloud Console inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service.
6.12.28. Additional resources

- See Working with stacks in the AWS documentation for more information about AWS CloudFormation stacks.

6.12.29. Next steps

- Validating an installation.
- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- If necessary, you can remove cloud provider credentials.

6.13. INSTALLING A CLUSTER ON AWS WITH WORKER NODES ON AWS LOCAL ZONES

You can quickly install an OpenShift Container Platform cluster in Amazon Web Services (AWS) Local Zones by setting the zone names in the edge compute pool of the `install-config.yaml` file, or install a cluster in an existing VPC that lists Local Zone subnets.

AWS Local Zones are a type of infrastructure that place Cloud Resources close to metropolitan regions. For more information, see the AWS Local Zones Documentation.

IMPORTANT

The steps for performing an installer-provisioned infrastructure installation are provided for example purposes only. Installing a cluster in an existing VPC requires that you have knowledge of the cloud provider and the installation process of OpenShift Container Platform. You can use a CloudFormation template to assist you with completing these steps or to help model your own cluster installation. Instead of using the CloudFormation template to create resources, you can decide to use other methods for generating these resources.

6.13.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You configured an AWS account to host the cluster.

IMPORTANT

If you have an AWS profile stored on your computer, it must not use a temporary session token that you generated while using a multi-factor authentication device. The cluster continues to use your current AWS credentials to create AWS resources for the entire life of the cluster, so you must use key-based, long-term credentials. To generate appropriate keys, see Managing Access Keys for IAM Users in the AWS documentation. You can supply the keys when you run the installation program.
• You noted the region and supported AWS Local Zones locations to create the network resources in.

• You read the Features for each AWS Local Zones location.

• You downloaded the AWS CLI and installed it on your computer. See Install the AWS CLI Using the Bundled Installer (Linux, macOS, or UNIX) in the AWS documentation.

• If you use a firewall, you configured it to allow the sites that your cluster requires access to.

  NOTE

  Be sure to also review this site list if you are configuring a proxy.

• Add permission for the user who creates the cluster to modify the Local Zone group with ec2:ModifyAvailabilityZoneGroup. For example:

  An example of a permissive IAM policy to attach to a user or role

  ```
  {
    "Version": "2012-10-17",
    "Statement": [
      {
        "Action": [
          "ec2:ModifyAvailabilityZoneGroup"
        ],
        "Effect": "Allow",
        "Resource": "*"
      }
    ]
  }
  ```

6.13.2. Cluster limitations in AWS Local Zones

Some limitations exist when you attempt to deploy a cluster with a default installation configuration in Amazon Web Services (AWS) Local Zones.
IMPORTANT

The following list details limitations when deploying a cluster in AWS Local Zones:

- The Maximum Transmission Unit (MTU) between an Amazon EC2 instance in a Local Zone and an Amazon EC2 instance in the Region is 1300. This causes the cluster-wide network MTU to change according to the network plugin that is used on the deployment.

- Network resources such as Network Load Balancer (NLB), Classic Load Balancer, and Network Address Translation (NAT) Gateways are not globally supported in AWS Local Zones.

- For an OpenShift Container Platform cluster on AWS, the AWS Elastic Block Storage (EBS) gp3 type volume is the default for node volumes and the default for the storage class. This volume type is not globally available on Local Zone locations. By default, the nodes running in Local Zones are deployed with the gp2 EBS volume. The gp2-csi StorageClass must be set when creating workloads on Local Zone nodes.

If you want the installation program to automatically create Local Zone subnets for your OpenShift Container Platform cluster, specific configuration limitations apply with this method.

IMPORTANT

The following configuration limitation applies when you set the installation program to automatically create subnets for your OpenShift Container Platform cluster:

- The private subnets for an AWS Local Zone associate with the route table of the parent zone, so that each private subnet can route egress traffic to the internet. If this route table does not exist during cluster installation, the private subnet associates with the first available private route table in the Virtual Private Cloud (VPC). This approach is valid only for AWS Local Zones subnets in an OpenShift Container Platform cluster.

Additional resources

- Storage classes
- Ingress Controller sharding

6.13.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager Hybrid Cloud Console to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- Access Quay.io to obtain the packages that are required to install your cluster.

- Obtain the packages that are required to perform cluster updates.
IMPORTANT

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

6.13.4. Obtaining an AWS Marketplace image

If you are deploying an OpenShift Container Platform cluster using an AWS Marketplace image, you must first subscribe through AWS. Subscribing to the offer provides you with the AMI ID that the installation program uses to deploy worker nodes.

Prerequisites

- You have an AWS account to purchase the offer. This account does not have to be the same account that is used to install the cluster.

Procedure

1. Complete the OpenShift Container Platform subscription from the AWS Marketplace.

2. Record the AMI ID for your specific region. As part of the installation process, you must update the `install-config.yaml` file with this value before deploying the cluster.

Sample `install-config.yaml` file with AWS Marketplace worker nodes

```yaml
apiVersion: v1
baseDomain: example.com
compute:
  - hyperthreading: Enabled
    name: worker
    platform:
      aws:
        amiID: ami-06c4d345f7c207239
        type: m5.4xlarge
        replicas: 3
    metadata:
      name: test-cluster
      platform:
        aws:
          region: us-east-2
    sshKey: ssh-ed25519 AAAA...
pullSecret: '{"auths": ...}'
```

1. The AMI ID from your AWS Marketplace subscription.

2. Your AMI ID is associated with a specific AWS region. When creating the installation configuration file, ensure that you select the same AWS region that you specified when configuring your subscription.
6.13.5. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of oc.

**Installing the OpenShift CLI on Linux**

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

**Procedure**

2. Select the architecture from the Product Variant drop-down list.
3. Select the appropriate version from the Version drop-down list.
4. Click Download Now next to the OpenShift v4.14 Linux Client entry and save the file.
5. Unpack the archive:
   
   ```
   $ tar xvf <file>
   ```
6. Place the oc binary in a directory that is on your PATH.
   
   To check your PATH, execute the following command:
   
   ```
   $ echo $PATH
   ```

**Verification**

- After you install the OpenShift CLI, it is available using the oc command:

  ```
  $ oc <command>
  ```

**Installing the OpenShift CLI on Windows**

You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version from the Version drop-down list.
3. Click Download Now next to the OpenShift v4.14 Windows Client entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the oc binary to a directory that is on your PATH.
To check your PATH, open the command prompt and execute the following command:

C:\> path

Verification

- After you install the OpenShift CLI, it is available using the `oc` command:

C:\> oc <command>

Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.

Procedure

2. Select the appropriate version from the Version drop-down list.

3. Click Download Now next to the OpenShift v4.14 macOS Client entry and save the file.

   **NOTE**
   
   For macOS arm64, choose the OpenShift v4.14 macOS arm64 Client entry.

4. Unpack and unzip the archive.

5. Move the `oc` binary to a directory on your PATH.

   To check your PATH, open a terminal and execute the following command:

   ```
   $ echo $PATH
   ```

Verification

- After you install the OpenShift CLI, it is available using the `oc` command:

   ```
   $ oc <command>
   ```

6.13.6. Preparing for the installation

Before you extend nodes to local zones, you must prepare certain resources for the cluster installation environment.

6.13.6.1. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.
Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

   **IMPORTANT**

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   **IMPORTANT**

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ tar -xvf openshift-install-linux.tar.gz
   ```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

6.13.6.2. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.
IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

NOTE

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N '' -f <path>/<file_name>
   ``

   Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

   **NOTE**
   If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   ```bash
   $ cat <path>/<file_name>.pub
   ``

   For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

   ```bash
   $ cat ~/.ssh/id_ed25519.pub
   ```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

   **NOTE**
   On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

   a. If the **ssh-agent** process is not already running for your local user, start it as a background task:

   ```bash
   $ eval "$(ssh-agent -s)"
   ```
NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the **ssh-agent**:

   ```
   $ ssh-add <path>/<file_name>  # 1
   ``

   1 Specify the path and file name for your SSH private key, such as ~/.ssh/id_ed25519

   **Example output**

   ```
   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
   ```

   **Next steps**

   - When you install OpenShift Container Platform, provide the SSH public key to the installation program.

6.13.6.3. Creating the installation files for AWS

To install OpenShift Container Platform on Amazon Web Services (AWS) using user-provisioned infrastructure, you must generate the files that the installation program needs to deploy your cluster and modify them so that the cluster creates only the machines that it will use. You generate and customize the **install-config.yaml** file, Kubernetes manifests, and Ignition config files. You also have the option to first set up a separate **var** partition during the preparation phases of installation.

6.13.6.4. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

**Table 6.19. Minimum resource requirements**

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS, RHEL 8.6 and later [3]</td>
<td>2</td>
<td>8 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
</tbody>
</table>
1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or hyperthreading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: \((\text{threads per core} \times \text{cores}) \times \text{sockets} = \text{vCPUs}\).

2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.

3. As with all user-provisioned installations, if you choose to use RHEL compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and has been removed in OpenShift Container Platform 4.10 and later.

   If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

6.13.6.5. Tested instance types for AWS

The following Amazon Web Services (AWS) instance types have been tested with OpenShift Container Platform for use with AWS Local Zones.

   **NOTE**

   Use the machine types included in the following charts for your AWS instances. If you use an instance type that is not listed in the chart, ensure that the instance size you use matches the minimum resource requirements that are listed in "Minimum resource requirements for cluster installation".

**Example 6.69. Machine types based on 64-bit x86 architecture for AWS Local Zones**

- c5.*
- c5d.*
- m6i.*
- m5.*
- r5.*
- t3.*

**Additional resources**

- See [AWS Local Zones features](#) in the AWS documentation for more information about AWS Local Zones and the supported instances types and services.

6.13.6.6. Creating the installation configuration file

Generate and customize the installation configuration file that the installation program needs to deploy your cluster.
Prerequisites

- You obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

- You checked that you are deploying your cluster to a region with an accompanying Red Hat Enterprise Linux CoreOS (RHCOS) AMI published by Red Hat. If you are deploying to a region that requires a custom AMI, such as an AWS GovCloud region, you must create the `install-config.yaml` file manually.

Procedure

1. Create the `install-config.yaml` file.
   
   a. Change to the directory that contains the installation program and run the following command:

   ```
   $ ./openshift-install create install-config --dir <installation_directory>
   ```

   **IMPORTANT**

   Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

   b. At the prompts, provide the configuration details for your cloud:

      i. Optional: Select an SSH key to use to access your cluster machines.

      **NOTE**

      For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

      ii. Select `aws` as the platform to target.

      iii. If you do not have an AWS profile stored on your computer, enter the AWS access key ID and secret access key for the user that you configured to run the installation program.
NOTE

The AWS access key ID and secret access key are stored in ~/.aws/credentials in the home directory of the current user on the installation host. You are prompted for the credentials by the installation program if the credentials for the exported profile are not present in the file. Any credentials that you provide to the installation program are stored in the file.

iv. Select the AWS region to deploy the cluster to. The region that you specify must be the same region that contains the Local Zone that you opted in to for your AWS account.

v. Select the base domain for the Route 53 service that you configured for your cluster.

vi. Enter a descriptive name for your cluster.

vii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

2. Optional: Back up the install-config.yaml file.

IMPORTANT

The install-config.yaml file is consumed during the installation process. If you want to reuse the file, you must back it up now.

6.13.6.7. Edge compute pools and AWS Local Zones

Edge worker nodes are tainted worker nodes that run in AWS Local Zones locations.

When deploying a cluster that uses Local Zones, consider the following points:

- Amazon EC2 instances in the Local Zones are more expensive than Amazon EC2 instances in the Availability Zones.

- Latency between applications and end users is lower in Local Zones, and latency might vary by location. A latency impact exists for some workloads if, for example, ingress traffic is mixed between Local Zones and Availability Zones.

IMPORTANT

Generally, the maximum transmission unit (MTU) between an Amazon EC2 instance in a Local Zone and an Amazon EC2 instance in the Region is 1300. For more information, see How Local Zones work in the AWS documentation. The cluster network MTU must be always less than the EC2 MTU to account for the overhead. The specific overhead is determined by the network plugin, for example:

- OVN-Kubernetes: 100 bytes
- OpenShift SDN: 50 bytes

The network plugin can provide additional features, like IPsec, that also must be decreased the MTU. For additional information, see the documentation.

OpenShift Container Platform 4.12 introduced a new compute pool, edge, that is designed for use in remote zones. The edge compute pool configuration is common between AWS Local Zones locations.
Because of the type and size limitations of resources like EC2 and EBS on Local Zone resources, the default instance type can vary from the traditional worker pool.

The default Elastic Block Store (EBS) for Local Zone locations is gp2, which differs from the regular worker pool. The instance type used for each Local Zone on edge compute pool also might differ from worker pools, depending on the instance offerings on the zone.

The edge compute pool creates new labels that developers can use to deploy applications onto AWS Local Zones nodes. The new labels are:

- `node-role.kubernetes.io/edge="`
- `machine.openshift.io/zone-type=local-zone`
- `machine.openshift.io/zone-group=$ZONE_GROUP_NAME`

By default, the machine sets for the edge compute pool defines the taint of `NoSchedule` to prevent regular workloads from spreading on Local Zone instances. Users can only run user workloads if they define tolerations in the pod specification.

The following examples show `install-config.yaml` files that use the edge machine pool.

**Configuration that uses an edge pool with a custom instance type**

```yaml
apiVersion: v1
baseDomain: devcluster.openshift.com
metadata:
  name: ipi-localzone
compute:
  - name: edge
    platform:
      aws:
        type: m5.4xlarge
platform:
  aws:
    region: us-west-2
pullSecret: '{"auths": ...}'
sshKey: ssh-ed25519 AAAA...
```

Instance types differ between locations. To verify availability in the Local Zone in which the cluster runs, see the AWS documentation.

**Configuration that uses an edge pool with a custom EBS type**

```yaml
apiVersion: v1
baseDomain: devcluster.openshift.com
metadata:
  name: ipi-localzone
compute:
  - name: edge
    platform:
      aws:
        rootVolume:
          type: gp3
          size: 120
```

---

CHAPTER 6. INSTALLING ON AWS
EBS types differ between locations. Check the AWS documentation to verify availability in the Local Zone in which the cluster runs.

**Configuration that uses an edge pool with custom security groups**

```yaml
apiVersion: v1
baseDomain: devcluster.openshift.com
metadata:
  name: ipi-localzone
compute:
  - name: edge
    platform:
      aws:
        additionalSecurityGroupIDs:
        - sg-1
        - sg-2
platform:
  aws:
    region: us-west-2
    pullSecret: '{"auths": ...}'
    sshKey: ssh-ed25519 AAAA...
```

1 Specify the name of the security group as it appears in the Amazon EC2 console, including the `sg` prefix.

**Additional resources**

- Changing the MTU for the cluster network
- Enabling IPsec encryption
- Understanding taints and tolerations

**6.13.7. Opting in to AWS Local Zones**

If you plan to create the subnets in AWS Local Zones, you must opt in to each zone group separately.

**Prerequisites**

- You have installed the AWS CLI.
- You have determined an AWS Region for where you want to deploy your OpenShift Container Platform cluster.
- You have attached a permissive IAM policy to a user or role account that opts in to the zone group. Consider the following configuration as an example IAM policy:

```json
{
  "Version": "2012-10-17",
..."...
}
Procedure

1. List the zones that are available in your AWS Region by running the following command:

```bash
$ aws --region "<value_of_AWS_Region>" ec2 describe-availability-zones \
  --query 'AvailabilityZones[].{{ZoneName: ZoneName, GroupName: GroupName, Status: OptInStatus}}' \
  --filters Name=zone-type,Values=local-zone \
  --all-availability-zones
```

Depending on the AWS Region, the list of available zones can be long. The command returns the following fields:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ZoneName</td>
<td>The name of the Local Zone.</td>
</tr>
<tr>
<td>GroupName</td>
<td>The group that comprises the zone. To opt in to the region, save the name.</td>
</tr>
<tr>
<td>Status</td>
<td>The status of the Local Zone group. If the status is not-opted-in, you must opt in the GroupName by running the commands that follow.</td>
</tr>
</tbody>
</table>

2. Opt in to the zone group on your AWS account by running the following command:

```bash
$ aws ec2 modify-availability-zone-group \
  --group-name "<value_of_GroupName>" \
  --opt-in-status opted-in
```

For `<value_of_GroupName>`, specify the name of the group of the Local Zone where you want to create subnets. For example, specify `us-east-1-nyc-1` to use the zone `us-east-1-nyc-1a` (US East New York).

6.13.8. Cluster installation options for an AWS Local Zones environment

To install an OpenShift Container Platform cluster in an AWS Local Zones environment on AWS infrastructure, choose one of the following installation options:

- Installing a cluster to quickly extend workers to edge compute pools, where the installation program automatically creates resources for the OpenShift Container Platform cluster.
- Installing a cluster on AWS into an existing VPC, where you must add Local Zone subnets to the `install-config.yaml` file.
Next steps

Choose one of the following options to install an OpenShift Container Platform cluster in an AWS Local Zones environment:

- Installing a cluster quickly in AWS Local Zones
- Installing a cluster in an existing VPC with defined Local Zone subnets

6.13.9. Install a cluster quickly in AWS Local Zones

For OpenShift Container Platform 4.14, you can quickly install a cluster on Amazon Web Services (AWS) to extend compute nodes to Local Zone locations. By using this installation route, the installation program automatically creates network resources and Local Zone subnets for each Local Zone that you defined in your configuration file. To customize the installation, you must modify parameters in the `install-config.yaml` file before you deploy the cluster.

6.13.9.1. Modifying an installation configuration file to use AWS Local Zones

Modify an `install-config.yaml` file to include AWS Local Zones.

Prerequisites

- You have configured an AWS account.
- You added your AWS keys and region to your local AWS profile by running `aws configure`.
- You have read the configuration limitations that apply when you specify the installation program to automatically create subnets for your OpenShift Container Platform cluster. See the section named "Cluster limitations in AWS Local Zones".
- You opted in to the Local Zone group for each zone.
- You created an `install-config.yaml` file by using the procedure "Creating the installation configuration file".

Procedure

1. Modify the `install-config.yaml` file by specifying Local Zone names in the `platform.aws.zones` property of the edge compute pool. For example:

```
...
platform:
  aws:
    region: <region_name> ¹
  compute:
    - name: edge
      platform:
        aws:
          zones: ²
            - <local_zone_name>
  #...
```

¹ The AWS Region name.

² The Local Zone names.
The list of Local Zone names that must belong in the same AWS Region.

Example of a configuration to install a cluster in the us-west-2 AWS Region that extends edge nodes to Local Zones in Los Angeles and Las Vegas locations.

```
apiVersion: v1
baseDomain: example.com
metadata:
  name: cluster-name
platform:
  aws:
    region: us-west-2
compute:
  name: edge
platform:
  aws:
    zones:
    - us-west-2-lax-1a
    - us-west-2-lax-1b
    - us-west-2-las-1a
pullSecret: '{"auths": ...}"
sshKey: 'ssh-ed25519 AAAAA...'
```

2. Deploy your cluster.

Additional resources

- Creating the installation configuration file
- Cluster limitations in AWS Local Zones

Next steps

- Deploying the cluster

6.13.10. Installing a cluster in an existing VPC that has Local Zone subnets

You can install a cluster into an existing Amazon Virtual Private Cloud (VPC) on Amazon Web Services (AWS). The installation program provisions the rest of the required infrastructure, which you can further customize. To customize the installation, modify parameters in the `install-config.yaml` file before you install the cluster.

Installing a cluster on AWS into an existing VPC requires extending workers to the edge of the Cloud Infrastructure by using AWS Local Zones.

Local Zone subnets extend regular workers' nodes to edge networks. Each edge worker node runs a user workload. After you create an Amazon Web Service (AWS) Local Zone environment, and you deploy your cluster, you can use edge worker nodes to create user workloads in Local Zone subnets.

You can use a provided CloudFormation template to create the VPC and public subnets. Additionally, you can modify a template to customize your infrastructure or use the information that they contain to create AWS objects according to your company's policies.
NOTE
If you want to create private subnets, you must either modify the provided CloudFormation template or create your own template.

6.13.10.1. Creating a VPC in AWS

You can create a Virtual Private Cloud (VPC), and subnets for each Local Zone location, in Amazon Web Services (AWS) for your OpenShift Container Platform cluster to extend worker nodes to the edge locations. You can further customize the VPC to meet your requirements, including VPN, route tables, and add new Local Zone subnets that are not included at initial deployment.

You can use the provided CloudFormation template and a custom parameter file to create a stack of AWS resources that represent the VPC.

NOTE
If you do not use the provided CloudFormation template to create your AWS infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

Prerequisites

- You configured an AWS account.
- You added your AWS keys and region to your local AWS profile by running `aws configure`.
- You opted in to the AWS Local Zones on your AWS account.

Procedure

1. Create a JSON file that contains the parameter values that the template requires:

```json
[
  {
    "ParameterKey": "VpcCidr", 1
    "ParameterValue": "10.0.0.0/16" 2
  },
  {
    "ParameterKey": "AvailabilityZoneCount", 3
    "ParameterValue": "3" 4
  },
  {
    "ParameterKey": "SubnetBits", 5
    "ParameterValue": "12" 6
  }
]
```

1. The CIDR block for the VPC.
2. Specify a CIDR block in the format `x.x.x.x/16-24`.
3. The number of availability zones to deploy the VPC in.
4. Specify an integer between 1 and 3.

5. The size of each subnet in each availability zone.

6. Specify an integer between 5 and 13, where 5 is \(27\) and 13 is \(19\).

2. Copy the template from the CloudFormation template for the VPC section of this topic and save it as a YAML file on your computer. This template describes the VPC that your cluster requires.

3. Launch the CloudFormation template to create a stack of AWS resources that represent the VPC by running the following command:

   **IMPORTANT**

   You must enter the command on a single line.

   ```
   $ aws cloudformation create-stack --stack-name <name> \
   --template-body file://<template>.yaml \
   --parameters file://<parameters>.json
   ```

   - `<name>` is the name for the CloudFormation stack, such as `cluster-vpc`. You need the name of this stack if you remove the cluster.
   - `<template>` is the relative path to and name of the CloudFormation template YAML file that you saved.
   - `<parameters>` is the relative path to and name of the CloudFormation parameters JSON file.

   Example output

   ```
   arn:aws:cloudformation:us-east-1:123456789012:stack/cluster-vpc/dbedae40-2fd3-11eb-820e-12a48460849f
   ```

4. Confirm that the template components exist by running the following command:

   ```
   $ aws cloudformation describe-stacks --stack-name <name>
   ```

   After the StackStatus displays `CREATE_COMPLETE`, the output displays values for the following parameters. You must provide these parameter values to the other CloudFormation templates that you run to create your cluster:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VpcId</td>
<td>The ID of your VPC.</td>
</tr>
<tr>
<td>PublicSubnetIds</td>
<td>The IDs of the new public subnets.</td>
</tr>
<tr>
<td>PrivateSubnetIds</td>
<td>The IDs of the new private subnets.</td>
</tr>
</tbody>
</table>
6.13.10.2. Creating a subnet in AWS Local Zones

You must create a subnet in AWS Local Zones before you configure a worker machineset for your OpenShift Container Platform cluster.

You must repeat the following process for each Local Zone you want to deploy worker nodes to.

You can use the provided CloudFormation template and a custom parameter file to create a stack of AWS resources that represent the subnet.

**NOTE**

If you do not use the provided CloudFormation template to create your AWS infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

**Prerequisites**

- You configured an AWS account.
- You added your AWS keys and region to your local AWS profile by running `aws configure`.
- You opted in to the Local Zone group.

**Procedure**

1. Create a JSON file that contains the parameter values that the template requires:

```json
[
  {
    "ParameterKey": "VpcId",
    "ParameterValue": "<value_of_VpcId>" ①
  },
  {
    "ParameterKey": "PublicRouteTableId",
    "ParameterValue": "<value_of_PublicRouteTableId>" ②
  },
  {
    "ParameterKey": "ZoneName",
    "ParameterValue": "<value_of_ZoneName>" ③
  },
  {
    "ParameterKey": "SubnetName",
    "ParameterValue": "<value_of_SubnetName>"
  },
  {
    "ParameterKey": "PublicSubnetCidr",
    "ParameterValue": "<value_of_PublicSubnetCidr>"
  }
]`
Specify the VPC ID, which is the value `VpcID` in the output of the CloudFormation template for the VPC.

Specify the Route Table ID, which is the value of the `PublicRouteTableId` in the CloudFormation stack for the VPC.

Specify the AWS Local Zone name, which is the value of the `ZoneName` field in the `AvailabilityZones` object that you retrieve in the section "Opting in to AWS Local Zones".

Specify a CIDR block that is used to create the Local Zone subnet. This block must be part of the VPC CIDR block `VpcCidr`.

2. Copy the template from the CloudFormation template for the subnet section of this topic and save it as a YAML file on your computer. This template describes the VPC that your cluster requires.

3. Launch the CloudFormation template to create a stack of AWS resources that represent the VPC by running the following command:

   ```
   IMPORTANT
   You must enter the command on a single line.
   
   $ aws cloudformation create-stack --stack-name <subnet_stack_name> \\
   --template-body file://<template>.yaml \\
   --parameters file://<parameters>.json
   ```

   - `<subnet_stack_name>` is the name for the CloudFormation stack, such as `cluster-lz-<local_zone_shortname>`. You need the name of this stack if you remove the cluster.
   - `<template>` is the relative path to and name of the CloudFormation template YAML file that you saved.
   - `<parameters>` is the relative path to and name of the CloudFormation parameters JSON file.

4. Confirm that the template components exist by running the following command:

   ```
   $ aws cloudformation describe-stacks --stack-name <subnet_stack_name>
   ```

   After the StackStatus displays CREATE_COMPLETE, the output displays values for the following parameters. You must provide these parameter values to the other CloudFormation templates that you run to create your cluster:
The IDs of the new public subnets.

6.13.10.3. CloudFormation template for the VPC

You can use the following CloudFormation template to deploy the VPC that you need for your OpenShift Container Platform cluster.

Example 6.70. CloudFormation template for the VPC

```yaml
AWSTemplateFormatVersion: 2010-09-09
Description: Template for Best Practice VPC with 1-3 AZs

Parameters:
  VpcCidr:
    AllowedPattern: ^((\[0-9]\[1-9]\[0-9]\[1-9]\[0-9]\[2][0-4]\[0-9]\[25]]\[0-5]\[\.]\[3]((0-9]\[1-9]\[0-9]\[1-9]\[0-9]\[2][0-4]\[0-9]\[25]]\[0-5]\[\]((16-9]\[20-4]))$)
    ConstraintDescription: CIDR block parameter must be in the form x.x.x.x/16-24.
    Default: 10.0.0.0/16
    Description: CIDR block for VPC.
    Type: String
  AvailabilityZoneCount:
    ConstraintDescription: "The number of availability zones. (Min: 1, Max: 3)"
    MinValue: 1
    MaxValue: 3
    Default: 1
    Description: "How many AZs to create VPC subnets for. (Min: 1, Max: 3)"
    Type: Number
  SubnetBits:
    ConstraintDescription: CIDR block parameter must be in the form x.x.x.x/19-27.
    MinValue: 5
    MaxValue: 13
    Default: 12
    Description: "Size of each subnet to create within the availability zones. (Min: 5 = /27, Max: 13 = /19)"
    Type: Number

Metadata:
AWS::CloudFormation::Interface:
  ParameterGroups:
    - Label: default:
        "Network Configuration"
      Parameters:
        - VpcCidr
        - SubnetBits
      - Label:
          default: "Availability Zones"
        Parameters:
          - AvailabilityZoneCount
      ParameterLabels:
        AvailabilityZoneCount:
          default: "Availability Zone Count"
        VpcCidr:
          default: "VPC CIDR"
```

    - - com.amazonaws.
6.13.10.4. AWS security groups

By default, the installation program creates and attaches security groups to control plane and compute machines. The rules associated with the default security groups cannot be modified.

However, you can apply additional existing AWS security groups, which are associated with your existing VPC, to control plane and compute machines. Applying custom security groups can help you meet the security needs of your organization, in such cases where you need to control the incoming or outgoing traffic of these machines.

As part of the installation process, you apply custom security groups by modifying the install-config.yaml file before deploying the cluster.

For more information, see “Edge compute pools and AWS Local Zones”.

6.13.10.5. CloudFormation template for the subnet that uses AWS Local Zones

You can use the following CloudFormation template to deploy the subnet that you need for your OpenShift Container Platform cluster that uses AWS Local Zones.

Example 6.71. CloudFormation template for the subnet

```yaml
# CloudFormation template used to create Local Zone subnets and dependencies
AWSTemplateFormatVersion: 2010-09-09
Description: Template for create Public Local Zone subnets
```
You can view details about the CloudFormation stacks that you create by navigating to the AWS CloudFormation console.

6.13.10.6. Modifying an installation configuration file to use AWS Local Zones subnets

Modify an install-config.yaml file to include AWS Local Zones subnets.
Prerequisites

- You created subnets by using the procedure "Creating a subnet in AWS Local Zones".
- You created an `install-config.yaml` file by using the procedure "Creating the installation configuration file".

Procedure

- Modify the `install-config.yaml` configuration file by specifying Local Zone subnets in the `platform.aws.subnets` property, as demonstrated in the following example:

```yaml
... 
platform:
  aws:
    region: us-west-2
    subnets:  
    - publicSubnetId-1
    - publicSubnetId-2
    - publicSubnetId-3
    - privateSubnetId-1
    - privateSubnetId-2
    - privateSubnetId-3
    - publicSubnetId-LocalZone-1
...
```

1 List of subnets created in the Availability and Local Zones.

Additional resources

- See Configuration and credential file settings in the AWS documentation for more information about AWS profile and credential configuration.

6.13.11. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.
- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.
Procedure

1. Change to the directory that contains the installation program and initialize the cluster deployment:

   ```bash
   $ ./openshift-install create cluster --dir <installation_directory> \ 1
   --log-level=info 2
   ```

   - For `<installation_directory>`, specify the location of your customized `.install-config.yaml` file.
   - To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

2. Optional: Remove or disable the `AdministratorAccess` policy from the IAM account that you used to install the cluster.

   **NOTE**
   The elevated permissions provided by the `AdministratorAccess` policy are required only during installation.

Verification

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the `kubeadmin` user.

  ```
  INFO Install complete!
  INFO To access the cluster as the system:admin user when using 'oc', run 'export
  KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
  INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
  INFO Login to the console with user: "kubeadmin", and password: "password"
  INFO Time elapsed: 36m22s
  ```

   - Credential information also outputs to `<installation_directory>/.openshift_install.log`.

   **IMPORTANT**
   Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

Example output

...
IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

Next steps

- Creating user workloads in AWS Local Zones

6.13.12. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

Procedure

1. Export the `kubeadmin` credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   
   1 For `<installation_directory>`, specify the path to the directory that you stored the installation files in.
   
2. Verify you can run `oc` commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   
   Example output
   
   system:admin
   
   6.13.13. Logging in to the cluster by using the web console
The `kubeadmin` user exists by default after an OpenShift Container Platform installation. You can log in to your cluster as the `kubeadmin` user by using the OpenShift Container Platform web console.

**Prerequisites**

- You have access to the installation host.
- You completed a cluster installation and all cluster Operators are available.

**Procedure**

1. Obtain the password for the `kubeadmin` user from the `kubeadmin-password` file on the installation host:

   ```bash
   $ cat <installation_directory>/auth/kubeadmin-password
   ``

   **NOTE**
   
   Alternatively, you can obtain the `kubeadmin` password from the `<installation_directory>/openshift_install.log` log file on the installation host.

2. List the OpenShift Container Platform web console route:

   ```bash
   $ oc get routes -n openshift-console | grep 'console-openshift'
   ``

   **NOTE**
   
   Alternatively, you can obtain the OpenShift Container Platform route from the `<installation_directory>/openshift_install.log` log file on the installation host.

   **Example output**

   ```
   console   console-openshift-console.apps.<cluster_name>.<base_domain>  console
   https     reencrypt/Redirect  None
   ```

3. Navigate to the route detailed in the output of the preceding command in a web browser and log in as the `kubeadmin` user.

**Additional resources**

- See [Accessing the web console](#) for more details about accessing and understanding the OpenShift Container Platform web console.

### 6.13.14. Verifying nodes that were created with edge compute pool

After you install a cluster that uses AWS Local Zones, check the status of the machine that was created by the machine set manifests created at install time.

1. To check the machine sets created from the subnet you added to the `install-config.yaml` file, run the following command:

   ```bash
   $ oc get machineset -n openshift-machine-api
   ```
Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>PHASE</th>
<th>TYPE</th>
<th>REGION</th>
<th>ZONE</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>cluster-7xw5g-edge-us-east-1-nyc-1a-wbclh</td>
<td>Running</td>
<td>c5d.2xlarge</td>
<td>us-east-1</td>
<td>us-east-1-nyc-1a</td>
<td>3h4m</td>
</tr>
<tr>
<td>cluster-7xw5g-master-0</td>
<td>Running</td>
<td>m6i.xlarge</td>
<td>us-east-1a</td>
<td></td>
<td>3h4m</td>
</tr>
<tr>
<td>cluster-7xw5g-master-1</td>
<td>Running</td>
<td>m6i.xlarge</td>
<td>us-east-1b</td>
<td></td>
<td>3h4m</td>
</tr>
<tr>
<td>cluster-7xw5g-master-2</td>
<td>Running</td>
<td>m6i.xlarge</td>
<td>us-east-1c</td>
<td></td>
<td>3h4m</td>
</tr>
<tr>
<td>cluster-7xw5g-worker-us-east-1a-rtp45</td>
<td>Running</td>
<td>m6i.xlarge</td>
<td>us-east-1a</td>
<td></td>
<td>3h</td>
</tr>
<tr>
<td>cluster-7xw5g-worker-us-east-1b-glm7c</td>
<td>Running</td>
<td>m6i.xlarge</td>
<td>us-east-1b</td>
<td></td>
<td>3h</td>
</tr>
<tr>
<td>cluster-7xw5g-worker-us-east-1c-qfvz4</td>
<td>Running</td>
<td>m6i.xlarge</td>
<td>us-east-1c</td>
<td></td>
<td>3h</td>
</tr>
</tbody>
</table>

2. To check the machines that were created from the machine sets, run the following command:

```
$ oc get machines -n openshift-machine-api
```

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>PHASE</th>
<th>TYPE</th>
<th>REGION</th>
<th>ZONE</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>cluster-7xw5g-edge-us-east-1-nyc-1a</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>3h4m</td>
</tr>
<tr>
<td>cluster-7xw5g-worker-us-east-1a</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>3h4m</td>
</tr>
<tr>
<td>cluster-7xw5g-worker-us-east-1b</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>3h4m</td>
</tr>
<tr>
<td>cluster-7xw5g-worker-us-east-1c</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>3h4m</td>
</tr>
</tbody>
</table>

3. To check nodes with edge roles, run the following command:

```
$ oc get nodes -l node-role.kubernetes.io/edge
```

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>ip-10-0-207-188.ec2.internal</td>
<td>Ready</td>
<td>edge,worker</td>
<td>172m</td>
<td>v1.25.2+d2e245f</td>
</tr>
</tbody>
</table>

6.13.15. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager Hybrid Cloud Console.

After you confirm that your OpenShift Cluster Manager Hybrid Cloud Console inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service.
6.13.16. Next steps

- Creating user workloads in AWS Local Zones.
- Validating an installation.
- Customize your cluster.
- If necessary, you can opt out of remote health reporting.

6.14. INSTALLING A CLUSTER ON AWS IN A RESTRICTED NETWORK WITH USER-PROVISIONED INFRASTRUCTURE

In OpenShift Container Platform version 4.14, you can install a cluster on Amazon Web Services (AWS) using infrastructure that you provide and an internal mirror of the installation release content.

**IMPORTANT**

While you can install an OpenShift Container Platform cluster by using mirrored installation release content, your cluster still requires internet access to use the AWS APIs.

One way to create this infrastructure is to use the provided CloudFormation templates. You can modify the templates to customize your infrastructure or use the information that they contain to create AWS objects according to your company’s policies.

**IMPORTANT**

The steps for performing a user-provisioned infrastructure installation are provided as an example only. Installing a cluster with infrastructure you provide requires knowledge of the cloud provider and the installation process of OpenShift Container Platform. Several CloudFormation templates are provided to assist in completing these steps or to help model your own. You are also free to create the required resources through other methods; the templates are just an example.

6.14.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You created a mirror registry on your mirror host and obtained the `imageContentSources` data for your version of OpenShift Container Platform.

**IMPORTANT**

Because the installation media is on the mirror host, you can use that computer to complete all installation steps.

- You configured an AWS account to host the cluster.
IMPORTANT

If you have an AWS profile stored on your computer, it must not use a temporary session token that you generated while using a multi-factor authentication device. The cluster continues to use your current AWS credentials to create AWS resources for the entire life of the cluster, so you must use key-based, long-term credentials. To generate appropriate keys, see Managing Access Keys for IAM Users in the AWS documentation. You can supply the keys when you run the installation program.

- You downloaded the AWS CLI and installed it on your computer. See Install the AWS CLI Using the Bundled Installer (Linux, macOS, or Unix) in the AWS documentation.

- If you use a firewall and plan to use the Telemetry service, you configured the firewall to allow the sites that your cluster requires access to.

NOTE

Be sure to also review this site list if you are configuring a proxy.

- If the cloud identity and access management (IAM) APIs are not accessible in your environment, or if you do not want to store an administrator-level credential secret in the kube-system namespace, you can manually create and maintain long-term credentials.

In OpenShift Container Platform 4.14, you can perform an installation that does not require an active connection to the internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service’s Route 53 DNS and IAM services, require internet access. Depending on your network, you might require less internet access for an installation on bare metal hardware, Nutanix, or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift image registry and contains the installation media. You can create this registry on a mirror host, which can access both the internet and your closed network, or by using other methods that meet your restrictions.

IMPORTANT

Because of the complexity of the configuration for user-provisioned installations, consider completing a standard user-provisioned infrastructure installation before you attempt a restricted network installation using user-provisioned infrastructure. Completing this test installation might make it easier to isolate and troubleshoot any issues that might arise during your installation in a restricted network.

6.14.2.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The ClusterVersion status includes an Unable to retrieve available updates error.
By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

### 6.14.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to obtain the images that are necessary to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager Hybrid Cloud Console](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- Access [Quay.io](#) to obtain the packages that are required to install your cluster.

- Obtain the packages that are required to perform cluster updates.

### 6.14.4. Requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

This section describes the requirements for deploying OpenShift Container Platform on user-provisioned infrastructure.

#### 6.14.4.1. Required machines for cluster installation

The smallest OpenShift Container Platform clusters require the following hosts:

<table>
<thead>
<tr>
<th>Hosts</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>One temporary bootstrap machine</td>
<td>The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.</td>
</tr>
<tr>
<td>Three control plane machines</td>
<td>The control plane machines run the Kubernetes and OpenShift Container Platform services that form the control plane.</td>
</tr>
<tr>
<td>At least two compute machines, which are also known as worker machines.</td>
<td>The workloads requested by OpenShift Container Platform users run on the compute machines.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

To maintain high availability of your cluster, use separate physical hosts for these cluster machines.

The bootstrap and control plane machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system. However, the compute machines can choose between Red Hat Enterprise Linux CoreOS (RHCOS), Red Hat Enterprise Linux (RHEL) 8.6 and later.
Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 9.2 and inherits all of its hardware certifications and requirements. See Red Hat Enterprise Linux technology capabilities and limits.

6.14.4.2. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

Table 6.21. Minimum resource requirements

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS, RHEL 8.6 and later [3]</td>
<td>2</td>
<td>8 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
</tbody>
</table>

1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or hyperthreading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: (threads per core × cores) × sockets = vCPUs.

2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.

3. As with all user-provisioned installations, if you choose to use RHEL compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and has been removed in OpenShift Container Platform 4.10 and later.

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

Additional resources

- Optimizing storage

6.14.4.3. Tested instance types for AWS

The following Amazon Web Services (AWS) instance types have been tested with OpenShift Container Platform.
NOTE

Use the machine types included in the following charts for your AWS instances. If you use an instance type that is not listed in the chart, ensure that the instance size you use matches the minimum resource requirements that are listed in "Minimum resource requirements for cluster installation".

Example 6.72. Machine types based on 64-bit x86 architecture

- c4.*
- c5.*
- c5a.*
- i3.*
- m4.*
- m5.*
- m5a.*
- m6i.*
- r4.*
- r5.*
- r5a.*
- r6i.*
- t3.*
- t3a.*

6.14.4.4. Tested instance types for AWS on 64-bit ARM infrastructures

The following Amazon Web Services (AWS) 64-bit ARM instance types have been tested with OpenShift Container Platform.

NOTE

Use the machine types included in the following charts for your AWS ARM instances. If you use an instance type that is not listed in the chart, ensure that the instance size you use matches the minimum resource requirements that are listed in "Minimum resource requirements for cluster installation".

Example 6.73. Machine types based on 64-bit ARM architecture

- c6g.*
- m6g.*
6.14.4.5. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The `kube-controller-manager` only approves the kubelet client CSRs. The `machine-approver` cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

6.14.5. Required AWS infrastructure components

To install OpenShift Container Platform on user-provisioned infrastructure in Amazon Web Services (AWS), you must manually create both the machines and their supporting infrastructure.

For more information about the integration testing for different platforms, see the OpenShift Container Platform 4.x Tested Integrations page.

By using the provided CloudFormation templates, you can create stacks of AWS resources that represent the following components:

- An AWS Virtual Private Cloud (VPC)
- Networking and load balancing components
- Security groups and roles
- An OpenShift Container Platform bootstrap node
- OpenShift Container Platform control plane nodes
- An OpenShift Container Platform compute node

Alternatively, you can manually create the components or you can reuse existing infrastructure that meets the cluster requirements. Review the CloudFormation templates for more details about how the components interrelate.

6.14.5.1. Other infrastructure components

- A VPC
- DNS entries
- Load balancers (classic or network) and listeners
- A public and a private Route 53 zone
- Security groups
- IAM roles
- S3 buckets
If you are working in a disconnected environment, you are unable to reach the public IP addresses for EC2, ELB, and S3 endpoints. Depending on the level to which you want to restrict internet traffic during the installation, the following configuration options are available:

**Option 1: Create VPC endpoints**
Create a VPC endpoint and attach it to the subnets that the clusters are using. Name the endpoints as follows:

- `ec2.<aws_region>.amazonaws.com`
- `elasticloadbalancing.<aws_region>.amazonaws.com`
- `s3.<aws_region>.amazonaws.com`

With this option, network traffic remains private between your VPC and the required AWS services.

**Option 2: Create a proxy without VPC endpoints**
As part of the installation process, you can configure an HTTP or HTTPS proxy. With this option, internet traffic goes through the proxy to reach the required AWS services.

**Option 3: Create a proxy with VPC endpoints**
As part of the installation process, you can configure an HTTP or HTTPS proxy with VPC endpoints. Create a VPC endpoint and attach it to the subnets that the clusters are using. Name the endpoints as follows:

- `ec2.<aws_region>.amazonaws.com`
- `elasticloadbalancing.<aws_region>.amazonaws.com`
- `s3.<aws_region>.amazonaws.com`

When configuring the proxy in the `install-config.yaml` file, add these endpoints to the `noProxy` field. With this option, the proxy prevents the cluster from accessing the internet directly. However, network traffic remains private between your VPC and the required AWS services.

**Required VPC components**
You must provide a suitable VPC and subnets that allow communication to your machines.

<table>
<thead>
<tr>
<th>Component</th>
<th>AWS type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VPC</td>
<td></td>
<td>You must provide a public VPC for the cluster to use. The VPC uses an endpoint that references the route tables for each subnet to improve communication with the registry that is hosted in S3.</td>
</tr>
<tr>
<td></td>
<td>AWS::EC2::VPC</td>
<td></td>
</tr>
<tr>
<td></td>
<td>AWS::EC2::VPC::Endpoint</td>
<td></td>
</tr>
<tr>
<td>Public subnets</td>
<td></td>
<td>Your VPC must have public subnets for between 1 and 3 availability zones and associate them with appropriate Ingress rules.</td>
</tr>
<tr>
<td></td>
<td>AWS::EC2::Subnet</td>
<td></td>
</tr>
<tr>
<td></td>
<td>AWS::EC2::Subnet::NetworkAclAssociation</td>
<td></td>
</tr>
</tbody>
</table>
You must have a public internet gateway, with public routes, attached to the VPC. In the provided templates, each public subnet has a NAT gateway with an EIP address. These NAT gateways allow cluster resources, like private subnet instances, to reach the internet and are not required for some restricted network or proxy scenarios.

You must allow the VPC to access the following ports:

<table>
<thead>
<tr>
<th>Port</th>
<th>Reason</th>
</tr>
</thead>
<tbody>
<tr>
<td>80</td>
<td>Inbound HTTP traffic</td>
</tr>
<tr>
<td>443</td>
<td>Inbound HTTPS traffic</td>
</tr>
<tr>
<td>22</td>
<td>Inbound SSH traffic</td>
</tr>
<tr>
<td>1024 - 65535</td>
<td>Inbound ephemeral traffic</td>
</tr>
<tr>
<td>0 - 65535</td>
<td>Outbound ephemeral traffic</td>
</tr>
</tbody>
</table>

Your VPC can have private subnets. The provided CloudFormation templates can create private subnets for between 1 and 3 availability zones. If you use private subnets, you must provide appropriate routes and tables for them.

Required DNS and load balancing components

Your DNS and load balancer configuration needs to use a public hosted zone and can use a private hosted zone similar to the one that the installation program uses if it provisions the cluster’s infrastructure. You must create a DNS entry that resolves to your load balancer. An entry for api.
<cluster_name>.<domain> must point to the external load balancer, and an entry for api-int. <cluster_name>.<domain> must point to the internal load balancer.

The cluster also requires load balancers and listeners for port 6443, which are required for the Kubernetes API and its extensions, and port 22623, which are required for the Ignition config files for new machines. The targets will be the control plane nodes. Port 6443 must be accessible to both clients external to the cluster and nodes within the cluster. Port 22623 must be accessible to nodes within the cluster.

<table>
<thead>
<tr>
<th>Component</th>
<th>AWS type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DNS</td>
<td>AWS::Route 53::HostedZone</td>
<td>The hosted zone for your internal DNS.</td>
</tr>
<tr>
<td>Public load balancer</td>
<td>AWS::Elastic LoadBalancingV2::LoadBalancer</td>
<td>The load balancer for your public subnets.</td>
</tr>
<tr>
<td>External API server record</td>
<td>AWS::Route 53::RecordSetGroup</td>
<td>Alias records for the external API server.</td>
</tr>
<tr>
<td>External listener</td>
<td>AWS::Elastic LoadBalancingV2::Listener</td>
<td>A listener on port 6443 for the external load balancer.</td>
</tr>
<tr>
<td>External target group</td>
<td>AWS::Elastic LoadBalancingV2::TargetGroup</td>
<td>The target group for the external load balancer.</td>
</tr>
<tr>
<td>Private load balancer</td>
<td>AWS::Elastic LoadBalancingV2::LoadBalancer</td>
<td>The load balancer for your private subnets.</td>
</tr>
<tr>
<td>Internal API server record</td>
<td>AWS::Route 53::RecordSetGroup</td>
<td>Alias records for the internal API server.</td>
</tr>
<tr>
<td>Internal listener</td>
<td>AWS::Elastic LoadBalancingV2::Listener</td>
<td>A listener on port 22623 for the internal load balancer.</td>
</tr>
<tr>
<td>Internal target group</td>
<td>AWS::Elastic LoadBalancingV2::TargetGroup</td>
<td>The target group for the internal load balancer.</td>
</tr>
</tbody>
</table>
**Internal listener**  
AWS::ElasticLoadBalancingV2::Listener  
A listener on port 6443 for the internal load balancer.

**Internal target group**  
AWS::ElasticLoadBalancingV2::TargetGroup  
The target group for the internal load balancer.

### Security groups

The control plane and worker machines require access to the following ports:

<table>
<thead>
<tr>
<th>Group</th>
<th>Type</th>
<th>IP Protocol</th>
<th>Port range</th>
</tr>
</thead>
<tbody>
<tr>
<td>MasterSecurityGroup</td>
<td>AWS::EC2::SecurityGroup</td>
<td>icmp</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>tcp</td>
<td>22</td>
</tr>
<tr>
<td></td>
<td></td>
<td>tcp</td>
<td>6443</td>
</tr>
<tr>
<td></td>
<td></td>
<td>tcp</td>
<td>22623</td>
</tr>
<tr>
<td>WorkerSecurityGroup</td>
<td>AWS::EC2::SecurityGroup</td>
<td>icmp</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>tcp</td>
<td>22</td>
</tr>
<tr>
<td>BootstrapSecurityGroup</td>
<td>AWS::EC2::SecurityGroup</td>
<td>tcp</td>
<td>22</td>
</tr>
<tr>
<td></td>
<td></td>
<td>tcp</td>
<td>19531</td>
</tr>
</tbody>
</table>

### Control plane Ingress

The control plane machines require the following Ingress groups. Each Ingress group is an AWS::EC2::SecurityGroupIngress resource.

<table>
<thead>
<tr>
<th>Ingress group</th>
<th>Description</th>
<th>IP protocol</th>
<th>Port range</th>
</tr>
</thead>
<tbody>
<tr>
<td>MasterIngress Etdc</td>
<td>etcd</td>
<td>tcp</td>
<td>2379– 2380</td>
</tr>
<tr>
<td>MasterIngress Vxlan</td>
<td>Vxlan packets</td>
<td>udp</td>
<td>4789</td>
</tr>
<tr>
<td>Ingress group</td>
<td>Description</td>
<td>IP protocol</td>
<td>Port range</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>--------------------------------------------------</td>
<td>-------------</td>
<td>---------------</td>
</tr>
<tr>
<td><strong>MasterIngress</strong></td>
<td>Vxlan packets</td>
<td>udp</td>
<td>4789</td>
</tr>
<tr>
<td><strong>WorkerVxlan</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Internal</strong></td>
<td>Internal cluster communication and Kubernetes</td>
<td>tcp</td>
<td>9000 - 9999</td>
</tr>
<tr>
<td><strong>WorkerInternal</strong></td>
<td>proxy metrics</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>WorkerInternal</strong></td>
<td>Internal cluster communication</td>
<td>tcp</td>
<td>9000 - 9999</td>
</tr>
<tr>
<td><strong>Kube</strong></td>
<td>Kubernetes kubelet, scheduler and controller</td>
<td>tcp</td>
<td>10250 - 10259</td>
</tr>
<tr>
<td><strong>Kube</strong></td>
<td>manager</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>WorkerKube</strong></td>
<td>Kubernetes kubelet, scheduler and controller</td>
<td>tcp</td>
<td>10250 - 10259</td>
</tr>
<tr>
<td><strong>WorkerKube</strong></td>
<td>manager</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>IngressServices</strong></td>
<td>Kubernetes Ingress services</td>
<td>tcp</td>
<td>30000 - 32767</td>
</tr>
<tr>
<td><strong>WorkerIngressServices</strong></td>
<td>Kubernetes Ingress services</td>
<td>tcp</td>
<td>30000 - 32767</td>
</tr>
<tr>
<td><strong>Geneve</strong></td>
<td>Geneve packets</td>
<td>udp</td>
<td>6081</td>
</tr>
<tr>
<td><strong>WorkerGeneve</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Geneve</strong></td>
<td></td>
<td>udp</td>
<td>6081</td>
</tr>
<tr>
<td><strong>IpsecIke</strong></td>
<td>IPsec IKE packets</td>
<td>udp</td>
<td>500</td>
</tr>
<tr>

## Roles and instance profiles

You must grant the machines permissions in AWS. The provided CloudFormation templates grant the machines `Allow` permissions for the following `AWS::IAM::Role` objects and provide a `AWS::IAM::InstanceProfile` for each set of roles. If you do not use the templates, you can grant the machines the following broad permissions or the following individual permissions.

<table>
<thead>
<tr>
<th>Role</th>

### 6.14.5.2. Cluster machines

You need `AWS::EC2::Instance` objects for the following machines:

- A bootstrap machine. This machine is required during installation, but you can remove it after your cluster deploys.
- Three control plane machines. The control plane machines are not governed by a control plane machine set.
- Compute machines. You must create at least two compute machines, which are also known as worker machines, during installation. These machines are not governed by a compute machine set.

### 6.14.5.3. Required AWS permissions for the IAM user

<table>
<thead>
<tr>
<th>Ingress group</th>
<th>Description</th>
<th>IP protocol</th>
<th>Port range</th>
</tr>
</thead>
<tbody>
<tr>
<td>WorkerIngress</td>
<td>Kubernetes Ingress services</td>
<td>udp</td>
<td>30000 - 32767</td>
</tr>
<tr>
<td>MasterIngress</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>ServicesUDP</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
NOTE

Your IAM user must have the permission `tag:GetResources` in the region `us-east-1` to delete the base cluster resources. As part of the AWS API requirement, the OpenShift Container Platform installation program performs various actions in this region.

When you attach the `AdministratorAccess` policy to the IAM user that you create in Amazon Web Services (AWS), you grant that user all of the required permissions. To deploy all components of an OpenShift Container Platform cluster, the IAM user requires the following permissions:

Example 6.74. Required EC2 permissions for installation

- `ec2:AuthorizeSecurityGroupEgress`
- `ec2:AuthorizeSecurityGroupIngress`
- `ec2:CopyImage`
- `ec2:CreateNetworkInterface`
- `ec2:AttachNetworkInterface`
- `ec2:CreateSecurityGroup`
- `ec2:CreateTags`
- `ec2:CreateVolume`
- `ec2:DeleteSecurityGroup`
- `ec2:DeleteSnapshot`
- `ec2:DeleteTags`
- `ec2:DeregisterImage`
- `ec2:DescribeAccountAttributes`
- `ec2:DescribeAddresses`
- `ec2:DescribeAvailabilityZones`
- `ec2:DescribeDhcpOptions`
- `ec2:DescribeInstanceAttribute`
- `ec2:DescribeInstanceCreditSpecifications`
- `ec2:DescribeInstances`
- `ec2:DescribeInstanceTypes`
- `ec2:DescribeInternetGateways`
- `ec2:DescribeKeyPairs`
Example 6.75. Required permissions for creating network resources during installation

- ec2:AllocateAddress
- ec2:AssociateAddress
- ec2:AssociateDhcpOptions
- ec2:AssociateRouteTable
- ec2:AttachInternetGateway
- ec2:CreateDhcpOptions
• ec2:CreateInternetGateway
• ec2:CreateNatGateway
• ec2:CreateRoute
• ec2:CreateRouteTable
• ec2:CreateSubnet
• ec2:CreateVpc
• ec2:CreateVpcEndpoint
• ec2:ModifySubnetAttribute
• ec2:ModifyVpcAttribute

NOTE
If you use an existing VPC, your account does not require these permissions for creating network resources.

Example 6.76. Required Elastic Load Balancing permissions (ELB) for installation
• elasticloadbalancing:AddTags
• elasticloadbalancing:ApplySecurityGroupsToLoadBalancer
• elasticloadbalancing:AttachLoadBalancerToSubnets
• elasticloadbalancing:ConfigureHealthCheck
• elasticloadbalancing:CreateLoadBalancer
• elasticloadbalancing:CreateLoadBalancerListeners
• elasticloadbalancing:DeleteLoadBalancer
• elasticloadbalancing:DeregisterInstancesFromLoadBalancer
• elasticloadbalancing:DescribeInstanceHealth
• elasticloadbalancing:DescribeLoadBalancerAttributes
• elasticloadbalancing:DescribeLoadBalancers
• elasticloadbalancing:DescribeTags
• elasticloadbalancing:ModifyLoadBalancerAttributes
• elasticloadbalancing:RegisterInstancesWithLoadBalancer
• elasticloadbalancing:SetLoadBalancerPoliciesOfListener
Example 6.77. Required Elastic Load Balancing permissions (ELBv2) for installation

- elasticloadbalancing:AddTags
- elasticloadbalancing:CreateListener
- elasticloadbalancing:CreateLoadBalancer
- elasticloadbalancing:CreateTargetGroup
- elasticloadbalancing:DeleteLoadBalancer
- elasticloadbalancing:DeregisterTargets
- elasticloadbalancing:DescribeListeners
- elasticloadbalancing:DescribeLoadBalancerAttributes
- elasticloadbalancing:DescribeLoadBalancers
- elasticloadbalancing:DescribeTargetGroupAttributes
- elasticloadbalancing:DescribeTargetHealth
- elasticloadbalancing:ModifyLoadBalancerAttributes
- elasticloadbalancing:ModifyTargetGroup
- elasticloadbalancing:ModifyTargetGroupAttributes
- elasticloadbalancing:RegisterTargets

Example 6.78. Required IAM permissions for installation

- iam:AddRoleToInstanceProfile
- iam:CreateInstanceProfile
- iam:CreateRole
- iam:DeleteInstanceProfile
- iam:DeleteRole
- iam:DeleteRolePolicy
- iam:GetInstanceProfile
- iam:GetRole
- iam:GetRolePolicy
- iam:GetUser
- iam:ListInstanceProfilesForRole
• iam:ListRoles
• iam:ListUsers
• iam:PassRole
• iam:PutRolePolicy
• iam:RemoveRoleFromInstanceProfile
• iam:SimulatePrincipalPolicy
• iam:TagRole

NOTE
If you have not created a load balancer in your AWS account, the IAM user also requires the `iam:CreateServiceLinkedRole` permission.

Example 6.79. Required Route 53 permissions for installation

• route53:ChangeResourceRecordSets
• route53:ChangeTagsForResource
• route53:CreateHostedZone
• route53:DeleteHostedZone
• route53:GetChange
• route53:GetHostedZone
• route53:ListHostedZones
• route53:ListHostedZonesByName
• route53:ListResourceRecordSets
• route53:ListTagsForResource
• route53:UpdateHostedZoneComment

Example 6.80. Required S3 permissions for installation

• s3:CreateBucket
• s3:DeleteBucket
• s3:GetAccelerateConfiguration
• s3:GetBucketAcl
• s3:GetBucketCors
Example 6.81. S3 permissions that cluster Operators require

- s3:DeleteObject
- s3:GetObject
- s3:GetObjectAcl
- s3:GetObjectTagging
- s3:GetObjectVersion
- s3:PutObject
- s3:PutObjectAcl
- s3:PutObjectTagging

Example 6.82. Required permissions to delete base cluster resources

- autoscaling:DescribeAutoScalingGroups
- ec2:DeletePlacementGroup
Example 6.83. Required permissions to delete network resources

- ec2:DeleteDhcpOptions
- ec2:DeleteInternetGateway
- ec2:DeleteNatGateway
- ec2:DeleteRoute
- ec2:DeleteRouteTable
- ec2:DeleteSubnet
- ec2:DeleteVpc
- ec2:DeleteVpcEndpoints
- ec2:DetachInternetGateway
- ec2:DisassociateRouteTable
- ec2:ReleaseAddress
- ec2:ReplaceRouteTableAssociation
NOTE
If you use an existing VPC, your account does not require these permissions to delete network resources. Instead, your account only requires the `tag:UntagResources` permission to delete network resources.

Example 6.84. Required permissions to delete a cluster with shared instance roles

- `iam:UntagRole`

Example 6.85. Additional IAM and S3 permissions that are required to create manifests

- `iam:DeleteAccessKey`
- `iam:DeleteUser`
- `iam:DeleteUserPolicy`
- `iam:GetUserPolicy`
- `iam:ListAccessKeys`
- `iam:PutUserPolicy`
- `iam:TagUser`
- `s3:PutBucketPublicAccessBlock`
- `s3:GetBucketPublicAccessBlock`
- `s3:PutLifecycleConfiguration`
- `s3:HeadBucket`
- `s3:ListBucketMultipartUploads`
- `s3:AbortMultipartUpload`

NOTE
If you are managing your cloud provider credentials with mint mode, the IAM user also requires the `iam:CreateAccessKey` and `iam:CreateUser` permissions.

Example 6.86. Optional permissions for instance and quota checks for installation

- `ec2:DescribeInstanceTypeOfferings`
- `servicequotas:ListAWSDefaultServiceQuotas`
Example 6.87. Optional permissions for the cluster owner account when installing a cluster on a shared VPC

- sts:AssumeRole

6.14.6. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

NOTE

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   $ ssh-keygen -t ed25519 -N " -f <path>/<file_name> 1

   Specify the path and file name, such as ~/.ssh/id_ed25519, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   NOTE

   If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

   2. View the public SSH key:
For example, run the following to view the ~/.ssh/id_ed25519.pub public key:

```
$ cat ~/.ssh/id_ed25519.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the ./openshift-install gather command.

```
$ eval "$(ssh-agent -s)"
```

Example output

```
Agent pid 31874
```

```
NOTE
On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.
```

a. If the ssh-agent process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

Example output

```
Agent pid 31874
```

```
NOTE
If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.
```

4. Add your SSH private key to the ssh-agent:

```
$ ssh-add <path>/<file_name>
```

Specify the path and file name for your SSH private key, such as ~/.ssh/id_ed25519

Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program. If you install a cluster on infrastructure that you provision, you must provide the key to the installation program.

**6.14.7. Creating the installation files for AWS**

To install OpenShift Container Platform on Amazon Web Services (AWS) using user-provisioned infrastructure, you must generate the files that the installation program needs to deploy your cluster and modify them so that the cluster creates only the machines that it will use. You generate and
customize the `install-config.yaml` file, Kubernetes manifests, and Ignition config files. You also have the option to first set up a separate `/var` partition during the preparation phases of installation.

### 6.14.7.1. Optional: Creating a separate `/var` partition

It is recommended that disk partitioning for OpenShift Container Platform be left to the installer. However, there are cases where you might want to create separate partitions in a part of the filesystem that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the `/var` partition or a subdirectory of `/var`. For example:

- `/var/lib/containers`: Holds container-related content that can grow as more images and containers are added to a system.
- `/var/lib/etcd`: Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.
- `/var`: Holds data that you might want to keep separate for purposes such as auditing.

Storing the contents of a `/var` directory separately makes it easier to grow storage for those areas as needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

Because `/var` must be in place before a fresh installation of Red Hat Enterprise Linux CoreOS (RHCOS), the following procedure sets up the separate `/var` partition by creating a machine config manifest that is inserted during the `openshift-install` preparation phases of an OpenShift Container Platform installation.

#### IMPORTANT

If you follow the steps to create a separate `/var` partition in this procedure, it is not necessary to create the Kubernetes manifest and Ignition config files again as described later in this section.

#### Procedure

1. Create a directory to hold the OpenShift Container Platform installation files:

   ```
   $ mkdir $HOME/clusterconfig
   ```

2. Run `openshift-install` to create a set of files in the **manifest** and **openshift** subdirectories. Answer the system questions as you are prompted:

   ```
   $ openshift-install create manifests --dir $HOME/clusterconfig
   ```

#### Example output

```
? SSH Public Key ...
INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
INFO Consuming Install Config from target directory
INFO Manifests created in: $HOME/clusterconfig/manifests and $HOME/clusterconfig/openshift
```
3. Optional: Confirm that the installation program created manifests in the `clusterconfig/openshift` directory:

```
$ ls $HOME/clusterconfig/openshift/
```

**Example output**

```
99_kubeadmin-password-secret.yaml
99_openshift-cluster-api_master-machines-0.yaml
99_openshift-cluster-api_master-machines-1.yaml
99_openshift-cluster-api_master-machines-2.yaml
... 
```

4. Create a Butane config that configures the additional partition. For example, name the file `$HOME/clusterconfig/98-var-partition.bu`, change the disk device name to the name of the storage device on the `worker` systems, and set the storage size as appropriate. This example places the `/var` directory on a separate partition:

```
variant: openshift
version: 4.14.0
metadata:
  labels:
    machineconfiguration.openshift.io/role: worker
  name: 98-var-partition
storage:
  disks:
    - device: /dev/disk/by-id/<device_name>  
      partitions:
        - label: var
          start_mib: <partition_start_offset>
          size_mib: <partition_size>
      filesystems:
        - device: /dev/disk/by-partlabel/var
          path: /var
          format: xfs
          mount_options: [defaults, prjquota]
          with_mount_unit: true
```

1. The storage device name of the disk that you want to partition.
2. When adding a data partition to the boot disk, a minimum value of 25000 MiB (Mebibytes) is recommended. The root file system is automatically resized to fill all available space up to the specified offset. If no value is specified, or if the specified value is smaller than the recommended minimum, the resulting root file system will be too small, and future reinstalls of RHCOs might overwrite the beginning of the data partition.
3. The size of the data partition in mebibytes.
4. The `prjquota` mount option must be enabled for filesystems used for container storage.
NOTE

When creating a separate /var partition, you cannot use different instance types for worker nodes, if the different instance types do not have the same device name.

5. Create a manifest from the Butane config and save it to the clusterconfig/openshift directory. For example, run the following command:

   ```bash
   $ butane $HOME/clusterconfig/98-var-partition.bu -o $HOME/clusterconfig/openshift/98-var-partition.yaml
   ```

6. Run openshift-install again to create Ignition configs from a set of files in the manifest and openshift subdirectories:

   ```bash
   $ openshift-install create ignition-configs --dir $HOME/clusterconfig
   $ ls $HOME/clusterconfig/
   auth bootstrap.ign master.ign metadata.json worker.ign
   ```

Now you can use the Ignition config files as input to the installation procedures to install Red Hat Enterprise Linux CoreOS (RHCOS) systems.

6.14.7.2. Creating the installation configuration file

Generate and customize the installation configuration file that the installation program needs to deploy your cluster.

**Prerequisites**

- You obtained the OpenShift Container Platform installation program for user-provisioned infrastructure and the pull secret for your cluster. For a restricted network installation, these files are on your mirror host.

- You checked that you are deploying your cluster to a region with an accompanying Red Hat Enterprise Linux CoreOS (RHCOS) AMI published by Red Hat. If you are deploying to a region that requires a custom AMI, such as an AWS GovCloud region, you must create the install-config.yaml file manually.

**Procedure**

1. Create the install-config.yaml file.

   a. Change to the directory that contains the installation program and run the following command:

   ```bash
   $ ./openshift-install create install-config --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the directory name to store the files that the installation program creates.
IMPORTANT

Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

b. At the prompts, provide the configuration details for your cloud:

i. Optional: Select an SSH key to use to access your cluster machines.

NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

ii. Select aws as the platform to target.

iii. If you do not have an AWS profile stored on your computer, enter the AWS access key ID and secret access key for the user that you configured to run the installation program.

NOTE

The AWS access key ID and secret access key are stored in ~/.aws/credentials in the home directory of the current user on the installation host. You are prompted for the credentials by the installation program if the credentials for the exported profile are not present in the file. Any credentials that you provide to the installation program are stored in the file.

iv. Select the AWS region to deploy the cluster to.

v. Select the base domain for the Route 53 service that you configured for your cluster.

vi. Enter a descriptive name for your cluster.

vii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

2. Edit the install-config.yaml file to give the additional information that is required for an installation in a restricted network.

a. Update the pullSecret value to contain the authentication information for your registry:

```yaml
pullSecret: '{"auths":{"<local_registry>": {"auth": "<credentials>"}},"email": "you@example.com"}}'
```

For `<local_registry>`, specify the registry domain name, and optionally the port, that your mirror registry uses to serve content. For example registry.example.com or registry.example.com:5000. For `<credentials>`, specify the base64-encoded user name and password for your mirror registry.
b. Add the `additionalTrustBundle` parameter and value. The value must be the contents of the certificate file that you used for your mirror registry. The certificate file can be an existing, trusted certificate authority or the self-signed certificate that you generated for the mirror registry.

```
additionalTrustBundle: |
-----BEGIN CERTIFICATE-----
ZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZ
-----END CERTIFICATE-----
```

c. Add the image content resources:

```
imageContentSources:
- mirrors:
  - `<local_registry>/<local_repository_name>/release`
    source: quay.io/openshift-release-dev/ocp-release
  - mirrors:
    - `<local_registry>/<local_repository_name>/release`
      source: quay.io/openshift-release-dev/ocp-v4.0-art-dev
```

Use the `imageContentSources` section from the output of the command to mirror the repository or the values that you used when you mirrored the content from the media that you brought into your restricted network.

d. Optional: Set the publishing strategy to `Internal`:

```
publish: Internal
```

By setting this option, you create an internal Ingress Controller and a private load balancer.

3. Optional: Back up the `install-config.yaml` file.

**IMPORTANT**

The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

**Additional resources**

- See [Configuration and credential file settings](#) in the AWS documentation for more information about AWS profile and credential configuration.

### 6.14.7.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**Prerequisites**

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of
them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

**Procedure**

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
     httpProxy: http://<username>:<pswd>@<ip>:<port>  
     httpsProxy: https://<username>:<pswd>@<ip>:<port>  
     noProxy: ec2.<aws_region>.amazonaws.com,elasticloadbalancing.<aws_region>.amazonaws.com,s3.<aws_region>.amazonaws.com  
   additionalTrustBundle: |  
     -----BEGIN CERTIFICATE-----  
     <MY_TRUSTED_CA_CERT>  
     -----END CERTIFICATE-----  
   additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle>  
   
   1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.
   2 A proxy URL to use for creating HTTPS connections outside the cluster.
   3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations. If you have added the Amazon EC2 Elastic Load Balancing, and S3 VPC endpoints to your VPC, you must add these endpoints to the noProxy field.
   4 If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the `trustedCA` field of the `Proxy` object. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.
   5 Optional: The policy to determine the configuration of the `Proxy` object to reference the `user-ca-bundle` config map in the `trustedCA` field. The allowed values are `Proxyonly` and `Always`. Use `Proxyonly` to reference the `user-ca-bundle` config map only when `http/https` proxy is configured. Use `Always` to always reference the `user-ca-bundle`
config map. The default value is **Proxyonly**.

**NOTE**

The installation program does not support the proxy **readinessEndpoints** field.

**NOTE**

If the installer times out, restart and then complete the deployment by using the **wait-for** command of the installer. For example:

```
$ ./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided **install-config.yaml** file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

**NOTE**

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

### 6.14.7.4. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to configure the machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to configure the cluster machines.

**IMPORTANT**

- The Ignition config files that the OpenShift Container Platform installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for **Recovering from expired control plane certificates** for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

**Prerequisites**

---

OpenShift Container Platform 4.14 Installing

744
• You obtained the OpenShift Container Platform installation program. For a restricted network installation, these files are on your mirror host.

• You created the `install-config.yaml` installation configuration file.

### Procedure

1. Change to the directory that contains the OpenShift Container Platform installation program and generate the Kubernetes manifests for the cluster:

   ```sh
   $ ./openshift-install create manifests --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.

2. Remove the Kubernetes manifest files that define the control plane machines:

   ```sh
   $ rm -f <installation_directory>/openshift/99_openshift-cluster-api_master-machines-*.yaml
   ```

   By removing these files, you prevent the cluster from automatically generating control plane machines.

3. Remove the Kubernetes manifest files that define the control plane machine set:

   ```sh
   $ rm -f <installation_directory>/openshift/99_openshift-machine-api_master-control-plane-machine-set.yaml
   ```

   ```sh
   $ rm -f <installation_directory>/openshift/99_openshift-cluster-api_worker-machineset-*.yaml
   ```

   **IMPORTANT**

   If you disabled the **MachineAPI** capability when installing a cluster on user-provisioned infrastructure, you must remove the Kubernetes manifest files that define the worker machines. Otherwise, your cluster fails to install.

   Because you create and manage the worker machines yourself, you do not need to initialize these machines.

4. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:

   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.

   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.

   c. Save and exit the file.

5. Optional: If you do not want the **Ingress Operator** to create DNS records on your behalf, remove the **privateZone** and **publicZone** sections from the `<installation_directory>/manifests/cluster-dns-02-config.yml` DNS configuration file:
If you do so, you must add ingress DNS records manually in a later step.

6. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

   ```bash
   $ ./openshift-install create ignition-configs --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the same installation directory.

   Ignition config files are created for the bootstrap, control plane, and compute nodes in the installation directory. The `kubeadmin-password` and `kubeconfig` files are created in the `./<installation_directory>/auth` directory:

   ```shell
   ├── auth
   │   └── kubeadmin-password
   │       └── kubeconfig
   │           └── bootstrap.ign
   │                   └── master.ign
   │                           └── metadata.json
   │                                   └── worker.ign
   │
   └── worker.ign
   ```

**Additional resources**

- [Manually creating long-term credentials](#)

### 6.14.8. Extracting the infrastructure name

The Ignition config files contain a unique cluster identifier that you can use to uniquely identify your cluster in Amazon Web Services (AWS). The infrastructure name is also used to locate the appropriate AWS resources during an OpenShift Container Platform installation. The provided CloudFormation templates contain references to this infrastructure name, so you must extract it.

**Prerequisites**

- You obtained the OpenShift Container Platform installation program and the pull secret for your cluster.
• You generated the Ignition config files for your cluster.

• You installed the `jq` package.

**Procedure**

• To extract and view the infrastructure name from the Ignition config file metadata, run the following command:

```bash
$ jq -r .infraID <installation_directory>/metadata.json
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

**Example output**

```
openshift-vw9j6
```

The output of this command is your cluster name and a random string.

### 6.14.9. Creating a VPC in AWS

You must create a Virtual Private Cloud (VPC) in Amazon Web Services (AWS) for your OpenShift Container Platform cluster to use. You can customize the VPC to meet your requirements, including VPN and route tables.

You can use the provided CloudFormation template and a custom parameter file to create a stack of AWS resources that represent the VPC.

**NOTE**

If you do not use the provided CloudFormation template to create your AWS infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

**Prerequisites**

• You configured an AWS account.

• You added your AWS keys and region to your local AWS profile by running `aws configure`.

• You generated the Ignition config files for your cluster.

**Procedure**

1. Create a JSON file that contains the parameter values that the template requires:

```json
[
  {
    "ParameterKey": "VpcCidr",  
    "ParameterValue": "10.0.0.0/16"
  }
]
```
1. The CIDR block for the VPC.
   2. Specify a CIDR block in the format `x.x.x.x/16-24`.
   3. The number of availability zones to deploy the VPC in.
   4. Specify an integer between 1 and 3.
   5. The size of each subnet in each availability zone.
   6. Specify an integer between 5 and 13, where 5 is /27 and 13 is /19.

2. Copy the template from the CloudFormation template for the VPC section of this topic and save it as a YAML file on your computer. This template describes the VPC that your cluster requires.

3. Launch the CloudFormation template to create a stack of AWS resources that represent the VPC:

   **IMPORTANT**
   You must enter the command on a single line.

   ```shell
   $ aws cloudformation create-stack --stack-name <name>  
   --template-body file://<template>.yaml  
   --parameters file://<parameters>.json
   
   <name> is the name for the CloudFormation stack, such as `cluster-vpc`. You need the name of this stack if you remove the cluster.
   
   <template> is the relative path to and name of the CloudFormation template YAML file that you saved.
   
   <parameters> is the relative path to and name of the CloudFormation parameters JSON file.
   
   Example output
   
   `arn:aws:cloudformation:us-east-1:269333783861:stack/cluster-vpc/dbedae40-2fd3-11eb-820e-12a48460849f`
4. Confirm that the template components exist:

```
$ aws cloudformation describe-stacks --stack-name <name>
```

After the StackStatus displays CREATE_COMPLETE, the output displays values for the following parameters. You must provide these parameter values to the other CloudFormation templates that you run to create your cluster:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VpcId</td>
<td>The ID of your VPC.</td>
</tr>
<tr>
<td>PublicSubnetIds</td>
<td>The IDs of the new public subnets.</td>
</tr>
<tr>
<td>PrivateSubnetIds</td>
<td>The IDs of the new private subnets.</td>
</tr>
</tbody>
</table>

6.14.9.1. CloudFormation template for the VPC

You can use the following CloudFormation template to deploy the VPC that you need for your OpenShift Container Platform cluster.

**Example 6.88. CloudFormation template for the VPC**

```
AWSTemplateFormatVersion: 2010-09-09
Description: Template for Best Practice VPC with 1-3 AZs

Parameters:
VpcCidr:
  AllowedPattern: ^((\[0-9\]|\[1-9\]\[0-9\]|1[0-9]\[0-9\]|2[0-4])\[0-9\]|25[0-5])\.(\[0-9\]|1[0-9]\[0-9\]|1[0-9]\[0-9\]|1[0-9]\[0-9\]|2[0-4]\[0-9\]|25[0-5])(/((0-4)|25))/16-24.$
  ConstraintDescription: CIDR block parameter must be in the form x.x.x/x/16-24.
  Default: 10.0.0.0/16
  Description: CIDR block for VPC.
  Type: String

AvailabilityZoneCount:
  ConstraintDescription: "The number of availability zones. (Min: 1, Max: 3)"
  MinValue: 1
  MaxValue: 3
  Default: 1
  Description: "How many AZs to create VPC subnets for. (Min: 1, Max: 3)"
  Type: Number

SubnetBits:
  ConstraintDescription: CIDR block parameter must be in the form x.x.x/x/19-27.
  MinValue: 5
  MaxValue: 13
  Default: 12
  Description: "Size of each subnet to create within the availability zones. (Min: 5 = /27, Max: 13 = /19)"
  Type: Number

Metadata:

      Statement:
You must configure networking and classic or network load balancing in Amazon Web Services (AWS) that your OpenShift Container Platform cluster can use.

You can use the provided CloudFormation template and a custom parameter file to create a stack of AWS resources. The stack represents the networking and load balancing components that your OpenShift Container Platform cluster requires. The template also creates a hosted zone and subnet tags.

You can run the template multiple times within a single Virtual Private Cloud (VPC).

---

### 6.14.10. Creating networking and load balancing components in AWS

You must configure networking and classic or network load balancing in Amazon Web Services (AWS) that your OpenShift Container Platform cluster can use.

You can use the provided CloudFormation template and a custom parameter file to create a stack of AWS resources. The stack represents the networking and load balancing components that your OpenShift Container Platform cluster requires. The template also creates a hosted zone and subnet tags.

You can run the template multiple times within a single Virtual Private Cloud (VPC).
NOTE
If you do not use the provided CloudFormation template to create your AWS infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

Prerequisites

- You configured an AWS account.
- You added your AWS keys and region to your local AWS profile by running `aws configure`.
- You generated the Ignition config files for your cluster.
- You created and configured a VPC and associated subnets in AWS.

Procedure

1. Obtain the hosted zone ID for the Route 53 base domain that you specified in the install-config.yaml file for your cluster. You can obtain details about your hosted zone by running the following command:

   ```bash
   $ aws route53 list-hosted-zones-by-name --dns-name <route53_domain>
   ```

   For the `<route53_domain>`, specify the Route 53 base domain that you used when you generated the install-config.yaml file for the cluster.

   Example output

   ```
   mycluster.example.com. False 100
   HOSTEDZONES 65F8F38E-2268-B835-E15C-AB55336FCBFA
   /hostedzone/Z21IXYZABCZ2A4 mycluster.example.com. 10
   ```

   In the example output, the hosted zone ID is Z21IXYZABCZ2A4.

2. Create a JSON file that contains the parameter values that the template requires:

   ```json
   [  
     
     {  
       "ParameterKey": "ClusterName",  
       "ParameterValue": "mycluster"
     },
     
     {  
       "ParameterKey": "InfrastructureName",  
       "ParameterValue": "mycluster-<random_string>"
     },
     
     {  
       "ParameterKey": "HostedZoneId",  
       "ParameterValue": "<random_string>"
     },
     
     {  
       "ParameterKey": "HostedZoneName",  
       "ParameterValue": "<random_string>"
     }
   ]
   ```
A short, representative cluster name to use for hostnames, etc.

Specify the cluster name that you used when you generated the `install-config.yaml` file for the cluster.

The name for your cluster infrastructure that is encoded in your Ignition config files for the cluster.

Specify the infrastructure name that you extracted from the Ignition config file metadata, which has the format `<cluster-name>-<random-string>`.

The Route 53 public zone ID to register the targets with.

Specify the Route 53 public zone ID, which as a format similar to `Z21IXYZABCZ2A4`. You can obtain this value from the AWS console.

The Route 53 zone to register the targets with.

Specify the Route 53 base domain that you used when you generated the `install-config.yaml` file for the cluster. Do not include the trailing period (.) that is displayed in the AWS console.

The public subnets that you created for your VPC.

Specify the `PublicSubnetIds` value from the output of the CloudFormation template for the VPC.

The private subnets that you created for your VPC.

Specify the `PrivateSubnetIds` value from the output of the CloudFormation template for the VPC.

The VPC that you created for the cluster.

Specify the `VpcId` value from the output of the CloudFormation template for the VPC.

3. Copy the template from the CloudFormation template for the network and load balancers section of this topic and save it as a YAML file on your computer. This template describes the networking and load balancing objects that your cluster requires.
4. Launch the CloudFormation template to create a stack of AWS resources that provide the networking and load balancing components:

```shell
$ aws cloudformation create-stack --stack-name <name>  
   --template-body file://<template>.yaml  
   --parameters file://<parameters>.json  
   --capabilities CAPABILITY_NAMED_IAM
```

1. `<name>` is the name for the CloudFormation stack, such as `cluster-dns`. You need the name of this stack if you remove the cluster.

2. `<template>` is the relative path to and name of the CloudFormation template YAML file that you saved.

3. `<parameters>` is the relative path to and name of the CloudFormation parameters JSON file.

4. You must explicitly declare the `CAPABILITY_NAMED_IAM` capability because the provided template creates some `AWS::IAM::Role` resources.

Example output

```
arn:aws:cloudformation:us-east-1:269333783861:stack/cluster-dns/cd3e5de0-2fd4-11eb-5cf0-12be5c33a183
```

5. Confirm that the template components exist:

```shell
$ aws cloudformation describe-stacks --stack-name <name>
```

After the `StackStatus` displays `CREATE_COMPLETE`, the output displays values for the following parameters. You must provide these parameter values to the other CloudFormation templates that you run to create your cluster:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PrivateHostedZoneId</td>
<td>Hosted zone ID for the private DNS.</td>
</tr>
</tbody>
</table>
6.14.10.1. CloudFormation template for the network and load balancers

You can use the following CloudFormation template to deploy the networking objects and load balancers that you need for your OpenShift Container Platform cluster.

Example 6.89. CloudFormation template for the network and load balancers

```
AWSTemplateFormatVersion: 2010-09-09
Description: Template for OpenShift Cluster Network Elements (Route53 & LBs)

Parameters:
  ClusterName:
    AllowedPattern: ^([a-zA-Z][a-zA-Z0-9-]{0,26})$
    MaxLength: 27
    MinLength: 1
    ConstraintDescription: Cluster name must be alphanumeric, start with a letter, and have a maximum of 27 characters.
    Description: A short, representative cluster name to use for host names and other identifying names.
    Type: String
  InfrastructureName:
    AllowedPattern: ^([a-zA-Z][a-zA-Z0-9-]{0,26})$
```
MaxLength: 27
MinLength: 1
ConstraintDescription: Infrastructure name must be alphanumeric, start with a letter, and have a maximum of 27 characters.
Description: A short, unique cluster ID used to tag cloud resources and identify items owned or used by the cluster.
Type: String
HostedZoneId:
Description: The Route53 public zone ID to register the targets with, such as Z21IXYZABCZ2A4.
Type: String
HostedZoneName:
Description: The Route53 zone to register the targets with, such as example.com. Omit the trailing period.
Type: String
Default: "example.com"
PublicSubnets:
Description: The internet-facing subnets.
Type: List<AWS::EC2::Subnet::Id>
PrivateSubnets:
Description: The internal subnets.
Type: List<AWS::EC2::Subnet::Id>
VpcId:
Description: The VPC-scoped resources will belong to this VPC.
Type: AWS::EC2::VPC::Id

Metadata:
AWS::CloudFormation::Interface:
  ParameterGroups:
  - Label: "Cluster Information"
    Parameters:

    Subnets: !Ref PrivateSubnets

Outputs:
  PrivateHostedZoneld:
    Description: Hosted zone ID for the private DNS, which is required for private records.
    Value: !Ref IntDns

  ExternalApiLoadBalancerName:
    Description: Full name of the external API load balancer.
    Value: !GetAtt ExtApiElb.LoadBalancerFullName

  InternalApiLoadBalancerName:
    Description: Full name of the internal API load balancer.
    Value: !GetAtt IntApiElb.LoadBalancerFullName

  ApiServerDnsName:
    Description: Full hostname of the API server, which is required for the Ignition config files.
    Value: !Join [",", ["api-int", !Ref ClusterName, !Ref HostedZoneName]]

  RegisterNlbIpTargetsLambda:
    Description: Lambda ARN useful to help register or deregister IP targets for these load balancers.
    Value: !GetAtt RegisterNlbIpTargets.Arn

  ExternalApiTargetGroupArn:
    Description: ARN of the external API target group.
    Value: !Ref ExternalApiTargetGroup

  InternalApiTargetGroupArn:
    Description: ARN of the internal API target group.
IMPORTANT

If you are deploying your cluster to an AWS government or secret region, you must update the `InternalApiServerRecord` to use `CNAME` records. Records of type `ALIAS` are not supported for AWS government regions. For example:

```plaintext
Type: CNAME
TTL: 10
ResourceRecords:
  - !GetAtt IntApiElb.DNSName
```

Additional resources

- See [Listing public hosted zones](#) in the AWS documentation for more information about listing public hosted zones.

### 6.14.11. Creating security group and roles in AWS

You must create security groups and roles in Amazon Web Services (AWS) for your OpenShift Container Platform cluster to use.

You can use the provided CloudFormation template and a custom parameter file to create a stack of AWS resources. The stack represents the security groups and roles that your OpenShift Container Platform cluster requires.

**NOTE**

If you do not use the provided CloudFormation template to create your AWS infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

**Prerequisites**

- You configured an AWS account.
- You added your AWS keys and region to your local AWS profile by running `aws configure`.
- You generated the Ignition config files for your cluster.
- You created and configured a VPC and associated subnets in AWS.

**Procedure**

1. Create a JSON file that contains the parameter values that the template requires:
The name for your cluster infrastructure that is encoded in your Ignition config files for the cluster.

Specify the infrastructure name that you extracted from the Ignition config file metadata, which has the format `<cluster-name>-<random-string>`.

The CIDR block for the VPC.

Specify the CIDR block parameter that you used for the VPC that you defined in the form `x.x.x.x/16-24`.

The private subnets that you created for your VPC.

Specify the `PrivateSubnetIds` value from the output of the CloudFormation template for the VPC.

The VPC that you created for the cluster.

Specify the `VpcId` value from the output of the CloudFormation template for the VPC.

2. Copy the template from the CloudFormation template for security objects section of this topic and save it as a YAML file on your computer. This template describes the security groups and roles that your cluster requires.

3. Launch the CloudFormation template to create a stack of AWS resources that represent the security groups and roles:

   IMPORTANT
   You must enter the command on a single line.

   ```
   $ aws cloudformation create-stack --stack-name <name>  
   --template-body file://<template>.yaml  
   --parameters file://<parameters>.json  
   --capabilities CAPABILITY_NAMED_IAM
   ```
1. `<name>` is the name for the CloudFormation stack, such as `cluster-sec`. You need the name of this stack if you remove the cluster.

2. `<template>` is the relative path to and name of the CloudFormation template YAML file that you saved.

3. `<parameters>` is the relative path to and name of the CloudFormation parameters JSON file.

4. You must explicitly declare the `CAPABILITY_NAMED_IAM` capability because the provided template creates some `AWS::IAM::Role` and `AWS::IAM::InstanceProfile` resources.

Example output

```
arn:aws:cloudformation:us-east-1:269333783861:stack/cluster-sec/03bd4210-2ed7-11eb-6d7a-13fc0b61e9db
```

4. Confirm that the template components exist:

```
$ aws cloudformation describe-stacks --stack-name <name>
```

After the `StackStatus` displays `CREATE_COMPLETE`, the output displays values for the following parameters. You must provide these parameter values to the other CloudFormation templates that you run to create your cluster:

<table>
<thead>
<tr>
<th>MasterSecurityGroupId</th>
<th>Master Security Group ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>WorkerSecurityGroupId</td>
<td>Worker Security Group ID</td>
</tr>
<tr>
<td>MasterInstanceProfile</td>
<td>Master IAM Instance Profile</td>
</tr>
<tr>
<td>WorkerInstanceProfile</td>
<td>Worker IAM Instance Profile</td>
</tr>
</tbody>
</table>

6.14.11.1. CloudFormation template for security objects

You can use the following CloudFormation template to deploy the security objects that you need for your OpenShift Container Platform cluster.

Example 6.90. CloudFormation template for security objects

```
AWSTemplateFormatVersion: 2010-09-09
Description: Template for OpenShift Cluster Security Elements (Security Groups & IAM)
```
Parameters:
InfrastructureName:
  AllowedPattern: ^([a-zA-Z][a-zA-Z0-9-]\{0,26}$
  MaxLength: 27
  MinLength: 1
  ConstraintDescription: Infrastructure name must be alphanumeric, start with a letter, and have a maximum of 27 characters.
  Description: A short, unique cluster ID used to tag cloud resources and identify items owned or used by the cluster.
  Type: String
VpcCidr:
  ConstraintDescription: CIDR block parameter must be in the form x.x.x.x/16-24.
  Default: 10.0.0.0/16
  Description: CIDR block for VPC.
  Type: String
VpcId:
  Description: The VPC-scoped resources will belong to this VPC.
  Type: AWS::EC2::VPC::Id
PrivateSubnets:
  Description: The internal subnets.
  Type: List<AWS::EC2::Subnet::Id>

Metadata:
AWS::CloudFormation::Interface:
  ParameterGroups:
  - Label: default: "Cluster Information"
    Parameters:
      InfrastructureName:
        - Label: default: "Infrastructure Name"
        Parameters:
          VpcId:
            - Label: default: "VPC ID"
          VpcCidr:
            - Label: default: "VPC CIDR"
          PrivateSubnets:
            - Label: default: "Private Subnets"

  Properties:
    AssumeRolePolicyDocument:
      Version: "2012-10-17"
      Statement:

In OpenShift Container Platform, stream metadata provides standardized metadata about RHCOS in the JSON format and injects the metadata into the cluster. Stream metadata is a stable format that supports multiple architectures and is intended to be self-documenting for maintaining automation.

You can use the coreos print-stream-json sub-command of openshift-install to access information about the boot images in the stream metadata format. This command provides a method for printing stream metadata in a scriptable, machine-readable format.

For user-provisioned installations, the openshift-install binary contains references to the version of RHCOS boot images that are tested for use with OpenShift Container Platform, such as the AWS AMI.

Procedure
To parse the stream metadata, use one of the following methods:

- From a Go program, use the official `stream-metadata-go` library at https://github.com/coreos/stream-metadata-go. You can also view example code in the library.
- From another programming language, such as Python or Ruby, use the JSON library of your preferred programming language.
- From a command-line utility that handles JSON data, such as `jq`:
  - Print the current x86_64 or aarch64 AMI for an AWS region, such as `us-west-1`:
    
    For x86_64
    
    ```bash
    $ openshift-install coreos print-stream-json | jq -r '.architectures.x86_64.images.aws.regions["us-west-1"].image'
    
    Example output
    
    ami-0d3e625f84626bbda
    
    For aarch64
    
    ```bash
    $ openshift-install coreos print-stream-json | jq -r '.architectures.aarch64.images.aws.regions["us-west-1"].image'
    
    Example output
    
    ami-0af1d3b7fa5be2131
    
    The output of this command is the AWS AMI ID for your designated architecture and the `us-west-1` region. The AMI must belong to the same region as the cluster.

6.14.13. RHCOS AMIs for the AWS infrastructure

Red Hat provides Red Hat Enterprise Linux CoreOS (RHCOS) AMIs that are valid for the various AWS regions and instance architectures that you can manually specify for your OpenShift Container Platform nodes.

NOTE

By importing your own AMI, you can also install to regions that do not have a published RHCOS AMI.

You must create the bootstrap node in Amazon Web Services (AWS) to use during OpenShift Container Platform cluster initialization. You do this by:

- Providing a location to serve the `bootstrap.ign` Ignition config file to your cluster. This file is located in your installation directory. The provided CloudFormation Template assumes that the Ignition config files for your cluster are served from an S3 bucket. If you choose to serve the files from another location, you must modify the templates.

- Using the provided CloudFormation template and a custom parameter file to create a stack of AWS resources. The stack represents the bootstrap node that your OpenShift Container Platform installation requires.

</tbody>
</table>
NOTE
If you do not use the provided CloudFormation template to create your bootstrap node, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

Prerequisites

- You configured an AWS account.
- You added your AWS keys and region to your local AWS profile by running `aws configure`.
- You generated the Ignition config files for your cluster.
- You created and configured a VPC and associated subnets in AWS.
- You created and configured DNS, load balancers, and listeners in AWS.
- You created the security groups and roles required for your cluster in AWS.

Procedure

1. Create the bucket by running the following command:

   ```bash
   $ aws s3 mb s3://<cluster-name>-infra
   ```

   `<cluster-name>-infra` is the bucket name. When creating the `install-config.yaml` file, replace `<cluster-name>` with the name specified for the cluster.

   You must use a presigned URL for your S3 bucket, instead of the `s3://` schema, if you are:
   - Deploying to a region that has endpoints that differ from the AWS SDK.
   - Deploying a proxy.
   - Providing your own custom endpoints.

2. Upload the `bootstrap.ign` Ignition config file to the bucket by running the following command:

   ```bash
   $ aws s3 cp <installation_directory>/bootstrap.ign s3://<cluster-name>-infra/bootstrap.ign
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

3. Verify that the file uploaded by running the following command:

   ```bash
   $ aws s3 ls s3://<cluster-name>-infra/
   ```

   Example output

   ```
   2019-04-03 16:15:16   314878 bootstrap.ign
   ```
NOTE

The bootstrap Ignition config file does contain secrets, like X.509 keys. The following steps provide basic security for the S3 bucket. To provide additional security, you can enable an S3 bucket policy to allow only certain users, such as the OpenShift IAM user, to access objects that the bucket contains. You can avoid S3 entirely and serve your bootstrap Ignition config file from any address that the bootstrap machine can reach.

4. Create a JSON file that contains the parameter values that the template requires:

```json
[
    {
        "ParameterKey": "InfrastructureName",
        "ParameterValue": "mycluster-<random_string>"
    },
    {
        "ParameterKey": "RhcosAmi",
        "ParameterValue": "ami-<random_string>"
    },
    {
        "ParameterKey": "AllowedBootstrapSshCidr",
        "ParameterValue": "0.0.0.0/0"
    },
    {
        "ParameterKey": "PublicSubnet",
        "ParameterValue": "subnet-<random_string>"
    },
    {
        "ParameterKey": "MasterSecurityGroupId",
        "ParameterValue": "sg-<random_string>"
    },
    {
        "ParameterKey": "VpcId",
        "ParameterValue": "vpc-<random_string>"
    },
    {
        "ParameterKey": "BootstrapIgnitionLocation",
        "ParameterValue": "s3://<bucket_name>/bootstrap.ign"
    },
    {
        "ParameterKey": "AutoRegisterELB",
        "ParameterValue": "yes"
    },
    {
        "ParameterKey": "RegisterNlbIpTargetsLambdaArn",
        "ParameterValue": "arn:aws:lambda:<aws_region>:<account_number>:function:<dns_stack_name>-RegisterNlbIpTargets-<random_string>"
    },
    {
        "ParameterKey": "ExternalApiTargetGroupArn",
        "ParameterValue": "arn:aws:elasticloadbalancing:<aws_region>:<account_number>:targetgroup/<dns_stack_name>-Exter-<random_string>"
    }
]```
The name for your cluster infrastructure that is encoded in your Ignition config files for the cluster.

Specify the infrastructure name that you extracted from the Ignition config file metadata, which has the format `<cluster-name><random-string>`.

Current Red Hat Enterprise Linux CoreOS (RHCOS) AMI to use for the bootstrap node based on your selected architecture.

Specify a valid `AWS::EC2::Image::Id` value.

CIDR block to allow SSH access to the bootstrap node.

Specify a CIDR block in the format `x.x.x.x/16-24`.

The public subnet that is associated with your VPC to launch the bootstrap node into.

Specify the `PublicSubnetIds` value from the output of the CloudFormation template for the VPC.

The master security group ID (for registering temporary rules)

Specify the `MasterSecurityGroupId` value from the output of the CloudFormation template for the security group and roles.

The VPC created resources will belong to.

Specify the `VpcId` value from the output of the CloudFormation template for the VPC.

Location to fetch bootstrap Ignition config file from.

Specify the S3 bucket and file name in the form `s3://<bucket_name>/bootstrap.ign`.

Whether or not to register a network load balancer (NLB).

Specify `yes` or `no`. If you specify `yes`, you must provide a Lambda Amazon Resource Name (ARN) value.

The ARN for NLB IP target registration lambda group.

Specify the `RegisterNlbIpTargetsLambda` value from the output of the CloudFormation template for DNS and load balancing. Use `arn:aws-us-gov` if deploying the cluster to an AWS GovCloud region.
The ARN for external API load balancer target group.

Specify the `ExternalApiTargetGroupArn` value from the output of the CloudFormation template for DNS and load balancing. Use `arn:aws-us-gov` if deploying the cluster to an AWS GovCloud region.

The ARN for internal API load balancer target group.

Specify the `InternalApiTargetGroupArn` value from the output of the CloudFormation template for DNS and load balancing. Use `arn:aws-us-gov` if deploying the cluster to an AWS GovCloud region.

The ARN for internal service load balancer target group.

Specify the `InternalServiceTargetGroupArn` value from the output of the CloudFormation template for DNS and load balancing. Use `arn:aws-us-gov` if deploying the cluster to an AWS GovCloud region.

5. Copy the template from the CloudFormation template for the bootstrap machine section of this topic and save it as a YAML file on your computer. This template describes the bootstrap machine that your cluster requires.

6. Optional: If you are deploying the cluster with a proxy, you must update the ignition in the template to add the `ignition.config.proxy` fields. Additionally, If you have added the Amazon EC2, Elastic Load Balancing, and S3 VPC endpoints to your VPC, you must add these endpoints to the `noProxy` field.

7. Launch the CloudFormation template to create a stack of AWS resources that represent the bootstrap node:

```
$ aws cloudformation create-stack --stack-name <name>  
   --template-body file://<template>.yaml  
   --parameters file://<parameters>.json  
   --capabilities CAPABILITY_NAMED_IAM
```

   1. `<name>` is the name for the CloudFormation stack, such as `cluster-bootstrap`. You need the name of this stack if you remove the cluster.

   2. `<template>` is the relative path to and name of the CloudFormation template YAML file that you saved.

   3. `<parameters>` is the relative path to and name of the CloudFormation parameters JSON file.

   4. You must explicitly declare the `CAPABILITY_NAMED_IAM` capability because the provided template creates some `AWS::IAM::Role` and `AWS::IAM::InstanceProfile` resources.

Example output
8. Confirm that the template components exist:

```
$ aws cloudformation describe-stacks --stack-name <name>
```

After the `StackStatus` displays `CREATE_COMPLETE`, the output displays values for the following parameters. You must provide these parameter values to the other CloudFormation templates that you run to create your cluster:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap InstanceId</td>
<td>The bootstrap Instance ID.</td>
</tr>
<tr>
<td>Bootstrap PublicIp</td>
<td>The bootstrap node public IP address.</td>
</tr>
<tr>
<td>Bootstrap PrivateIp</td>
<td>The bootstrap node private IP address.</td>
</tr>
</tbody>
</table>

You can use the following CloudFormation template to deploy the bootstrap machine that you need for your OpenShift Container Platform cluster.

**Example 6.91. CloudFormation template for the bootstrap machine**

```yaml
AWSTemplateFormatVersion: 2010-09-09
Description: Template for OpenShift Cluster Bootstrap (EC2 Instance, Security Groups and IAM)

Parameters:
InfrastructureName:
  AllowedPattern: ^([a-zA-Z][a-zA-Z0-9-]{0,26})$
  MaxLength: 27
  MinLength: 1
  ConstraintDescription: Infrastructure name must be alphanumeric, start with a letter, and have a maximum of 27 characters.
  Description: A short, unique cluster ID used to tag cloud resources and identify items owned or used by the cluster.
  Type: String
RhcosAmi:
  Description: Current Red Hat Enterprise Linux CoreOS AMI to use for bootstrap.
  Type: AWS::EC2::Image::Id
AllowedBootstrapSshCidr:
  AllowedPattern: ('^([0-9]{1,3}\.){3}[0-9]{1,3}(/[0-32])$'
  Description: CIDR block parameter must be in the form x.x.x.x/0-32.
  Default: 0.0.0.0/0
  Description: CIDR block to allow SSH access to the bootstrap node.
  Type: String
PublicSubnet:
  Description: The public subnet to launch the bootstrap node into.
```
Type: AWS::EC2::Subnet::Id
MasterSecurityGroupId:
   Description: The master security group ID for registering temporary rules.
   Type: AWS::EC2::SecurityGroup::Id
VpcId:
   Description: The VPC-scoped resources will belong to this VPC.
   Type: AWS::EC2::VPC::Id
BootstrapIgnitionLocation:
   Default: s3://my-s3-bucket/bootstrap.ign
   Description: Ignition config file location.
   Type: String
AutoRegisterELB:
   Default: "yes"
   AllowedValues:
      - "yes"
      - "no"
   Description: Do you want to invoke NLB registration, which requires a Lambda ARN parameter?
   Type: String
RegisterNlbIpTargetsLambdaArn:
   Description: ARN for NLB IP target registration lambda.
   Type: String
ExternalApiTargetGroupArn:
   Description: ARN for external API load balancer target group.
   Type: String
InternalApiTargetGroupArn:
   Description: ARN for internal API load balancer target group.
   Type: String
InternalServiceTargetGroupArn:
   Description: ARN for internal service load balancer target group.
   Type: String
BootstrapInstanceType:
   Description: Instance type for the bootstrap EC2 instance
   Default: "i3.large"
   Type: String

Metadata:
AWS::CloudFormation::Interface:
   ParameterGroups:
      - Label: "Cluster Information"
        Parameters:
           - InfrastructureName

    Value: !GetAtt BootstrapInstance.PublicIp

  BootstrapPrivateIp:
    Description: The bootstrap node private IP address.
    Value: !GetAtt BootstrapInstance.PrivateIp

Additional resources

- See RHCOS AMIs for the AWS infrastructure for details about the Red Hat Enterprise Linux CoreOS (RHCOS) AMIs for the AWS zones.

### 6.14.15. Creating the control plane machines in AWS

You must create the control plane machines in Amazon Web Services (AWS) that your cluster will use.

You can use the provided CloudFormation template and a custom parameter file to create a stack of AWS resources that represent the control plane nodes.

**IMPORTANT**

The CloudFormation template creates a stack that represents three control plane nodes.

**NOTE**

If you do not use the provided CloudFormation template to create your control plane nodes, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

**Prerequisites**

- You configured an AWS account.
• You added your AWS keys and region to your local AWS profile by running `aws configure`.
• You generated the Ignition config files for your cluster.
• You created and configured a VPC and associated subnets in AWS.
• You created and configured DNS, load balancers, and listeners in AWS.
• You created the security groups and roles required for your cluster in AWS.
• You created the bootstrap machine.

Procedure

1. Create a JSON file that contains the parameter values that the template requires:

```json
[{
  "ParameterKey": "InfrastructureName", 1
  "ParameterValue": "mycluster-<random_string>" 2
},
{
  "ParameterKey": "RhcosAmi", 3
  "ParameterValue": "ami-<random_string>" 4
},
{
  "ParameterKey": "AutoRegisterDNS", 5
  "ParameterValue": "yes" 6
},
{
  "ParameterKey": "PrivateHostedZoneld", 7
  "ParameterValue": "<random_string>" 8
},
{
  "ParameterKey": "PrivateHostedZoneName", 9
  "ParameterValue": "mycluster.example.com" 10
},
{
  "ParameterKey": "Master0Subnet", 11
  "ParameterValue": "subnet-<random_string>" 12
},
{
  "ParameterKey": "Master1Subnet", 13
  "ParameterValue": "subnet-<random_string>" 14
},
{
  "ParameterKey": "Master2Subnet", 15
  "ParameterValue": "subnet-<random_string>" 16
},
{
  "ParameterKey": "MasterSecurityGroupId", 17
  "ParameterValue": "sg-<random_string>" 18
}]
```
The name for your cluster infrastructure that is encoded in your Ignition config files for the cluster.

Specify the infrastructure name that you extracted from the Ignition config file metadata, which has the format <cluster-name>-<random-string>.

Current Red Hat Enterprise Linux CoreOS (RHCOS) AMI to use for the control plane machines based on your selected architecture.

Specify an AWS::EC2::Image::Id value.

Whether or not to perform DNS etcd registration.
Specify **yes** or **no**. If you specify **yes**, you must provide hosted zone information.

The Route 53 private zone ID to register the etcd targets with.

Specify the **PrivateHostedZoneId** value from the output of the CloudFormation template for DNS and load balancing.

The Route 53 zone to register the targets with.

Specify `<cluster_name>..<domain_name>` where `<domain_name>` is the Route 53 base domain that you used when you generated `install-config.yaml` file for the cluster. Do not include the trailing period (.) that is displayed in the AWS console.

A subnet, preferably private, to launch the control plane machines on.

Specify a subnet from the **PrivateSubnets** value from the output of the CloudFormation template for DNS and load balancing.

The master security group ID to associate with control plane nodes.

Specify the **MasterSecurityGroupId** value from the output of the CloudFormation template for the security group and roles.

The location to fetch control plane Ignition config file from.

Specify the generated Ignition config file location, `https://api-int.<cluster_name>..<domain_name>:22623/config/master`.

The base64 encoded certificate authority string to use.

Specify the value from the `master.ign` file that is in the installation directory. This value is the long string with the format `data:text/plain;charset=utf-8;base64,ABC...xYz==`.

The IAM profile to associate with control plane nodes.

Specify the **MasterInstanceProfile** parameter value from the output of the CloudFormation template for the security group and roles.

The type of AWS instance to use for the control plane machines based on your selected architecture.

The instance type value corresponds to the minimum resource requirements for control plane machines. For example **m6i.xlarge** is a type for AMD64 and **m6g.xlarge** is a type for ARM64.

Whether or not to register a network load balancer (NLB).

Specify **yes** or **no**. If you specify **yes**, you must provide a Lambda Amazon Resource Name (ARN) value.

The ARN for NLB IP target registration lambda group.

Specify the **RegisterNlbIpTargetsLambda** value from the output of the CloudFormation template for DNS and load balancing. Use `arn:aws-us-gov` if deploying the cluster to an AWS GovCloud region.

The ARN for external API load balancer target group.
Specify the `ExternalApiTargetGroupArn` value from the output of the CloudFormation template for DNS and load balancing. Use `arn:aws-us-gov` if deploying the cluster to an AWS GovCloud region.

The ARN for internal API load balancer target group.

Specify the `InternalApiTargetGroupArn` value from the output of the CloudFormation template for DNS and load balancing. Use `arn:aws-us-gov` if deploying the cluster to an AWS GovCloud region.

The ARN for internal service load balancer target group.

Specify the `InternalServiceTargetGroupArn` value from the output of the CloudFormation template for DNS and load balancing. Use `arn:aws-us-gov` if deploying the cluster to an AWS GovCloud region.

2. Copy the template from the CloudFormation template for control plane machines section of this topic and save it as a YAML file on your computer. This template describes the control plane machines that your cluster requires.

3. If you specified an `m5` instance type as the value for `MasterInstanceType`, add that instance type to the `MasterInstanceType.AllowedValues` parameter in the CloudFormation template.

4. Launch the CloudFormation template to create a stack of AWS resources that represent the control plane nodes:

   **IMPORTANT**

   You must enter the command on a single line.

   ```bash
   $ aws cloudformation create-stack --stack-name <name>  
   --template-body file://<template>.yaml  
   --parameters file://<parameters>.json
   ``

   - `<name>` is the name for the CloudFormation stack, such as `cluster-control-plane`. You need the name of this stack if you remove the cluster.
   - `<template>` is the relative path to and name of the CloudFormation template YAML file that you saved.
   - `<parameters>` is the relative path to and name of the CloudFormation parameters JSON file.

   **Example output**

   ```
   arn:aws:cloudformation:us-east-1:269333783861:stack/cluster-control-plane/21c7e2b0-2ee2-11eb-c6f6-0aa34627df4b
   ```

   **NOTE**

   The CloudFormation template creates a stack that represents three control plane nodes.
5. Confirm that the template components exist:

```
$ aws cloudformation describe-stacks --stack-name <name>
```

### 6.14.15.1. CloudFormation template for control plane machines

You can use the following CloudFormation template to deploy the control plane machines that you need for your OpenShift Container Platform cluster.

**Example 6.92. CloudFormation template for control plane machines**

AWSTemplateFormatVersion: 2010-09-09
Description: Template for OpenShift Cluster Node Launch (EC2 master instances)

Parameters:
- InfrastructureName:
  - AllowedPattern: ^([a-zA-Z][a-zA-Z0-9-]{0,26})$
  - MaxLength: 27
  - MinLength: 1
  - ConstraintDescription: Infrastructure name must be alphanumeric, start with a letter, and have a maximum of 27 characters.
- Description: A short, unique cluster ID used to tag nodes for the kubelet cloud provider.
  - Type: String
- RhcosAmi:
  - Description: Current Red Hat Enterprise Linux CoreOS AMI to use for bootstrap.
  - Type: AWS::EC2::Image::Id
- AutoRegisterDNS:
  - Default: ""
  - Description: unused
  - Type: String
- PrivateHostedZoneld:
  - Default: ""
  - Description: unused
  - Type: String
- PrivateHostedZoneName:
  - Default: ""
  - Description: unused
  - Type: String
- Master0Subnet:
  - Description: The subnets, recommend private, to launch the master nodes into.
  - Type: AWS::EC2::Subnet::Id
- Master1Subnet:
  - Description: The subnets, recommend private, to launch the master nodes into.
  - Type: AWS::EC2::Subnet::Id
- Master2Subnet:
  - Description: The subnets, recommend private, to launch the master nodes into.
  - Type: AWS::EC2::Subnet::Id
- MasterSecurityGroupId:
  - Description: The master security group ID to associate with master nodes.
  - Type: AWS::EC2::SecurityGroup::Id
- IgnitionLocation:
  - Default: https://api-int.$CLUSTER_NAME.$DOMAIN:22623/config/master
  - Description: Ignition config file location.
  - Type: String
- CertificateAuthorities:
Default: data:text/plain;charset=utf-8;base64,ABC...xYz==
Description: Base64 encoded certificate authority string to use.
Type: String
MasterInstanceProfileName:
Description: IAM profile to associate with master nodes.
Type: String
MasterInstanceType:
Default: m5.xlarge
Type: String

AutoRegisterELB:
Default: "yes"
AllowedValues:
- "yes"
- "no"
Description: Do you want to invoke NLB registration, which requires a Lambda ARN parameter?
Type: String
RegisterNlbIpTargetsLambdaArn:
Description: ARN for NLB IP target registration lambda. Supply the value from the cluster infrastructure or select "no" for AutoRegisterELB.
Type: String
ExternalApiTargetGroupArn:
Description: ARN for external API load balancer target group. Supply the value from the cluster infrastructure or select "no" for AutoRegisterELB.
Type: String
InternalApiTargetGroupArn:
Description: ARN for internal API load balancer target group. Supply the value from the cluster infrastructure or select "no" for AutoRegisterELB.
Type: String
InternalServiceTargetGroupArn:
Description: ARN for internal service load balancer target group. Supply the value from the cluster infrastructure or select "no" for AutoRegisterELB.
Type: String

Metadata:
AWS::CloudFormation::Interface:
ParameterGroups:
- Label:
  default: "Cluster Information"
Parameters:
- InfrastructureName
- Label:
  default: "Host Information"
Parameters:
- MasterInstanceType
- RhcosAmi
- IgnitionLocation
- CertificateAuthorities
- MasterSecurityGroupId
- MasterInstanceProfileName
- Label:
  default: "Network Configuration"
Parameters:
- VpcId
- AllowedBootstrapSshCidr
- Master0Subnet
- Master1Subnet
- Master2Subnet
- Label:
  default: "Load Balancer Automation"
Parameters:
- AutoRegisterELB
- RegisterNlbIpTargetsLambdaArn
- ExternalApiTargetGroupArn
- InternalApiTargetGroupArn
- InternalServiceTargetGroupArn
ParameterLabels:
  InfrastructureName:
    default: "Infrastructure Name"
VpcId:
  default: "VPC ID"
Master0Subnet:
  default: "Master-0 Subnet"
Master1Subnet:
  default: "Master-1 Subnet"
Master2Subnet:
  default: "Master-2 Subnet"
MasterInstanceType:
  default: "Master Instance Type"
MasterInstanceProfileName:
  default: "Master Instance Profile Name"
RhcosAmi:
  default: "Red Hat Enterprise Linux CoreOS AMI ID"
BootstrapIgnitionLocation:
  default: "Master Ignition Source"
CertificateAuthorities:
  default: "Ignition CA String"
MasterSecurityGroupId:
  default: "Master Security Group ID"
AutoRegisterELB:
  default: "Use Provided ELB Automation"

Conditions:
  DoRegistration: !Equals ["yes", !Ref AutoRegisterELB]

CHAPTER 6. INSTALLING ON AWS

801

You can create worker nodes in Amazon Web Services (AWS) for your cluster to use.

You can use the provided CloudFormation template and a custom parameter file to create a stack of AWS resources that represent a worker node.

**IMPORTANT**

The CloudFormation template creates a stack that represents one worker node. You must create a stack for each worker node.
NOTE
If you do not use the provided CloudFormation template to create your worker nodes, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

Prerequisites

- You configured an AWS account.
- You added your AWS keys and region to your local AWS profile by running `aws configure`.
- You generated the Ignition config files for your cluster.
- You created and configured a VPC and associated subnets in AWS.
- You created and configured DNS, load balancers, and listeners in AWS.
- You created the security groups and roles required for your cluster in AWS.
- You created the bootstrap machine.
- You created the control plane machines.

Procedure

1. Create a JSON file that contains the parameter values that the CloudFormation template requires:

```json
[
  {
    "ParameterKey": "InfrastructureName", 1
    "ParameterValue": "mycluster-<random_string>" 2
  },
  {
    "ParameterKey": "RhcosAmi", 3
    "ParameterValue": "ami-<random_string>" 4
  },
  {
    "ParameterKey": "Subnet", 5
    "ParameterValue": "subnet-<random_string>" 6
  },
  {
    "ParameterKey": "WorkerSecurityGroupId", 7
    "ParameterValue": "sg-<random_string>" 8
  },
  {
    "ParameterKey": "IgnitionLocation", 9
    "ParameterValue": "https://api-int.<cluster_name>.<domain_name>:22623/config/worker" 10
  },
  {
    "ParameterKey": "CertificateAuthorities", 11
    "ParameterValue": "" 12
  }
]```
The name for your cluster infrastructure that is encoded in your Ignition config files for the cluster.

Specify the infrastructure name that you extracted from the Ignition config file metadata, which has the format `<cluster-name>-<random-string>`.

Current Red Hat Enterprise Linux CoreOS (RHCOS) AMI to use for the worker nodes based on your selected architecture.

Specify an AWS::EC2::Image::Id value.

A subnet, preferably private, to start the worker nodes on.

Specify a subnet from the PrivateSubnets value from the output of the CloudFormation template for DNS and load balancing.

The worker security group ID to associate with worker nodes.

Specify the WorkerSecurityGroupId value from the output of the CloudFormation template for the security group and roles.

The location to fetch the bootstrap Ignition config file from.

Specify the generated Ignition config location, `https://api-int.<cluster_name>.<domain_name>:22623/config/worker`.

Base64 encoded certificate authority string to use.

Specify the value from the worker.ign file that is in the installation directory. This value is the long string with the format `data:text/plain;charset=utf-8;base64,ABC...xYz==`.

The IAM profile to associate with worker nodes.

Specify the WorkerInstanceProfile parameter value from the output of the CloudFormation template for the security group and roles.

The type of AWS instance to use for the compute machines based on your selected architecture.

The instance type value corresponds to the minimum resource requirements for compute machines. For example `m6i.large` is a type for AMD64 and `m6g.large` is a type for ARM64.

2. Copy the template from the CloudFormation template for worker machines section of this topic and save it as a YAML file on your computer. This template describes the networking objects and load balancers that your cluster requires.
3. Optional: If you specified an m5 instance type as the value for `WorkerInstanceType`, add that instance type to the `WorkerInstanceType.AllowedValues` parameter in the CloudFormation template.

4. Optional: If you are deploying with an AWS Marketplace image, update the `Worker0.type.properties.ImageID` parameter with the AMI ID that you obtained from your subscription.

5. Use the CloudFormation template to create a stack of AWS resources that represent a worker node:

   **IMPORTANT**
   
   You must enter the command on a single line.

   ```
   $ aws cloudformation create-stack --stack-name <name> 
   --template-body file://<template>.yaml 
   --parameters file://<parameters>.json
   ```

   - `<name>` is the name for the CloudFormation stack, such as `cluster-worker-1`. You need the name of this stack if you remove the cluster.
   - `<template>` is the relative path to and name of the CloudFormation template YAML file that you saved.
   - `<parameters>` is the relative path to and name of the CloudFormation parameters JSON file.

   **Example output**

   ```
   ```

   **NOTE**
   
   The CloudFormation template creates a stack that represents one worker node.

6. Confirm that the template components exist:

   ```
   $ aws cloudformation describe-stacks --stack-name <name>
   ```

7. Continue to create worker stacks until you have created enough worker machines for your cluster. You can create additional worker stacks by referencing the same template and parameter files and specifying a different stack name.

   **IMPORTANT**
   
   You must create at least two worker machines, so you must create at least two stacks that use this CloudFormation template.

You can use the following CloudFormation template to deploy the worker machines that you need for your OpenShift Container Platform cluster.

Example 6.93. CloudFormation template for worker machines

AWSTemplateFormatVersion: 2010-09-09
Description: Template for OpenShift Cluster Node Launch (EC2 worker instance)

Parameters:
InfrastructureName:
  AllowedPattern: ^([a-zA-Z][a-zA-Z0-9-]{0,26})$
  MaxLength: 27
  MinLength: 1
  ConstraintDescription: Infrastructure name must be alphanumeric, start with a letter, and have a maximum of 27 characters.
  Type: String
RhcosAmi:
  Description: Current Red Hat Enterprise Linux CoreOS AMI to use for bootstrap.
  Type: AWS::EC2::Image::Id
Subnet:
  Description: The subnets, recommend private, to launch the master nodes into.
  Type: AWS::EC2::Subnet::Id
WorkerSecurityGroupId:
  Description: The master security group ID to associate with master nodes.
  Type: AWS::EC2::SecurityGroup::Id
IgnitionLocation:
  Default: https://api-int.$CLUSTER_NAME.$DOMAIN:22623/config/worker
  Description: Ignition config file location.
  Type: String
CertificateAuthorities:
  Default: data:text/plain;charset=utf-8;base64,ABC...xYz==
  Description: Base64 encoded certificate authority string to use.
  Type: String
WorkerInstanceProfileName:
  Description: IAM profile to associate with master nodes.
  Type: String
WorkerInstanceType:
  Default: m5.large
  Type: String

Metadata:
AWS::CloudFormation::Interface:
  ParameterGroups:
    - Label: "Cluster Information"
      Parameters:
        - InfrastructureName
          - Label: "Host Information"
            Parameters:
              - WorkerInstanceType
                - RhcosAmi
                - IgnitionLocation
                - CertificateAuthorities
                - WorkerSecurityGroupId
- WorkerInstanceProfileName
- Label:
  - default: "Network Configuration"
Parameters:
- Subnet
ParameterLabels:
  Subnet:
    - default: "Subnet"
InfrastructureName:
    - default: "Infrastructure Name"
WorkerInstanceType:
    - default: "Worker Instance Type"
WorkerInstanceProfileName:
    - default: "Worker Instance Profile Name"
RhcosAmi:
    - default: "Red Hat Enterprise Linux CoreOS AMI ID"
IgnitionLocation:
    - default: "Worker Ignition Source"
CertificateAuthorities:
    - default: "Ignition CA String"
WorkerSecurityGroupId:
    - default: "Worker Security Group ID"

        Value: "shared"

Outputs:
6.14.17. Initializing the bootstrap sequence on AWS with user-provisioned infrastructure

After you create all of the required infrastructure in Amazon Web Services (AWS), you can start the bootstrap sequence that initializes the OpenShift Container Platform control plane.

Prerequisites

- You configured an AWS account.
- You added your AWS keys and region to your local AWS profile by running `aws configure`.
- You generated the Ignition config files for your cluster.
- You created and configured a VPC and associated subnets in AWS.
- You created and configured DNS, load balancers, and listeners in AWS.
- You created the security groups and roles required for your cluster in AWS.
- You created the bootstrap machine.
- You created the control plane machines.
- You created the worker nodes.

Procedure

1. Change to the directory that contains the installation program and start the bootstrap process that initializes the OpenShift Container Platform control plane:

   $ ./openshift-install wait-for bootstrap-complete --dir <installation_directory> \
   --log-level=info

   - For `<installation_directory>`, specify the path to the directory that you stored the installation files in.
   - To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

Example output

INFO Waiting up to 20m0s for the Kubernetes API at https://api.mycluster.example.com:6443...
INFO API v1.27.3 up
INFO Waiting up to 30m0s for bootstrapping to complete...
INFO It is now safe to remove the bootstrap resources
INFO Time elapsed: 1s
If the command exits without a **FATAL** warning, your OpenShift Container Platform control plane has initialized.

**NOTE**

After the control plane initializes, it sets up the compute nodes and installs additional services in the form of Operators.

Additional resources

- See [Monitoring installation progress](#) for details about monitoring the installation, bootstrap, and control plane logs as an OpenShift Container Platform installation progresses.

- See [Gathering bootstrap node diagnostic data](#) for information about troubleshooting issues related to the bootstrap process.

### 6.14.18. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.

- You installed the **oc** CLI.

**Procedure**

1. Export the **kubeadmin** credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   ```

   **Example output**

   ```
   system:admin
   ```

### 6.14.19. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

**Prerequisites**

```bash
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig
```

1. **Example output**

```
$ oc whoami
```
Prerequisites

- You added machines to your cluster.

Procedure

1. Confirm that the cluster recognizes the machines:

```
$ oc get nodes
```

Example output

```
NAME      STATUS    ROLES   AGE  VERSION
master-0  Ready     master  63m  v1.27.3
master-1  Ready     master  63m  v1.27.3
master-2  Ready     master  64m  v1.27.3
```

The output lists all of the machines that you created.

**NOTE**

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```
$ oc get csr
```

Example output

```
NAME        AGE     REQUESTOR                                                   CONDITION
csr-8b2br   15m     system:serviceaccount:openshift-machine-config-operator:node-bootstrapper   Pending
csr-8vnps   15m     system:serviceaccount:openshift-machine-config-operator:node-bootstrapper   Pending
...          
```

In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:
NOTE

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. After the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the machine-approver if the Kubelet requests a new certificate with identical parameters.

NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the oc exec, oc rsh, and oc logs commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the node-bootstrapper service account in the system:node or system:admin groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

  ```bash
  $ oc adm certificate approve <csr_name>
  ```

  <csr_name> is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

  ```bash
  $ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
  ```

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

  ```bash
  $ oc get csr
  ```

Example output

```
NAME    AGE        REQUESTOR                                                                 CONDITION
csr-bfd72 5m26s  system:node:ip-10-0-50-126.us-east-2.compute.internal             Pending
csr-c57lv 5m26s  system:node:ip-10-0-95-157.us-east-2.compute.internal             Pending
...```

Some Operators might not become available until some CSRs are approved.
5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:
  
  ```bash
  $ oc adm certificate approve <csr_name>
  ```

  where `<csr_name>` is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:
  
  ```bash
  $ oc get csr -o go-template='{range .items}{if not .status}{.metadata.name}{"\n"}{end}{end}' | xargs oc adm certificate approve
  ```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```bash
$ oc get nodes
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>74m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>worker-0</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.27.3</td>
</tr>
<tr>
<td>worker-1</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.27.3</td>
</tr>
</tbody>
</table>

**NOTE**

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

**Additional information**

- For more information on CSRs, see Certificate Signing Requests.

### 6.14.20. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

**Prerequisites**

- Your control plane has initialized.

**Procedure**

1. Watch the cluster components come online:

```bash
$ watch -n5 oc get clusteroperators
```
Example output

<table>

</table>

2. Configure the Operators that are not available.

**6.14.20.1. Disabling the default OperatorHub catalog sources**

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

**Procedure**

- Disable the sources for the default catalogs by adding `disableAllDefaultSources: true` to the `OperatorHub` object:

```bash
$ oc patch OperatorHub cluster --type json \
  -p '[{"op": "add", "path": "/spec/disableAllDefaultSources", "value": true}]'
```
TIP

Alternatively, you can use the web console to manage catalog sources. From the Administration → Cluster Settings → Configuration → OperatorHub page, click the Sources tab, where you can create, update, delete, disable, and enable individual sources.

6.14.20.2. Image registry storage configuration

Amazon Web Services provides default storage, which means the Image Registry Operator is available after installation. However, if the Registry Operator cannot create an S3 bucket and automatically configure storage, you must manually configure registry storage.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the Recreate rollout strategy during upgrades.

6.14.20.2.1. Configuring registry storage for AWS with user-provisioned infrastructure

During installation, your cloud credentials are sufficient to create an Amazon S3 bucket and the Registry Operator will automatically configure storage.

If the Registry Operator cannot create an S3 bucket and automatically configure storage, you can create an S3 bucket and configure storage with the following procedure.

Prerequisites

- You have a cluster on AWS with user-provisioned infrastructure.
- For Amazon S3 storage, the secret is expected to contain two keys:
  - REGISTRY_STORAGE_S3_ACCESSKEY
  - REGISTRY_STORAGE_S3_SECRETKEY

Procedure

Use the following procedure if the Registry Operator cannot create an S3 bucket and automatically configure storage.

1. Set up a Bucket Lifecycle Policy to abort incomplete multipart uploads that are one day old.

2. Fill in the storage configuration in configs.imageregistry.operator.openshift.io/cluster:

   ```
   $ oc edit configs.imageregistry.operator.openshift.io/cluster
   ```

   Example configuration

   ```yaml
   storage:
   s3:
     bucket: <bucket-name>
     region: <region-name>
   ```
6.14.20.2.2. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

Procedure

- To set the image registry storage to an empty directory:

  ```
  $ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec":
  {"storage":{"emptyDir":{}}}}'
  ```

WARNING

Configure this option for only non-production clusters.

If you run this command before the Image Registry Operator initializes its components, the `oc patch` command fails with the following error:

```
Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
```

Wait a few minutes and run the command again.

6.14.21. Deleting the bootstrap resources

After you complete the initial Operator configuration for the cluster, remove the bootstrap resources from Amazon Web Services (AWS).

Prerequisites

- You completed the initial Operator configuration for your cluster.

Procedure

1. Delete the bootstrap resources. If you used the CloudFormation template, delete its stack:

   ```
   $ aws cloudformation delete-stack --stack-name <name>
   ```

   1
<name> is the name of your bootstrap stack.

- Delete the stack by using the AWS CloudFormation console.

If you removed the DNS Zone configuration, manually create DNS records that point to the Ingress load balancer. You can create either a wildcard record or specific records. While the following procedure uses A records, you can use other record types that you require, such as CNAME or alias.

Prerequisites

- You deployed an OpenShift Container Platform cluster on Amazon Web Services (AWS) that uses infrastructure that you provisioned.
- You installed the OpenShift CLI (`oc`).
- You installed the `jq` package.
- You downloaded the AWS CLI and installed it on your computer. See Install the AWS CLI Using the Bundled Installer (Linux, macOS, or Unix).

Procedure

1. Determine the routes to create.

   - To create a wildcard record, use `*.apps.<cluster_name>.<domain_name>`, where <cluster_name> is your cluster name, and <domain_name> is the Route 53 base domain for your OpenShift Container Platform cluster.

   - To create specific records, you must create a record for each route that your cluster uses, as shown in the output of the following command:

     ```
     $ oc get --all-namespaces -o jsonpath='{range .items[*]}{range .status.ingress[*]}{.host}{"\n"}{end}{end}' routes
     ```

   ```
   oauth-openshift.apps.<cluster_name>.<domain_name>
   console-openshift-console.apps.<cluster_name>.<domain_name>
   downloads-openshift-console.apps.<cluster_name>.<domain_name>
   alertmanager-main-openshift-monitoring.apps.<cluster_name>.<domain_name>
   prometheus-k8s-openshift-monitoring.apps.<cluster_name>.<domain_name>
   ```

2. Retrieve the Ingress Operator load balancer status and note the value of the external IP address that it uses, which is shown in the `EXTERNAL-IP` column:

   ```
   $ oc -n openshift-ingress get service router-default
   ```

   **Example output**

   ```
   NAME               TYPE     CLUSTER-IP     EXTERNAL-IP     PORT(S)
   AGE
   ```
3. Locate the hosted zone ID for the load balancer:

   ```bash
   $ aws elb describe-load-balancers | jq -r '.LoadBalancerDescriptions[] | select(.DNSName == "<external_ip>").CanonicalHostedZoneNameID'
   ```

   For `<external_ip>`, specify the value of the external IP address of the Ingress Operator load balancer that you obtained.

   **Example output**

   ```bash
   Z3AADJGX6KTTL2
   ```

   The output of this command is the load balancer hosted zone ID.

4. Obtain the public hosted zone ID for your cluster's domain:

   ```bash
   $ aws route53 list-hosted-zones-by-name \
   --dns-name "<domain_name>" \
   --query 'HostedZones[? Config.PrivateZone != `true` && Name == `<domain_name>.`].Id' \
   --output text
   ```

   For `<domain_name>`, specify the Route 53 base domain for your OpenShift Container Platform cluster.

   **Example output**

   ```bash
   /hostedzone/Z3URY6TWQ91KVV
   ```

   The public hosted zone ID for your domain is shown in the command output. In this example, it is Z3URY6TWQ91KVV.

5. Add the alias records to your private zone:

   ```bash
   $ aws route53 change-resource-record-sets --hosted-zone-id "<private_hosted_zone_id>" --change-batch '{
   "Changes": [
   { "Action": "CREATE", "ResourceRecordSet": { "Name": ".apps.<cluster_domain>", "Type": "A", "AliasTarget": { "HostedZoneId": "<hosted_zone_id>", "DNSName": "<external_ip>", "EvaluateTargetHealth": false } } }
   }
   ```

   These commands create the necessary alias records to forward the load balancer traffic to your application.
For `<private_hosted_zone_id>`, specify the value from the output of the CloudFormation template for DNS and load balancing.

For `<cluster_domain>`, specify the domain or subdomain that you use with your OpenShift Container Platform cluster.

For `<hosted_zone_id>`, specify the public hosted zone ID for the load balancer that you obtained.

For `<external_ip>`, specify the value of the external IP address of the Ingress Operator load balancer. Ensure that you include the trailing period (.) in this parameter value.

6. Add the records to your public zone:

```bash
$ aws route53 change-resource-record-sets --hosted-zone-id "<public_hosted_zone_id>" --change-batch '{
  "Changes": [
    {
      "Action": "CREATE",
      "ResourceRecordSet": {
        "Name": "\052.apps.<cluster_domain>",
        "Type": "A",
        "AliasTarget": {
          "HostedZoneId": "<hosted_zone_id>",
          "DNSName": "<external_ip>",
          "EvaluateTargetHealth": false
        }
      }
    }
  ]
}'
```

For `<public_hosted_zone_id>`, specify the public hosted zone for your domain.

For `<cluster_domain>`, specify the domain or subdomain that you use with your OpenShift Container Platform cluster.

For `<hosted_zone_id>`, specify the public hosted zone ID for the load balancer that you obtained.

For `<external_ip>`, specify the value of the external IP address of the Ingress Operator load balancer. Ensure that you include the trailing period (.) in this parameter value.

6.14.23. Completing an AWS installation on user-provisioned infrastructure

After you start the OpenShift Container Platform installation on Amazon Web Service (AWS) user-provisioned infrastructure, monitor the deployment to completion.

Prerequisites
You removed the bootstrap node for an OpenShift Container Platform cluster on user-provisioned AWS infrastructure.

You installed the `oc` CLI.

**Procedure**

1. From the directory that contains the installation program, complete the cluster installation:

   ```bash
   $ ./openshift-install --dir <installation_directory> wait-for install-complete
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   **Example output**

   ```
   INFO Waiting up to 40m0s for the cluster at https://api.mycluster.example.com:6443 to initialize...
   INFO Waiting up to 10m0s for the openshift-console route to be created...
   INFO Install complete!
   INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
   INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
   INFO Login to the console with user: "kubeadmin", and password: "password"
   INFO Time elapsed: 1s
   ```

   **IMPORTANT**

   - The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

   - It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

2. Register your cluster on the Cluster registration page.

**6.14.24. Logging in to the cluster by using the web console**

The `kubeadmin` user exists by default after an OpenShift Container Platform installation. You can log in to your cluster as the `kubeadmin` user by using the OpenShift Container Platform web console.

**Prerequisites**
You have access to the installation host.

You completed a cluster installation and all cluster Operators are available.

**Procedure**

1. Obtain the password for the **kubeadmin** user from the **kubeadmin-password** file on the installation host:

   ```
   $ cat <installation_directory>/auth/kubeadmin-password
   ```

   **NOTE**

   Alternatively, you can obtain the **kubeadmin** password from the `<installation_directory>/openshift_install.log` log file on the installation host.

2. List the OpenShift Container Platform web console route:

   ```
   $ oc get routes -n openshift-console | grep 'console-openshift'
   ```

   **NOTE**

   Alternatively, you can obtain the OpenShift Container Platform route from the `<installation_directory>/openshift_install.log` log file on the installation host.

   **Example output**

   ```
   console     console-openshift-console.apps.<cluster_name>.<base_domain>            console
   https   reencrypt/Redirect   None
   ```

3. Navigate to the route detailed in the output of the preceding command in a web browser and log in as the **kubeadmin** user.

**Additional resources**

- See [Accessing the web console](#) for more details about accessing and understanding the OpenShift Container Platform web console.

**6.14.25. Telemetry access for OpenShift Container Platform**

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to **OpenShift Cluster Manager Hybrid Cloud Console**.

After you confirm that your **OpenShift Cluster Manager Hybrid Cloud Console** inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use `subscription watch` to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- See [Accessing the web console](#) for more details about accessing and understanding the OpenShift Container Platform web console.

- See About remote health monitoring for more information about the Telemetry service.

6.14.27. Next steps

- Validate an installation.
- Customize your cluster.
- Configure image streams for the Cluster Samples Operator and the must-gather tool.
- Learn how to use Operator Lifecycle Manager (OLM) on restricted networks.
- If the mirror registry that you used to install your cluster has a trusted CA, add it to the cluster by configuring additional trust stores.
- If necessary, you can opt out of remote health reporting.
- If necessary, see Registering your disconnected cluster.
- If necessary, you can remove cloud provider credentials.

6.15. INSTALLING A CLUSTER ON AWS WITH REMOTE WORKERS ON AWS OUTPOSTS

In OpenShift Container Platform version 4.14, you can install a cluster on Amazon Web Services (AWS) with remote workers running in AWS Outposts. This can be achieved by customizing the default AWS installation and performing some manual steps.

For more info about AWS Outposts see AWS Outposts Documentation.

**IMPORTANT**

In order to install a cluster with remote workers in AWS Outposts, all worker instances must be located within the same Outpost instance and cannot be located in an AWS region. It is not possible for the cluster to have instances in both AWS Outposts and AWS region. In addition, it also follows that control plane nodes mustn’t be schedulable.

6.15.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You configured an AWS account to host the cluster.
- You are familiar with the instance types are supported in the AWS Outpost instance you use. This can be validated with get-outpost-instance-types AWS CLI command.
You are familiar with the AWS Outpost instance details, such as OutpostArn and AvailabilityZone. This can be validated with `list-outposts` AWS CLI command.

**IMPORTANT**

Since the cluster uses the provided AWS credentials to create AWS resources for its entire life cycle, the credentials must be key-based and long-term. So, if you have an AWS profile stored on your computer, it must not use a temporary session token, generated while using a multi-factor authentication device. For more information about generating the appropriate keys, see *Managing Access Keys for IAM Users* in the AWS documentation. You may supply the keys when you run the installation program.

- You have access to an existing Amazon Virtual Private Cloud (VPC) in Amazon Web Services (AWS). See the section "About using a custom VPC" for more information.

- If a firewall is used, it was configured to allow the sites that your cluster requires access to.

### 6.15.2. About using a custom VPC

OpenShift Container Platform 4.14 installer cannot automatically deploy AWS Subnets on AWS Outposts, so you will need to manually configure the VPC. Therefore, you have to deploy the cluster into existing subnets in an existing Amazon Virtual Private Cloud (VPC) in Amazon Web Services (AWS). In addition, by deploying OpenShift Container Platform into an existing AWS VPC, you might be able to avoid limit constraints in new accounts or more easily abide by the operational constraints that your company’s guidelines set.

Because the installation program cannot know what other components are also in your existing subnets, it cannot choose subnet CIDRs and so forth on your behalf. You must configure networking for the subnets that you install your cluster to yourself.

#### 6.15.2.1. Requirements for using your VPC

The installation program no longer creates the following components:

- Internet gateways
- NAT gateways
- Subnets
- Route tables
- VPCs
- VPC DHCP options
- VPC endpoints

**NOTE**

The installation program requires that you use the cloud-provided DNS server. Using a custom DNS server is not supported and causes the installation to fail.
If you use a custom VPC, you must correctly configure it and its subnets for the installation program and the cluster to use. See Amazon VPC console wizard configurations and Work with VPCs and subnets in the AWS documentation for more information on creating and managing an AWS VPC.

The installation program cannot:

- Subdivide network ranges for the cluster to use.
- Set route tables for the subnets.
- Set VPC options like DHCP.

You must complete these tasks before you install the cluster. See VPC networking components and Route tables for your VPC for more information on configuring networking in an AWS VPC.

Your VPC must meet the following characteristics:

**NOTE**

To allow the creation of OpenShift Container Platform with remote workers in the AWS Outposts, you must create at least one private subnet in the AWS Outpost instance for the workload instances creation and one private subnet in an AWS region for the control plane instances creation. If you specify more than one private subnet in the region, the control plane instances will be distributed across these subnets. You will also need to create a public subnet in each of the availability zones used for private subnets, including the Outpost private subnet, as Network Load Balancers will be created in the AWS region for the API server and Ingress network as part of the cluster installation. It is possible to create an AWS region private subnet in the same Availability zone as an Outpost private subnet.

- Create a public and private subnet in the AWS Region for each availability zone that your control plane uses. Each availability zone can contain no more than one public and one private subnet in the AWS region. For an example of this type of configuration, see VPC with public and private subnets (NAT) in the AWS documentation.
  
  To create a private subnet in the AWS Outposts, you need to first ensure that the Outpost instance is located in the desired availability zone. Then, you can create the private subnet within that availability zone within the Outpost instance, by adding the Outpost ARN. Make sure there is another public subnet in the AWS Region created in the same availability zone.

Record each subnet ID. Completing the installation requires that you enter all the subnets IDs, created in the AWS Region, in the platform section of the `install-config.yaml` file and changing the workers `machineset` to use the private subnet ID created in the Outpost. See Finding a subnet ID in the AWS documentation.

**IMPORTANT**

In case you need to create a public subnet in the AWS Outposts, verify that this subnet is not used for the Network or Classic LoadBalancer, otherwise the LoadBalancer creation fails. To achieve that, the `kubernetes.io/cluster/.*-outposts: owned` special tag must be included in the subnet.

- The VPC’s CIDR block must contain the Networking.MachineCIDR range, which is the IP address pool for cluster machines. The subnet CIDR blocks must belong to the machine CIDR that you specify.
The VPC must have a public internet gateway attached to it. For each availability zone:
  
  - The public subnet requires a route to the internet gateway.
  - The public subnet requires a NAT gateway with an EIP address.
  - The private subnet requires a route to the NAT gateway in public subnet.

NOTE

To access your local cluster over your local network, the VPC must be associated with your Outpost’s local gateway route table. For more information, see VPC associations in the AWS Outposts User Guide.

The VPC must not use the `kubernetes.io/cluster/.*: owned, Name, and openshift.io/cluster` tags.

The installation program modifies your subnets to add the `kubernetes.io/cluster/.*: shared` tag, so your subnets must have at least one free tag slot available for it. See Tag Restrictions in the AWS documentation to confirm that the installation program can add a tag to each subnet that you specify. You cannot use a Name tag, because it overlaps with the EC2 Name field and the installation fails.

You must enable the `enableDnsSupport` and `enableDnsHostnames` attributes in your VPC, so that the cluster can use the Route 53 zones that are attached to the VPC to resolve cluster’s internal DNS records. See DNS Support in Your VPC in the AWS documentation.

If you prefer to use your own Route 53 hosted private zone, you must associate the existing hosted zone with your VPC prior to installing a cluster. You can define your hosted zone using the `platform.aws.hostedZone` and `platform.aws.hostedZoneRole` fields in the `install-config.yaml` file. You can use a private hosted zone from another account by sharing it with the account where you install the cluster. If you use a private hosted zone from another account, you must use the Passthrough or Manual credentials mode.

Option 1: Create VPC endpoints

Create a VPC endpoint and attach it to the subnets that the clusters are using. Name the endpoints as follows:

- `ec2.<aws_region>.amazonaws.com`
- `elasticloadbalancing.<aws_region>.amazonaws.com`
- `s3.<aws_region>.amazonaws.com`

With this option, network traffic remains private between your VPC and the required AWS services.

Option 2: Create a proxy without VPC endpoints

As part of the installation process, you can configure an HTTP or HTTPS proxy. With this option, internet traffic goes through the proxy to reach the required AWS services.

Option 3: Create a proxy with VPC endpoints

As part of the installation process, you can configure an HTTP or HTTPS proxy with VPC endpoints. Create a VPC endpoint and attach it to the subnets that the clusters are using. Name the endpoints as follows:

- `ec2.<aws_region>.amazonaws.com`
- `elasticloadbalancing.<aws_region>.amazonaws.com`
When configuring the proxy in the `install-config.yaml` file, add these endpoints to the `noProxy` field. With this option, the proxy prevents the cluster from accessing the internet directly. However, network traffic remains private between your VPC and the required AWS services.

**Required VPC components**

You must provide a suitable VPC and subnets that allow communication to your machines.

<table>
<thead>
<tr>
<th>Component</th>
<th>AWS type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VPC</td>
<td><strong>AWS::EC2::VPC</strong>  &lt;br&gt; <strong>AWS::EC2::VPCEndpoint</strong></td>

</table>

### 6.15.2.2. VPC validation

To ensure that the subnets that you provide are suitable, the installation program confirms the following data:

- All the subnets that you specify exist.
- You provide private subnets.
- The subnet CIDRs belong to the machine CIDR that you specified.
- You provide subnets for each availability zone. Each availability zone contains exactly one public and one private subnet in the AWS region (not created in the Outpost instance). The availability zone in which the Outpost instance is installed should include one additional private subnet in the Outpost instance.
- You provide a public subnet for each private subnet availability zone. Machines are not provisioned in availability zones that you do not provide private subnets for.

If you destroy a cluster that uses an existing VPC, the VPC is not deleted. When you remove the OpenShift Container Platform cluster from a VPC, the `kubernetes.io/cluster/*`: shared tag is removed from the subnets that it used.

### 6.15.2.3. Division of permissions

Starting with OpenShift Container Platform 4.3, you do not need all of the permissions that are required for an installation program-provisioned infrastructure cluster to deploy a cluster. This change mimics the division of permissions that you might have at your company: some individuals can create different
resource in your clouds than others. For example, you might be able to create application-specific items, like instances, buckets, and load balancers, but not networking-related components such as VPCs, subnets, or ingress rules.

The AWS credentials that you use when you create your cluster do not need the networking permissions that are required to make VPCs and core networking components within the VPC, such as subnets, routing tables, internet gateways, NAT, and VPN. You still need permission to make the application resources that the machines within the cluster require, such as ELBs, security groups, S3 buckets, and nodes.

6.15.2.4. Isolation between clusters

If you deploy OpenShift Container Platform to an existing network, the isolation of cluster services is reduced in the following ways:

- You can install multiple OpenShift Container Platform clusters in the same VPC.
- ICMP ingress is allowed from the entire network.
- TCP 22 ingress (SSH) is allowed to the entire network.
- Control plane TCP 6443 ingress (Kubernetes API) is allowed to the entire network.
- Control plane TCP 22623 ingress (MCS) is allowed to the entire network.

6.15.2.5. AWS security groups

By default, the installation program creates and attaches security groups to control plane and compute machines. The rules associated with the default security groups cannot be modified.

However, you can apply additional existing AWS security groups, which are associated with your existing VPC, to control plane and compute machines. Applying custom security groups can help you meet the security needs of your organization, in such cases where you need to control the incoming or outgoing traffic of these machines.

As part of the installation process, you apply custom security groups by modifying the install-config.yaml file before deploying the cluster.

For more information, see “Applying existing AWS security groups to the cluster”.

6.15.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager Hybrid Cloud Console to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.
If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

6.15.4. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The ./openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

NOTE

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>

   Specify the path and file name, such as ~/.ssh/id_ed25519, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   IMPORTANT

   If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.
2. View the public SSH key:

```bash
$ cat <path>/<file_name>.pub
```

For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

```bash
$ cat ~/.ssh/id_ed25519.pub
```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

**NOTE**

On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

a. If the `ssh-agent` process is not already running for your local user, start it as a background task:

```bash
$ eval "$(ssh-agent -s)"
```

**Example output**

```
Agent pid 31874
```

**NOTE**

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the `ssh-agent`:

```bash
$ ssh-add <path>/<file_name>  # 1
```

1. Specify the path and file name for your SSH private key, such as `~/.ssh/id_ed25519`

**Example output**

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

**6.15.5. Obtaining the installation program**

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.
Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

   IMPORTANT

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   IMPORTANT

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   $ tar -xvf openshift-install-linux.tar.gz

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

6.15.6. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

Table 6.24. Minimum resource requirements

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
</tbody>
</table>
### Machine Specifications

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Compute</td>
<td>RHCOS, RHEL 8.6 and later [3]</td>
<td>2</td>
<td>8 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
</tbody>
</table>

1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or hyperthreading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: \((\text{threads per core} \times \text{cores}) \times \text{sockets} = \text{vCPUs}\).

2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.

3. As with all user-provisioned installations, if you choose to use RHEL compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and has been removed in OpenShift Container Platform 4.10 and later.

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

**Additional resources**

- [Optimizing storage](#)

### 6.15.7. Identifying your AWS Outposts instance types

AWS Outposts rack catalog includes options supporting the latest generation Intel powered EC2 instance types with or without local instance storage. Identify which instance types are configured in your AWS Outpost instance. As part of the installation process, you must update the `install-config.yaml` file with the instance type that the installation program will use to deploy worker nodes.

**Procedure**

Use the AWS CLI to get the list of supported instance types by running the following command:

```bash
$ aws outposts get-outpost-instance-types --outpost-id <outpost_id>  
```

For `<outpost_id>`, specify the Outpost ID, used in the AWS account for the worker instances.
IMPORTANT

When you purchase capacity for your AWS Outpost instance, you specify an EC2 capacity layout that each server provides. Each server supports a single family of instance types. A layout can offer a single instance type or multiple instance types. Dedicated Hosts allows you to alter whatever you chose for that initial layout. If you allocate a host to support a single instance type for the entire capacity, you can only start a single instance type from that host.

Supported instance types in AWS Outposts might be changed. For more information, you can check the Compute and Storage page in AWS Outposts documents.

6.15.8. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Amazon Web Services (AWS).

Prerequisites

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Create the `install-config.yaml` file.
   a. Change to the directory that contains the installation program and run the following command:

```
$ ./openshift-install create install-config --dir <installation_directory>  
```

   For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

When specifying the directory:

- Verify that the directory has the `execute` permission. This permission is required to run Terraform binaries under the installation directory.

- Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

NOTE

Always delete the `~/.powervs` directory to avoid reusing a stale configuration. Run the following command:

```
$ rm -rf ~/.powervs
```
b. At the prompts, provide the configuration details for your cloud:

   i. Optional: Select an SSH key to use to access your cluster machines.

   **NOTE**

   For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

   ii. Select AWS as the platform to target.

   iii. If you do not have an Amazon Web Services (AWS) profile stored on your computer, enter the AWS access key ID and secret access key for the user that you configured to run the installation program.

   iv. Select the AWS region to deploy the cluster to.

   v. Select the base domain for the Route 53 service that you configured for your cluster.

   vi. Enter a descriptive name for your cluster.

2. Modify the `install-config.yaml` file. The AWS Outposts installation has the following limitations which require manual modification of the `install-config.yaml` file:

   - Unlike AWS Regions, which offer near-infinite scale, AWS Outposts are limited by their provisioned capacity, EC2 family and generations, configured instance sizes, and availability of compute capacity that is not already consumed by other workloads. Therefore, when creating new OpenShift Container Platform cluster, you need to provide the supported instance type in the `compute.platform.aws.type` section in the configuration file.

   - When deploying OpenShift Container Platform cluster with remote workers running in AWS Outposts, only one Availability Zone can be used for the compute instances - the Availability Zone in which the Outpost instance was created in. Therefore, when creating new OpenShift Container Platform cluster, it recommended to provide the relevant Availability Zone in the `compute.platform.aws.zones` section in the configuration file, in order to limit the compute instances to this Availability Zone.

   - Amazon Elastic Block Store (EBS) gp3 volumes aren’t supported by the AWS Outposts service. This volume type is the default type used by the OpenShift Container Platform cluster. Therefore, when creating new OpenShift Container Platform cluster, you must change the volume type in the `compute.platform.aws.rootVolume.type` section to gp2. You will find more information about how to change these values below.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

   **IMPORTANT**

   The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

Additional resources

- Installation configuration parameters for AWS
6.15.8.1. Sample customized install-config.yaml file for AWS

You can customize the installation configuration file (install-config.yaml) to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

**IMPORTANT**

This sample YAML file is provided for reference only. You must obtain your install-config.yaml file by using the installation program and modify it.

```yaml
apiVersion: v1
baseDomain: example.com
credentialsMode: Mint
controlPlane:
  hyperthreading: Enabled
  name: master
  platform: {}
  replicas: 3
compute:
  - hyperthreading: Enabled
    name: worker
    platform:
      aws:
        type: m5.large
        zones:
        - us-east-1a
        rootVolume:
          type: gp2
          size: 120
          replicas: 3
metadata:
  name: test-cluster
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
    hostPrefix: 23
  machineNetwork:
    - cidr: 10.0.0.0/16
  networkType: OVNKubernetes
  serviceNetwork:
    - 172.30.0.0/16
platform:
  aws:
    region: us-west-2
  propagateUserTags: true
  userTags:
    adminContact: jdoe
    costCenter: 7536
subnets:
- subnet-1
- subnet-2
```
- subnet-3  
sshKey: ssh-ed25519 AAAA...  
pullSecret: {"auths": ...}  

1 Required. The installation program prompts you for this value.

2 Optional: Add this parameter to force the Cloud Credential Operator (CCO) to use the specified mode. By default, the CCO uses the root credentials in the **kube-system** namespace to dynamically try to determine the capabilities of the credentials. For details about CCO modes, see the "About the Cloud Credential Operator" section in the [Authentication and authorization guide](#).

3 If you do not provide these parameters and values, the installation program provides the default value.

4 The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, `-`, and the first line of the **controlPlane** section must not. Only one control plane pool is used.

5 Whether to enable or disable simultaneous multithreading, or **hyperthreading**. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to **Disabled**. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

   **IMPORTANT**

   If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger instance types, such as **m4.2xlarge** or **m5.2xlarge**, for your machines if you disable simultaneous multithreading.

6 For compute instances running in an AWS Outpost instance, specify a supported instance type in the AWS Outpost instance.

7 For compute instances running in AWS Outpost instance, specify the Availability Zone where the Outpost instance is located.

8 For compute instances running in AWS Outpost instance, specify volume type gp2, to avoid using gp3 volume type which is not supported.

9 The cluster network plugin to install. The supported values are **OVNKubernetes** and **OpenShiftSDN**. The default value is **OVNKubernetes**.

10 If you provide your own VPC, specify subnets for each availability zone that your cluster uses.

11 You can optionally provide the **sshKey** value that you use to access the machines in your cluster.

   **NOTE**

   For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.
6.15.8.2. Applying existing AWS security groups to the cluster

Applying existing AWS security groups to your control plane and compute machines can help you meet the security needs of your organization, in such cases where you need to control the incoming or outgoing traffic of these machines.

Prerequisites

- You have created the security groups in AWS. For more information, see the AWS documentation about working with security groups.
- The security groups must be associated with the existing VPC that you are deploying the cluster to. The security groups cannot be associated with another VPC.
- You have an existing `install-config.yaml` file.

Procedure

1. In the `install-config.yaml` file, edit the `compute.platform.aws.additionalSecurityGroupIDs` parameter to specify one or more custom security groups for your compute machines.

2. Edit the `controlPlane.platform.aws.additionalSecurityGroupIDs` parameter to specify one or more custom security groups for your control plane machines.

3. Save the file and reference it when deploying the cluster.

Sample `install-config.yaml` file that specifies custom security groups

```yaml
# ...
compute:
- hyperthreading: Enabled
  name: worker
  platform:
    aws:
      additionalSecurityGroupIDs:
        - sg-1
        - sg-2
  replicas: 3
controlPlane:
  hyperthreading: Enabled
  name: master
  platform:
    aws:
      additionalSecurityGroupIDs:
        - sg-3
        - sg-4
  replicas: 3
# ...
```
Specify the name of the security group as it appears in the Amazon EC2 console, including the `sg` prefix.

Specify subnets for each availability zone that your cluster uses.

### 6.15.9. Generating manifest files

Use the installation program to generate a set of manifest files in the assets directory. Manifest files are required to specify the AWS Outposts subnets to use for worker machines, and to specify settings required by the network provider.

If you plan to reuse the `install-config.yaml` file, create a backup file before you generate the manifest files.

**Procedure**

1. Optional: Create a backup copy of the `install-config.yaml` file:

   ```
   $ cp install-config.yaml install-config.yaml.backup
   ```

2. Generate a set of manifests in your assets directory:

   ```
   $ openshift-install create manifests --dir <installation_directory>
   ```

   This command displays the following messages.

**Example output**

```
INFO Consuming Install Config from target directory
INFO Manifests created in: <installation_directory>/manifests and <installation_directory>/openshift
```

The command generates the following manifest files:

**Example output**

```
$ tree
.
   manifests
   ├── cluster-config.yaml
   ├── cluster-dns-02-config.yml
   ├── cluster-infrastructure-02-config.yml
   ├── cluster-ingress-02-config.yml
   ├── cluster-network-01-crd.yml
   ├── cluster-network-02-config.yml
   ├── cluster-proxy-01-config.yaml
   ├── cluster-scheduler-02-config.yml
   ├── cvo-overrides.yaml
   ├── kube-cloud-config.yaml
   ├── kube-system-configmap-root-ca.yaml
   └── machine-config-server-tls-secret.yaml

   openshift-config-secret-pull-secret.yaml
   openshift
```
### 6.15.9.1. Modifying manifest files

**NOTE**

The AWS Outposts environments has the following limitations which require manual modification in the manifest generated files:

- The maximum transmission unit (MTU) of a network connection is the size, in bytes, of the largest permissible packet that can be passed over the connection. The Outpost service link supports a maximum packet size of 1300 bytes. For more information about the service link, see [Outpost connectivity to AWS Regions](#)

You will find more information about how to change these values below.

- **Use Outpost Subnet for workers machineset**
  Modify the following file: `<installation_directory>/openshift/99_openshift-cluster-api_worker-machineset-0.yaml` Find the subnet ID and replace it with the ID of the private subnet created in the Outpost. As a result, all the worker machines will be created in the Outpost.

- **Specify MTU value for the Network Provider**
  Outpost service links support a maximum packet size of 1300 bytes. It’s required to modify the MTU of the Network Provider to follow this requirement. Create a new file under manifests directory, named `cluster-network-03-config.yml`

  If OpenShift SDN network provider is used, set the MTU value to 1250

  ```yaml
  apiVersion: operator.openshift.io/v1
  kind: Network
  metadata:
    name: cluster
  spec:
    defaultNetwork:
      openshiftSDNConfig:
        mtu: 1250
  ```

  If OVN-Kubernetes network provider is used, set the MTU value to 1200

  ```yaml
  apiVersion: operator.openshift.io/v1
  kind: Network
  metadata:
  ```
6.15.10. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of oc.

### Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

**Procedure**

2. Select the architecture from the Product Variant drop-down list.
3. Select the appropriate version from the Version drop-down list.
4. Click Download Now next to the OpenShift v4.14 Linux Client entry and save the file.
5. Unpack the archive:
   ```shell
   $ tar xvf <file>
   ```
6. Place the oc binary in a directory that is on your PATH.
   To check your PATH, execute the following command:
   ```shell
   $ echo $PATH
   ```

**Verification**

- After you install the OpenShift CLI, it is available using the oc command:
  ```shell
  $ oc <command>
  ```

### Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version from the Version drop-down list.

3. Click Download Now next to the OpenShift v4.14 Windows Client entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the **oc** binary to a directory that is on your PATH.
   To check your PATH, open the command prompt and execute the following command:

   ```
   C:\> path
   ```

Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

   ```
   C:\> oc <command>
   ```

**Installing the OpenShift CLI on macOS**

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version from the Version drop-down list.

3. Click Download Now next to the OpenShift v4.14 macOS Client entry and save the file.

   **NOTE**
   For macOS arm64, choose the OpenShift v4.14 macOS arm64 Client entry.

4. Unpack and unzip the archive.

5. Move the **oc** binary to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:

   ```
   $ echo $PATH
   ```

Verification

- After you install the OpenShift CLI, it is available using the **oc** command:

   ```
   $ oc <command>
   ```

**6.15.11. Alternatives to storing administrator-level secrets in the kube-system project**

By default, administrator secrets are stored in the **kube-system** project. If you configured the **credentialsMode** parameter in the **install-config.yaml** file to **Manual**, you must use one of the following alternatives:
To manage long-term cloud credentials manually, follow the procedure in Manually creating long-term credentials.

To implement short-term credentials that are managed outside the cluster for individual components, follow the procedures in Configuring an AWS cluster to use short-term credentials.

6.15.11.1. Manually creating long-term credentials

The Cloud Credential Operator (CCO) can be put into manual mode prior to installation in environments where the cloud identity and access management (IAM) APIs are not reachable, or the administrator prefers not to store an administrator-level credential secret in the cluster kube-system namespace.

Procedure

1. If you did not set the credentialsMode parameter in the install-config.yaml configuration file to Manual, modify the value as shown:

Sample configuration file snippet

```yaml
apiVersion: v1
baseDomain: example.com
credentialsMode: Manual
# ...
```

2. If you have not previously created installation manifest files, do so by running the following command:

```bash
$ openshift-install create manifests --dir <installation_directory>
```

where `<installation_directory>` is the directory in which the installation program creates files.

3. Set a $RELEASE_IMAGE variable with the release image from your installation file by running the following command:

```bash
$ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
```

4. Extract the list of CredentialsRequest custom resources (CRs) from the OpenShift Container Platform release image by running the following command:

```bash
$ oc adm release extract \
--from=$RELEASE_IMAGE \
--credentials-requests \
--included 1 \
--install-config=<path_to_directory_with_installation_configuration>/install-config.yaml 2 \
--to=<path_to_directory_for_credentials_requests> 3
```

1. The --included parameter includes only the manifests that your specific cluster configuration requires.

2. Specify the location of the install-config.yaml file.

3. Specify the path to the directory where you want to store the CredentialsRequest
This command creates a YAML file for each `CredentialsRequest` object.

**Sample CredentialsRequest object**

```yaml
apiVersion: cloudcredential.openshift.io/v1
type: CredentialsRequest
metadata:
  name: <component_credentials_request>
  namespace: openshift-cloud-credential-operator
...
spec:
  providerSpec:
    apiVersion: cloudcredential.openshift.io/v1
type: AWSProviderSpec
    statementEntries:
      - effect: Allow
        action:
          - iam:GetUser
          - iam:GetUserPolicy
          - iam:ListAccessKeys
        resource: "*"
    ...
```

5. Create YAML files for secrets in the `openshift-install` manifests directory that you generated previously. The secrets must be stored using the namespace and secret name defined in the `spec.secretRef` for each `CredentialsRequest` object.

**Sample CredentialsRequest object with secrets**

```yaml
apiVersion: cloudcredential.openshift.io/v1
type: CredentialsRequest
metadata:
  name: <component_credentials_request>
  namespace: openshift-cloud-credential-operator
...
spec:
  providerSpec:
    apiVersion: cloudcredential.openshift.io/v1
type: AWSProviderSpec
    statementEntries:
      - effect: Allow
        action:
          - s3:CreateBucket
          - s3:DeleteBucket
        resource: "*"
    ...
  secretRef:
    name: <component_secret>
    namespace: <component_namespace>
    ...
```

**Sample Secret object**

```yaml
apiVersion: v1
```
IMPORTANT

Before upgrading a cluster that uses manually maintained credentials, you must ensure that the CCO is in an upgradeable state.

6.15.11.2. Configuring an AWS cluster to use short-term credentials

To install a cluster that is configured to use the AWS Security Token Service (STS), you must configure the CCO utility and create the required AWS resources for your cluster.

6.15.11.2.1. Configuring the Cloud Credential Operator utility

To create and manage cloud credentials from outside of the cluster when the Cloud Credential Operator (CCO) is operating in manual mode, extract and prepare the CCO utility (ccoctl) binary.

NOTE

The ccoctl utility is a Linux binary that must run in a Linux environment.

Prerequisites

- You have access to an OpenShift Container Platform account with cluster administrator access.
- You have installed the OpenShift CLI (oc).
- You have created an AWS account for the ccoctl utility to use with the following permissions:

  Example 6.94. Required AWS permissions

  Required iam permissions
  - iam:CreateOpenIDConnectProvider
  - iam:CreateRole
  - iam:DeleteOpenIDConnectProvider
  - iam:DeleteRole
  - iam:DeleteRolePolicy
  - iam:GetOpenIDConnectProvider
  - iam:GetRole
  - iam:GetUser
  - iam:ListOpenIDConnectProviders

kind: Secret
metadata:
  name: <component_secret>
  namespace: <component_namespace>
data:
  aws_access_key_id: <base64_encoded_aws_access_key_id>
  aws_secret_access_key: <base64_encoded_aws_secret_access_key>
- `iam:ListRolePolicies`
- `iam:ListRoles`
- `iam:PutRolePolicy`
- `iam:TagOpenIDConnectProvider`
- `iam:TagRole`

Required `s3` permissions
- `s3:CreateBucket`
- `s3:DeleteBucket`
- `s3:DeleteObject`
- `s3:GetBucketAcl`
- `s3:GetBucketTagging`
- `s3:GetObject`
- `s3:GetObjectAcl`
- `s3:GetObjectTagging`
- `s3:ListBucket`
- `s3:PutBucketAcl`
- `s3:PutBucketPolicy`
- `s3:PutBucketPublicAccessBlock`
- `s3:PutBucketTagging`
- `s3:PutObject`
- `s3:PutObjectAcl`
- `s3:PutObjectTagging`

Required `cloudfront` permissions
- `cloudfront:ListCloudFrontOriginAccessIdentities`
- `cloudfront:ListDistributions`
- `cloudfront:ListTagsForResource`

If you plan to store the OIDC configuration in a private S3 bucket that is accessed by the IAM identity provider through a public CloudFront distribution URL, the AWS account that runs the `ccoctl` utility requires the following additional permissions:
Example 6.95. Additional permissions for a private S3 bucket with CloudFront

- cloudfront:CreateCloudFrontOriginAccessIdentity
- cloudfront:CreateDistribution
- cloudfront:DeleteCloudFrontOriginAccessIdentity
- cloudfront:DeleteDistribution
- cloudfront:GetCloudFrontOriginAccessIdentity
- cloudfront:GetCloudFrontOriginAccessIdentityConfig
- cloudfront:GetDistribution
- cloudfront:TagResource
- cloudfront:UpdateDistribution

**NOTE**

These additional permissions support the use of the `--create-private-s3-bucket` option when processing credentials requests with the `ccoctl aws create-all` command.

**Procedure**

1. Obtain the OpenShift Container Platform release image by running the following command:

   ```bash
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
   ```

2. Obtain the CCO container image from the OpenShift Container Platform release image by running the following command:

   ```bash
   $ CCO_IMAGE=$(oc adm release info --image-for='cloud-credential-operator' $RELEASE_IMAGE -a ~/.pull-secret)
   ```

   **NOTE**

   Ensure that the architecture of the `$RELEASE_IMAGE` matches the architecture of the environment in which you will use the `ccoctl` tool.

3. Extract the `ccoctl` binary from the CCO container image within the OpenShift Container Platform release image by running the following command:

   ```bash
   $ oc image extract $CCO_IMAGE --file="/usr/bin/ccoctl" -a ~/.pull-secret
   ```

4. Change the permissions to make `ccoctl` executable by running the following command:

   ```bash
   $ chmod 775 ccoctl
   ```
Verification

- To verify that `ccoctl` is ready to use, display the help file by running the following command:

```
$ ccoctl --help
```

**Output of ccoctl --help**

OpenShift credentials provisioning tool

Usage:
```
ccoctl [command]
```

Available Commands:
- `alibabacloud` Manage credentials objects for alibaba cloud
- `aws` Manage credentials objects for AWS cloud
- `azure` Manage credentials objects for Azure
- `gcp` Manage credentials objects for Google cloud
- `help` Help about any command
- `ibmcloud` Manage credentials objects for IBM Cloud
- `nutanix` Manage credentials objects for Nutanix

Flags:
- `-h, --help` help for ccoctl

Use "ccoctl [command] --help" for more information about a command.

### 6.15.11.2.2. Creating AWS resources with the Cloud Credential Operator utility

You have the following options when creating AWS resources:

- You can use the `ccoctl aws create-all` command to create the AWS resources automatically. This is the quickest way to create the resources. See Creating AWS resources with a single command.

- If you need to review the JSON files that the `ccoctl` tool creates before modifying AWS resources, or if the process the `ccoctl` tool uses to create AWS resources automatically does not meet the requirements of your organization, you can create the AWS resources individually. See Creating AWS resources individually.

#### 6.15.11.2.2.1. Creating AWS resources with a single command

If the process the `ccoctl` tool uses to create AWS resources automatically meets the requirements of your organization, you can use the `ccoctl aws create-all` command to automate the creation of AWS resources.

Otherwise, you can create the AWS resources individually. For more information, see "Creating AWS resources individually".

**NOTE**

By default, `ccoctl` creates objects in the directory in which the commands are run. To create the objects in a different directory, use the `--output-dir` flag. This procedure uses `<path_to_ccoctl_output_dir>` to refer to this directory.
Prerequisites
You must have:

- Extracted and prepared the `ccoctl` binary.

Procedure

1. Set a `$RELEASE_IMAGE` variable with the release image from your installation file by running the following command:

   ```
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
   ```

2. Extract the list of `CredentialsRequest` objects from the OpenShift Container Platform release image by running the following command:

   ```
   $ oc adm release extract \
   --from=$RELEASE_IMAGE \
   --credentials-requests \
   --included \ 
   --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \  
   --to=<path_to_directory_for_credentials_requests>
   ```

   1. The `--included` parameter includes only the manifests that your specific cluster configuration requires.
   2. Specify the location of the `install-config.yaml` file.
   3. Specify the path to the directory where you want to store the `CredentialsRequest` objects. If the specified directory does not exist, this command creates it.

   **NOTE**
   This command might take a few moments to run.

3. Use the `ccoctl` tool to process all `CredentialsRequest` objects by running the following command:

   ```
   $ ccoctl aws create-all \
   --name=<name> \  
   --region=<aws_region> \  
   --credentials-requests-dir=<path_to_credentials_requests_directory> \  
   --output-dir=<path_to_ccoctl_output_dir> \  
   --create-private-s3-bucket
   ```

   1. Specify the name used to tag any cloud resources that are created for tracking.
   2. Specify the AWS region in which cloud resources will be created.
   3. Specify the directory containing the files for the component `CredentialsRequest` objects.
   4. Optional: Specify the directory in which you want the `ccoctl` utility to create objects. By default, the utility creates objects in the directory in which the commands are run.
Optional: By default, the ccoctl utility stores the OpenID Connect (OIDC) configuration files in a public S3 bucket and uses the S3 URL as the public OIDC endpoint. To store the

NOTE
If your cluster uses Technology Preview features that are enabled by the TechPreviewNoUpgrade feature set, you must include the --enable-tech-preview parameter.

Verification
- To verify that the OpenShift Container Platform secrets are created, list the files in the <path_to_ccoctl_output_dir>/manifests directory:

$ ls <path_to_ccoctl_output_dir>/manifests

Example output

cluster-authentication-02-config.yaml
openshift-cloud-credential-operator-cloud-credential-operator-iam-ro-creds-credentials.yaml
openshift-cloud-network-config-controller-cloud-credentials-credentials.yaml
openshift-cluster-api-capa-manager-bootstrap-credentials-credentials.yaml
openshift-cluster-csi-drivers-ebs-cloud-credentials-credentials.yaml
openshift-image-registry-installer-cloud-credentials-credentials.yaml
openshift-ingress-operator-cloud-credentials-credentials.yaml
openshift-machine-api-aws-cloud-credentials-credentials.yaml

You can verify that the IAM roles are created by querying AWS. For more information, refer to AWS documentation on listing IAM roles.

6.15.11.2.2.2. Creating AWS resources individually

You can use the ccoctl tool to create AWS resources individually. This option might be useful for an organization that shares the responsibility for creating these resources among different users or departments.

Otherwise, you can use the ccoctl aws create-all command to create the AWS resources automatically. For more information, see "Creating AWS resources with a single command".

NOTE
By default, ccoctl creates objects in the directory in which the commands are run. To create the objects in a different directory, use the --output-dir flag. This procedure uses <path_to_ccoctl_output_dir> to refer to this directory.

Some ccoctl commands make AWS API calls to create or modify AWS resources. You can use the --dry-run flag to avoid making API calls. Using this flag creates JSON files on the local file system instead. You can review and modify the JSON files and then apply them with the AWS CLI tool using the --cli-input-json parameters.

Prerequisites
- Extract and prepare the ccoctl binary.
CHAPTER 6. INSTALLING ON AWS

Procedure

1. Generate the public and private RSA key files that are used to set up the OpenID Connect provider for the cluster by running the following command:

   ```bash
   $ ccoctl aws create-key-pair
   ```

   Example output

   ```
   2021/04/13 11:01:02 Generating RSA keypair
   2021/04/13 11:01:03 Writing private key to /<path_to_ccoctl_output_dir>/serviceaccount-signer.private
   2021/04/13 11:01:03 Writing public key to /<path_to_ccoctl_output_dir>/serviceaccount-signer.public
   2021/04/13 11:01:03 Copying signing key for use by installer
   ```

   where `serviceaccount-signer.private` and `serviceaccount-signer.public` are the generated key files.

   This command also creates a private key that the cluster requires during installation in `/<path_to_ccoctl_output_dir>/tls/bound-service-account-signing-key.key`.

2. Create an OpenID Connect identity provider and S3 bucket on AWS by running the following command:

   ```bash
   $ ccoctl aws create-identity-provider \
   --name=<name> \  
   --region=<aws_region> \  
   --public-key-file=<path_to_ccoctl_output_dir>/serviceaccount-signer.public
   ```

   ```
   2021/04/13 11:16:09 Bucket <name>-oidc created
   2021/04/13 11:16:10 OpenID Connect discovery document in the S3 bucket <name>-oidc at .well-known/openid-configuration updated
   2021/04/13 11:16:10 Reading public key
   2021/04/13 11:16:10 JSON web key set (JWKS) in the S3 bucket <name>-oidc at keys.json updated
   ```

   where `openid-configuration` is a discovery document and `keys.json` is a JSON web key set file.

   This command also creates a YAML configuration file in `/<path_to_ccoctl_output_dir>/manifests/cluster-authentication-02-config.yaml`. This file sets the issuer URL field for the service account tokens that the cluster generates, so that the
AWS IAM identity provider trusts the tokens.

3. Create IAM roles for each component in the cluster:
   
   a. Set a $RELEASE_IMAGE variable with the release image from your installation file by running the following command:
      
      ```
      $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
      ```

   b. Extract the list of CredentialsRequest objects from the OpenShift Container Platform release image:
      
      ```
      $ oc adm release extract \ 
          --from=$RELEASE_IMAGE \ 
          --credentials-requests \ 
          --included \ 
          --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \ 
          --to=<path_to_directory_for_credentials_requests>
      ```

      1 The --included parameter includes only the manifests that your specific cluster configuration requires.

      2 Specify the location of the install-config.yaml file.

      3 Specify the path to the directory where you want to store the CredentialsRequest objects. If the specified directory does not exist, this command creates it.

   c. Use the ccoctl tool to process all CredentialsRequest objects by running the following command:
      
      ```
      $ ccoctl aws create-iam-roles \ 
          --name=<name> \ 
          --region=<aws_region> \ 
          --credentials-requests-dir=<path_to_credentials_requests_directory> \ 
      ```

      **NOTE**

      For AWS environments that use alternative IAM API endpoints, such as GovCloud, you must also specify your region with the --region parameter.

      If your cluster uses Technology Preview features that are enabled by the TechPreviewNoUpgrade feature set, you must include the --enable-tech-preview parameter.

      For each CredentialsRequest object, ccoctl creates an IAM role with a trust policy that is tied to the specified OIDC identity provider, and a permissions policy as defined in each CredentialsRequest object from the OpenShift Container Platform release image.

Verification
To verify that the OpenShift Container Platform secrets are created, list the files in the `<path_to_ccoctl_output_dir>/manifests` directory:

```
$ ls <path_to_ccoctl_output_dir>/manifests
```

Example output

```
cluster-authentication-02-config.yaml
openshift-cloud-credential-operator-cloud-credential-operator-iam-ro-creds-credentials.yaml
openshift-cloud-network-config-controller-cloud-credentials-credentials.yaml
openshift-cluster-api-capa-manager-bootstrap-credentials-credentials.yaml
openshift-cluster-csi-drivers-ebs-cloud-credentials-credentials.yaml
openshift-image-registry-installer-cloud-credentials-credentials.yaml
openshift-ingress-operator-cloud-credentials-credentials.yaml
openshift-machine-api-aws-cloud-credentials-credentials.yaml
```

You can verify that the IAM roles are created by querying AWS. For more information, refer to AWS documentation on listing IAM roles.

### 6.15.11.2.3. Incorporating the Cloud Credential Operator utility manifests

To implement short-term security credentials managed outside the cluster for individual components, you must move the manifest files that the Cloud Credential Operator utility (`ccoctl`) created to the correct directories for the installation program.

#### Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.
- You have configured the Cloud Credential Operator utility (`ccoctl`).
- You have created the cloud provider resources that are required for your cluster with the `ccoctl` utility.

#### Procedure

1. If you did not set the `credentialsMode` parameter in the `install-config.yaml` configuration file to `Manual`, modify the value as shown:

   **Sample configuration file snippet**

   ```yaml
   apiVersion: v1
   baseDomain: example.com
   credentialsMode: Manual
   # ...
   ```

2. If you have not previously created installation manifest files, do so by running the following command:

   ```
   $ openshift-install create manifests --dir <installation_directory>
   ```

   where `<installation_directory>` is the directory in which the installation program creates files.
3. Copy the manifests that the `ccoctl` utility generated to the `manifests` directory that the installation program created by running the following command:

   ```bash
   $ cp /<path_to_ccoctl_output_dir>/manifests/* ./manifests/
   ```

4. Copy the private key that the `ccoctl` utility generated in the `tls` directory to the installation directory by running the following command:

   ```bash
   $ cp -a /<path_to_ccoctl_output_dir>/tls .
   ```

### 6.15.12. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

**Prerequisites**

- You have configured an account with the cloud platform that hosts your cluster.
- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have verified that the cloud provider account on your host has the correct permissions to deploy the cluster. An account with incorrect permissions causes the installation process to fail with an error message that displays the missing permissions.

**Procedure**

1. Change to the directory that contains the installation program and initialize the cluster deployment:

   ```bash
   $ ./openshift-install create cluster --dir <installation_directory> \
   --log-level=info
   ```

   1. For `<installation_directory>`, specify the location of your customized `./install-config.yaml` file.

   2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

2. Optional: Remove or disable the `AdministratorAccess` policy from the IAM account that you used to install the cluster.

   **NOTE**

   The elevated permissions provided by the `AdministratorAccess` policy are required only during installation.

**Verification**
When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the *kubeadmin* user.

- Credential information also outputs to `<installation_directory>/.openshift_install.log`.

**IMPORTANT**

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

Example output

```
... INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending *node-bootstrapper* certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

### 6.15.13. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster *kubeconfig* file. The *kubeconfig* file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.

- You installed the *oc* CLI.

**Procedure**
1. Export the `kubeadmin` credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   
   Example output
   
   system:admin
   ```

### 6.15.14. Logging in to the cluster by using the web console

The `kubeadmin` user exists by default after an OpenShift Container Platform installation. You can log in to your cluster as the `kubeadmin` user by using the OpenShift Container Platform web console.

**Prerequisites**

- You have access to the installation host.
- You completed a cluster installation and all cluster Operators are available.

**Procedure**

1. Obtain the password for the `kubeadmin` user from the `kubeadmin-password` file on the installation host:

   ```bash
   $ cat <installation_directory>/auth/kubeadmin-password
   ```

   **NOTE**

   Alternatively, you can obtain the `kubeadmin` password from the `<installation_directory>/openshift_install.log` log file on the installation host.

2. List the OpenShift Container Platform web console route:

   ```bash
   $ oc get routes -n openshift-console | grep 'console-openshift'
   ```

   **NOTE**

   Alternatively, you can obtain the OpenShift Container Platform route from the `<installation_directory>/openshift_install.log` log file on the installation host.

**Example output**
3. Navigate to the route detailed in the output of the preceding command in a web browser and log in as the kubeadmin user.

6.15.15. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager Hybrid Cloud Console.

After you confirm that your OpenShift Cluster Manager Hybrid Cloud Console inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See Accessing the web console for more details about accessing and understanding the OpenShift Container Platform web console.
- See About remote health monitoring for more information about the Telemetry service.

6.15.16. Cluster Limitations

**IMPORTANT**

Network Load Balancer (NLB) and Classic Load Balancer are not supported on AWS Outposts. After the cluster is created, all the Load Balancers are created in the AWS region. In order to use Load Balancers created inside the Outpost instances, Application Load Balancer should be used. The AWS Load Balancer Operator can be used in order to achieve that goal.

If you want to use a public subnet located in the outpost instance for the ALB, you need to remove the special tag (kubernetes.io/cluster/*/outposts: owned) that was added earlier during the VPC creation. This will prevent you from creating new Services of type LoadBalancer (Network Load Balancer).

See Understanding the AWS Load Balancer Operator for more information.
IMPORTANT

Persistent storage using AWS Elastic Block Store limitations

- AWS Outposts does not support Amazon Elastic Block Store (EBS) gp3 volumes. After installation, the cluster includes two storage classes - gp3-csi and gp2-csi, with gp3-csi being the default storage class. It is important to always use gp2-csi. You can change the default storage class using the following OpenShift CLI (oc) commands:

  ```
  $ oc annotate --overwrite storageclass gp3-csi storageclass.kubernetes.io/is-default-class=false
  $ oc annotate --overwrite storageclass gp2-csi storageclass.kubernetes.io/is-default-class=true
  ```

- To create a Volume in the Outpost instance, the CSI driver determines the Outpost ARN based on the topology keys stored on the CSINode objects. To ensure that the CSI driver uses the correct topology values, it is necessary to use the `WaitForConsumer` volume binding mode and avoid setting allowed topologies on any new storage class created.

6.15.17. Next steps

- Validating an installation.
- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- If necessary, you can remove cloud provider credentials.

6.16. INSTALLING A THREE-NODE CLUSTER ON AWS

In OpenShift Container Platform version 4.14, you can install a three-node cluster on Amazon Web Services (AWS). A three-node cluster consists of three control plane machines, which also act as compute machines. This type of cluster provides a smaller, more resource efficient cluster, for cluster administrators and developers to use for testing, development, and production.

You can install a three-node cluster using either installer-provisioned or user-provisioned infrastructure.

NOTE

Deploying a three-node cluster using an AWS Marketplace image is not supported.

6.16.1. Configuring a three-node cluster

You configure a three-node cluster by setting the number of worker nodes to 0 in the `install-config.yaml` file before deploying the cluster. Setting the number of worker nodes to 0 ensures that the control plane machines are schedulable. This allows application workloads to be scheduled to run from the control plane nodes.
NOTE
Because application workloads run from control plane nodes, additional subscriptions are required, as the control plane nodes are considered to be compute nodes.

Prerequisites
- You have an existing `install-config.yaml` file.

Procedure
1. Set the number of compute replicas to 0 in your `install-config.yaml` file, as shown in the following `compute` stanza:

   Example `install-config.yaml` file for a three-node cluster
   ```yaml
   apiVersion: v1
   baseDomain: example.com
   compute:
     - name: worker
       platform: {}
       replicas: 0
   # ...
   ```

2. If you are deploying a cluster with user-provisioned infrastructure:
   - After you create the Kubernetes manifest files, make sure that the `spec.mastersSchedulable` parameter is set to `true` in `cluster-scheduler-02-config.yml` file. You can locate this file in `<installation_directory>/manifests`. For more information, see "Creating the Kubernetes manifest and Ignition config files" in "Installing a cluster on user-provisioned infrastructure in AWS by using CloudFormation templates".
   - Do not create additional worker nodes.

Example `cluster-scheduler-02-config.yml` file for a three-node cluster
```yaml
apiVersion: config.openshift.io/v1
kind: Scheduler
metadata:
  creationTimestamp: null
  name: cluster
spec:
  mastersSchedulable: true
  policy:
    name: ""
status: {}
```

6.16.2. Next steps
- Installing a cluster on AWS with customizations
- Installing a cluster on user-provisioned infrastructure in AWS by using CloudFormation templates
6.17. UNINSTALLING A CLUSTER ON AWS

You can remove a cluster that you deployed to Amazon Web Services (AWS).

6.17.1. Removing a cluster that uses installer-provisioned infrastructure

You can remove a cluster that uses installer-provisioned infrastructure from your cloud.

NOTE
After uninstallation, check your cloud provider for any resources not removed properly, especially with User Provisioned Infrastructure (UPI) clusters. There might be resources that the installer did not create or that the installer is unable to access.

Prerequisites

- You have a copy of the installation program that you used to deploy the cluster.
- You have the files that the installation program generated when you created your cluster.

Procedure

1. From the directory that contains the installation program on the computer that you used to install the cluster, run the following command:

   `$ ./openshift-install destroy cluster --dir <installation_directory> --log-level info`

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   To view different details, specify `warn`, `debug`, or `error` instead of `info`.

   **NOTE**
   You must specify the directory that contains the cluster definition files for your cluster. The installation program requires the `metadata.json` file in this directory to delete the cluster.

2. Optional: Delete the `<installation_directory>` directory and the OpenShift Container Platform installation program.

6.17.2. Deleting Amazon Web Services resources with the Cloud Credential Operator utility

After uninstalling an OpenShift Container Platform cluster that uses short-term credentials managed outside the cluster, you can use the CCO utility (`ccoctl`) to remove the Amazon Web Services (AWS) resources that `ccoctl` created during installation.

Prerequisites

- Extract and prepare the `ccoctl` binary.
Uninstall an OpenShift Container Platform cluster on AWS that uses short-term credentials.

Procedure

- Delete the AWS resources that `ccoctl` created by running the following command:

  ```bash
  $ ccoctl aws delete \
  --name=<name> \n  --region=<aws_region>
  ```

  1. `<name>` matches the name that was originally used to create and tag the cloud resources.
  2. `<aws_region>` is the AWS region in which to delete cloud resources.

Example output

2021/04/08 17:50:41 Identity Provider object .well-known/openid-configuration deleted from the bucket <name>-oidc
2021/04/08 17:50:42 Identity Provider object keys.json deleted from the bucket <name>-oidc
2021/04/08 17:50:43 Identity Provider bucket <name>-oidc deleted
2021/04/08 17:51:05 Policy <name>-openshift-cloud-credential-operator-cloud-credential-o associated with IAM Role <name>-openshift-cloud-credential-operator-cloud-credential-o deleted
2021/04/08 17:51:05 IAM Role <name>-openshift-cloud-credential-operator-cloud-credential-o deleted
2021/04/08 17:51:07 IAM Role <name>-openshift-cluster-csi-drivers-ebs-cloud-credentials deleted
2021/04/08 17:51:08 Policy <name>-openshift-image-registry-installer-cloud-credentials associated with IAM Role <name>-openshift-image-registry-installer-cloud-credentials deleted
2021/04/08 17:51:08 IAM Role <name>-openshift-image-registry-installer-cloud-credentials deleted
2021/04/08 17:51:10 IAM Role <name>-openshift-ingress-operator-cloud-credentials deleted
2021/04/08 17:51:11 IAM Role <name>-openshift-machine-api-aws-cloud-credentials deleted

Verification

- To verify that the resources are deleted, query AWS. For more information, refer to AWS documentation.

6.17.3. Deleting a cluster with a configured AWS Local Zone infrastructure

After you install a cluster on Amazon Web Services (AWS) into an existing Virtual Private Cloud (VPC), and you set subnets for each Local Zone location, you can delete the cluster and any AWS resources associated with it.
The example in the procedure assumes that you created a VPC and its subnets by using a CloudFormation template.

**Prerequisites**

- You know the name of the CloudFormation stacks, `<local_zone_stack_name>` and `<vpc_stack_name>`, that were used during the creation of the network. You need the name of the stack to delete the cluster.
- You have access rights to the directory that contains the installation files that were created by the installation program.
- Your account includes a policy that provides you with permissions to delete the CloudFormation stack.

**Procedure**

1. Change to the directory that contains the stored installation program, and delete the cluster by using the `destroy cluster` command:

   ```bash
   $ ./openshift-install destroy cluster --dir <installation_directory>  
   --log-level=debug
   ```

   1. For `<installation_directory>`, specify the directory that stored any files created by the installation program.
   2. To view different log details, specify `error`, `info`, or `warn` instead of `debug`.

2. Delete the CloudFormation stack for the Local Zone subnet:

   ```bash
   $ aws cloudformation delete-stack --stack-name <local_zone_stack_name>
   ```

3. Delete the stack of resources that represent the VPC:

   ```bash
   $ aws cloudformation delete-stack --stack-name <vpc_stack_name>
   ```

**Verification**

- Check that you removed the stack resources by issuing the following commands in the AWS CLI. The AWS CLI outputs that no template component exists.

  ```bash
  $ aws cloudformation describe-stacks --stack-name <local_zone_stack_name>
  $ aws cloudformation describe-stacks --stack-name <vpc_stack_name>
  ```

**Additional resources**

- See Working with stacks in the AWS documentation for more information about AWS CloudFormation stacks.
- Opt into AWS Local Zones
6.18. INSTALLATION CONFIGURATION PARAMETERS FOR AWS

Before you deploy an OpenShift Container Platform cluster on AWS, you provide parameters to customize your cluster and the platform that hosts it. When you create the `install-config.yaml` file, you provide values for the required parameters through the command line. You can then modify the `install-config.yaml` file to customize your cluster further.

6.18.1. Available installation configuration parameters for AWS

The following tables specify the required, optional, and AWS-specific installation configuration parameters that you can set as part of the installation process.

**NOTE**

After installation, you cannot modify these parameters in the `install-config.yaml` file.

6.18.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

**Table 6.25. Required parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion:</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is <code>v1</code>. The installation program may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>baseDomain:</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the <code>baseDomain</code> and <code>metadata.name</code> parameter values that uses the <code>&lt;metadata.name&gt;</code>, <code>&lt;baseDomain&gt;</code> format.</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
</tr>
<tr>
<td>metadata:</td>
<td>Kubernetes resource <code>ObjectMeta</code>, from which only the <code>name</code> parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td>metadata: name:</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of {{.metadata.name}}. {{.baseDomain}}.</td>
<td>String of lowercase letters, hyphens (-), and periods (.), such as dev.</td>
</tr>
<tr>
<td>platform:</td>
<td>The configuration for the specific platform upon which to perform the installation: alibabacloud, aws, baremetal, azure, gcp, ibmcloud, nutanix, openstack, powervs, vsphere, or {}. For additional information about platform. &lt;platform&gt; parameters, consult the table for your specific platform that follows.</td>
<td>Object</td>
</tr>
<tr>
<td>pullSecret:</td>
<td>Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.</td>
<td>{ &quot;auths&quot;:{ &quot;cloud.openshift.com&quot;:{ &quot;auth&quot;:&quot;b3Blb=&quot;, &quot;email&quot;:&quot;<a href="mailto:you@example.com">you@example.com</a>&quot; }, &quot;quay.io&quot;:{ &quot;auth&quot;:&quot;b3Blb=&quot;, &quot;email&quot;:&quot;<a href="mailto:you@example.com">you@example.com</a>&quot; } } }</td>
</tr>
</tbody>
</table>

6.18.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

**NOTE**

Globalnet is not supported with Red Hat OpenShift Data Foundation disaster recovery solutions. For regional disaster recovery scenarios, ensure that you use a nonoverlapping range of private IP addresses for the cluster and service networks in each cluster.

Table 6.26. Network parameters

<td>The OpenShift SDN and OVN-Kubernetes network plugins support only a single IP</td>
<td></td>
</tr>
<tr>
<td></td>
<td>address block for the service network.</td>
<td></td>
</tr>
</tbody>
</table>
### 6.18.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>additionalTrustBundle</code></td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td><code>capabilities:</code></td>
<td>Controls the installation of optional core cluster components. You can reduce the footprint of your OpenShift Container Platform cluster by disabling optional components. For more information, see the “Cluster capabilities” page in Installing.</td>
<td>String array</td>
</tr>
<tr>
<td><code>baselineCapabilitySet</code></td>
<td>Selects an initial set of optional capabilities to enable. Valid values are None, v4.11, v4.12 and vCurrent. The default value is vCurrent.</td>
<td>String</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------</td>
</tr>
<tr>
<td>capabilities:</td>
<td>Extends the set of optional capabilities beyond what you specify in <code>baselineCapabilitySet</code>. You may specify multiple capabilities in this parameter.</td>
<td>String array</td>
</tr>
<tr>
<td>additionalEnabledC</td>
<td></td>
<td></td>
</tr>
<tr>
<td>apabilities:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>cpuPartitioningMode:</td>
<td>Enables workload partitioning, which isolates OpenShift Container Platform services, cluster management workloads, and infrastructure pods to run on a reserved set of CPUs. Workload partitioning can only be enabled during installation and cannot be disabled after installation. While this field enables workload partitioning, it does not configure workloads to use specific CPUs. For more information, see the <code>Workload partitioning</code> page in the <code>Scalability and Performance</code> section.</td>
<td>None or AllNodes. None is the default value.</td>
</tr>
<tr>
<td>compute:</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of <code>MachinePool</code> objects.</td>
</tr>
<tr>
<td>compute: architecture:</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, clusters with varied architectures are not supported. All pools must specify the same architecture. Valid values are <code>amd64</code> and <code>arm64</code>. Not all installation options support the 64-bit ARM architecture. To verify if your installation option is supported on your platform, see <code>Supported installation methods for different platforms</code> in <code>Selecting a cluster installation method and preparing it for users</code>.</td>
<td>String</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>---------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>----------------------</td>
</tr>
<tr>
<td>compute: hyperthreading:</td>
<td>Whether to enable or disable simultaneous multithreading, or <strong>hyperthreading</strong>, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td><strong>Enabled</strong> or <strong>Disabled</strong></td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td></td>
</tr>
<tr>
<td>compute: name:</td>
<td>Required if you use <strong>compute</strong>. The name of the machine pool.</td>
<td>worker</td>
</tr>
<tr>
<td>compute: platform:</td>
<td>Required if you use <strong>compute</strong>. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <strong>controlPlane.platform</strong> parameter value.</td>
<td><code>alibabacloud, aws, azure, gcp, ibmcloud, nutanix, openstack, powervs, vsphere, or {}</code></td>
</tr>
<tr>
<td>compute: replicas:</td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td>featureSet:</td>
<td>Enables the cluster for a feature set. A feature set is a collection of OpenShift Container Platform features that are not enabled by default. For more information about enabling a feature set during installation, see &quot;Enabling features using feature gates&quot;.</td>
<td>String. The name of the feature set to enable, such as <strong>TechPreviewNoUpgrade</strong>.</td>

<td></td>
</tr>
<tr>
<td>credentialsMode:</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual or an empty string (“”).[1]</td>
</tr>
<tr>
<td>fips:</td>
<td>Enable or disable FIPS mode. The default is false (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</td>
<td>false or true</td>
</tr>
</tbody>
</table>

**IMPORTANT**

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see [Installing the system in FIPS mode](#). When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>NOTE</td>
<td>If you are using Azure File storage, you cannot enable FIPS mode.</td>
<td></td>
</tr>
<tr>
<td>imageContentSources:</td>

<tr>
<td>platform: aws: lbType:</td>
<td>Required to set the NLB load balancer type in AWS. Valid values are <code>Classic</code> or <code>NLB</code>. If no value is specified, the installation program defaults to <code>Classic</code>. The installation program sets the value provided here in the ingress cluster configuration object. If you do not specify a load balancer type for other Ingress Controllers, they use the type set in this parameter.</td>
<td><code>Classic</code> or <code>NLB</code>. The default value is <code>Classic</code>.</td>
</tr>
<tr>
<td>publish:</td>
<td>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</td>
<td><code>Internal</code> or <code>External</code>. To deploy a private cluster, which cannot be accessed from the internet, set <code>publish</code> to <code>Internal</code>. The default value is <code>External</code>.</td>
</tr>
</tbody>
</table>
sshKey:
The SSH key to authenticate access to your cluster machines.

**NOTE**
For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

For example, `sshKey: ssh-ed25519 AAAA...`

1. Not all CCO modes are supported for all cloud providers. For more information about CCO modes, see the "Managing cloud provider credentials" entry in the Authentication and authorization content.

**NOTE**
If your AWS account has service control policies (SCP) enabled, you must configure the `credentialsMode` parameter to Mint, Passthrough, or Manual.

**IMPORTANT**
Setting this parameter to Manual enables alternatives to storing administrator-level secrets in the `kube-system` project, which require additional configuration steps. For more information, see "Alternatives to storing administrator-level secrets in the kube-system project".

### 6.18.1.4. Optional AWS configuration parameters

Optional AWS configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>compute:</td>
<td>The AWS AMI used to boot compute machines for the cluster. This is required for regions that require a custom RHCOS AMI.</td>
<td>Any published or custom RHCOS AMI that belongs to the set AWS region. See RHCOS AMIs for AWS infrastructure for available AMI IDs.</td>
</tr>
<tr>
<td>platform:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>aws:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>amiID:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td>compute: platform: aws: iamRole:</td>
<td>A pre-existing AWS IAM role applied to the compute machine pool instance profiles. You can use these fields to match naming schemes and include predefined permissions boundaries for your IAM roles. If undefined, the installation program creates a new IAM role.</td>
<td>The name of a valid AWS IAM role.</td>
</tr>
<tr>
<td>compute: platform: aws: rootVolume: iops:</td>
<td>The Input/Output Operations Per Second (IOPS) that is reserved for the root volume.</td>
<td>Integer, for example 4000.</td>
</tr>
<tr>
<td>compute: platform: aws: rootVolume: type:</td>
<td>The type of the root volume.</td>
<td>Valid AWS EBS volume type, such as io1.</td>
</tr>
<tr>
<td>compute: platform: aws: rootVolume: kmsKeyARN:</td>
<td>The Amazon Resource Name (key ARN) of a KMS key. This is required to encrypt operating system volumes of worker nodes with a specific KMS key.</td>
<td>Valid key ID or the key ARN</td>
</tr>
</tbody>
</table>
### OpenShift Container Platform 4.14 Installing

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>compute:</strong></td>
<td>The EC2 instance type for the compute machines.</td>
<td>Valid AWS instance type, such as <code>m4.2xlarge</code>. See the <strong>Supported AWS machine types</strong> table that follows.</td>
</tr>
<tr>
<td><strong>platform:</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>aws:</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>type:</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>zones:</strong></td>
<td>The availability zones where the installation program creates machines for the compute machine pool. If you provide your own VPC, you must provide a subnet in that availability zone.</td>
<td>A list of valid AWS availability zones, such as <code>us-east-1c</code>, in a YAML sequence.</td>
</tr>
<tr>
<td><strong>region:</strong></td>
<td>The AWS region that the installation program creates compute resources in.</td>
<td>Any valid <strong>AWS region</strong>, such as <code>us-east-1</code>. You can use the AWS CLI to access the regions available based on your selected instance type. For example:</td>
</tr>
<tr>
<td><strong>controlPlane:</strong></td>
<td>The AWS AMI used to boot control plane machines for the cluster. This is required for regions that require a custom RHCOS AMI.</td>
<td>Any published or custom RHCOS AMI that belongs to the set AWS region. See <strong>RHCOS AMIs for AWS infrastructure</strong> for available AMI IDs.</td>
</tr>
<tr>
<td><strong>platform:</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>aws:</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>amiID:</strong></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### Parameter | Description | Values
--- | --- | ---
controlPlane: | A pre-existing AWS IAM role applied to the control plane machine pool instance profiles. You can use these fields to match naming schemes and include predefined permissions boundaries for your IAM roles. If undefined, the installation program creates a new IAM role. | The name of a valid AWS IAM role.
platform: |  |  
aws: |  |  
iamRole: |  |  
controlPlane: | The Input/Output Operations Per Second (IOPS) that is reserved for the root volume on control plane machines. | Integer, for example **4000**.
platform: |  |  
aws: |  |  
rootVolume: |  |  
iops: |  |  
controlPlane: | The size in GiB of the root volume for control plane machines. | Integer, for example **500**.
platform: |  |  
aws: |  |  
rootVolume: |  |  
size: |  |  
controlPlane: | The type of the root volume for control plane machines. | Valid **AWS EBS volume type**, such as *io1*.
platform: |  |  
aws: |  |  
rootVolume: |  |  
type: |  |  
controlPlane: | The Amazon Resource Name (key ARN) of a KMS key. This is required to encrypt operating system volumes of control plane nodes with a specific KMS key. | Valid **key ID and the key ARN**
platform: |  |  
aws: |  |  
rootVolume: |  |  
kmsKeyARN: |  |  

---

**CHAPTER 6. INSTALLING ON AWS**
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>controlPlane</strong>: platform: aws: type:</td>
<td>The EC2 instance type for the control plane machines.</td>
<td>Valid AWS instance type, such as <code>m6i.xlarge</code>. See the <a href="#">Supported AWS machine types</a> table that follows.</td>
</tr>
<tr>
<td><strong>controlPlane</strong>: platform: aws: zones:</td>
<td>The availability zones where the installation program creates machines for the control plane machine pool.</td>
<td>A list of valid AWS availability zones, such as <code>us-east-1c</code>, in a YAML sequence.</td>
</tr>
<tr>
<td><strong>controlPlane</strong>: platform: aws: region:</td>
<td>The AWS region that the installation program creates control plane resources in.</td>
<td>Valid AWS region, such as <code>us-east-1</code>.</td>
</tr>
<tr>
<td><strong>platform</strong>: aws: amiID:</td>
<td>The AWS AMI used to boot all machines for the cluster. If set, the AMI must belong to the same region as the cluster. This is required for regions that require a custom RHCOS AMI.</td>
<td>Any published or custom RHCOS AMI that belongs to the set AWS region. See <a href="#">RHCOS AMIs for AWS infrastructure</a> for available AMI IDs.</td>
</tr>
<tr>
<td><strong>platform</strong>: aws: hostedZone:</td>
<td>An existing Route 53 private hosted zone for the cluster. You can only use a pre-existing hosted zone when also supplying your own VPC. The hosted zone must already be associated with the user-provided VPC before installation. Also, the domain of the hosted zone must be the cluster domain or a parent of the cluster domain. If undefined, the installation program creates a new hosted zone.</td>
<td>String, for example <code>Z3URY6TWQ91KVV</code>.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>--------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>platform: aws:</td>
<td>An Amazon Resource Name (ARN) for an existing IAM role in the account containing the specified hosted zone. The installation program and cluster operators will assume this role when performing operations on the hosted zone. This parameter should only be used if you are installing a cluster into a shared VPC.</td>
<td>String, for example <code>arn:aws:iam::1234567890:role/shared-vpc-role</code>.</td>
</tr>
<tr>
<td>platform: aws:</td>
<td>The AWS service endpoint name and URL. Custom endpoints are only required for cases where alternative AWS endpoints, like FIPS, must be used. Custom API endpoints can be specified for EC2, S3, IAM, Elastic Load Balancing, Tagging, Route 53, and STS AWS services.</td>
<td>Valid AWS service endpoint name and valid AWS service endpoint URL.</td>
</tr>
<tr>
<td>platform: aws:</td>
<td>A map of keys and values that the installation program adds as tags to all resources that it creates.</td>
<td>Any valid YAML map, such as key value pairs in the <code>&lt;key&gt;: &lt;value&gt;</code> format. For more information about AWS tags, see Tagging Your Amazon EC2 Resources in the AWS documentation.</td>
</tr>
<tr>
<td>platform: aws:</td>
<td>A flag that directs in-cluster Operators to include the specified user tags in the tags of the AWS resources that the Operators create.</td>
<td>Boolean values, for example <code>true</code> or <code>false</code>.</td>
</tr>
</tbody>
</table>

NOTE

You can add up to 25 user defined tags during installation. The remaining 25 tags are reserved for OpenShift Container Platform.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>platform:</strong> aws: subnets:</td>
<td>If you provide the VPC instead of allowing the installation program to create the VPC for you, specify the subnet for the cluster to use. The subnet must be part of the same <code>machineNetwork[].cidr</code> ranges that you specify. For a standard cluster, specify a public and a private subnet for each availability zone. For a private cluster, specify a private subnet for each availability zone. For clusters that use AWS Local Zones, you must add AWS Local Zone subnets to this list to ensure edge machine pool creation.</td>
<td>Valid subnet IDs.</td>
</tr>
<tr>
<td><strong>platform:</strong> aws: PreserveBootstrapStrapIgnition:</td>
<td>Prevents the S3 bucket from being deleted after completion of bootstrapping.</td>
<td><strong>true</strong> or <strong>false</strong>. The default value is <strong>false</strong>, which results in the S3 bucket being deleted.</td>
</tr>
</tbody>
</table>
CHAPTER 7. INSTALLING ON AZURE

7.1. PREPARING TO INSTALL ON AZURE

7.1.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.

7.1.2. Requirements for installing OpenShift Container Platform on Azure

Before installing OpenShift Container Platform on Microsoft Azure, you must configure an Azure account. See Configuring an Azure account for details about account configuration, account limits, public DNS zone configuration, required roles, creating service principals, and supported Azure regions.

If the cloud identity and access management (IAM) APIs are not accessible in your environment, or if you do not want to store an administrator-level credential secret in the kube-system namespace, see Alternatives to storing administrator-level secrets in the kube-system project for other options.

7.1.3. Choosing a method to install OpenShift Container Platform on Azure

You can install OpenShift Container Platform on installer-provisioned or user-provisioned infrastructure. The default installation type uses installer-provisioned infrastructure, where the installation program provisions the underlying infrastructure for the cluster. You can also install OpenShift Container Platform on infrastructure that you provision. If you do not use infrastructure that the installation program provisions, you must manage and maintain the cluster resources yourself.

See Installation process for more information about installer-provisioned and user-provisioned installation processes.

7.1.3.1. Installing a cluster on installer-provisioned infrastructure

You can install a cluster on Azure infrastructure that is provisioned by the OpenShift Container Platform installation program, by using one of the following methods:

- **Installing a cluster quickly on Azure** You can install OpenShift Container Platform on Azure infrastructure that is provisioned by the OpenShift Container Platform installation program. You can install a cluster quickly by using the default configuration options.

- **Installing a customized cluster on Azure** You can install a customized cluster on Azure infrastructure that the installation program provisions. The installation program allows for some customization to be applied at the installation stage. Many other customization options are available post-installation.

- **Installing a cluster on Azure with network customizations** You can customize your OpenShift Container Platform network configuration during installation, so that your cluster can coexist with your existing IP address allocations and adhere to your network requirements.

- **Installing a cluster on Azure into an existing VNet** You can install OpenShift Container Platform on an existing Azure Virtual Network (VNet) on Azure. You can use this installation method if you have constraints set by the guidelines of your company, such as limits when
creating new accounts or infrastructure.

- **Installing a private cluster on Azure** You can install a private cluster into an existing Azure Virtual Network (VNet) on Azure. You can use this method to deploy OpenShift Container Platform on an internal network that is not visible to the internet.

- **Installing a cluster on Azure into a government region** OpenShift Container Platform can be deployed into Microsoft Azure Government (MAG) regions that are specifically designed for US government agencies at the federal, state, and local level, as well as contractors, educational institutions, and other US customers that must run sensitive workloads on Azure.

7.1.3.2. Installing a cluster on user-provisioned infrastructure

You can install a cluster on Azure infrastructure that you provision, by using the following method:

- **Installing a cluster on Azure using ARM templates** You can install OpenShift Container Platform on Azure by using infrastructure that you provide. You can use the provided Azure Resource Manager (ARM) templates to assist with an installation.

7.1.4. Next steps

- **Configuring an Azure account**

7.2. CONFIGURING AN AZURE ACCOUNT

Before you can install OpenShift Container Platform, you must configure a Microsoft Azure account to meet installation requirements.

**IMPORTANT**

All Azure resources that are available through public endpoints are subject to resource name restrictions, and you cannot create resources that use certain terms. For a list of terms that Azure restricts, see Resolve reserved resource name errors in the Azure documentation.

7.2.1. Azure account limits

The OpenShift Container Platform cluster uses a number of Microsoft Azure components, and the default Azure subscription and service limits, quotas, and constraints affect your ability to install OpenShift Container Platform clusters.

**IMPORTANT**

Default limits vary by offer category types, such as Free Trial and Pay-As-You-Go, and by series, such as Dv2, F, and G. For example, the default for Enterprise Agreement subscriptions is 350 cores.

Check the limits for your subscription type and if necessary, increase quota limits for your account before you install a default cluster on Azure.

The following table summarizes the Azure components whose limits can impact your ability to install and run OpenShift Container Platform clusters.
<table>
<thead>
<tr>
<th>Component</th>
<th>Number of components required by default</th>
<th>Default Azure limit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>vCPU</td>
<td>44</td>
<td>20 per region</td>
<td>A default cluster requires 44 vCPUs, so you must increase the account limit. By default, each cluster creates the following instances:</td>
</tr>
</tbody>
</table>
|                |                                          |                    |  - One bootstrap machine, which is removed after installation  
|                |                                          |                    |  - Three control plane machines  
|                |                                          |                    |  - Three compute machines  
|                |                                          |                    | Because the bootstrap and control plane machines use **Standard_D8s_v3** virtual machines, which use 8 vCPUs, and the compute machines use **Standard_D4s_v3** virtual machines, which use 4 vCPUs, a default cluster requires 44 vCPUs. The bootstrap node VM, which uses 8 vCPUs, is used only during installation.  
|                |                                          |                    | To deploy more worker nodes, enable autoscaling, deploy large workloads, or use a different instance type, you must further increase the vCPU limit for your account to ensure that your cluster can deploy the machines that you require. |
| OS Disk        | 7                                        |                    | Each cluster machine must have a minimum of 100 GB of storage and 300 IOPS. While these are the minimum supported values, faster storage is recommended for production clusters and clusters with intensive workloads. For more information about optimizing storage for performance, see the page titled “Optimizing storage” in the “Scalability and performance” section. |
| VNet           | 1                                        | 1000 per region    | Each default cluster requires one Virtual Network (VNet), which contains two subnets.                                                                                                                          |
| Network interfaces | 7                                        | 65,536 per region  | Each default cluster requires seven network interfaces. If you create more machines or your deployed workloads create load balancers, your cluster uses more network interfaces.                                                                                      |
### Network Security Groups

<table>
<thead>
<tr>
<th>Component</th>
<th>Number of components required by default</th>
<th>Default Azure limit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Each cluster creates network security groups for each subnet in the VNet. The default cluster creates network security groups for the control plane and for the compute node subnets:</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>5000</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>co ntr ol</td>
<td>Allows the control plane machines to be reached on port 6443 from anywhere</td>
</tr>
<tr>
<td></td>
<td></td>
<td>pl an e</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>no de</td>
<td>Allows worker nodes to be reached from the internet on ports 80 and 443</td>
</tr>
</tbody>
</table>

### Network Load Balancers

<table>
<thead>
<tr>
<th>Component</th>
<th>Number of components required by default</th>
<th>Default Azure limit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Each cluster creates the following load balancers:</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>1000 per region</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>def au lt</td>
<td>Public IP address that load balances requests to ports 80 and 443 across worker machines</td>
</tr>
<tr>
<td></td>
<td></td>
<td>int ern al</td>
<td>Private IP address that load balances requests to ports 6443 and 22623 across control plane machines</td>
</tr>
<tr>
<td></td>
<td></td>
<td>ext ern al</td>
<td>Public IP address that load balances requests to port 6443 across control plane machines</td>
</tr>
</tbody>
</table>

If your applications create more Kubernetes LoadBalancer service objects, your cluster uses more load balancers.

### Public IP Addresses

<table>
<thead>
<tr>
<th>Component</th>
<th>Number of components required by default</th>
<th>Default Azure limit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Each of the two public load balancers uses a public IP address. The bootstrap machine also uses a public IP address so that you can SSH into the machine to troubleshoot issues during installation. The IP address for the bootstrap node is used only during installation.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>3</td>
<td></td>
</tr>
</tbody>
</table>

### Private IP Addresses

<table>
<thead>
<tr>
<th>Component</th>
<th>Number of components required by default</th>
<th>Default Azure limit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>The internal load balancer, each of the three control plane machines, and each of the three worker machines each use a private IP address.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>7</td>
<td></td>
</tr>
</tbody>
</table>
If you configure spot VMs, your cluster must have two spot VM vCPUs for every compute node.

**NOTE**

Using spot VMs for control plane nodes is not recommended.

### Additional resources

- Optimizing storage.

#### 7.2.2. Configuring a public DNS zone in Azure

To install OpenShift Container Platform, the Microsoft Azure account you use must have a dedicated public hosted DNS zone in your account. This zone must be authoritative for the domain. This service provides cluster DNS resolution and name lookup for external connections to the cluster.

**Procedure**

1. Identify your domain, or subdomain, and registrar. You can transfer an existing domain and registrar or obtain a new one through Azure or another source.

   **NOTE**

   For more information about purchasing domains through Azure, see Buy a custom domain name for Azure App Service in the Azure documentation.

2. If you are using an existing domain and registrar, migrate its DNS to Azure. See Migrate an active DNS name to Azure App Service in the Azure documentation.

3. Configure DNS for your domain. Follow the steps in the Tutorial: Host your domain in Azure DNS in the Azure documentation to create a public hosted zone for your domain or subdomain, extract the new authoritative name servers, and update the registrar records for the name servers that your domain uses.

   Use an appropriate root domain, such as openshiftcorp.com, or subdomain, such as clusters.openshiftcorp.com.

4. If you use a subdomain, follow your company's procedures to add its delegation records to the parent domain.

#### 7.2.3. Increasing Azure account limits

To increase an account limit, file a support request on the Azure portal.
NOTE

You can increase only one type of quota per support request.

Procedure

1. From the Azure portal, click Help + support in the lower left corner.

2. Click New support request and then select the required values:
   a. From the Issue type list, select Service and subscription limits (quotas)
   b. From the Subscription list, select the subscription to modify.
   c. From the Quota type list, select the quota to increase. For example, select Compute-VM (cores-vCPUs) subscription limit increases to increase the number of vCPUs, which is required to install a cluster.
   d. Click Next: Solutions.

3. On the Problem Details page, provide the required information for your quota increase:
   a. Click Provide details and provide the required details in the Quota details window.
   b. In the SUPPORT METHOD and CONTACT INFO sections, provide the issue severity and your contact details.

4. Click Next: Review + create and then click Create.

7.2.4. Recording the subscription and tenant IDs

The installation program requires the subscription and tenant IDs that are associated with your Azure account. You can use the Azure CLI to gather this information.

Prerequisites

- You have installed or updated the Azure CLI.

Procedure

1. Log in to the Azure CLI by running the following command:

   $ az login

2. Ensure that you are using the right subscription:
   a. View a list of available subscriptions by running the following command:

   $ az account list --refresh

   Example output

   ```
   [  
     {  
       "cloudName": "AzureCloud",
   ```
b. View the details of the active account, and confirm that this is the subscription you want to use, by running the following command:

```
$ az account show
```

**Example output**

```
{
  "environmentName": "AzureCloud",
  "id": "8xxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx",
  "isDefault": true,
  "name": "Subscription Name 1",
  "state": "Enabled",
  "tenantId": "6xxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx",
  "user": {
    "name": "you@example.com",
    "type": "user"
  }
}
```

3. If you are not using the right subscription:

   a. Change the active subscription by running the following command:

   ```
   $ az account set -s <subscription_id>
   ```

   b. Verify that you are using the subscription you need by running the following command:

   ```
   $ az account show
   ```
4. Record the `id` and `tenantId` parameter values from the output. You require these values to install an OpenShift Container Platform cluster.

7.2.5. Supported identities to access Azure resources

An OpenShift Container Platform cluster requires an Azure identity to create and manage Azure resources. As such, you need one of the following types of identities to complete the installation:

- A service principal
- A system-assigned managed identity
- A user-assigned managed identity

7.2.5.1. Required Azure roles

An OpenShift Container Platform cluster requires an Azure identity to create and manage Azure resources. Before you create the identity, verify that your environment meets the following requirements:

- The Azure account that you use to create the identity is assigned the **User Access Administrator** and **Contributor** roles. These roles are required when:
  - Creating a service principal or user-assigned managed identity.
  - Enabling a system-assigned managed identity on a virtual machine.
- If you are going to use a service principal to complete the installation, verify that the Azure account that you use to create the identity is assigned the `microsoft.directory/servicePrincipals/createAsOwner` permission in Azure Active Directory.

To set roles on the Azure portal, see the [Manage access to Azure resources using RBAC and the Azure portal](#) in the Azure documentation.

7.2.5.2. Required Azure permissions for installer-provisioned infrastructure

The installation program requires access to an Azure service principal or managed identity with the necessary permissions to deploy the cluster and to maintain its daily operation. These permissions must be granted to the Azure subscription that is associated with the identity.
The following options are available to you:

- You can assign the identity the **Contributor** and **User Access Administrator** roles. Assigning these roles is the quickest way to grant all of the required permissions. For more information about assigning roles, see the Azure documentation for managing access to Azure resources using the Azure portal.

- If your organization's security policies require a more restrictive set of permissions, you can create a **custom role** with the necessary permissions.

The following permissions are required for creating an OpenShift Container Platform cluster on Microsoft Azure.

**Example 7.1. Required permissions for creating authorization resources**

- `Microsoft.Authorization/policies/audit/action`
- `Microsoft.Authorization/policies/auditIfNotExists/action`
- `Microsoft.Authorization/roleAssignments/read`
- `Microsoft.Authorization/roleAssignments/write`

**Example 7.2. Required permissions for creating compute resources**

- `Microsoft.Compute/availabilitySets/write`
- `Microsoft.Compute/availabilitySets/read`
- `Microsoft.Compute/disks/beginGetAccess/action`
- `Microsoft.Compute/disks/delete`
- `Microsoft.Compute/disks/read`
- `Microsoft.Compute/disks/write`
- `Microsoft.Compute/galleries/images/read`
- `Microsoft.Compute/galleries/images/versions/read`
- `Microsoft.Compute/galleries/images/versions/write`
- `Microsoft.Compute/galleries/images/write`
- `Microsoft.Compute/galleries/read`
- `Microsoft.Compute/galleries/write`
- `Microsoft.Compute/snapshots/read`
- `Microsoft.Compute/snapshots/write`
- `Microsoft.Compute/snapshots/delete`
- `Microsoft.Compute/virtualMachines/delete`
Example 7.3. Required permissions for creating identity management resources

- Microsoft.ManagedIdentity/userAssignedIdentities/assign/action
- Microsoft.ManagedIdentity/userAssignedIdentities/read
- Microsoft.ManagedIdentity/userAssignedIdentities/write

Example 7.4. Required permissions for creating network resources

- Microsoft.Network/dnsZones/A/write
- Microsoft.Network/dnsZones/CNAME/write
- Microsoft.Network/dnszones/CNAME/read
- Microsoft.Network/dnszones/read
- Microsoft.Network/loadBalancers/backendAddressPools/join/action
- Microsoft.Network/loadBalancers/backendAddressPools/read
- Microsoft.Network/loadBalancers/backendAddressPools/write
- Microsoft.Network/loadBalancers/read
- Microsoft.Network/loadBalancers/write
- Microsoft.Network/networkInterfaces/delete
- Microsoft.Network/networkInterfaces/join/action
- Microsoft.Network/networkInterfaces/read
- Microsoft.Network/networkInterfaces/write
- Microsoft.Network/networkSecurityGroups/join/action
- Microsoft.Network/networkSecurityGroups/read
- Microsoft.Network/networkSecurityGroups/write
- Microsoft.Network/privateDnsZones/A/read
• Microsoft.Network/privateDnsZones/A/write
• Microsoft.Network/privateDnsZones/A/delete
• Microsoft.Network/privateDnsZones/SOA/read
• Microsoft.Network/privateDnsZones/read
• Microsoft.Network/privateDnsZones/virtualNetworkLinks/read
• Microsoft.Network/privateDnsZones/virtualNetworkLinks/write
• Microsoft.Network/privateDnsZones/write
• Microsoft.Network/publicIPAddresses/delete
• Microsoft.Network/publicIPAddresses/join/action
• Microsoft.Network/publicIPAddresses/read
• Microsoft.Network/publicIPAddresses/write
• Microsoft.Network/virtualNetworks/join/action
• Microsoft.Network/virtualNetworks/read
• Microsoft.Network/virtualNetworks/subnets/join/action
• Microsoft.Network/virtualNetworks/subnets/read
• Microsoft.Network/virtualNetworks/subnets/write
• Microsoft.Network/virtualNetworks/write

NOTE

The following permissions are not required to create the private OpenShift Container Platform cluster on Azure.

• Microsoft.Network/dnsZones/A/write
• Microsoft.Network/dnsZones/CNAME/write
• Microsoft.Network/dnszones/CNAME/read
• Microsoft.Network/dnszones/read

Example 7.5. Required permissions for checking the health of resources

• Microsoft.Resourcehealth/healthevent/Activated/action
• Microsoft.Resourcehealth/healthevent/InProgress/action
• Microsoft.Resourcehealth/healthevent/Pending/action
• Microsoft.Resourcehealth/healthevent/Resolved/action
Example 7.6. Required permissions for creating a resource group
- Microsoft.Resources/subscriptions/resourceGroups/read
- Microsoft.Resources/subscriptions/resourceGroups/write

Example 7.7. Required permissions for creating resource tags
- Microsoft.Resources/tags/write

Example 7.8. Required permissions for creating storage resources
- Microsoft.Storage/storageAccounts/blobServices/read
- Microsoft.Storage/storageAccounts/blobServices/containers/write
- Microsoft.Storage/storageAccounts/fileServices/read
- Microsoft.Storage/storageAccounts/fileServices/shares/read
- Microsoft.Storage/storageAccounts/fileServices/shares/write
- Microsoft.Storage/storageAccounts/fileServices/shares/delete
- Microsoft.Storage/storageAccounts/listKeys/action
- Microsoft.Storage/storageAccounts/read
- Microsoft.Storage/storageAccounts/write

Example 7.9. Optional permissions for creating marketplace virtual machine resources
- Microsoft.MarketplaceOrdering/offertypes/publishers/offers/plans/agreements/read
- Microsoft.MarketplaceOrdering/offertypes/publishers/offers/plans/agreements/write

Example 7.10. Optional permissions for creating compute resources
- Microsoft.Compute/images/read
- Microsoft.Compute/images/write
- Microsoft.Compute/images/delete

Example 7.11. Optional permissions for enabling user-managed encryption
- Microsoft.Compute/diskEncryptionSets/read
Example 7.12. Optional permissions for installing a cluster using the `NatGateway` outbound type
- Microsoft.Network/natGateways/read
- Microsoft.Network/natGateways/write

Example 7.13. Optional permissions for installing a private cluster with Azure Network Address Translation (NAT)
- Microsoft.Network/natGateways/join/action
- Microsoft.Network/natGateways/read
- Microsoft.Network/natGateways/write

Example 7.14. Optional permissions for installing a private cluster with Azure firewall
- Microsoft.Network/azureFirewalls/applicationRuleCollections/write
- Microsoft.Network/azureFirewalls/read
- Microsoft.Network/azureFirewalls/write
- Microsoft.Network/routeTables/join/action
- Microsoft.Network/routeTables/read
- Microsoft.Network/routeTables/routes/read
- Microsoft.Network/routeTables/routes/write
- Microsoft.Network/routeTables/write
- Microsoft.Network/virtualNetworks/peer/action
Example 7.15. Optional permission for running gather bootstrap

- Microsoft.Compute/virtualMachines/instanceView/read

The following permissions are required for deleting an OpenShift Container Platform cluster on Microsoft Azure. You can use the same permissions to delete a private OpenShift Container Platform cluster on Azure.

Example 7.16. Required permissions for deleting authorization resources

- Microsoft.Authorization/roleAssignments/delete

Example 7.17. Required permissions for deleting compute resources

- Microsoft.Compute/disks/delete
- Microsoft.Compute/galleries/delete
- Microsoft.Compute/galleries/images/delete
- Microsoft.Compute/galleries/images/versions/delete
- Microsoft.Compute/virtualMachines/delete

Example 7.18. Required permissions for deleting identity management resources

- Microsoft.ManagedIdentity/userAssignedIdentities/delete

Example 7.19. Required permissions for deleting network resources

- Microsoft.Network/dnszones/read
- Microsoft.Network/dnsZones/A/read
- Microsoft.Network/dnsZones/A/delete
- Microsoft.Network/dnsZones/CNAME/read
- Microsoft.Network/dnsZones/CNAME/delete
- Microsoft.Network/loadBalancers/delete
- Microsoft.Network/networkInterfaces/delete
- Microsoft.Network/networkSecurityGroups/delete
• Microsoft.Network/privateDnsZones/read
• Microsoft.Network/privateDnsZones/A/read
• Microsoft.Network/privateDnsZones/delete
• Microsoft.Network/privateDnsZones/virtualNetworkLinks/delete
• Microsoft.Network/publicIPAddresses/delete
• Microsoft.Network/virtualNetworks/delete

NOTE
The following permissions are not required to delete a private OpenShift Container Platform cluster on Azure.

• Microsoft.Network/dnszones/read
• Microsoft.Network/dnsZones/A/read
• Microsoft.Network/dnsZones/A/delete
• Microsoft.Network/dnsZones/CNAME/read
• Microsoft.Network/dnsZones/CNAME/delete

Example 7.20. Required permissions for checking the health of resources

• Microsoft.Resourcehealth/healthevent/Activated/action
• Microsoft.Resourcehealth/healthevent/Resolved/action
• Microsoft.Resourcehealth/healthevent/Updated/action

Example 7.21. Required permissions for deleting a resource group

• Microsoft.Resources/subscriptions/resourcegroups/delete

Example 7.22. Required permissions for deleting storage resources

• Microsoft.Storage/storageAccounts/delete
• Microsoft.Storage/storageAccounts/listKeys/action
NOTE
To install OpenShift Container Platform on Azure, you must scope the permissions to your subscription. Later, you can re-scope these permissions to the installer created resource group. If the public DNS zone is present in a different resource group, then the network DNS zone related permissions must always be applied to your subscription. By default, the OpenShift Container Platform installation program assigns the Azure identity the Contributor role.

You can scope all the permissions to your subscription when deleting an OpenShift Container Platform cluster.

7.2.5.3. Using Azure managed identities
The installation program requires an Azure identity to complete the installation. You can use either a system-assigned or user-assigned managed identity.

If you are unable to use a managed identity, you can use a service principal.

Procedure
1. If you are using a system-assigned managed identity, enable it on the virtual machine that you will run the installation program from.

2. If you are using a user-assigned managed identity:
   a. Assign it to the virtual machine that you will run the installation program from.
   b. Record its client ID. You require this value when installing the cluster.
      For more information about viewing the details of a user-assigned managed identity, see the Microsoft Azure documentation for listing user-assigned managed identities.

3. Verify that the required permissions are assigned to the managed identity.

7.2.5.4. Creating a service principal
The installation program requires an Azure identity to complete the installation. You can use a service principal.

If you are unable to use a service principal, you can use a managed identity.

Prerequisites
- You have installed or updated the Azure CLI.
- You have an Azure subscription ID.
- If you are not going to assign the Contributor and User Administrator Access roles to the service principal, you have created a custom role with the required Azure permissions.

Procedure
1. Create the service principal for your account by running the following command:
$ az ad sp create-for-rbac --role <role_name> \
   --name <service_principal> \ 
   --scopes /subscriptions/<subscription_id> 

1. Defines the role name. You can use the **Contributor** role, or you can specify a custom role which contains the necessary permissions.

2. Defines the service principal name.

3. Specifies the subscription ID.

**Example output**

Creating 'Contributor' role assignment under scope '/subscriptions/<subscription_id>,'
The output includes credentials that you must protect. Be sure that you do not include these credentials in your code or check the credentials into your source control. For more information, see https://aka.ms/azadsp-cli

```
{
  "appId": "axxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx",
  "displayName": <service_principal>",
  "password": "00000000-0000-0000-0000-000000000000",
  "tenantId": "8xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx"
}
```

2. Record the values of the **appId** and **password** parameters from the output. You require these values when installing the cluster.

3. If you applied the **Contributor** role to your service principal, assign the **User Administrator Access** role by running the following command:

```
$ az role assignment create --role "User Access Administrator" \
   --assignee-object-id $(az ad sp show --id <appId> --query id -o tsv) \
   --scope /subscriptions/<subscription_id> 
```

1. Specify the **appId** parameter value for your service principal.

2. Specifies the subscription ID.

**Additional resources**

- About the Cloud Credential Operator

**7.2.6. Supported Azure Marketplace regions**

Installing a cluster using the Azure Marketplace image is available to customers who purchase the offer in North America and EMEA.

While the offer must be purchased in North America or EMEA, you can deploy the cluster to any of the Azure public partitions that OpenShift Container Platform supports.
NOTE
Deploying a cluster using the Azure Marketplace image is not supported for the Azure
Government regions.

7.2.7. Supported Azure regions

The installation program dynamically generates the list of available Microsoft Azure regions based on
your subscription.

Supported Azure public regions

- australiacentral (Australia Central)
- australiasteast (Australia East)
- australiasoutheast (Australia South East)
- brazilsouth (Brazil South)
- canadacentral (Canada Central)
- canadasteast (Canada East)
- centralindia (Central India)
- centralus (Central US)
- eastasia (East Asia)
- eastus (East US)
- eastus2 (East US 2)
- francecentral (France Central)
- germanywestcentral (Germany West Central)
- israelcentral (Israel Central)
- italynorth (Italy North)
- japaneast (Japan East)
- japanwest (Japan West)
- koreacentral (Korea Central)
- koreasouth (Korea South)
- northcentralus (North Central US)
- northeurope (North Europe)
- norwayeast (Norway East)
- polandcentral (Poland Central)
- qatarcentral (Qatar Central)
- southafricanorth (South Africa North)
- southcentralus (South Central US)
- southeastasia (Southeast Asia)
- southindia (South India)
- swedencentral (Sweden Central)
- switzerlandnorth (Switzerland North)
- uenorth (UAE North)
- uksouth (UK South)
- ukwest (UK West)
- westcentralus (West Central US)
- westerurope (West Europe)
- westindia (West India)
- westus (West US)
- westus2 (West US 2)
- westus3 (West US 3)

**Supported Azure Government regions**
Support for the following Microsoft Azure Government (MAG) regions was added in OpenShift Container Platform version 4.6:

- usgovtexas (US Gov Texas)
- usgovvirginia (US Gov Virginia)

You can reference all available MAG regions in the Azure documentation. Other provided MAG regions are expected to work with OpenShift Container Platform, but have not been tested.

### 7.2.8. Next steps

- Install an OpenShift Container Platform cluster on Azure. You can install a customized cluster or quickly install a cluster with default options.

### 7.3. ENABLING USER-MANAGED ENCRYPTION FOR AZURE

In OpenShift Container Platform version 4.14, you can install a cluster with a user-managed encryption key in Azure. To enable this feature, you can prepare an Azure DiskEncryptionSet before installation, modify the `install-config.yaml` file, and then complete the installation.

#### 7.3.1. Preparing an Azure Disk Encryption Set
The OpenShift Container Platform installer can use an existing Disk Encryption Set with a user-managed key. To enable this feature, you can create a Disk Encryption Set in Azure and provide the key to the installer.

**Procedure**

1. Set the following environment variables for the Azure resource group by running the following command:

   ```
   $ export RESOURCEGROUP="<resource_group>" 
   LOCATION="<location>
   ```

   1. Specifies the name of the Azure resource group where you will create the Disk Encryption Set and encryption key. To avoid losing access to your keys after destroying the cluster, you should create the Disk Encryption Set in a different resource group than the resource group where you install the cluster.

   2. Specifies the Azure location where you will create the resource group.

2. Set the following environment variables for the Azure Key Vault and Disk Encryption Set by running the following command:

   ```
   $ export KEYVAULT_NAME="<keyvault_name>" 
   KEYVAULT_KEY_NAME="<keyvault_key_name>" 
   DISK_ENCRYPTION_SET_NAME="<disk_encryption_set_name>
   ```

   1. Specifies the name of the Azure Key Vault you will create.

   2. Specifies the name of the encryption key you will create.

   3. Specifies the name of the disk encryption set you will create.

3. Set the environment variable for the ID of your Azure Service Principal by running the following command:

   ```
   $ export CLUSTER_SP_ID="<service_principal_id>
   ```

   1. Specifies the ID of the service principal you will use for this installation.

4. Enable host-level encryption in Azure by running the following commands:

   ```
   $ az feature register --namespace "Microsoft.Compute" --name "EncryptionAtHost"
   $ az feature show --namespace Microsoft.Compute --name EncryptionAtHost
   $ az provider register -n Microsoft.Compute
   ```

5. Create an Azure Resource Group to hold the disk encryption set and associated resources by running the following command:
Create an Azure key vault by running the following command:

```
$ az group create --name $RESOURCEGROUP --location $LOCATION
```

6. 

Create an encryption key in the key vault by running the following command:

```
$ az keyvault key create -n $KEYVAULT_NAME -g $RESOURCEGROUP -l $LOCATION
```

7. 

Capture the ID of the key vault by running the following command:

```
$ KEYVAULT_ID=$(az keyvault show --name $KEYVAULT_NAME --query '[id]')
```

8. 

Capture the key URL in the key vault by running the following command:

```
$ KEYVAULT_KEY_URL=$(az keyvault key show --vault-name $KEYVAULT_NAME --name $KEYVAULT_KEY_NAME --query '[key.kid]')
```

9. 

Create a disk encryption set by running the following command:

```
$ az disk-encryption-set create -n $DISK_ENCRYPTION_SET_NAME -l $LOCATION -g $RESOURCEGROUP --source-vault $KEYVAULT_ID --key-url $KEYVAULT_KEY_URL
```

10. 

Grant the DiskEncryptionSet resource access to the key vault by running the following commands:

```
$ DES_IDENTITY=$(az disk-encryption-set show -n $DISK_ENCRYPTION_SET_NAME -g $RESOURCEGROUP --query '[identity.principalId]')
$ az keyvault set-policy -n $KEYVAULT_NAME -g $RESOURCEGROUP --object-id $DES_IDENTITY --key-permissions wrapkey unwrapkey get
```

11. 

Grant the Azure Service Principal permission to read the DiskEncryptionSet by running the following commands:

```
$ DES_RESOURCE_ID=$(az disk-encryption-set show -n $DISK_ENCRYPTION_SET_NAME -g $RESOURCEGROUP --query '[id]')
$ az role assignment create --assignee $CLUSTER_SP_ID --role "<reader_role>" --scope $DESRESOURCE_ID
```

12. 

Specifies an Azure role with read permissions to the disk encryption set. You can use the **Owner** role or a custom role with the necessary permissions.

**7.3.2. Next steps**
Install an OpenShift Container Platform cluster:

- Install a cluster with customizations on installer-provisioned infrastructure
- Install a cluster with network customizations on installer-provisioned infrastructure
- Install a cluster into an existing VNet on installer-provisioned infrastructure
- Install a private cluster on installer-provisioned infrastructure
- Install a cluster into a government region on installer-provisioned infrastructure

### 7.4. INSTALLING A CLUSTER QUICKLY ON AZURE

In OpenShift Container Platform version 4.14, you can install a cluster on Microsoft Azure that uses the default configuration options.

#### 7.4.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You configured an Azure account to host the cluster and determined the tested and validated region to deploy the cluster to.
- If you use a firewall, you configured it to allow the sites that your cluster requires access to.

#### 7.4.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager Hybrid Cloud Console to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

#### 7.4.3. Generating a key pair for cluster node SSH access
During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>
   ```

   Specify the path and file name, such as ~/.ssh/id_ed25519, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   ```bash
   $ cat <path>/<file_name>.pub
   
   For example, run the following to view the ~/.ssh/id_ed25519.pub public key:
   ```

   ```bash
   $ cat ~/.ssh/id_ed25519.pub
   ```
3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the ./openshift-install gather command.

   NOTE

   On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.

   a. If the ssh-agent process is not already running for your local user, start it as a background task:

   $ eval "$(ssh-agent -s)"

   Example output

   Agent pid 31874

   NOTE

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the ssh-agent:

   $ ssh-add <path>/<file_name>

[1] Specify the path and file name for your SSH private key, such as ~/.ssh/id_ed25519

   Example output

   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

7.4.4. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

Procedure
1. Access the **Infrastructure Provider** page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

   **IMPORTANT**

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   **IMPORTANT**

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ tar -xvf openshift-install-linux.tar.gz
   ```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 7.4.5. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the **create cluster** command of the installation program only once, during initial installation.

**Prerequisites**

- You have configured an account with the cloud platform that hosts your cluster.
- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have an Azure subscription ID and tenant ID.
- You have the application ID and password of a service principal.

**Procedure**
1. Optional: If you have run the installation program on this computer before, and want to use an alternative service principal, go to the ~/.azure/ directory and delete the osServicePrincipal.json configuration file.
   Deleting this file prevents the installation program from automatically reusing subscription and authentication values from a previous installation.

2. Change to the directory that contains the installation program and initialize the cluster deployment:

   ```bash
   $ ./openshift-install create cluster --dir <installation_directory> \[1
   --log-level=info \[2
   ```

   \[1\] For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

   \[2\] To view different installation details, specify warn, debug, or error instead of info.

   When specifying the directory:

   - Verify that the directory has the execute permission. This permission is required to run Terraform binaries under the installation directory.

   - Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

3. Provide values at the prompts:

   a. Optional: Select an SSH key to use to access your cluster machines.

      **NOTE**

      For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

   b. Select azure as the platform to target.
      If the installation program cannot locate the osServicePrincipal.json configuration file from a previous installation, you are prompted for Azure subscription and authentication values.

   c. Specify the following Azure parameter values for your subscription and service principal:

      - **azure subscription id** Enter the subscription ID to use for the cluster.
      - **azure tenant id** Enter the tenant ID.
      - **azure service principal client id** Enter its application ID.
      - **azure service principal client secret** Enter its password.

   d. Select the region to deploy the cluster to.
e. Select the base domain to deploy the cluster to. The base domain corresponds to the Azure DNS Zone that you created for your cluster.

f. Enter a descriptive name for your cluster.

**IMPORTANT**

All Azure resources that are available through public endpoints are subject to resource name restrictions, and you cannot create resources that use certain terms. For a list of terms that Azure restricts, see [Resolve reserved resource name errors](#) in the Azure documentation.

g. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

If previously not detected, the installation program creates an `osServicePrincipal.json` configuration file and stores this file in the `~/.azure/` directory on your computer. This ensures that the installation program can load the profile when it is creating an OpenShift Container Platform cluster on the target platform.

**Verification**

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the `kubeadmin` user.

- Credential information also outputs to `<installation_directory>/.openshift_install.log`.

**IMPORTANT**

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

**Example output**

...  
INFO Install complete!  
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'  
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com  
INFO Login to the console with user: "kubeadmin", and password: "password"  
INFO Time elapsed: 36m22s
7.4.6. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

### IMPORTANT

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of oc.

#### Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

**Procedure**

2. Select the architecture from the **Product Variant** drop-down list.

3. Select the appropriate version from the **Version** drop-down list.

4. Click **Download Now** next to the **OpenShift v4.14 Linux Client** entry and save the file.

5. Unpack the archive:

   ```bash
   $ tar xvf <file>
   ```

6. Place the oc binary in a directory that is on your PATH.

   To check your PATH, execute the following command:

   ```bash
   $ echo $PATH
   ```

**Verification**

- After you install the OpenShift CLI, it is available using the oc command:

  ```bash
  $ oc <command>
  ```
Installing the OpenShift CLI on Windows
You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version from the Version drop-down list.
3. Click Download Now next to the OpenShift v4.14 Windows Client entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the oc binary to a directory that is on your PATH.
   To check your PATH, open the command prompt and execute the following command:
   ```
   C:\> path
   ```

**Verification**

- After you install the OpenShift CLI, it is available using the oc command:
  ```
  C:\> oc <command>
  ```

Installing the OpenShift CLI on macOS
You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version from the Version drop-down list.
3. Click Download Now next to the OpenShift v4.14 macOS Client entry and save the file.
   
   **NOTE**
   For macOS arm64, choose the OpenShift v4.14 macOS arm64 Client entry.
4. Unpack and unzip the archive.
5. Move the oc binary to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:
   ```
   $ echo $PATH
   ```

**Verification**

- After you install the OpenShift CLI, it is available using the oc command:
$ oc <command>

### 7.4.7. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

   ```
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```
   $ oc whoami
   ```

   **Example output**

   ```
   system:admin
   ```

**Additional resources**

- See [Accessing the web console](#) for more details about accessing and understanding the OpenShift Container Platform web console.

### 7.4.8. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager Hybrid Cloud Console](#).

After you confirm that your [OpenShift Cluster Manager Hybrid Cloud Console](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use `subscription watch` to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- See [About remote health monitoring](#) for more information about the Telemetry service
7.4.9. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.

7.5. INSTALLING A CLUSTER ON AZURE WITH CUSTOMIZATIONS

In OpenShift Container Platform version 4.14, you can install a customized cluster on infrastructure that the installation program provisions on Microsoft Azure. To customize the installation, you modify parameters in the `install-config.yaml` file before you install the cluster.

7.5.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You configured an Azure account to host the cluster and determined the tested and validated region to deploy the cluster to.
- If you use a firewall, you configured it to allow the sites that your cluster requires access to.
- If you use customer-managed encryption keys, you prepared your Azure environment for encryption.

7.5.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager Hybrid Cloud Console to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

7.5.3. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes
through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the `core` user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user `core`. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `/openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N '' -f <path>/<file_name>
   ```

   Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the `x86_64`, `ppc64le`, and `s390x` architectures, do not create a key that uses the `ed25519` algorithm. Instead, create a key that uses the `rsa` or `ecdsa` algorithm.

2. View the public SSH key:

   ```bash
   $ cat <path>/<file_name>.pub
   ```

   For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

   ```bash
   $ cat ~/.ssh/id_ed25519.pub
   ```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `/openshift-install gather` command.
NOTE
On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.

a. If the ssh-agent process is not already running for your local user, start it as a background task:

```
$ eval "$(ssh-agent -s)"
```

Example output

```
Agent pid 31874
```

NOTE
If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the ssh-agent:

```
$ ssh-add <path>/<file_name>
```

Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

7.5.4. Using the Azure Marketplace offering

Using the Azure Marketplace offering lets you deploy an OpenShift Container Platform cluster, which is billed on pay-per-use basis (hourly, per core) through Azure, while still being supported directly by Red Hat.

To deploy an OpenShift Container Platform cluster using the Azure Marketplace offering, you must first obtain the Azure Marketplace image. The installation program uses this image to deploy worker nodes. When obtaining your image, consider the following:

- While the images are the same, the Azure Marketplace publisher is different depending on your region. If you are located in North America, specify redhat as the publisher. If you are located in EMEA, specify redhat-limited as the publisher.

- The offer includes a rh-ocp-worker SKU and a rh-ocp-worker-gen1 SKU. The rh-ocp-worker SKU represents a Hyper-V generation version 2 VM image. The default instance types used in OpenShift Container Platform are version 2 compatible. If you plan to use an instance type that
is only version 1 compatible, use the image associated with the \texttt{rh-ocp-worker-gen1} SKU. The \texttt{rh-ocp-worker-gen1} SKU represents a Hyper-V version 1 VM image.

**IMPORTANT**

Installing images with the Azure marketplace is not supported on clusters with 64-bit ARM instances.

**Prerequisites**

- You have installed the Azure CLI client (\texttt{az}).
- Your Azure account is entitled for the offer and you have logged into this account with the Azure CLI client.

**Procedure**

1. Display all of the available OpenShift Container Platform images by running one of the following commands:

   - North America:
     
     ```bash
     $ az vm image list --all --offer rh-ocp-worker --publisher redhat -o table
     
     Offer          Publisher       Sku                 Urn                                                             Version
     -------------  --------------  ------------------  ----------------------------------------------------------
     
     $ az vm image list --all --offer rh-ocp-worker --publisher redhat-limited -o table
     
     Offer          Publisher       Sku                 Urn                                                             Version
     -------------  --------------  ------------------  ----------------------------------------------------------
     ```

   - EMEA:
     
     ```bash
     Example output
     
     Offer          Publisher       Sku                 Urn                                                             Version
     -------------  --------------  ------------------  ----------------------------------------------------------
     
     $ az vm image list --all --offer rh-ocp-worker --publisher redhat-limited -o table
     
     Example output
     
     Offer          Publisher       Sku                 Urn                                                             Version
     -------------  --------------  ------------------  ----------------------------------------------------------
     ```
Regardless of the version of OpenShift Container Platform that you install, the correct version of the Azure Marketplace image to use is 4.13. If required, your VMs are automatically upgraded as part of the installation process.

2. Inspect the image for your offer by running one of the following commands:
   - North America:
     ```
     $ az vm image show --urn redhat:rh-ocp-worker:rh-ocp-worker:<version>
     ```
   - EMEA:
     ```
     $ az vm image show --urn redhat-limited:rh-ocp-worker:rh-ocp-worker:<version>
     ```

3. Review the terms of the offer by running one of the following commands:
   - North America:
     ```
     $ az vm image terms show --urn redhat:rh-ocp-worker:rh-ocp-worker:<version>
     ```
   - EMEA:
     ```
     $ az vm image terms show --urn redhat-limited:rh-ocp-worker:rh-ocp-worker:<version>
     ```

4. Accept the terms of the offering by running one of the following commands:
   - North America:
     ```
     $ az vm image terms accept --urn redhat:rh-ocp-worker:rh-ocp-worker:<version>
     ```
   - EMEA:
     ```
     $ az vm image terms accept --urn redhat-limited:rh-ocp-worker:rh-ocp-worker:<version>
     ```

5. Record the image details of your offer. You must update the compute section in the `install-config.yaml` file with values for `publisher`, `offer`, `sku`, and `version` before deploying the cluster.

Sample `install-config.yaml` file with the Azure Marketplace worker nodes

```yaml
apiVersion: v1
baseDomain: example.com
compute:
  - hyperthreading: Enabled
    name: worker
    platform:
      azure:
        type: Standard_D4s_v5
        osImage:
          publisher: redhat
          offer: rh-ocp-worker
```
7.5.5. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

   **IMPORTANT**

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   **IMPORTANT**

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ tar -xvf openshift-install-linux.tar.gz
   ```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

7.5.6. Configuring the user-defined tags for Azure

In OpenShift Container Platform, you can use the tags for grouping resources and for managing resource access and cost. You can define the tags on the Azure resources in the `install-config.yaml` file only during OpenShift Container Platform cluster creation. You cannot modify the user-defined tags.
after cluster creation.

Support for user-defined tags is available only for the resources created in the Azure Public Cloud. User-defined tags are not supported for the OpenShift Container Platform clusters upgraded to OpenShift Container Platform 4.14.

User-defined and OpenShift Container Platform specific tags are applied only to the resources created by the OpenShift Container Platform installer and its core operators such as Machine api provider azure Operator, Cluster Ingress Operator, Cluster Image Registry Operator.

By default, OpenShift Container Platform installer attaches the OpenShift Container Platform tags to the Azure resources. These OpenShift Container Platform tags are not accessible for the users.

You can use the .platform.azure.userTags field in the install-config.yaml file to define the list of user-defined tags as shown in the following install-config.yaml file.

Sample install-config.yaml file

```yaml
additionalTrustBundlePolicy: Proxyonly
apiVersion: v1
baseDomain: catchall.azure.devcluster.openshift.com
compute:
  - architecture: amd64
    hyperthreading: Enabled
    name: worker
    platform: {}
    replicas: 3
controlPlane:
  architecture: amd64
  hyperthreading: Enabled
  name: master
  platform: {}
  replicas: 3
metadata:
  creationTimestamp: null
  name: user
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
    hostPrefix: 23
  machineNetwork:
    - cidr: 10.0.0.0/16
  networkType: OVNKubernetes
  serviceNetwork:
    - 172.30.0.0/16
platform:
  azure:
    baseDomainResourceGroupName: os4-common
    cloudName: AzurePublicCloud
    outboundType: Loadbalancer
    region: southindia
    userTags:
      createdBy: user
      environment: dev
```

Defines the trust bundle policy.

Required. The `baseDomain` parameter specifies the base domain of your cloud provider. The installation program prompts you for this value.

The configuration for the machines that comprise compute. The `compute` section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the `compute` section must begin with a hyphen, `-`. If you do not provide these parameters and values, the installation program provides the default value.

To enable or disable simultaneous multithreading, or `hyperthreading`. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores. You can disable it by setting the parameter value to `Disabled`. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

The configuration for the machines that comprise the control plane. The `controlPlane` section is a single mapping. The first line of the `controlPlane` section must not begin with a hyphen, `-`. You can use only one control plane pool. If you do not provide these parameters and values, the installation program provides the default value.

To enable or disable simultaneous multithreading, or `hyperthreading`. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores. You can disable it by setting the parameter value to `Disabled`. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

The installation program prompts you for this value.

The cluster network plugin to install. The supported values are `OVNKubernetes` and `OpenShiftSDN`. The default value is `OVNKubernetes`.

Specifies the resource group for the base domain of the Azure DNS zone.

Specifies the name of the Azure cloud environment. You can use the `cloudName` field to configure the Azure SDK with the Azure API endpoints. If you do not provide value, the default value is Azure Public Cloud.

Required. Specifies the name of the Azure region that hosts your cluster. The installation program prompts you for this value.

Defines the additional keys and values that the installation program adds as tags to all Azure resources that it creates.

The user-defined tags have the following limitations:

- A tag key can have a maximum of 128 characters.
- A tag key must begin with a letter, end with a letter, number or underscore, and can contain only letters, numbers, underscores, periods, and hyphens.
- Tag keys are case-insensitive.
- Tag keys cannot be `name`. It cannot have prefixes such as `kubernetes.io`, `openshift.io`, `microsoft`, `azure`, and `windows`.
- A tag value can have a maximum of 256 characters.
- You can configure a maximum of 10 tags for resource group and resources.
For more information about Azure tags, see Azure user-defined tags

### 7.5.7. Querying user-defined tags for Azure

After creating the OpenShift Container Platform cluster, you can access the list of defined tags for the Azure resources. The format of the OpenShift Container Platform tags is `kubernetes.io_cluster.<cluster_id>:owned`. The `cluster_id` parameter is the value of `.status.infrastructureName` present in `config.openshift.io/Infrastructure`.

- Query the tags defined for Azure resources by running the following command:

  ```
  $ oc get infrastructures.config.openshift.io cluster -o=jsonpath-as-json='{.status.platformStatus.azure.resourceTags}[
  
  
  
  
  
  
  
  
  ]
  ```

**Example output**

```json
[
  [
    {
      "key": "createdBy",
      "value": "user"
    },
    {
      "key": "environment",
      "value": "dev"
    }
  ]
]
```

### 7.5.8. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Microsoft Azure.

**Prerequisites**

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have an Azure subscription ID and tenant ID.
- If you are installing the cluster using a service principal, you have its application ID and password.
- If you are installing the cluster using a system-assigned managed identity, you have enabled it on the virtual machine that you will run the installation program from.
- If you are installing the cluster using a user-assigned managed identity, you have met these prerequisites:
  - You have its client ID.
  - You have assigned it to the virtual machine that you will run the installation program from.

**Procedure**
1. Optional: If you have run the installation program on this computer before, and want to use an alternative service principal or managed identity, go to the ~/.azure/ directory and delete the osServicePrincipal.json configuration file. Deleting this file prevents the installation program from automatically reusing subscription and authentication values from a previous installation.

2. Create the install-config.yaml file.

   a. Change to the directory that contains the installation program and run the following command:

   ```
   $ ./openshift-install create install-config --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

   When specifying the directory:

   - Verify that the directory has the execute permission. This permission is required to run Terraform binaries under the installation directory.
   - Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

   **NOTE**

   Always delete the ~/.powervs directory to avoid reusing a stale configuration. Run the following command:

   ```
   $ rm -rf ~/.powervs
   ```

   b. At the prompts, provide the configuration details for your cloud:

      i. Optional: Select an SSH key to use to access your cluster machines.

      **NOTE**

      For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

      ii. Select `azure` as the platform to target.

      If the installation program cannot locate the osServicePrincipal.json configuration file from a previous installation, you are prompted for Azure subscription and authentication values.

      iii. Enter the following Azure parameter values for your subscription:

         - `azure subscription id` Enter the subscription ID to use for the cluster.
• **azure tenant id** Enter the tenant ID.

iv. Depending on the Azure identity you are using to deploy the cluster, do one of the following when prompted for the **azure service principal client id**

- If you are using a service principal, enter its application ID.
- If you are using a system-assigned managed identity, leave this value blank.
- If you are using a user-assigned managed identity, specify its client ID.

v. Depending on the Azure identity you are using to deploy the cluster, do one of the following when prompted for the **azure service principal client secret**

- If you are using a service principal, enter its password.
- If you are using a system-assigned managed identity, leave this value blank.
- If you are using a user-assigned managed identity, leave this value blank.

vi. Select the region to deploy the cluster to.

vii. Select the base domain to deploy the cluster to. The base domain corresponds to the Azure DNS Zone that you created for your cluster.

viii. Enter a descriptive name for your cluster.

**IMPORTANT**

All Azure resources that are available through public endpoints are subject to resource name restrictions, and you cannot create resources that use certain terms. For a list of terms that Azure restricts, see Resolve reserved resource name errors in the Azure documentation.

3. Modify the install-config.yaml file. You can find more information about the available parameters in the “Installation configuration parameters” section.

**NOTE**

If you are installing a three-node cluster, be sure to set the compute.replicas parameter to 0. This ensures that the cluster’s control planes are schedulable. For more information, see “Installing a three-node cluster on Azure”.

4. Back up the install-config.yaml file so that you can use it to install multiple clusters.

**IMPORTANT**

The install-config.yaml file is consumed during the installation process. If you want to reuse the file, you must back it up now.

If previously not detected, the installation program creates an osServicePrincipal.json configuration file and stores this file in the ~/.azure/ directory on your computer. This ensures that the installation program can load the profile when it is creating an OpenShift Container Platform cluster on the target platform.
Additional resources

- Installation configuration parameters for Azure

### 7.5.8.1. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS, RHEL 8.6 and later [3]</td>
<td>2</td>
<td>8 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
</tbody>
</table>

1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or hyperthreading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: (threads per core × cores) × sockets = vCPUs.

2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.

3. As with all user-provisioned installations, if you choose to use RHEL compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and has been removed in OpenShift Container Platform 4.10 and later.

**IMPORTANT**

You are required to use Azure virtual machines that have the `premiumIO` parameter set to `true`.

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

**Additional resources**

- Optimizing storage

### 7.5.8.2. Tested instance types for Azure

The following Microsoft Azure instance types have been tested with OpenShift Container Platform.
Example 7.23. Machine types based on 64-bit x86 architecture

- c4.*
- c5.*
- c5a.*
- i3.*
- m4.*
- m5.*
- m5a.*
- m6i.*
- r4.*
- r5.*
- r5a.*
- r6i.*
- t3.*
- t3a.*

7.5.8.3. Tested instance types for Azure on 64-bit ARM infrastructures

The following Microsoft Azure ARM64 instance types have been tested with OpenShift Container Platform.

Example 7.24. Machine types based on 64-bit ARM architecture

- c6g.*
- m6g.*

7.5.8.4. Enabling trusted launch for Azure VMs

You can enable two trusted launch features when installing your cluster on Azure: secure boot and virtualized Trusted Platform Modules.

See the Azure documentation about virtual machine sizes to learn what sizes of virtual machines support these features.
IMPORTANT

Trusted launch is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see Technology Preview Features Support Scope.

Prerequisites

- You have created an `install-config.yaml` file.

Procedure

- Use a text editor to edit the `install-config.yaml` file prior to deploying your cluster and add the following stanza:

```yaml
controlPlane:
  platform:
    azure:
      settings:
        securityType: TrustedLaunch
        trustedLaunch:
          uefiSettings:
            secureBoot: Enabled
            virtualizedTrustedPlatformModule: Enabled
```

1. Specify `controlPlane.platform.azure` or `compute.platform.azure` to enable trusted launch on only control plane or compute nodes respectively. Specify `platform.azure.defaultMachinePlatform` to enable trusted launch on all nodes.

2. Enable trusted launch features.

3. Enable secure boot. For more information, see the Azure documentation about secure boot.

4. Enable the virtualized Trusted Platform Module. For more information, see the Azure documentation about virtualized Trusted Platform Modules.

7.5.8.5. Enabling confidential VMs

You can enable confidential VMs when installing your cluster. You can enable confidential VMs for compute nodes, control plane nodes, or all nodes.
IMPORTANT

Using confidential VMs is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see Technology Preview Features Support Scope.

You can use confidential VMs with the following VM sizes:

- DCasv5-series
- DCadsv5-series
- ECasv5-series
- ECadsv5-series

IMPORTANT

Confidential VMs are currently not supported on 64-bit ARM architectures.

Prerequisites

- You have created an install-config.yaml file.

Procedure

- Use a text editor to edit the install-config.yaml file prior to deploying your cluster and add the following stanza:

```yaml
controlPlane:
  platform:
    azure:
      settings:
        securityType: ConfidentialVM
        confidentialVM:
          uefiSettings:
            secureBoot: Enabled
            virtualizedTrustedPlatformModule: Enabled
          osDisk:
            securityProfile:
              securityEncryptionType: VMGuestStateOnly
```

1 Specify controlPlane.platform.azure or compute.platform.azure to deploy confidential VMs on only control plane or compute nodes respectively. Specify platform.azure.defaultMachinePlatform to deploy confidential VMs on all nodes.

2 Enable confidential VMs.

3 Enable secure boot. For more information, see the Azure documentation about secure boot.
Enable the virtualized Trusted Platform Module. For more information, see the Azure documentation about virtualized Trusted Platform Modules.

Specify `VMGuestStateOnly` to encrypt the VM guest state.

### 7.5.8.6. Sample customized `install-config.yaml` file for Azure

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

**IMPORTANT**

This sample YAML file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program and modify it.

```yaml
apiVersion: v1
baseDomain: example.com
controlPlane:
  hyperthreading: Enabled
  name: master
  platform:
    azure:
      encryptionAtHost: true
      ultraSSDCapability: Enabled
      osDisk:
        diskSizeGB: 1024
        diskType: Premium_LRS
        diskEncryptionSet:
          resourceGroup: disk_encryption_set_resource_group
          name: disk_encryption_set_name
          subscriptionId: secondary_subscription_id
      osImage:
        publisher: example_publisher_name
        offer: example_image_offer
        sku: example_offerSKU
        version: example_image_version
        type: Standard_D8s_v3
      replicas: 3
    compute:
      - hyperthreading: Enabled
        name: worker
        platform:
          azure:
            ultraSSDCapability: Enabled
            type: Standard_D2s_v3
            encryptionAtHost: true
            osDisk:
              diskSizeGB: 512
              diskType: Standard_LRS
              diskEncryptionSet:
                resourceGroup: disk_encryption_set_resource_group
                name: disk_encryption_set_name
                subscriptionId: secondary_subscription_id
```

OpenShift Container Platform 4.14 Installing
osImage:
  publisher: example_publisher_name
  offer: example_image_offer
  sku: example_offer_sku
  version: example_image_version
zones: 3
  - "1"
  - "2"
  - "3"
replicas: 5
metadata:
  name: test-cluster
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
    hostPrefix: 23
  machineNetwork:
    - cidr: 10.0.0.0/16
  networkType: OVNKubernetes
serviceNetwork:
  - 172.30.0.0/16
platform:
defaultMachinePlatform:

resourceGroupName: existing_resource_group
outboundType: Loadbalancer
cloudName: AzurePublicCloud
pullSecret: '{"auths": ...}'
fips: false
sshKey: ssh-ed25519 AAAA...

---

1 Required. The installation program prompts you for this value.
2 If you do not provide these parameters and values, the installation program provides the default value.
3 The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, -, and the first line of the controlPlane section must not. Only one control plane pool is used.
4 Whether to enable or disable simultaneous multithreading, or hyperthreading. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to Disabled. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.
IMPORTANT

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger virtual machine types, such as **Standard_D8s_v3**, for your machines if you disable simultaneous multithreading.

You can specify the size of the disk to use in GB. Minimum recommendation for control plane nodes is 1024 GB.

Specify a list of zones to deploy your machines to. For high availability, specify at least two zones.

The cluster network plugin to install. The supported values are **OVNKubernetes** and **OpenShiftSDN**. The default value is **OVNKubernetes**.

Optional: A custom Red Hat Enterprise Linux CoreOS (RHCOS) image that should be used to boot control plane and compute machines. The `publisher`, `offer`, `sku`, and `version` parameters under `platform.azure.defaultMachinePlatform.osImage` apply to both control plane and compute machines. If the parameters under `controlPlane.platform.azure.osImage` or `compute.platform.azure.osImage` are set, they override the `platform.azure.defaultMachinePlatform.osImage` parameters.

Specify the name of the resource group that contains the DNS zone for your base domain.

Specify the name of an already existing resource group to install your cluster to. If undefined, a new resource group is created for the cluster.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

IMPORTANT

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see **Installing the system in FIPS mode**. When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures.

You can optionally provide the `sshKey` value that you use to access the machines in your cluster.

NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

7.5.8.7. Configuring the cluster-wide proxy during installation
Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**Prerequisites**

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[] . cidr`, `networking.clusterNetwork[] . cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

**Procedure**

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

```
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port> 1
  httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
  noProxy: example.com 3
additionalTrustBundle: | 4
  -----BEGIN CERTIFICATE-----
  <MY_TRUSTED_CA_CERT>
  -----END CERTIFICATE-----
additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle> 5
```

1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.
2 A proxy URL to use for creating HTTPS connections outside the cluster.
3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.
4 If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the
trustedCA field of the Proxy object. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

Optional: The policy to determine the configuration of the Proxy object to reference the user-ca-bundle config map in the trustedCA field. The allowed values are Proxyonly and Always. Use Proxyonly to reference the user-ca-bundle config map only when http/https proxy is configured. Use Always to always reference the user-ca-bundle config map. The default value is Proxyonly.

NOTE
The installation program does not support the proxy readinessEndpoints field.

NOTE
If the installer times out, restart and then complete the deployment by using the wait-for command of the installer. For example:

```
$ ./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

NOTE
Only the Proxy object named cluster is supported, and no additional proxies can be created.

Additional resources

- For more details about Accelerated Networking, see Accelerated Networking for Microsoft Azure VMs.

7.5.9. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

IMPORTANT
If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of oc.

Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

2. Select the architecture from the Product Variant drop-down list.

3. Select the appropriate version from the Version drop-down list.

4. Click Download Now next to the OpenShift v4.14 Linux Client entry and save the file.

5. Unpack the archive:

   ```
   $ tar xvf <file>
   ```

6. Place the oc binary in a directory that is on your PATH. To check your PATH, execute the following command:

   ```
   $ echo $PATH
   ```

**Verification**

- After you install the OpenShift CLI, it is available using the oc command:

  ```
  $ oc <command>
  ```

**Installing the OpenShift CLI on Windows**

You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version from the Version drop-down list.

3. Click Download Now next to the OpenShift v4.14 Windows Client entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the oc binary to a directory that is on your PATH. To check your PATH, open the command prompt and execute the following command:

   ```
   C:\> path
   ```

**Verification**

- After you install the OpenShift CLI, it is available using the oc command:

  ```
  C:\> oc <command>
  ```

**Installing the OpenShift CLI on macOS**

You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version from the Version drop-down list.

3. Click Download Now next to the OpenShift v4.14 macOS Client entry and save the file.

   NOTE

   For macOS arm64, choose the OpenShift v4.14 macOS arm64 Client entry.

4. Unpack and unzip the archive.

5. Move the oc binary to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:

   $ echo $PATH

   Verification

   - After you install the OpenShift CLI, it is available using the oc command:

   $ oc <command>

7.5.10. Alternatives to storing administrator-level secrets in the kube-system project

By default, administrator secrets are stored in the kube-system project. If you configured the credentialsMode parameter in the install-config.yaml file to Manual, you must use one of the following alternatives:

- To manage long-term cloud credentials manually, follow the procedure in Manually creating long-term credentials.

- To implement short-term credentials that are managed outside the cluster for individual components, follow the procedures in Configuring an Azure cluster to use short-term credentials.

7.5.10.1. Manually creating long-term credentials

The Cloud Credential Operator (CCO) can be put into manual mode prior to installation in environments where the cloud identity and access management (IAM) APIs are not reachable, or the administrator prefers not to store an administrator-level credential secret in the cluster kube-system namespace.

Procedure

1. If you did not set the credentialsMode parameter in the install-config.yaml configuration file to Manual, modify the value as shown:

   Sample configuration file snippet

   ```yaml
   apiVersion: v1
   ```
2. If you have not previously created installation manifest files, do so by running the following command:

$ openshift-install create manifests --dir <installation_directory>

where `<installation_directory>` is the directory in which the installation program creates files.

3. Set a `$RELEASE_IMAGE` variable with the release image from your installation file by running the following command:

$ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')

4. Extract the list of `CredentialsRequest` custom resources (CRs) from the OpenShift Container Platform release image by running the following command:

$ oc adm release extract \
   --from=$RELEASE_IMAGE \
   --credentials-requests \
   --included \
   --install-config=<path_to_directory_with.installation_configuration>/install-config.yaml \
   --to=<path_to_directory_for_credentials_requests>

   1 The `--included` parameter includes only the manifests that your specific cluster configuration requires.

   2 Specify the location of the `install-config.yaml` file.

   3 Specify the path to the directory where you want to store the `CredentialsRequest` objects. If the specified directory does not exist, this command creates it.

This command creates a YAML file for each `CredentialsRequest` object.

**Sample CredentialsRequest object**

```yaml
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
  name: <component_credentials_request>
  namespace: openshift-cloud-credential-operator
...
spec:
  providerSpec:
    apiVersion: cloudcredential.openshift.io/v1
    kind: AzureProviderSpec
    roleBindings:
      - role: Contributor
    ...
```

5. Create YAML files for secrets in the `openshift-install` directory that you created.
5. Create YAML files for secrets in the `openshift-install` manifests directory that you generated previously. The secrets must be stored using the namespace and secret name defined in the `spec.secretRef` for each `CredentialsRequest` object.

**Sample CredentialsRequest object with secrets**

```yaml
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
  name: <component_credentials_request>
  namespace: openshift-cloud-credential-operator
...
spec:
  providerSpec:
    apiVersion: cloudcredential.openshift.io/v1
    kind: AzureProviderSpec
    roleBindings:
      - role: Contributor
        ...
  secretRef:
    name: <component_secret>
    namespace: <component_namespace>
...
```

**Sample Secret object**

```yaml
apiVersion: v1
kind: Secret
metadata:
  name: <component_secret>
  namespace: <component_namespace>
data:
  azure_subscription_id: <base64_encoded_azure_subscription_id>
  azure_client_id: <base64_encoded_azure_client_id>
  azure_client_secret: <base64_encoded_azure_client_secret>
  azure_tenant_id: <base64_encoded_azure_tenant_id>
  azure_resource_prefix: <base64_encoded_azure_resource_prefix>
  azure_resourcegroup: <base64_encoded_azure_resourcegroup>
  azure_region: <base64_encoded_azure_region>
```

**IMPORTANT**

Before upgrading a cluster that uses manually maintained credentials, you must ensure that the CCO is in an upgradeable state.

### 7.5.10.2. Configuring an Azure cluster to use short-term credentials

To install a cluster that uses Azure AD Workload Identity, you must configure the Cloud Credential Operator utility and create the required Azure resources for your cluster.

#### 7.5.10.2.1. Configuring the Cloud Credential Operator utility

To create and manage cloud credentials from outside of the cluster when the Cloud Credential Operator (CCO) is operating in manual mode, extract and prepare the CCO utility (`ccoctl`) binary.
NOTE
The ccocctl utility is a Linux binary that must run in a Linux environment.

Prerequisites

- You have access to an OpenShift Container Platform account with cluster administrator access.
- You have installed the OpenShift CLI (oc).
- You have created a global Microsoft Azure account for the ccocctl utility to use with the following permissions:

Example 7.25. Required Azure permissions

- Microsoft.Resources/subscriptions/resourceGroups/read
- Microsoft.Resources/subscriptions/resourceGroups/write
- Microsoft.Resources/subscriptions/resourceGroups/delete
- Microsoft.Authorization/roleAssignments/read
- Microsoft.Authorization/roleAssignments/delete
- Microsoft.Authorization/roleAssignments/write
- Microsoft.Authorization/roleDefinitions/read
- Microsoft.Authorization/roleDefinitions/write
- Microsoft.Authorization/roleDefinitions/delete
- Microsoft.Storage/storageAccounts/listkeys/action
- Microsoft.Storage/storageAccounts/delete
- Microsoft.Storage/storageAccounts/read
- Microsoft.Storage/storageAccounts/write
- Microsoft.Storage/storageAccounts/blobServices/containers/write
- Microsoft.Storage/storageAccounts/blobServices/containers/delete
- Microsoft.Storage/storageAccounts/blobServices/containers/read
- Microsoft.ManagedIdentity/userAssignedIdentities/delete
- Microsoft.ManagedIdentity/userAssignedIdentities/read
- Microsoft.ManagedIdentity/userAssignedIdentities/write
- Microsoft.ManagedIdentity/userAssignedIdentities/federatedIdentityCredentials/read
- Microsoft.ManagedIdentity/userAssignedIdentities/federatedIdentityCredentials/write
- Microsoft.ManagedIdentity/userAssignedIdentities/federatedIdentityCredentials/delete
Procedure

1. Obtain the OpenShift Container Platform release image by running the following command:

   ```bash
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
   ```

2. Obtain the CCO container image from the OpenShift Container Platform release image by running the following command:

   ```bash
   $ CCO_IMAGE=$(oc adm release info --image-for='cloud-credential-operator'
   $RELEASE_IMAGE -a ~/.pull-secret)
   ```

   **NOTE**

   Ensure that the architecture of the $RELEASE_IMAGE matches the architecture of the environment in which you will use the ccoctl tool.

3. Extract the ccoctl binary from the CCO container image within the OpenShift Container Platform release image by running the following command:

   ```bash
   $ oc image extract $CCO_IMAGE --file="/usr/bin/ccoctl" -a ~/.pull-secret
   ```

4. Change the permissions to make ccoctl executable by running the following command:

   ```bash
   $ chmod 775 ccoctl
   ```

Verification

- To verify that ccoctl is ready to use, display the help file by running the following command:

  ```bash
  $ ccoctl --help
  ```

**Output of ccoctl --help**

OpenShift credentials provisioning tool

Usage:

ccoctl [command]

Available Commands:

- alibabacloud Manage credentials objects for alibaba cloud
- aws Manage credentials objects for AWS cloud
- azure Manage credentials objects for Azure
- gcp Manage credentials objects for Google cloud
- help Help about any command
- ibmcloud Manage credentials objects for IBM Cloud
- nutanix Manage credentials objects for Nutanix
7.5.10.2.2. Creating Azure resources with the Cloud Credential Operator utility

You can use the `ccoctl azure create-all` command to automate the creation of Azure resources.

**NOTE**

By default, `ccoctl` creates objects in the directory in which the commands are run. To create the objects in a different directory, use the `--output-dir` flag. This procedure uses `<path_to_ccoctl_output_dir>` to refer to this directory.

**Prerequisites**

You must have:

- Extracted and prepared the `ccoctl` binary.
- Access to your Microsoft Azure account by using the Azure CLI.

**Procedure**

1. Set a `$RELEASE_IMAGE` variable with the release image from your installation file by running the following command:

   ```
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
   ```

2. Extract the list of `CredentialsRequest` objects from the OpenShift Container Platform release image by running the following command:

   ```
   $ oc adm release extract \
   --from=$RELEASE_IMAGE \
   --credentials-requests \
   --included \1
   --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \2
   --to=<path_to_directory_for_credentials_requests> \3
   ```

   **1** The `--included` parameter includes only the manifests that your specific cluster configuration requires.

   **2** Specify the location of the `install-config.yaml` file.

   **3** Specify the path to the directory where you want to store the `CredentialsRequest` objects. If the specified directory does not exist, this command creates it.

**NOTE**

This command might take a few moments to run.
3. To enable the `ccoctl` utility to detect your Azure credentials automatically, log in to the Azure CLI by running the following command:

```
$ az login
```

4. Use the `ccoctl` tool to process all `CredentialsRequest` objects by running the following command:

```
$ ccoctl azure create-all \
   --name=<azure_infra_name> \ 1
   --output-dir=<ccoctl_output_dir> \ 2
   --region=<azure_region> \ 3
   --subscription-id=<azure_subscription_id> \ 4
   --credentials-requests-dir=<path_to_credentials_requests_directory> \ 5
   --dnszone-resource-group-name=<azure_dns_zone_resource_group_name> \ 6
   --tenant-id=<azure_tenant_id> 7
```

1. Specify the user-defined name for all created Azure resources used for tracking.
2. Optional: Specify the directory in which you want the `ccoctl` utility to create objects. By default, the utility creates objects in the directory in which the commands are run.
3. Specify the Azure region in which cloud resources will be created.
4. Specify the Azure subscription ID to use.
5. Specify the directory containing the files for the component `CredentialsRequest` objects.
6. Specify the name of the resource group containing the cluster’s base domain Azure DNS zone.
7. Specify the Azure tenant ID to use.

**NOTE**

If your cluster uses Technology Preview features that are enabled by the `TechPreviewNoUpgrade` feature set, you must include the `--enable-tech-preview` parameter.

To see additional optional parameters and explanations of how to use them, run the `azure create-all --help` command.

**Verification**

- To verify that the OpenShift Container Platform secrets are created, list the files in the `<path_to_ccoctl_output_dir>/manifests` directory:

```
$ ls <path_to_ccoctl_output_dir>/manifests
```

**Example output**

```
azure-ad-pod-identity-webhook-config.yaml
cluster-authentication-02-config.yaml
```
You can verify that the Azure AD service accounts are created by querying Azure. For more information, refer to Azure documentation on listing AD service accounts.

7.5.10.2.3. Incorporating the Cloud Credential Operator utility manifests

To implement short-term security credentials managed outside the cluster for individual components, you must move the manifest files that the Cloud Credential Operator utility (ccoctl) created to the correct directories for the installation program.

Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.
- You have configured the Cloud Credential Operator utility (ccoctl).
- You have created the cloud provider resources that are required for your cluster with the ccoctl utility.

Procedure

1. If you did not set the credentialsMode parameter in the install-config.yaml configuration file to Manual, modify the value as shown:

   Sample configuration file snippet

   ```yaml
   apiVersion: v1
   baseDomain: example.com
   credentialsMode: Manual
   # ...
   ```

2. If you used the ccoctl utility to create a new Azure resource group instead of using an existing resource group, modify the resourceGroupName parameter in the install-config.yaml as shown:

   Sample configuration file snippet

   ```yaml
   apiVersion: v1
   baseDomain: example.com
   # ...
   platform:
     azure:
       resourceGroupName: <azure_infra_name>  # 
   # ...
   ```
This value must match the user-defined name for Azure resources that was specified with the \texttt{--name} argument of the \texttt{ccoctl azure create-all} command.

3. If you have not previously created installation manifest files, do so by running the following command:

\begin{verbatim}
$ openshift-install create manifests --dir <installation_directory>
\end{verbatim}

where \texttt{<installation_directory>} is the directory in which the installation program creates files.

4. Copy the manifests that the \texttt{ccoctl} utility generated to the \texttt{manifests} directory that the installation program created by running the following command:

\begin{verbatim}
$ cp /<path_to_ccoctl_output_dir>/manifests/* ./manifests/
\end{verbatim}

5. Copy the private key that the \texttt{ccoctl} utility generated in the \texttt{tls} directory to the installation directory by running the following command:

\begin{verbatim}
$ cp -a /<path_to_ccoctl_output_dir>/tls .
\end{verbatim}

7.5.11. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

\begin{quote}
\textbf{IMPORTANT}

You can run the \texttt{create cluster} command of the installation program only once, during initial installation.
\end{quote}

\textbf{Prerequisites}

- You have configured an account with the cloud platform that hosts your cluster.
- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have an Azure subscription ID and tenant ID.

\textbf{Procedure}

- Change to the directory that contains the installation program and initialize the cluster deployment:

\begin{verbatim}
$ ./openshift-install create cluster --dir <installation_directory> \1
   --log-level=info \2
\end{verbatim}

\textbf{1} For \texttt{<installation_directory>}, specify the location of your customized \texttt{./install-config.yaml} file.

\textbf{2} To view different installation details, specify \texttt{warn}, \texttt{debug}, or \texttt{error} instead of \texttt{info}.

\textbf{Verification}
When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the **kubeadmin** user.

- Credential information also outputs to `<installation_directory>/openshift_install.log`.

**IMPORTANT**

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

**Example output**

```
... 
INFO Install complete! 
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig' 
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com 
INFO Login to the console with user: "kubeadmin", and password: "password" 
INFO Time elapsed: 36m22s
```

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for **Recovering from expired control plane certificates** for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

### 7.5.12. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.

- You installed the **oc** CLI.

**Procedure**

```
1. Export the **kubeadmin** credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   ```

   **Example output**

   ```text
   system:admin
   ```

**Additional resources**

- See [Accessing the web console](#) for more details about accessing and understanding the OpenShift Container Platform web console.

### 7.5.13. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager Hybrid Cloud Console](#).

After you confirm that your [OpenShift Cluster Manager Hybrid Cloud Console](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use `subscription watch` to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- See [About remote health monitoring](#) for more information about the Telemetry service.

### 7.5.14. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.

### 7.6. INSTALLING A CLUSTER ON AZURE WITH NETWORK CUSTOMIZATIONS

In OpenShift Container Platform version 4.14, you can install a cluster with a customized network configuration on infrastructure that the installation program provisions on Microsoft Azure. By customizing your network configuration, your cluster can coexist with existing IP address allocations in your environment and integrate with existing MTU and VXLAN configurations.

You must set most of the network configuration parameters during installation, and you can modify only `kubeProxy` configuration parameters in a running cluster.
7.6.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You configured an Azure account to host the cluster and determined the tested and validated region to deploy the cluster to.
- If you use a firewall, you configured it to allow the sites that your cluster requires access to.
- If you use customer-managed encryption keys, you prepared your Azure environment for encryption.

7.6.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager Hybrid Cloud Console to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

7.6.3. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the `core` user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user `core`. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.
IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

NOTE

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   $ ssh-keygen -t ed25519 -N " -f <path>/<file_name>  

1 Specify the path and file name, such as ~/.ssh/id_ed25519, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   NOTE

   If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   $ cat <path>/<file_name>.pub

   For example, run the following to view the ~/.ssh/id_ed25519.pub public key:

   $ cat ~/.ssh/id_ed25519.pub

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the ./openshift-install gather command.

   NOTE

   On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.

   a. If the ssh-agent process is not already running for your local user, start it as a background task:

      $ eval "$(ssh-agent -s)"

Example output
If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the `ssh-agent`:

   ```bash
   $ ssh-add /path/to/file
   
   Example output
   
   Identity added: /home/you/path/file (<computer_name>)
   ```

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

### 7.6.4. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

**Prerequisites**

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

**Procedure**

1. Access the **Infrastructure Provider** page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.
IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   $ tar -xvf openshift-install-linux.tar.gz

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

7.6.5. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Microsoft Azure.

Prerequisites

- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have an Azure subscription ID and tenant ID.
- If you are installing the cluster using a service principal, you have its application ID and password.
- If you are installing the cluster using a system-assigned managed identity, you have enabled it on the virtual machine that you will run the installation program from.
- If you are installing the cluster using a user-assigned managed identity, you have met these prerequisites:
  - You have its client ID.
  - You have assigned it to the virtual machine that you will run the installation program from.

Procedure

1. Optional: If you have run the installation program on this computer before, and want to use an alternative service principal or managed identity, go to the ~/.azure/ directory and delete the osServicePrincipal.json configuration file.
   Deleting this file prevents the installation program from automatically reusing subscription and authentication values from a previous installation.

2. Create the install-config.yaml file.

   a. Change to the directory that contains the installation program and run the following command:

      $ ./openshift-install create install-config --dir <installation_directory>
For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

When specifying the directory:

- Verify that the directory has the **execute** permission. This permission is required to run Terraform binaries under the installation directory.

- Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

**NOTE**

Always delete the `~/.powervs` directory to avoid reusing a stale configuration. Run the following command:

```
$ rm -rf ~/.powervs
```

b. At the prompts, provide the configuration details for your cloud:

  i. Optional: Select an SSH key to use to access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

ii. Select **azure** as the platform to target.
If the installation program cannot locate the `osServicePrincipal.json` configuration file from a previous installation, you are prompted for Azure subscription and authentication values.

iii. Enter the following Azure parameter values for your subscription:

- **azure subscription id** Enter the subscription ID to use for the cluster.
- **azure tenant id** Enter the tenant ID.

iv. Depending on the Azure identity you are using to deploy the cluster, do one of the following when prompted for the **azure service principal client id**

  - If you are using a service principal, enter its application ID.
  - If you are using a system-assigned managed identity, leave this value blank.
  - If you are using a user-assigned managed identity, specify its client ID.

v. Depending on the Azure identity you are using to deploy the cluster, do one of the following when prompted for the **azure service principal client secret**
If you are using a service principal, enter its password.

If you are using a system-assigned managed identity, leave this value blank.

If you are using a user-assigned managed identity, leave this value blank.

vi. Select the region to deploy the cluster to.

vii. Select the base domain to deploy the cluster to. The base domain corresponds to the Azure DNS Zone that you created for your cluster.

viii. Enter a descriptive name for your cluster.

IMPORTANT

All Azure resources that are available through public endpoints are subject to resource name restrictions, and you cannot create resources that use certain terms. For a list of terms that Azure restricts, see Resolve reserved resource name errors in the Azure documentation.

3. Modify the `install-config.yaml` file. You can find more information about the available parameters in the "Installation configuration parameters” section.

4. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

IMPORTANT

The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

If previously not detected, the installation program creates an `osServicePrincipal.json` configuration file and stores this file in the `~/.azure/` directory on your computer. This ensures that the installation program can load the profile when it is creating an OpenShift Container Platform cluster on the target platform.

Additional resources

- Installation configuration parameters for Azure

7.6.5.1. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>---------</td>
<td>----------------------------------</td>
<td>----------</td>
<td>-------------</td>
<td>---------</td>
<td>----------------------------------</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS, RHEL 8.6 and later [3]</td>
<td>2</td>
<td>8 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
</tbody>
</table>

1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or hyperthreading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: \((\text{threads per core} \times \text{cores}) \times \text{sockets} = \text{vCPUs}\).

2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.

3. As with all user-provisioned installations, if you choose to use RHEL compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and has been removed in OpenShift Container Platform 4.10 and later.

**IMPORTANT**

You are required to use Azure virtual machines that have the `premiumIO` parameter set to `true`.

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

**Additional resources**

- Optimizing storage

**7.6.5.2. Tested instance types for Azure**

The following Microsoft Azure instance types have been tested with OpenShift Container Platform.

**Example 7.26. Machine types based on 64-bit x86 architecture**

- c4.*
- c5.*
- c5a.*
- i3.*
- m4.*
- m5.*
7.6.5.3. Tested instance types for Azure on 64-bit ARM infrastructures

The following Microsoft Azure ARM64 instance types have been tested with OpenShift Container Platform.

Example 7.27. Machine types based on 64-bit ARM architecture

- c6g.*
- m6g.*

7.6.5.4. Enabling trusted launch for Azure VMs

You can enable two trusted launch features when installing your cluster on Azure: secure boot and virtualized Trusted Platform Modules.

See the Azure documentation about virtual machine sizes to learn what sizes of virtual machines support these features.

**IMPORTANT**

Trusted launch is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see Technology Preview Features Support Scope.

**Prerequisites**

- You have created an `install-config.yaml` file.

**Procedure**
7.6.5.5. Enabling confidential VMs

You can enable confidential VMs when installing your cluster. You can enable confidential VMs for compute nodes, control plane nodes, or all nodes.

**IMPORTANT**

Using confidential VMs is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see Technology Preview Features Support Scope.

You can use confidential VMs with the following VM sizes:

- DCasv5-series
- DCadsv5-series
- ECasv5-series
- ECadsv5-series

**IMPORTANT**

Confidential VMs are currently not supported on 64-bit ARM architectures.
**Prerequisites**

- You have created an `install-config.yaml` file.

**Procedure**

- Use a text editor to edit the `install-config.yaml` file prior to deploying your cluster and add the following stanza:

```yaml
controlPlane: 1
   platform: 2
       azure: 3
           settings: 4
               securityType: ConfidentialVM 5
               confidentialVM:
                   uefiSettings:
                       secureBoot: Enabled 6
                       virtualizedTrustedPlatformModule: Enabled 7

   osDisk:
       securityProfile:
           securityEncryptionType: VMGuestStateOnly 8
```

1. Specify `controlPlane.platform.azure` or `compute.platform.azure` to deploy confidential VMs on only control plane or compute nodes respectively. Specify `platform.azure.defaultMachinePlatform` to deploy confidential VMs on all nodes.

2. Enable confidential VMs.

3. Enable secure boot. For more information, see the Azure documentation about secure boot.

4. Enable the virtualized Trusted Platform Module. For more information, see the Azure documentation about virtualized Trusted Platform Modules.

5. Specify `VMGuestStateOnly` to encrypt the VM guest state.

**7.6.5.6. Sample customized install-config.yaml file for Azure**

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

**IMPORTANT**

This sample YAML file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program and modify it.

```yaml
apiVersion: v1
baseDomain: example.com 1
controlPlane: 2
   hyperthreading: Enabled 3
   name: master
   platform:
       azure:
```

948
encryptionAtHost: true
ultraSSDCapability: Enabled
osDisk:
  diskSizeGB: 1024
  diskType: Premium_LRS
diskEncryptionSet:
  resourceGroup: disk_encryption_set_resource_group
  name: disk_encryption_set_name
  subscriptionId: secondary_subscription_id
osImage:
  publisher: example_publisher_name
  offer: example_image_offer
  sku: example_offer_sku
  version: example_image_version
  type: Standard_D8s_v3
replicas: 3
compute:
  - hyperthreading: Enabled
name: worker
platform:
  azure:
    ultraSSDCapability: Enabled
    type: Standard_D2s_v3
    encryptionAtHost: true
osDisk:
  diskSizeGB: 512
  diskType: Standard_LRS
diskEncryptionSet:
  resourceGroup: disk_encryption_set_resource_group
  name: disk_encryption_set_name
  subscriptionId: secondary_subscription_id
osImage:
  publisher: example_publisher_name
  offer: example_image_offer
  sku: example_offer_sku
  version: example_image_version
zones:
  - "1"
  - "2"
  - "3"
replicas: 5
metadata:
  name: test-cluster

    - cidr: 10.128.0.0/14
    hostPrefix: 23
  machineNetwork:
    - cidr: 10.0.0.0/16
  networkType: OVNKubernetes
  serviceNetwork:
    - 172.30.0.0/16
platform:
  azure:
    defaultMachinePlatform:
The installation program prompts you for this value.

If you do not provide these parameters and values, the installation program provides the default value.

The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, -, and the first line of the controlPlane section must not. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading, or hyperthreading. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores. You can disable it by setting the parameter value to Disabled. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger virtual machine types, such as Standard_D8s_v3, for your machines if you disable simultaneous multithreading.

You can specify the size of the disk to use in GB. Minimum recommendation for control plane nodes is 1024 GB.

Specify a list of zones to deploy your machines to. For high availability, specify at least two zones.

The cluster network plugin to install. The supported values are OVNKubernetes and OpenShiftSDN. The default value is OVNKubernetes.

Optional: A custom Red Hat Enterprise Linux CoreOS (RHCOS) image that should be used to boot control plane and compute machines. The publisher, offer, sku, and version parameters under platform.azure.defaultMachinePlatform.osImage apply to both control plane and compute machines. If the parameters under controlPlane.platform.azure.osImage or compute.platform.azure.osImage are set, they override the platform.azure.defaultMachinePlatform.osImage parameters.

Specify the name of the resource group that contains the DNS zone for your base domain.

Specify the name of an already existing resource group to install your cluster to. If undefined, a new
Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container

**IMPORTANT**
To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see Installing the system in FIPS mode. When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures.

You can optionally provide the `sshKey` value that you use to access the machines in your cluster.

**NOTE**
For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

7.6.5.7. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**Prerequisites**
- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**
The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

**Procedure**
1. Edit your `install-config.yaml` file and add the proxy settings. For example:
A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.

A proxy URL to use for creating HTTPS connections outside the cluster.

A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.

If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the `trustedCA` field of the `Proxy` object. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

Optional: The policy to determine the configuration of the `Proxy` object to reference the `user-ca-bundle` config map in the `trustedCA` field. The allowed values are `Proxyonly` and `Always`. Use `Proxyonly` to reference the `user-ca-bundle` config map only when http/https proxy is configured. Use `Always` to always reference the `user-ca-bundle` config map. The default value is `Proxyonly`.

The installation program does not support the proxy `readinessEndpoints` field.

If the installer times out, restart and then complete the deployment by using the `wait-for` command of the installer. For example:

```
$ ./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`. 
Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

### 7.6.6. Network configuration phases

There are two phases prior to OpenShift Container Platform installation where you can customize the network configuration.

**Phase 1**

You can customize the following network-related fields in the `install-config.yaml` file before you create the manifest files:

- `networking.networkType`
- `networking.clusterNetwork`
- `networking.serviceNetwork`
- `networking.machineNetwork`

For more information on these fields, refer to *Installation configuration parameters*.

**NOTE**

Set the `networking.machineNetwork` to match the CIDR that the preferred NIC resides in.

**IMPORTANT**

The CIDR range `172.17.0.0/16` is reserved by libVirt. You cannot use this range or any range that overlaps with this range for any networks in your cluster.

**Phase 2**

After creating the manifest files by running `openshift-install create manifests`, you can define a customized Cluster Network Operator manifest with only the fields you want to modify. You can use the manifest to specify advanced network configuration.

You cannot override the values specified in phase 1 in the `install-config.yaml` file during phase 2. However, you can further customize the network plugin during phase 2.

### 7.6.7. Specifying advanced network configuration

You can use advanced network configuration for your network plugin to integrate your cluster into your existing network environment. You can specify advanced network configuration only before you install the cluster.

**IMPORTANT**

Customizing your network configuration by modifying the OpenShift Container Platform manifest files created by the installation program is not supported. Applying a manifest file that you create, as in the following procedure, is supported.
Prerequisites

- You have created the `install-config.yaml` file and completed any modifications to it.

Procedure

1. Change to the directory that contains the installation program and create the manifests:

   ```
   $ ./openshift-install create manifests --dir <installation_directory>
   ```

   `<installation_directory>` specifies the name of the directory that contains the `install-config.yaml` file for your cluster.

2. Create a stub manifest file for the advanced network configuration that is named `cluster-network-03-config.yml` in the `<installation_directory>/manifests/` directory:

   ```yaml
   apiVersion: operator.openshift.io/v1
   kind: Network
   metadata:
     name: cluster
   spec:
     defaultNetwork:
       openshiftSDNConfig:
         vxlanPort: 4800
   ```

3. Specify the advanced network configuration for your cluster in the `cluster-network-03-config.yml` file, such as in the following examples:

   **Specify a different VXLAN port for the OpenShift SDN network provider**

   ```yaml
   apiVersion: operator.openshift.io/v1
   kind: Network
   metadata:
     name: cluster
   spec:
     defaultNetwork:
       openshiftSDNConfig:
         vxlanPort: 4800
   ```

   **Enable IPsec for the OVN-Kubernetes network provider**

   ```yaml
   apiVersion: operator.openshift.io/v1
   kind: Network
   metadata:
     name: cluster
   spec:
     defaultNetwork:
       ovnKubernetesConfig:
         ipsecConfig: {}
   ```

4. Optional: Back up the `manifests/cluster-network-03-config.yml` file. The installation program consumes the `manifests/` directory when you create the Ignition config files.

7.6.8. Cluster Network Operator configuration
The configuration for the cluster network is specified as part of the Cluster Network Operator (CNO) configuration and stored in a custom resource (CR) object that is named `cluster`. The CR specifies the fields for the `Network` API in the `operator.openshift.io` API group.

The CNO configuration inherits the following fields during cluster installation from the `Network` API in the `Network.config.openshift.io` API group and these fields cannot be changed:

- **clusterNetwork**
  - IP address pools from which pod IP addresses are allocated.
- **serviceNetwork**
  - IP address pool for services.
- **defaultNetwork.type**
  - Cluster network plugin, such as OpenShift SDN or OVN-Kubernetes.

You can specify the cluster network plugin configuration for your cluster by setting the fields for the `defaultNetwork` object in the CNO object named `cluster`.

### 7.6.8.1. Cluster Network Operator configuration object

The fields for the Cluster Network Operator (CNO) are described in the following table:

**Table 7.3. Cluster Network Operator configuration object**

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>metadata.name</td>
<td>string</td>
<td>The name of the CNO object. This name is always <code>cluster</code>.</td>
</tr>
<tr>
<td>spec.clusterNetwork</td>
<td>array</td>
<td>A list specifying the blocks of IP addresses from which pod IP addresses are allocated and the subnet prefix length assigned to each individual node in the cluster. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>spec:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>clusterNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- cidr: 10.128.0.0/19</td>
</tr>
<tr>
<td></td>
<td></td>
<td>hostPrefix: 23</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- cidr: 10.128.32.0/19</td>
</tr>
<tr>
<td></td>
<td></td>
<td>hostPrefix: 23</td>
</tr>
</tbody>
</table>

You can customize this field only in the `install-config.yaml` file before you create the manifests. The value is read-only in the manifest file.
### Field | Type | Description
--- | --- | ---
| spec.serviceNetwork | array | A block of IP addresses for services. The OpenShift SDN and OVN-Kubernetes network plugins support only a single IP address block for the service network. For example:

```
spec:
  serviceNetwork:
  - 172.30.0.0/14
```

You can customize this field only in the `install-config.yaml` file before you create the manifests. The value is read-only in the manifest file.

| spec.defaultNetwork | object | Configures the network plugin for the cluster network.
| spec.kubeProxyConfig | object | The fields for this object specify the kube-proxy configuration. If you are using the OVN-Kubernetes cluster network plugin, the kube-proxy configuration has no effect.

#### defaultNetwork object configuration
The values for the `defaultNetwork` object are defined in the following table:

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| type | string | Either **OpenShiftSDN** or **OVNKubernetes**. The Red Hat OpenShift Networking network plugin is selected during installation. This value cannot be changed after cluster installation.

**NOTE**

OpenShift Container Platform uses the OVN-Kubernetes network plugin by default.

| openshiftSDNConfig | object | This object is only valid for the OpenShift SDN network plugin.
| ovnKubernetesConfig | object | This object is only valid for the OVN-Kubernetes network plugin.

#### Configuration for the OpenShift SDN network plugin
The following table describes the configuration fields for the OpenShift SDN network plugin:
Table 7.5. openshiftSDNConfig object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mode</td>
<td>string</td>
<td>Configures the network isolation mode for OpenShift SDN. The default value is NetworkPolicy. The values Multitenant and Subnet are available for backwards compatibility with OpenShift Container Platform 3.x but are not recommended. This value cannot be changed after cluster installation.</td>
</tr>
<tr>
<td>mtu</td>
<td>integer</td>
<td>The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU. If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes. If your cluster requires different MTU values for different nodes, you must set this value to 50 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1450. This value cannot be changed after cluster installation.</td>
</tr>
<tr>
<td>vxlanPort</td>
<td>integer</td>
<td>The port to use for all VXLAN packets. The default value is 4789. This value cannot be changed after cluster installation. If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number. On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port 9000 and port 9999.</td>
</tr>
</tbody>
</table>

Example OpenShift SDN configuration

defaultNetwork:
  type: OpenShiftSDN
  openshiftSDNConfig:
    mode: NetworkPolicy
    mtu: 1450
    vxlanPort: 4789

Configuration for the OVN-Kubernetes network plugin
The following table describes the configuration fields for the OVN-Kubernetes network plugin:
<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mtu</td>
<td>integer</td>
<td>The maximum transmission unit (MTU) for the Geneve (Generic Network Virtualization Encapsulation) overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU. If the auto-detected value is not what you expect it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes. If your cluster requires different MTU values for different nodes, you must set this value to 100 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1400.</td>
</tr>
<tr>
<td>genevePort</td>
<td>integer</td>
<td>The port to use for all Geneve packets. The default value is 6081. This value cannot be changed after cluster installation.</td>
</tr>
<tr>
<td>ipsecConfig</td>
<td>object</td>
<td>Specify an empty object to enable IPsec encryption.</td>
</tr>
<tr>
<td>policyAuditConfig</td>
<td>object</td>
<td>Specify a configuration object for customizing network policy audit logging. If unset, the defaults audit log settings are used.</td>
</tr>
<tr>
<td>gatewayConfig</td>
<td>object</td>
<td>Optional: Specify a configuration object for customizing how egress traffic is sent to the node gateway.</td>
</tr>
</tbody>
</table>

**NOTE**

While migrating egress traffic, you can expect some disruption to workloads and service traffic until the Cluster Network Operator (CNO) successfully rolls out the changes.
If your existing network infrastructure overlaps with the 100.64.0.0/16 IPv4 subnet, you can specify a different IP address range for internal use by OVN-Kubernetes. You must ensure that the IP address range does not overlap with any other subnet used by your OpenShift Container Platform installation. The IP address range must be larger than the maximum number of nodes that can be added to the cluster. For example, if the `clusterNetwork.cidr` value is 10.128.0.0/14 and the `clusterNetwork.hostPrefix` value is /23, then the maximum number of nodes is $2^{(23-14)}=512$.

This field cannot be changed after installation.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>v4InternalSubnet</td>
<td>If your existing network infrastructure overlaps with the <strong>100.64.0.0/16</strong> IPv4 subnet, you can specify a different IP address range for internal use by OVN-Kubernetes. You must ensure that the IP address range does not overlap with any other subnet used by your OpenShift Container Platform installation. The IP address range must be larger than the maximum number of nodes that can be added to the cluster. For example, if the <code>clusterNetwork.cidr</code> value is <strong>10.128.0.0/14</strong> and the <code>clusterNetwork.hostPrefix</code> value is /23, then the maximum number of nodes is $2^{(23-14)}=512$. This field cannot be changed after installation.</td>
<td>The default value is <strong>100.64.0.0/16</strong>.</td>
</tr>
</tbody>
</table>
If your existing network infrastructure overlaps with the `fd98::/48` IPv6 subnet, you can specify a different IP address range for internal use by OVN-Kubernetes. You must ensure that the IP address range does not overlap with any other subnet used by your OpenShift Container Platform installation. The IP address range must be larger than the maximum number of nodes that can be added to the cluster.

This field cannot be changed after installation.

The default value is `fd98::/48`.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>v6InternalSubnet</td>
<td>If your existing network infrastructure overlaps with the <code>fd98::/48</code> IPv6 subnet, you can specify a different IP address range for internal use by OVN-Kubernetes. You must ensure that the IP address range does not overlap with any other subnet used by your OpenShift Container Platform installation. The IP address range must be larger than the maximum number of nodes that can be added to the cluster. This field cannot be changed after installation.</td>
<td>The default value is <code>fd98::/48</code>.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rateLimit</td>
<td>integer</td>
<td>The maximum number of messages to generate every second per node. The default value is 20 messages per second.</td>
</tr>
<tr>
<td>maxFileSize</td>
<td>integer</td>
<td>The maximum size for the audit log in bytes. The default value is 50000000 or 50 MB.</td>
</tr>
</tbody>
</table>
One of the following additional audit log targets:

- **libc**
  - The libc `syslog()` function of the journald process on the host.

- **udp:<host>:<port>**
  - A syslog server. Replace `<host>:<port>` with the host and port of the syslog server.

- **unix:<file>**
  - A Unix Domain Socket file specified by `<file>`.

- **null**
  - Do not send the audit logs to any additional target.

The syslog facility, such as `kern`, as defined by RFC5424. The default value is `local0`.

### Table 7.8. gatewayConfig object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>routingViaHost</td>
<td>boolean</td>
<td>Set this field to <code>true</code> to send egress traffic from pods to the host networking stack. For highly-specialized installations and applications that rely on manually configured routes in the kernel routing table, you might want to route egress traffic to the host networking stack. By default, egress traffic is processed in OVN to exit the cluster and is not affected by specialized routes in the kernel routing table. The default value is <code>false</code>. This field has an interaction with the Open vSwitch hardware offloading feature. If you set this field to <code>true</code>, you do not receive the performance benefits of the offloading because egress traffic is processed by the host networking stack.</td>
</tr>
<tr>
<td>ipForwarding</td>
<td>object</td>
<td>You can control IP forwarding for all traffic on OVN-Kubernetes managed interfaces by using the <code>ipForwarding</code> specification in the Network resource. Specify <code>Restricted</code> to only allow IP forwarding for Kubernetes related traffic. Specify <code>Global</code> to allow forwarding of all IP traffic. For new installations, the default is <code>Restricted</code>. For updates to OpenShift Container Platform 4.14, the default is <code>Global</code>.</td>
</tr>
</tbody>
</table>

Example OVN-Kubernetes configuration with IPSec enabled

```yaml
defaultNetwork:
  type: OVNKubernetes
  ovnKubernetesConfig:

```
KubeProxyConfig object configuration

The values for the kubeProxyConfig object are defined in the following table:

Table 7.9. kubeProxyConfig object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>iptablesSyncPeriod</td>
<td>string</td>
<td>The refresh period for iptables rules. The default value is 30s. Valid suffixes include s, m, and h and are described in the Go time package documentation.</td>
</tr>
<tr>
<td>proxyArguments.iptables-min-sync-period</td>
<td>array</td>
<td>The minimum duration before refreshing iptables rules. This field ensures that the refresh does not happen too frequently. Valid suffixes include s, m, and h and are described in the Go time package. The default value is:</td>
</tr>
</tbody>
</table>

```
kubeProxyConfig:
  proxyArguments:
    iptables-min-sync-period:
      - 0s
```

7.6.9. Configuring hybrid networking with OVN-Kubernetes

You can configure your cluster to use hybrid networking with the OVN-Kubernetes network plugin. This allows a hybrid cluster that supports different node networking configurations.

```
mtu: 1400
genevePort: 6081
ipsecConfig: {}
```

NOTE

Because of performance improvements introduced in OpenShift Container Platform 4.3 and greater, adjusting the iptablesSyncPeriod parameter is no longer necessary.

NOTE

This configuration is necessary to run both Linux and Windows nodes in the same cluster.

Prerequisites

- You defined OVNKubernetes for the networking.networkType parameter in the install-config.yaml file. See the installation documentation for configuring OpenShift Container Platform network customizations on your chosen cloud provider for more information.

Procedure
1. Change to the directory that contains the installation program and create the manifests:

   ```bash
   $ ./openshift-install create manifests --dir <installation_directory>
   ```

   where:

   `<installation_directory>`
   Specifies the name of the directory that contains the `install-config.yaml` file for your cluster.

2. Create a stub manifest file for the advanced network configuration that is named `cluster-network-03-config.yml` in the `<installation_directory>/manifests/` directory:

   ```bash
   $ cat <<EOF > <installation_directory>/manifests/cluster-network-03-config.yml
   apiVersion: operator.openshift.io/v1
   kind: Network
   metadata:
     name: cluster
   spec:
   EOF
   ```

   where:

   `<installation_directory>`
   Specifies the directory name that contains the `manifests/` directory for your cluster.

3. Open the `cluster-network-03-config.yml` file in an editor and configure OVN-Kubernetes with hybrid networking, such as in the following example:

   **Specify a hybrid networking configuration**

   ```yaml
   apiVersion: operator.openshift.io/v1
   kind: Network
   metadata:
     name: cluster
   spec:
     defaultNetwork:
       ovnKubernetesConfig:
         hybridOverlayConfig:
           hybridClusterNetwork: 1
           - cidr: 10.132.0.0/14
             hostPrefix: 23
           hybridOverlayVXLANPort: 9898 2
   ```

   where:

   **1** Specify the CIDR configuration used for nodes on the additional overlay network. The `hybridClusterNetwork` CIDR cannot overlap with the `clusterNetwork` CIDR.

   **2** Specify a custom VXLAN port for the additional overlay network. This is required for running Windows nodes in a cluster installed on vSphere, and must not be configured for any other cloud provider. The custom port can be any open port excluding the default 4789 port. For more information on this requirement, see the Microsoft documentation on Pod-to-pod connectivity between hosts is broken.
NOTE

Windows Server Long-Term Servicing Channel (LTSC): Windows Server 2019 is not supported on clusters with a custom `hybridOverlayVXLANPort` value because this Windows server version does not support selecting a custom VXLAN port.

4. Save the `cluster-network-03-config.yml` file and quit the text editor.

5. Optional: Back up the `manifests/cluster-network-03-config.yml` file. The installation program deletes the `manifests/` directory when creating the cluster.

NOTE

For more information on using Linux and Windows nodes in the same cluster, see Understanding Windows container workloads.

Additional resources

- For more details about Accelerated Networking, see Accelerated Networking for Microsoft Azure VMs.

7.6.10. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

IMPORTANT

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of oc.

Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure

2. Select the architecture from the Product Variant drop-down list.

3. Select the appropriate version from the Version drop-down list.

4. Click Download Now next to the OpenShift v4.14 Linux Client entry and save the file.

5. Unpack the archive:

```
$ tar xvf <file>
```

6. Place the oc binary in a directory that is on your PATH.

   To check your PATH, execute the following command:
After you install the OpenShift CLI, it is available using the `oc` command:

```shell
$ oc <command>
```

### Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (`oc`) binary on Windows by using the following procedure.

#### Procedure

2. Select the appropriate version from the Version drop-down list.
3. Click Download Now next to the OpenShift v4.14 Windows Client entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the `oc` binary to a directory that is on your PATH.
   - To check your PATH, open the command prompt and execute the following command:

   ```bash
   C:\> path
   ```

### Verification

- After you install the OpenShift CLI, it is available using the `oc` command:

  ```bash
  C:\> oc <command>
  ```

### Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (`oc`) binary on macOS by using the following procedure.

#### Procedure

2. Select the appropriate version from the Version drop-down list.
3. Click Download Now next to the OpenShift v4.14 macOS Client entry and save the file.
4. Unpack and unzip the archive.
5. Move the `oc` binary to a directory on your PATH.
   - To check your PATH, open a terminal and execute the following command:

   ```bash
   $ echo $PATH
   $ oc <command>
   ```

### Verification

- After you install the OpenShift CLI, it is available using the `oc` command:

  ```bash
  C:\> oc <command>
  ```

### NOTE

For macOS arm64, choose the OpenShift v4.14 macOS arm64 Client entry.
Verification

- After you install the OpenShift CLI, it is available using the `oc` command:

  ```
  $ oc <command>
  ```

7.6.11. Alternatives to storing administrator-level secrets in the kube-system project

By default, administrator secrets are stored in the `kube-system` project. If you configured the `credentialsMode` parameter in the `install-config.yaml` file to `Manual`, you must use one of the following alternatives:

- To manage long-term cloud credentials manually, follow the procedure in Manually creating long-term credentials.

- To implement short-term credentials that are managed outside the cluster for individual components, follow the procedures in Configuring an Azure cluster to use short-term credentials.

7.6.11.1. Manually creating long-term credentials

The Cloud Credential Operator (CCO) can be put into manual mode prior to installation in environments where the cloud identity and access management (IAM) APIs are not reachable, or the administrator prefers not to store an administrator-level credential secret in the cluster `kube-system` namespace.

Procedure

1. If you did not set the `credentialsMode` parameter in the `install-config.yaml` configuration file to `Manual`, modify the value as shown:

   Sample configuration file snippet

   ```yaml
   apiVersion: v1
   baseDomain: example.com
   credentialsMode: Manual
   ```

2. If you have not previously created installation manifest files, do so by running the following command:

   ```
   $ openshift-install create manifests --dir <installation_directory>
   ```

   where `<installation_directory>` is the directory in which the installation program creates files.

3. Set a `$RELEASE_IMAGE` variable with the release image from your installation file by running the following command:

   ```
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
   ```
4. Extract the list of CredentialsRequest custom resources (CRs) from the OpenShift Container Platform release image by running the following command:

```
$ oc adm release extract \
--from=$RELEASE_IMAGE \ 
--credentials-requests \ 
--included \ 
--install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \ 
--to=<path_to_directory_for_credentials_requests>
```

1. The `--included` parameter includes only the manifests that your specific cluster configuration requires.

2. Specify the location of the `install-config.yaml` file.

3. Specify the path to the directory where you want to store the CredentialsRequest objects. If the specified directory does not exist, this command creates it.

   This command creates a YAML file for each CredentialsRequest object.

**Sample CredentialsRequest object**

```yaml
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
  name: <component_credentials_request>
  namespace: openshift-cloud-credential-operator
...
spec:
  providerSpec:
    apiVersion: cloudcredential.openshift.io/v1
    kind: AzureProviderSpec
    roleBindings:
      - role: Contributor
```

5. Create YAML files for secrets in the `openshift-install` manifests directory that you generated previously. The secrets must be stored using the namespace and secret name defined in the `spec.secretRef` for each CredentialsRequest object.

**Sample CredentialsRequest object with secrets**

```yaml
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
  name: <component_credentials_request>
  namespace: openshift-cloud-credential-operator
...
spec:
  providerSpec:
    apiVersion: cloudcredential.openshift.io/v1
    kind: AzureProviderSpec
    roleBindings:
      - role: Contributor
```
Before upgrading a cluster that uses manually maintained credentials, you must ensure that the CCO is in an upgradeable state.

7.6.11.2. Configuring an Azure cluster to use short-term credentials

To install a cluster that uses Azure AD Workload Identity, you must configure the Cloud Credential Operator utility and create the required Azure resources for your cluster.

7.6.11.2.1. Configuring the Cloud Credential Operator utility

To create and manage cloud credentials from outside of the cluster when the Cloud Credential Operator (CCO) is operating in manual mode, extract and prepare the CCO utility (ccoctl) binary.

NOTE

The ccoctl utility is a Linux binary that must run in a Linux environment.

Prerequisites

- You have access to an OpenShift Container Platform account with cluster administrator access.
- You have installed the OpenShift CLI (oc).
- You have created a global Microsoft Azure account for the ccoctl utility to use with the following permissions:

  Example 7.28. Required Azure permissions
  - Microsoft.Resources/subscriptions/resourceGroups/read
  - Microsoft.Resources/subscriptions/resourceGroups/write

Sample Secret object

apiVersion: v1
kind: Secret
metadata:
  name: <component_secret>
  namespace: <component_namespace>
data:
  azure_subscription_id: <base64_encoded_azure_subscription_id>
  azure_client_id: <base64_encoded_azure_client_id>
  azure_client_secret: <base64_encoded_azure_client_secret>
  azure_tenant_id: <base64_encoded_azure_tenant_id>
  azure_resource_prefix: <base64_encoded_azure_resource_prefix>
  azure_resourcegroup: <base64_encoded_azure_resourcegroup>
  azure_region: <base64_encoded_azure_region>
Procedure

1. Obtain the OpenShift Container Platform release image by running the following command:

   ```
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3})
   ```

2. Obtain the CCO container image from the OpenShift Container Platform release image by running the following command:

   ```
   $ CCO_IMAGE=$(oc adm release info --image-for='cloud-credential-operator' $RELEASE_IMAGE -a ~/.pull-secret)
   ```
NOTE

Ensure that the architecture of the $RELEASE_IMAGE matches the architecture of the environment in which you will use the ccoctl tool.

3. Extract the ccoctl binary from the CCO container image within the OpenShift Container Platform release image by running the following command:

   $ oc image extract $CCO_IMAGE --file="/usr/bin/ccocctl" -a ~/.pull-secret

4. Change the permissions to make ccoctl executable by running the following command:

   $ chmod 775 ccoctl

Verification

- To verify that ccoctl is ready to use, display the help file by running the following command:

  $ ccoctl --help

Output of ccoctl --help

OpenShift credentials provisioning tool

Usage:
ccoctl [command]

Available Commands:
alibabacloud Manage credentials objects for alibaba cloud
aws Manage credentials objects for AWS cloud
azure Manage credentials objects for Azure
gcp Manage credentials objects for Google cloud
help Help about any command
ibmcloud Manage credentials objects for IBM Cloud
nutanix Manage credentials objects for Nutanix

Flags:
-h, --help help for ccoctl

Use "ccoctl [command] --help" for more information about a command.

7.6.11.2.2. Creating Azure resources with the Cloud Credential Operator utility

You can use the ccoctl azure create-all command to automate the creation of Azure resources.

NOTE

By default, ccoctl creates objects in the directory in which the commands are run. To create the objects in a different directory, use the --output-dir flag. This procedure uses <path_to_ccoctl_output_dir> to refer to this directory.

Prerequisites
You must have:

- Extracted and prepared the `ccoctl` binary.
- Access to your Microsoft Azure account by using the Azure CLI.

**Procedure**

1. Set a `$RELEASE_IMAGE` variable with the release image from your installation file by running the following command:

   ```bash
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
   ```

2. Extract the list of `CredentialsRequest` objects from the OpenShift Container Platform release image by running the following command:

   ```bash
   $ oc adm release extract \
   --from=$RELEASE_IMAGE \
   --credentials-requests \
   --included 1 \
   --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml 2 \
   --to=<path_to_directory_for_credentials_requests> 3
   ```

   1. The `--included` parameter includes only the manifests that your specific cluster configuration requires.
   2. Specify the location of the `install-config.yaml` file.
   3. Specify the path to the directory where you want to store the `CredentialsRequest` objects. If the specified directory does not exist, this command creates it.

   **NOTE**
   This command might take a few moments to run.

3. To enable the `ccoctl` utility to detect your Azure credentials automatically, log in to the Azure CLI by running the following command:

   ```bash
   $ az login
   ```

4. Use the `ccoctl` tool to process all `CredentialsRequest` objects by running the following command:

   ```bash
   $ ccoctl azure create-all \
   --name=<azure_infra_name> 1 \
   --output-dir=<ccoctl_output_dir> 2 \
   --region=<azure_region> 3 \
   --subscription-id=<azure_subscription_id> 4 \
   --credentials-requests-dir=<path_to_credentials_requests_directory> 5 \
   --dnszone-resource-group-name=<azure_dns_zone_resource_group_name> 6 \
   --tenant-id=<azure_tenant_id> 7
   ```
Specify the user-defined name for all created Azure resources used for tracking.

Optional: Specify the directory in which you want the `ccoctl` utility to create objects. By default, the utility creates objects in the directory in which the commands are run.

Specify the Azure region in which cloud resources will be created.

Specify the Azure subscription ID to use.

Specify the directory containing the files for the component `CredentialsRequest` objects.

Specify the name of the resource group containing the cluster’s base domain Azure DNS zone.

Specify the Azure tenant ID to use.

**NOTE**

If your cluster uses Technology Preview features that are enabled by the `TechPreviewNoUpgrade` feature set, you must include the `--enable-tech-preview` parameter.

To see additional optional parameters and explanations of how to use them, run the `azure create-all --help` command.

**Verification**

- To verify that the OpenShift Container Platform secrets are created, list the files in the `<path_to_ccoctl_output_dir>/manifests` directory:

```
$ ls <path_to_ccoctl_output_dir>/manifests
```

**Example output**

```
azure-ad-pod-identity-webhook-config.yaml
cluster-authentication-02-config.yaml
openshift-cloud-controller-manager-azure-cloud-credentials-credentials.yaml
openshift-cloud-network-config-controller-azure-cloud-credentials-credentials.yaml
openshift-cluster-api-capz-manager-bootstrap-credentials-credentials.yaml
openshift-cluster-csi-drivers-azure-disk-credentials-credentials.yaml
openshift-cluster-csi-drivers-azure-file-credentials-credentials.yaml
openshift-image-registry-installer-cloud-credentials-credentials.yaml
openshift-ingress-operator-cloud-credentials-credentials.yaml
openshift-machine-api-azure-cloud-credentials-credentials.yaml
```

You can verify that the Azure AD service accounts are created by querying Azure. For more information, refer to Azure documentation on listing AD service accounts.

**7.6.11.2.3. Incorporating the Cloud Credential Operator utility manifests**

To implement short-term security credentials managed outside the cluster for individual components, you must move the manifest files that the Cloud Credential Operator utility (`ccoctl`) created to the correct directories for the installation program.
Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.
- You have configured the Cloud Credential Operator utility (ccoctl).
- You have created the cloud provider resources that are required for your cluster with the ccoctl utility.

Procedure

1. If you did not set the credentialsMode parameter in the install-config.yaml configuration file to Manual, modify the value as shown:

   **Sample configuration file snippet**

   ```yaml
   apiVersion: v1
   baseDomain: example.com
   credentialsMode: Manual
   # ...
   ```

2. If you used the ccoctl utility to create a new Azure resource group instead of using an existing resource group, modify the resourceGroupName parameter in the install-config.yaml as shown:

   **Sample configuration file snippet**

   ```yaml
   apiVersion: v1
   baseDomain: example.com
   # ...
   platform:
     azure:
       resourceGroupName: <azure_infra_name> ①
   # ...
   ```

   ① This value must match the user-defined name for Azure resources that was specified with the --name argument of the ccoctl azure create-all command.

3. If you have not previously created installation manifest files, do so by running the following command:

   $ openshift-install create manifests --dir <installation_directory>

   where `<installation_directory>` is the directory in which the installation program creates files.

4. Copy the manifests that the ccoctl utility generated to the manifests directory that the installation program created by running the following command:

   $ cp /<path_to_ccoctl_output_dir>/manifests/* ./manifests/

5. Copy the private key that the ccoctl utility generated in the tls directory to the installation directory by running the following command:
7.6.12. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

**Prerequisites**

- You have configured an account with the cloud platform that hosts your cluster.
- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have an Azure subscription ID and tenant ID.

**Procedure**

- Change to the directory that contains the installation program and initialize the cluster deployment:

```
$ ./openshift-install create cluster --dir <installation_directory>  
  --log-level=info
```

1. For `<installation_directory>`, specify the location of your customized `./install-config.yaml` file.

2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

**Verification**

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the `kubeadmin` user.

- Credential information also outputs to `<installation_directory>/openshift_install.log`.

**IMPORTANT**

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

**Example output**

```
...  
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export
```
IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

7.6.13. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster kubeconfig file. The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the oc CLI.

Procedure

1. Export the kubeadmin credentials:

   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig

   For <installation_directory>, specify the path to the directory that you stored the installation files in.

2. Verify you can run oc commands successfully using the exported configuration:

   $ oc whoami

   Example output

   system:admin
Additional resources

- See Accessing the web console for more details about accessing and understanding the OpenShift Container Platform web console.

### 7.6.14. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager Hybrid Cloud Console.

After you confirm that your OpenShift Cluster Manager Hybrid Cloud Console inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service

### 7.6.15. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.

### 7.7. INSTALLING A CLUSTER ON AZURE INTO AN EXISTING VNET

In OpenShift Container Platform version 4.14, you can install a cluster into an existing Azure Virtual Network (VNet) on Microsoft Azure. The installation program provisions the rest of the required infrastructure, which you can further customize. To customize the installation, you modify parameters in the `install-config.yaml` file before you install the cluster.

#### 7.7.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You configured an Azure account to host the cluster and determined the tested and validated region to deploy the cluster to.
- If you use a firewall, you configured it to allow the sites that your cluster requires access to.
- If you use customer-managed encryption keys, you prepared your Azure environment for encryption.

#### 7.7.2. About reusing a VNet for your OpenShift Container Platform cluster

In OpenShift Container Platform 4.14, you can deploy a cluster into an existing Azure Virtual Network (VNet) in Microsoft Azure. If you do, you must also use existing subnets within the VNet and routing rules.
By deploying OpenShift Container Platform into an existing Azure VNet, you might be able to avoid service limit constraints in new accounts or more easily abide by the operational constraints that your company’s guidelines set. This is a good option to use if you cannot obtain the infrastructure creation permissions that are required to create the VNet.

### 7.7.2.1. Requirements for using your VNet

When you deploy a cluster by using an existing VNet, you must perform additional network configuration before you install the cluster. In installer-provisioned infrastructure clusters, the installer usually creates the following components, but it does not create them when you install into an existing VNet:

- Subnets
- Route tables
- VNets
- Network Security Groups

**NOTE**

The installation program requires that you use the cloud-provided DNS server. Using a custom DNS server is not supported and causes the installation to fail.

If you use a custom VNet, you must correctly configure it and its subnets for the installation program and the cluster to use. The installation program cannot subdivide network ranges for the cluster to use, set route tables for the subnets, or set VNet options like DHCP, so you must do so before you install the cluster.

The cluster must be able to access the resource group that contains the existing VNet and subnets. While all of the resources that the cluster creates are placed in a separate resource group that it creates, some network resources are used from a separate group. Some cluster Operators must be able to access resources in both resource groups. For example, the Machine API controller attaches NICS for the virtual machines that it creates to subnets from the networking resource group.

Your VNet must meet the following characteristics:

- The VNet’s CIDR block must contain the `Networking.MachineCIDR` range, which is the IP address pool for cluster machines.
- The VNet and its subnets must belong to the same resource group, and the subnets must be configured to use Azure-assigned DHCP IP addresses instead of static IP addresses.

You must provide two subnets within your VNet, one for the control plane machines and one for the compute machines. Because Azure distributes machines in different availability zones within the region that you specify, your cluster will have high availability by default.

**NOTE**

By default, if you specify availability zones in the `install-config.yaml` file, the installation program distributes the control plane machines and the compute machines across these availability zones within a region. To ensure high availability for your cluster, select a region with at least three availability zones. If your region contains fewer than three availability zones, the installation program places more than one control plane machine in the available zones.
To ensure that the subnets that you provide are suitable, the installation program confirms the following data:

- All the specified subnets exist.
- There are two private subnets, one for the control plane machines and one for the compute machines.
- The subnet CIDRs belong to the machine CIDR that you specified. Machines are not provisioned in availability zones that you do not provide private subnets for. If required, the installation program creates public load balancers that manage the control plane and worker nodes, and Azure allocates a public IP address to them.

**NOTE**

If you destroy a cluster that uses an existing VNet, the VNet is not deleted.

### 7.7.2.1.1. Network security group requirements

The network security groups for the subnets that host the compute and control plane machines require specific access to ensure that the cluster communication is correct. You must create rules to allow access to the required cluster communication ports.

**IMPORTANT**

The network security group rules must be in place before you install the cluster. If you attempt to install a cluster without the required access, the installation program cannot reach the Azure APIs, and installation fails.

**Table 7.10. Required ports**

<table>
<thead>
<tr>
<th>Port</th>
<th>Description</th>
<th>Control plane</th>
<th>Compute</th>
</tr>
</thead>
<tbody>
<tr>
<td>80</td>
<td>Allows HTTP traffic</td>
<td></td>
<td>x</td>
</tr>
<tr>
<td>443</td>
<td>Allows HTTPS traffic</td>
<td></td>
<td>x</td>
</tr>
<tr>
<td>6443</td>
<td>Allows communication to the control plane machines</td>
<td>x</td>
<td></td>
</tr>
<tr>
<td>22623</td>
<td>Allows internal communication to the machine config server for provisioning machines</td>
<td>x</td>
<td></td>
</tr>
</tbody>
</table>

1. If you are using Azure Firewall to restrict the internet access, then you can configure Azure Firewall to allow the Azure APIs. A network security group rule is not needed.
IMPORTANT

Currently, there is no supported way to block or restrict the machine config server endpoint. The machine config server must be exposed to the network so that newly-provisioned machines, which have no existing configuration or state, are able to fetch their configuration. In this model, the root of trust is the certificate signing requests (CSR) endpoint, which is where the kubelet sends its certificate signing request for approval to join the cluster. Because of this, machine configs should not be used to distribute sensitive information, such as secrets and certificates.

To ensure that the machine config server endpoints, ports 22623 and 22624, are secured in bare metal scenarios, customers must configure proper network policies.

Because cluster components do not modify the user-provided network security groups, which the Kubernetes controllers update, a pseudo-network security group is created for the Kubernetes controller to modify without impacting the rest of the environment.

Additional resources

- About the OpenShift SDN network plugin
- Configuring your firewall

7.7.2.2. Division of permissions

Starting with OpenShift Container Platform 4.3, you do not need all of the permissions that are required for an installation program-provisioned infrastructure cluster to deploy a cluster. This change mimics the division of permissions that you might have at your company: some individuals can create different resources in your clouds than others. For example, you might be able to create application-specific items, like instances, storage, and load balancers, but not networking-related components such as V Nets, subnet, or ingress rules.

The Azure credentials that you use when you create your cluster do not need the networking permissions that are required to make V Nets and core networking components within the VNet, such as subnets, routing tables, internet gateways, NAT, and VPN. You still need permission to make the application resources that the machines within the cluster require, such as load balancers, security groups, storage accounts, and nodes.

7.7.2.3. Isolation between clusters

Because the cluster is unable to modify network security groups in an existing subnet, there is no way to isolate clusters from each other on the VNet.

7.7.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager Hybrid Cloud Console to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- Access Quay.io to obtain the packages that are required to install your cluster.
Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 7.7.4. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the `~/.ssh/authorized_keys` list for the `core` user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user `core`. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The `./openshift-install gather` command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```sh
   $ ssh-keygen -t ed25519 -N " -f <path>/<file_name>
   ``

   Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.
NOTE
If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   $ cat <path>/<file_name>.pub

   For example, run the following to view the ~/.ssh/id_ed25519.pub public key:

   $ cat ~/.ssh/id_ed25519.pub

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the ./openshift-install gather command.

   NOTE
   On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.

   a. If the ssh-agent process is not already running for your local user, start it as a background task:

   $ eval "$(ssh-agent -s)"

   Example output

   Agent pid 31874

   NOTE
   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the ssh-agent:

   $ ssh-add <path>/<file_name> 1

   1 Specify the path and file name for your SSH private key, such as ~/.ssh/id_ed25519

   Example output

   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

Next steps
• When you install OpenShift Container Platform, provide the SSH public key to the installation program.

7.7.5. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

Prerequisites

• You have a computer that runs Linux or macOS, with 500 MB of local disk space.

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

   **IMPORTANT**

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   **IMPORTANT**

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ tar -xvf openshift-install-linux.tar.gz
   ```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

7.7.6. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Microsoft Azure.

Prerequisites
• You have the OpenShift Container Platform installation program and the pull secret for your cluster.

• You have an Azure subscription ID and tenant ID.

• If you are installing the cluster using a service principal, you have its application ID and password.

• If you are installing the cluster using a system-assigned managed identity, you have enabled it on the virtual machine that you will run the installation program from.

• If you are installing the cluster using a user-assigned managed identity, you have met these prerequisites:
  o You have its client ID.
  o You have assigned it to the virtual machine that you will run the installation program from.

**Procedure**

1. Optional: If you have run the installation program on this computer before, and want to use an alternative service principal or managed identity, go to the `~/.azure/` directory and delete the `osServicePrincipal.json` configuration file.
   Deleting this file prevents the installation program from automatically reusing subscription and authentication values from a previous installation.

2. Create the `install-config.yaml` file.
   a. Change to the directory that contains the installation program and run the following command:

   ```bash
   $ ./openshift-install create install-config --dir <installation_directory> 1
   ``

   For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

   When specifying the directory:
   
   • Verify that the directory has the `execute` permission. This permission is required to run Terraform binaries under the installation directory.
   
   • Use an empty directory. Some installation assets, such as bootstrap X.509 certificates, have short expiration intervals, therefore you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

   **NOTE**

   Always delete the `~/.powervs` directory to avoid reusing a stale configuration. Run the following command:

   ```bash
   $ rm -rf ~/.powervs
   ```
b. At the prompts, provide the configuration details for your cloud:

i. Optional: Select an SSH key to use to access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

ii. Select `azure` as the platform to target.

If the installation program cannot locate the `osServicePrincipal.json` configuration file from a previous installation, you are prompted for Azure subscription and authentication values.

iii. Enter the following Azure parameter values for your subscription:

- `azure subscription id`: Enter the subscription ID to use for the cluster.
- `azure tenant id`: Enter the tenant ID.

iv. Depending on the Azure identity you are using to deploy the cluster, do one of the following when prompted for the `azure service principal client id`:

- If you are using a service principal, enter its application ID.
- If you are using a system-assigned managed identity, leave this value blank.
- If you are using a user-assigned managed identity, specify its client ID.

v. Depending on the Azure identity you are using to deploy the cluster, do one of the following when prompted for the `azure service principal client secret`:

- If you are using a service principal, enter its password.
- If you are using a system-assigned managed identity, leave this value blank.
- If you are using a user-assigned managed identity, leave this value blank.

vi. Select the region to deploy the cluster to.

vii. Select the base domain to deploy the cluster to. The base domain corresponds to the Azure DNS Zone that you created for your cluster.

viii. Enter a descriptive name for your cluster.

**IMPORTANT**

All Azure resources that are available through public endpoints are subject to resource name restrictions, and you cannot create resources that use certain terms. For a list of terms that Azure restricts, see Resolve reserved resource name errors in the Azure documentation.

3. Modify the `install-config.yaml` file. You can find more information about the available parameters in the "Installation configuration parameters" section.
4. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

**IMPORTANT**

The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

If previously not detected, the installation program creates an `osServicePrincipal.json` configuration file and stores this file in the `~/.azure/` directory on your computer. This ensures that the installation program can load the profile when it is creating an OpenShift Container Platform cluster on the target platform.

**Additional resources**

- Installation configuration parameters for Azure

### 7.7.6.1. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

**Table 7.11. Minimum resource requirements**

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS, RHEL 8.6 and later [3]</td>
<td>2</td>
<td>8 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
</tbody>
</table>

1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or hyperthreading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: \((\text{threads per core} \times \text{cores}) \times \text{sockets} = \text{vCPUs}\).

2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.

3. As with all user-provisioned installations, if you choose to use RHEL compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and has been removed in OpenShift Container Platform 4.10 and later.
IMPORTANT

You are required to use Azure virtual machines that have the `premiumIO` parameter set to `true`.

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

Additional resources

- Optimizing storage

7.7.6.2. Tested instance types for Azure

The following Microsoft Azure instance types have been tested with OpenShift Container Platform.

Example 7.29. Machine types based on 64-bit x86 architecture

- c4.*
- c5.*
- c5a.*
- i3.*
- m4.*
- m5.*
- m5a.*
- m6i.*
- r4.*
- r5.*
- r5a.*
- r6i.*
- t3.*
- t3a.*

7.7.6.3. Tested instance types for Azure on 64-bit ARM infrastructures

The following Microsoft Azure ARM64 instance types have been tested with OpenShift Container Platform.

Example 7.30. Machine types based on 64-bit ARM architecture

- c6g.*
7.7.6.4. Enabling trusted launch for Azure VMs

You can enable two trusted launch features when installing your cluster on Azure: secure boot and virtualized Trusted Platform Modules.

See the Azure documentation about virtual machine sizes to learn what sizes of virtual machines support these features.

**IMPORTANT**

Trusted launch is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see Technology Preview Features Support Scope.

**Prerequisites**

- You have created an `install-config.yaml` file.

**Procedure**

- Use a text editor to edit the `install-config.yaml` file prior to deploying your cluster and add the following stanza:

```yaml
controlPlane:
  platform:
    azure:
      settings:
        securityType: TrustedLaunch
        trustedLaunch:
          uefiSettings:
            secureBoot: Enabled
            virtualizedTrustedPlatformModule: Enabled
```

1. Specify `controlPlane.platform.azure` or `compute.platform.azure` to enable trusted launch on only control plane or compute nodes respectively. Specify `platform.azure.defaultMachinePlatform` to enable trusted launch on all nodes.

2. Enable trusted launch features.

3. Enable secure boot. For more information, see the Azure documentation about secure boot.

4. Enable the virtualized Trusted Platform Module. For more information, see the Azure documentation about virtualized Trusted Platform Modules.
7.7.6.5. Enabling confidential VMs

You can enable confidential VMs when installing your cluster. You can enable confidential VMs for compute nodes, control plane nodes, or all nodes.

**IMPORTANT**

Using confidential VMs is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see Technology Preview Features Support Scope.

You can use confidential VMs with the following VM sizes:

- DCasv5-series
- DCadsv5-series
- ECasv5-series
- ECadsv5-series

**IMPORTANT**

Confidential VMs are currently not supported on 64-bit ARM architectures.

**Prerequisites**

- You have created an `install-config.yaml` file.

**Procedure**

- Use a text editor to edit the `install-config.yaml` file prior to deploying your cluster and add the following stanza:

```yaml
controlPlane: 1
platform:
  azure:
    settings:
      securityType: ConfidentialVM 2
      confidentialVM:
        uefiSettings:
          secureBoot: Enabled 3
          virtualizedTrustedPlatformModule: Enabled 4
        osDisk:
          securityProfile:
            securityEncryptionType: VMGuestStateOnly 5
```

OpenShift Container Platform 4.14 Installing
Specify `controlPlane.platform.azure` or `compute.platform.azure` to deploy confidential VMs on only control plane or compute nodes respectively. Specify `platform.azure.defaultMachinePlatform` to deploy confidential VMs on all nodes.

Enable confidential VMs.

Enable secure boot. For more information, see the Azure documentation about secure boot.

Enable the virtualized Trusted Platform Module. For more information, see the Azure documentation about virtualized Trusted Platform Modules.

Specify `VMGuestStateOnly` to encrypt the VM guest state.

### 7.7.6.6. Sample customized install-config.yaml file for Azure

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

**IMPORTANT**

This sample YAML file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program and modify it.

```yaml
apiVersion: v1
baseDomain: example.com
controlPlane:
  name: master
  platform:
    azure:
      encryptionAtHost: true
      ultraSSDCapability: Enabled
  osDisk:
    diskSizeGB: 1024
    diskType: Premium_LRS
    diskEncryptionSet:
      resourceGroup: disk_encryption_set_resource_group
      name: disk_encryption_set_name
      subscriptionId: secondary_subscription_id
  osImage:
    publisher: example_publisher_name
    offer: example_image_offer
    sku: example_offer_sku
    version: example_image_version
    type: Standard_D8s_v3
    replicas: 3
compute:
- name: worker
  platform:
    azure:
      ultraSSDCapability: Enabled
```
Required. The installation program prompts you for this value.
If you do not provide these parameters and values, the installation program provides the default value.

The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, -, and the first line of the controlPlane section must not. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading, or hyperthreading. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to Disabled. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger virtual machine types, such as Standard_D8s_v3, for your machines if you disable simultaneous multithreading.

You can specify the size of the disk to use in GB. Minimum recommendation for control plane nodes is 1024 GB.

Specify a list of zones to deploy your machines to. For high availability, specify at least two zones.

The cluster network plugin to install. The supported values are OVNKubernetes and OpenShiftSDN. The default value is OVNKubernetes.

Optional: A custom Red Hat Enterprise Linux CoreOS (RHCOS) image that should be used to boot control plane and compute machines. The publisher, offer, sku, and version parameters under platform.azure.defaultMachinePlatform.osImage apply to both control plane and compute machines. If the parameters under controlPlane.platform.azure.osImage or compute.platform.azure.osImage are set, they override the platform.azure.defaultMachinePlatform.osImage parameters.

Specify the name of the resource group that contains the DNS zone for your base domain.

Specify the name of an already existing resource group to install your cluster to. If undefined, a new resource group is created for the cluster.

If you use an existing VNet, specify the name of the resource group that contains it.

If you use an existing VNet, specify its name.

If you use an existing VNet, specify the name of the subnet to host the control plane machines.

If you use an existing VNet, specify the name of the subnet to host the compute machines.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.
IMPORTANT

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see Installing the system in FIPS mode. When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures.

You can optionally provide the sshKey value that you use to access the machines in your cluster.

NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

7.7.6.7. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the install-config.yaml file.

Prerequisites

- You have an existing install-config.yaml file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the Proxy object’s spec.noProxy field to bypass the proxy if necessary.

NOTE

The Proxy object status.noProxy field is populated with the values of the networking.machineNetwork[].cidr, networking.clusterNetwork[].cidr, and networking.serviceNetwork[] fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object status.noProxy field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your install-config.yaml file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port>  # 1
```
A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.

A proxy URL to use for creating HTTPS connections outside the cluster.

A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.

If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the trustedCA field of the Proxy object. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

Optional: The policy to determine the configuration of the Proxy object to reference the user-ca-bundle config map in the trustedCA field. The allowed values are Proxyonly and Always. Use Proxyonly to reference the user-ca-bundle config map only when http/https proxy is configured. Use Always to always reference the user-ca-bundle config map. The default value is Proxyonly.

### NOTE

The installation program does not support the proxy readinessEndpoints field.

### NOTE

If the installer times out, restart and then complete the deployment by using the wait-for command of the installer. For example:

```
$ ./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

### NOTE

Only the Proxy object named cluster is supported, and no additional proxies can be created.
Additional resources

- For more details about Accelerated Networking, see Accelerated Networking for Microsoft Azure VMs.

### 7.7.7. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of oc.

### Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

**Procedure**

2. Select the architecture from the Product Variant drop-down list.

3. Select the appropriate version from the Version drop-down list.

4. Click Download Now next to the OpenShift v4.14 Linux Client entry and save the file.

5. Unpack the archive:

   - $ tar xvf <file>

6. Place the oc binary in a directory that is on your PATH.

   To check your PATH, execute the following command:

   - $ echo $PATH

**Verification**

- After you install the OpenShift CLI, it is available using the oc command:

   - $ oc <command>

### Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version from the Version drop-down list.
3. Click **Download Now** next to the **OpenShift v4.14 Windows Client** entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the `oc` binary to a directory that is on your **PATH**.
   To check your **PATH**, open the command prompt and execute the following command:
   ```
   C:\> path
   ```

**Verification**

- After you install the OpenShift CLI, it is available using the `oc` command:
  ```
  C:\> oc <command>
  ```

**Installing the OpenShift CLI on macOS**

You can install the OpenShift CLI (`oc`) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version from the **Version** drop-down list.

3. Click **Download Now** next to the **OpenShift v4.14 macOS Client** entry and save the file.

   **NOTE**
   
   For macOS arm64, choose the **OpenShift v4.14 macOS arm64 Client** entry.

4. Unpack and unzip the archive.

5. Move the `oc` binary to a directory on your **PATH**.
   To check your **PATH**, open a terminal and execute the following command:
   ```
   $ echo $PATH
   ```

**Verification**

- After you install the OpenShift CLI, it is available using the `oc` command:
  ```
  $ oc <command>
  ```

**7.7.8. Alternatives to storing administrator-level secrets in the kube-system project**

By default, administrator secrets are stored in the **kube-system** project. If you configured the **credentialsMode** parameter in the **install-config.yaml** file to **Manual**, you must use one of the following alternatives:

- To manage long-term cloud credentials manually, follow the procedure in **Manually creating long-term credentials**.
To implement short-term credentials that are managed outside the cluster for individual components, follow the procedures in Configuring an Azure cluster to use short-term credentials.

### 7.7.8.1. Manually creating long-term credentials

The Cloud Credential Operator (CCO) can be put into manual mode prior to installation in environments where the cloud identity and access management (IAM) APIs are not reachable, or the administrator prefers not to store an administrator-level credential secret in the cluster `kube-system` namespace.

**Procedure**

1. If you did not set the `credentialsMode` parameter in the `install-config.yaml` configuration file to Manual, modify the value as shown:

   **Sample configuration file snippet**
   ```yaml
   apiVersion: v1
   baseDomain: example.com
   credentialsMode: Manual
   # ...
   ```

2. If you have not previously created installation manifest files, do so by running the following command:

   ```bash
   $ openshift-install create manifests --dir <installation_directory>
   ```

   where `<installation_directory>` is the directory in which the installation program creates files.

3. Set a `$RELEASE_IMAGE` variable with the release image from your installation file by running the following command:

   ```bash
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
   ```

4. Extract the list of `CredentialsRequest` custom resources (CRs) from the OpenShift Container Platform release image by running the following command:

   ```bash
   $ oc adm release extract \ 
   --from=$RELEASE_IMAGE \ 
   --credentials-requests \ 
   --included \ 
   --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \ 
   --to=<path_to_directory_for_credentials_requests>
   ```

   - **1** The `--included` parameter includes only the manifests that your specific cluster configuration requires.
   - **2** Specify the location of the `install-config.yaml` file.
   - **3** Specify the path to the directory where you want to store the `CredentialsRequest` objects. If the specified directory does not exist, this command creates it.
This command creates a YAML file for each **CredentialsRequest** object.

### Sample CredentialsRequest object

```yaml
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
  name: <component_credentials_request>
  namespace: openshift-cloud-credential-operator
...
spec:
  providerSpec:
    apiVersion: cloudcredential.openshift.io/v1
    kind: AzureProviderSpec
    roleBindings:
      - role: Contributor
...
```

5. Create YAML files for secrets in the `openshift-install` manifests directory that you generated previously. The secrets must be stored using the namespace and secret name defined in the **spec.secretRef** for each **CredentialsRequest** object.

### Sample CredentialsRequest object with secrets

```yaml
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
  name: <component_credentials_request>
  namespace: openshift-cloud-credential-operator
...
spec:
  providerSpec:
    apiVersion: cloudcredential.openshift.io/v1
    kind: AzureProviderSpec
    roleBindings:
      - role: Contributor
...
  secretRef:
    name: <component_secret>
    namespace: <component_namespace>
...
```

### Sample Secret object

```yaml
apiVersion: v1
kind: Secret
metadata:
  name: <component_secret>
  namespace: <component_namespace>
data:
  azure_subscription_id: <base64_encoded_azure_subscription_id>
  azure_client_id: <base64_encoded_azure_client_id>
  azure_client_secret: <base64_encoded_azure_client_secret>
  azure_tenant_id: <base64_encoded_azure_tenant_id>
```
Before upgrading a cluster that uses manually maintained credentials, you must ensure that the CCO is in an upgradeable state.

7.7.8.2. Configuring an Azure cluster to use short-term credentials

To install a cluster that uses Azure AD Workload Identity, you must configure the Cloud Credential Operator utility and create the required Azure resources for your cluster.

7.7.8.2.1. Configuring the Cloud Credential Operator utility

To create and manage cloud credentials from outside of the cluster when the Cloud Credential Operator (CCO) is operating in manual mode, extract and prepare the CCO utility (`ccoctl`) binary.

```
azure_resource_prefix: <base64_encoded_azure_resource_prefix>
azure_resourcegroup: <base64_encoded_azure_resourcegroup>
azure_region: <base64_encoded_azure_region>
```

### IMPORTANT

Before upgrading a cluster that uses manually maintained credentials, you must ensure that the CCO is in an upgradeable state.

**NOTE**

The `ccoctl` utility is a Linux binary that must run in a Linux environment.

**Prerequisites**

- You have access to an OpenShift Container Platform account with cluster administrator access.
- You have installed the OpenShift CLI (`oc`).
- You have created a global Microsoft Azure account for the `ccoctl` utility to use with the following permissions:

**Example 7.31. Required Azure permissions**

- Microsoft.Resources/subscriptions/resourceGroups/read
- Microsoft.Resources/subscriptions/resourceGroups/write
- Microsoft.Resources/subscriptions/resourceGroups/delete
- Microsoft.Authorization/roleAssignments/read
- Microsoft.Authorization/roleAssignments/delete
- Microsoft.Authorization/roleAssignments/write
- Microsoft.Authorization/roleDefinitions/read
- Microsoft.Authorization/roleDefinitions/write
- Microsoft.Authorization/roleDefinitions/delete
- Microsoft.Storage/storageAccounts/listkeys/action
- Microsoft.Storage/storageAccounts/delete
Procedure

1. Obtain the OpenShift Container Platform release image by running the following command:

   ```bash
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
   ```

2. Obtain the CCO container image from the OpenShift Container Platform release image by running the following command:

   ```bash
   $ CCO_IMAGE=$(oc adm release info --image-for='cloud-credential-operator' $RELEASE_IMAGE -a ~/.pull-secret)
   ```

   **NOTE**

   Ensure that the architecture of the $RELEASE_IMAGE matches the architecture of the environment in which you will use the ccoctl tool.

3. Extract the ccoctl binary from the CCO container image within the OpenShift Container Platform release image by running the following command:

   ```bash
   $ oc image extract $CCO_IMAGE --file="/usr/bin/ccoctl" -a ~/.pull-secret
   ```

4. Change the permissions to make ccoctl executable by running the following command:

   ```bash
   $ chmod 775 ccoctl
   ```
Verification

- To verify that `ccoctl` is ready to use, display the help file by running the following command:

  ```
  $ ccoctl --help
  ```

**Output of `ccoctl --help`**

OpenShift credentials provisioning tool

Usage:

`ccoctl [command]`

Available Commands:

- `alibabacloud` Manage credentials objects for Alibaba cloud
- `aws` Manage credentials objects for AWS cloud
- `azure` Manage credentials objects for Azure
- `gcp` Manage credentials objects for Google cloud
- `help` Help about any command
- `ibmcloud` Manage credentials objects for IBM Cloud
- `nutanix` Manage credentials objects for Nutanix

Flags:

- `-h, --help` help for ccoctl

Use "ccoctl [command] --help" for more information about a command.

**7.7.8.2.2. Creating Azure resources with the Cloud Credential Operator utility**

You can use the `ccoctl azure create-all` command to automate the creation of Azure resources.

**NOTE**

By default, `ccoctl` creates objects in the directory in which the commands are run. To create the objects in a different directory, use the `--output-dir` flag. This procedure uses `<path_to_ccoctl_output_dir>` to refer to this directory.

**Prerequisites**

You must have:

- Extracted and prepared the `ccoctl` binary.
- Access to your Microsoft Azure account by using the Azure CLI.

**Procedure**

1. Set a `$RELEASE_IMAGE` variable with the release image from your installation file by running the following command:

   ```
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
   ```

2. Extract the list of `CredentialsRequest` objects from the OpenShift Container Platform release image by running the following command:
The `--included` parameter includes only the manifests that your specific cluster configuration requires.

Specify the path to the install-config.yaml file.

Specify the path to the directory where you want to store the CredentialsRequest objects. If the specified directory does not exist, this command creates it.

**NOTE**

This command might take a few moments to run.

3. To enable the ccoctl utility to detect your Azure credentials automatically, log in to the Azure CLI by running the following command:

```bash
$ az login
```

4. Use the ccoctl tool to process all CredentialsRequest objects by running the following command:

```bash
$ ccoctl azure create-all
```

Specify the user-defined name for all created Azure resources used for tracking.

Optional: Specify the directory in which you want the ccoctl utility to create objects. By default, the utility creates objects in the directory in which the commands are run.

Specify the Azure region in which cloud resources will be created.

Specify the Azure subscription ID to use.

Specify the directory containing the files for the component CredentialsRequest objects.

Specify the name of the resource group containing the cluster’s base domain Azure DNS zone.

Specify the Azure tenant ID to use.
NOTE
If your cluster uses Technology Preview features that are enabled by the TechPreviewNoUpgrade feature set, you must include the --enable-tech-preview parameter.

To see additional optional parameters and explanations of how to use them, run the azure create-all --help command.

Verification

- To verify that the OpenShift Container Platform secrets are created, list the files in the <path_to_ccoctl_output_dir>/manifests directory:

  ```
  $ ls <path_to_ccoctl_output_dir>/manifests
  ```

Example output

- azure-ad-pod-identity-webhook-config.yaml
- cluster-authentication-02-config.yaml
- openshift-cloud-controller-manager-azure-cloud-credentials-credentials.yaml
- openshift-cloud-network-config-controller-cloud-credentials-credentials.yaml
- openshift-cluster-api-capz-manager-bootstrap-credentials-credentials.yaml
- openshift-cluster-csi-drivers-azure-disk-credentials-credentials.yaml
- openshift-cluster-csi-drivers-azure-file-credentials-credentials.yaml
- openshift-image-registry-installer-cloud-credentials-credentials.yaml
- openshift-ingress-operator-cloud-credentials-credentials.yaml
- openshift-machine-api-azure-cloud-credentials-credentials.yaml

You can verify that the Azure AD service accounts are created by querying Azure. For more information, refer to Azure documentation on listing AD service accounts.

7.7.8.2.3. Incorporating the Cloud Credential Operator utility manifests

To implement short-term security credentials managed outside the cluster for individual components, you must move the manifest files that the Cloud Credential Operator utility (ccoctl) created to the correct directories for the installation program.

Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.
- You have configured the Cloud Credential Operator utility (ccoctl).
- You have created the cloud provider resources that are required for your cluster with the ccoctl utility.

Procedure

1. If you did not set the credentialsMode parameter in the install-config.yaml configuration file to Manual, modify the value as shown:

   Sample configuration file snippet
2. If you used the `ccoctl` utility to create a new Azure resource group instead of using an existing resource group, modify the `resourceGroupName` parameter in the `install-config.yaml` as shown:

**Sample configuration file snippet**

```yaml
apiVersion: v1
baseDomain: example.com
# ...
platform:
  azure:
    resourceGroupName: <azure_infra_name> ①
# ...
```

① This value must match the user-defined name for Azure resources that was specified with the `--name` argument of the `ccoctl azure create-all` command.

3. If you have not previously created installation manifest files, do so by running the following command:

```bash
$ openshift-install create manifests --dir <installation_directory>
```

where `<installation_directory>` is the directory in which the installation program creates files.

4. Copy the manifests that the `ccoctl` utility generated to the `manifests` directory that the installation program created by running the following command:

```bash
$ cp /<path_to_ccoctl_output_dir>/manifests/* ./manifests/
```

5. Copy the private key that the `ccoctl` utility generated in the `tls` directory to the installation directory by running the following command:

```bash
$ cp -a /<path_to_ccoctl_output_dir>/tls .
```

### 7.7.9. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

**Prerequisites**

- You have configured an account with the cloud platform that hosts your cluster.
- You have the OpenShift Container Platform installation program and the pull secret for your cluster.

- You have an Azure subscription ID and tenant ID.

**Procedure**

- Change to the directory that contains the installation program and initialize the cluster deployment:

  ```
  $ ./openshift-install create cluster --dir <installation_directory> \ 
  --log-level=info
  ```

  1. For `<installation_directory>`, specify the location of your customized `./install-config.yaml` file.

  2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

**Verification**

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the `kubeadm` user.

- Credential information also outputs to `<installation_directory>/.openshift_install.log`.

**IMPORTANT**

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

**Example output**

```
...  
INFO Install complete!  
INFO To access the cluster as the system:admin user when using 'oc', run 'export
KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubadmin", and password: "password"
INFO Time elapsed: 36m22s
```
**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

Additional resources

- See Accessing the web console for more details about accessing and understanding the OpenShift Container Platform web console.

### 7.7.10. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager Hybrid Cloud Console.

After you confirm that your OpenShift Cluster Manager Hybrid Cloud Console inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service

### 7.7.11. Next steps

- Customize your cluster.

- If necessary, you can opt out of remote health reporting.

### 7.8. INSTALLING A PRIVATE CLUSTER ON AZURE

In OpenShift Container Platform version 4.14, you can install a private cluster into an existing Azure Virtual Network (VNet) on Microsoft Azure. The installation program provisions the rest of the required infrastructure, which you can further customize. To customize the installation, you modify parameters in the `install-config.yaml` file before you install the cluster.

#### 7.8.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.

- You configured an Azure account to host the cluster and determined the tested and validated region to deploy the cluster to.

- If you use a firewall, you configured it to allow the sites that your cluster requires access to.

- If you use customer-managed encryption keys, you prepared your Azure environment for encryption.

### 7.8.2. Private clusters

You can deploy a private OpenShift Container Platform cluster that does not expose external endpoints. Private clusters are accessible from only an internal network and are not visible to the internet.

By default, OpenShift Container Platform is provisioned to use publicly-accessible DNS and endpoints. A private cluster sets the DNS, Ingress Controller, and API server to private when you deploy your cluster. This means that the cluster resources are only accessible from your internal network and are not visible to the internet.

**IMPORTANT**

If the cluster has any public subnets, load balancer services created by administrators might be publicly accessible. To ensure cluster security, verify that these services are explicitly annotated as private.

To deploy a private cluster, you must:

- Use existing networking that meets your requirements. Your cluster resources might be shared between other clusters on the network.

- Deploy from a machine that has access to:
  - The API services for the cloud to which you provision.
  - The hosts on the network that you provision.
  - The internet to obtain installation media.

You can use any machine that meets these access requirements and follows your company’s guidelines. For example, this machine can be a bastion host on your cloud network or a machine that has access to the network through a VPN.

#### 7.8.2.1. Private clusters in Azure

To create a private cluster on Microsoft Azure, you must provide an existing private VNet and subnets to host the cluster. The installation program must also be able to resolve the DNS records that the cluster requires. The installation program configures the Ingress Operator and API server for only internal traffic.

Depending how your network connects to the private VNET, you might need to use a DNS forwarder to resolve the cluster’s private DNS records. The cluster’s machines use **168.63.129.16** internally for DNS resolution. For more information, see What is Azure Private DNS? and What is IP address 168.63.129.16? in the Azure documentation.
The cluster still requires access to internet to access the Azure APIs.

The following items are not required or created when you install a private cluster:

- A **BaseDomainResourceGroup**, since the cluster does not create public records
- Public IP addresses
- Public DNS records
- Public endpoints

The cluster is configured so that the Operators do not create public records for the cluster and all cluster machines are placed in the private subnets that you specify.

### 7.8.2.1.1. Limitations

Private clusters on Azure are subject to only the limitations that are associated with the use of an existing VNet.

### 7.8.2.2. User-defined outbound routing

In OpenShift Container Platform, you can choose your own outbound routing for a cluster to connect to the internet. This allows you to skip the creation of public IP addresses and the public load balancer.

You can configure user-defined routing by modifying parameters in the `install-config.yaml` file before installing your cluster. A pre-existing VNet is required to use outbound routing when installing a cluster; the installation program is not responsible for configuring this.

When configuring a cluster to use user-defined routing, the installation program does not create the following resources:

- Outbound rules for access to the internet.
- Public IPs for the public load balancer.
- Kubernetes Service object to add the cluster machines to the public load balancer for outbound requests.

You must ensure the following items are available before setting user-defined routing:

- Egress to the internet is possible to pull container images, unless using an OpenShift image registry mirror.
- The cluster can access Azure APIs.
- Various allowlist endpoints are configured. You can reference these endpoints in the Configuring your firewall section.

There are several pre-existing networking setups that are supported for internet access using user-defined routing.

**Private cluster with network address translation**

You can use **Azure VNET network address translation (NAT)** to provide outbound internet access for the subnets in your cluster. You can reference Create a NAT gateway using Azure CLI in the Azure documentation for configuration instructions.
When using a VNet setup with Azure NAT and user-defined routing configured, you can create a private cluster with no public endpoints.

**Private cluster with Azure Firewall**
You can use Azure Firewall to provide outbound routing for the VNet used to install the cluster. You can learn more about providing user-defined routing with Azure Firewall in the Azure documentation.

When using a VNet setup with Azure Firewall and user-defined routing configured, you can create a private cluster with no public endpoints.

**Private cluster with a proxy configuration**
You can use a proxy with user-defined routing to allow egress to the internet. You must ensure that cluster Operators do not access Azure APIs using a proxy; Operators must have access to Azure APIs outside of the proxy.

When using the default route table for subnets, with \texttt{0.0.0.0/0} populated automatically by Azure, all Azure API requests are routed over Azure’s internal network even though the IP addresses are public. As long as the Network Security Group rules allow egress to Azure API endpoints, proxies with user-defined routing configured allow you to create private clusters with no public endpoints.

**Private cluster with no internet access**
You can install a private network that restricts all access to the internet, except the Azure API. This is accomplished by mirroring the release image registry locally. Your cluster must have access to the following:

- An OpenShift image registry mirror that allows for pulling container images
- Access to Azure APIs

With these requirements available, you can use user-defined routing to create private clusters with no public endpoints.

### 7.8.3. About reusing a VNet for your OpenShift Container Platform cluster

In OpenShift Container Platform 4.14, you can deploy a cluster into an existing Azure Virtual Network (VNet) in Microsoft Azure. If you do, you must also use existing subnets within the VNet and routing rules.

By deploying OpenShift Container Platform into an existing Azure VNet, you might be able to avoid service limit constraints in new accounts or more easily abide by the operational constraints that your company’s guidelines set. This is a good option to use if you cannot obtain the infrastructure creation permissions that are required to create the VNet.

#### 7.8.3.1. Requirements for using your VNet

When you deploy a cluster by using an existing VNet, you must perform additional network configuration before you install the cluster. In installer-provisioned infrastructure clusters, the installer usually creates the following components, but it does not create them when you install into an existing VNet:

- Subnets
- Route tables
- VNets
- Network Security Groups
NOTE

The installation program requires that you use the cloud-provided DNS server. Using a custom DNS server is not supported and causes the installation to fail.

If you use a custom VNet, you must correctly configure it and its subnets for the installation program and the cluster to use. The installation program cannot subdivide network ranges for the cluster to use, set route tables for the subnets, or set VNet options like DHCP, so you must do so before you install the cluster.

The cluster must be able to access the resource group that contains the existing VNet and subnets. While all of the resources that the cluster creates are placed in a separate resource group that it creates, some network resources are used from a separate group. Some cluster Operators must be able to access resources in both resource groups. For example, the Machine API controller attaches NICS for the virtual machines that it creates to subnets from the networking resource group.

Your VNet must meet the following characteristics:

- The VNet’s CIDR block must contain the Networking.MachineCIDR range, which is the IP address pool for cluster machines.
- The VNet and its subnets must belong to the same resource group, and the subnets must be configured to use Azure-assigned DHCP IP addresses instead of static IP addresses.

You must provide two subnets within your VNet, one for the control plane machines and one for the compute machines. Because Azure distributes machines in different availability zones within the region that you specify, your cluster will have high availability by default.

NOTE

By default, if you specify availability zones in the install-config.yaml file, the installation program distributes the control plane machines and the compute machines across these availability zones within a region. To ensure high availability for your cluster, select a region with at least three availability zones. If your region contains fewer than three availability zones, the installation program places more than one control plane machine in the available zones.

To ensure that the subnets that you provide are suitable, the installation program confirms the following data:

- All the specified subnets exist.
- There are two private subnets, one for the control plane machines and one for the compute machines.
- The subnet CIDRs belong to the machine CIDR that you specified. Machines are not provisioned in availability zones that you do not provide private subnets for.

NOTE

If you destroy a cluster that uses an existing VNet, the VNet is not deleted.

7.8.3.1.1. Network security group requirements
The network security groups for the subnets that host the compute and control plane machines require specific access to ensure that the cluster communication is correct. You must create rules to allow access to the required cluster communication ports.

**IMPORTANT**

The network security group rules must be in place before you install the cluster. If you attempt to install a cluster without the required access, the installation program cannot reach the Azure APIs, and installation fails.

Table 7.12. Required ports

<table>
<thead>
<tr>
<th>Port</th>
<th>Description</th>
<th>Control plane</th>
<th>Compute</th>
</tr>
</thead>
<tbody>
<tr>
<td>80</td>
<td>Allows HTTP traffic</td>
<td></td>
<td>x</td>
</tr>
<tr>
<td>443</td>
<td>Allows HTTPS traffic</td>
<td></td>
<td>x</td>
</tr>
<tr>
<td>6443</td>
<td>Allows communication to the control plane machines</td>
<td>x</td>
<td></td>
</tr>
<tr>
<td>22623</td>
<td>Allows internal communication to the machine config server for provisioning machines</td>
<td>x</td>
<td></td>
</tr>
</tbody>
</table>

1. If you are using Azure Firewall to restrict the internet access, then you can configure Azure Firewall to allow the Azure APIs. A network security group rule is not needed.

**IMPORTANT**

Currently, there is no supported way to block or restrict the machine config server endpoint. The machine config server must be exposed to the network so that newly-provisioned machines, which have no existing configuration or state, are able to fetch their configuration. In this model, the root of trust is the certificate signing requests (CSR) endpoint, which is where the kubelet sends its certificate signing request for approval to join the cluster. Because of this, machine configs should not be used to distribute sensitive information, such as secrets and certificates.

To ensure that the machine config server endpoints, ports 22623 and 22624, are secured in bare metal scenarios, customers must configure proper network policies.

Because cluster components do not modify the user-provided network security groups, which the Kubernetes controllers update, a pseudo-network security group is created for the Kubernetes controller to modify without impacting the rest of the environment.

**Additional resources**

- About the OpenShift SDN network plugin
- Configuring your firewall

**7.8.3.2. Division of permissions**

Starting with OpenShift Container Platform 4.3, you do not need all of the permissions that are required
for an installation program-provisioned infrastructure cluster to deploy a cluster. This change mimics the division of permissions that you might have at your company: some individuals can create different resources in your clouds than others. For example, you might be able to create application-specific items, like instances, storage, and load balancers, but not networking-related components such as VNets, subnet, or ingress rules.

The Azure credentials that you use when you create your cluster do not need the networking permissions that are required to make VNets and core networking components within the VNet, such as subnets, routing tables, internet gateways, NAT, and VPN. You still need permission to make the application resources that the machines within the cluster require, such as load balancers, security groups, storage accounts, and nodes.

7.8.3.3. Isolation between clusters

Because the cluster is unable to modify network security groups in an existing subnet, there is no way to isolate clusters from each other on the VNet.

7.8.4. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager Hybrid Cloud Console to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- Access Quay.io to obtain the packages that are required to install your cluster.

- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

7.8.5. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.
IMPORTANT

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

NOTE

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

Procedure

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>  
   ```

   Specify the path and file name, such as `~/.ssh/id_ed25519`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   ```
   $ cat <path>/<file_name>.pub  
   ```

   For example, run the following to view the `~/.ssh/id_ed25519.pub` public key:

   ```
   $ cat ~/.ssh/id_ed25519.pub  
   ```

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the `./openshift-install gather` command.

   **NOTE**

   On some distributions, default SSH private key identities such as `~/.ssh/id_rsa` and `~/.ssh/id_dsa` are managed automatically.

   a. If the `ssh-agent` process is not already running for your local user, start it as a background task:

   ```
   $ eval "$(ssh-agent -s)"  
   ```
Example output
Agent pid 31874

NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the ssh-agent:

   $ ssh-add <path>/<file_name>  

1 Specify the path and file name for your SSH private key, such as ~/.ssh/id_ed25519

Example output
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

7.8.6. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

   IMPORTANT

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.
Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar -xvf openshift-install-linux.tar.gz
```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 7.8.7. Manually creating the installation configuration file

When installing a private OpenShift Container Platform cluster, you must manually generate the installation configuration file.

**Prerequisites**

- You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.

- You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Create an installation directory to store your required installation assets in:

```
$ mkdir <installation_directory>
```

**IMPORTANT**

You must create a directory. Some installation assets, like bootstrap X.509 certificates, have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample `install-config.yaml` file template that is provided and save it in the `<installation_directory>`.

**NOTE**

You must name this configuration file `install-config.yaml`. 

```
$ tar -xvf openshift-install-linux.tar.gz
$ mkdir <installation_directory>
```

OpenShift Container Platform 4.14 Installing

```
NOTE

For some platform types, you can alternatively run `./openshift-install create install-config --dir <installation_directory>` to generate an `install-config.yaml` file. You can provide details about your cluster configuration at the prompts.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

IMPORTANT

The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.

Additional resources

- Installation configuration parameters for Azure

### 7.8.7.1. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

**Table 7.13. Minimum resource requirements**

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS, RHEL 8.6 and later [3]</td>
<td>2</td>
<td>8 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
</tbody>
</table>

1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or hyperthreading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: \((\text{threads per core} \times \text{cores}) \times \text{sockets} = \text{vCPUs}\).

2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.

3. As with all user-provisioned installations, if you choose to use RHEL compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and has been removed in OpenShift Container Platform 4.10 and later.
IMPORTANT

You are required to use Azure virtual machines that have the `premiumIO` parameter set to `true`.

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

Additional resources

- Optimizing storage

7.8.7.2. Tested instance types for Azure

The following Microsoft Azure instance types have been tested with OpenShift Container Platform.

Example 7.32. Machine types based on 64-bit x86 architecture

- c4.*
- c5.*
- c5a.*
- i3.*
- m4.*
- m5.*
- m5a.*
- m6i.*
- r4.*
- r5.*
- r5a.*
- r6i.*
- t3.*
- t3a.*

7.8.7.3. Tested instance types for Azure on 64-bit ARM infrastructures

The following Microsoft Azure ARM64 instance types have been tested with OpenShift Container Platform.

Example 7.33. Machine types based on 64-bit ARM architecture

- c6g.*
7.8.7.4. Enabling trusted launch for Azure VMs

You can enable two trusted launch features when installing your cluster on Azure: secure boot and virtualized Trusted Platform Modules.

See the Azure documentation about virtual machine sizes to learn what sizes of virtual machines support these features.

**IMPORTANT**

Trusted launch is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see Technology Preview Features Support Scope.

**Prerequisites**

- You have created an install-config.yaml file.

**Procedure**

- Use a text editor to edit the install-config.yaml file prior to deploying your cluster and add the following stanza:

```
controlPlane: 1
platform:
    azure:
        settings:
            securityType: TrustedLaunch 2
            trustedLaunch:
                uefiSettings:
                    secureBoot: Enabled 3
                    virtualizedTrustedPlatformModule: Enabled 4
```

1. Specify controlPlane.platform.azure or compute.platform.azure to enable trusted launch on only control plane or compute nodes respectively. Specify platform.azure.defaultMachinePlatform to enable trusted launch on all nodes.

2. Enable trusted launch features.

3. Enable secure boot. For more information, see the Azure documentation about secure boot.

4. Enable the virtualized Trusted Platform Module. For more information, see the Azure documentation about virtualized Trusted Platform Modules.
### 7.8.7.5. Enabling confidential VMs

You can enable confidential VMs when installing your cluster. You can enable confidential VMs for compute nodes, control plane nodes, or all nodes.

**IMPORTANT**

Using confidential VMs is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see [Technology Preview Features Support Scope](#).

You can use confidential VMs with the following VM sizes:

- DCasv5-series
- DCadsv5-series
- ECasv5-series
- ECadsv5-series

**IMPORTANT**

Confidential VMs are currently not supported on 64-bit ARM architectures.

**Prerequisites**

- You have created an `install-config.yaml` file.

**Procedure**

- Use a text editor to edit the `install-config.yaml` file prior to deploying your cluster and add the following stanza:

  ```yaml
  controlPlane: 1
  platform:
    azure:
      settings:
        securityType: ConfidentialVM 2
        confidentialVM:
          uefiSettings:
            secureBoot: Enabled 3
            virtualizedTrustedPlatformModule: Enabled 4
          osDisk:
            securityProfile:
              securityEncryptionType: VMGuestStateOnly 5
  ```
Specify `controlPlane.platform.azure` or `compute.platform.azure` to deploy confidential VMs on only control plane or compute nodes respectively. Specify `platform.azure.defaultMachinePlatform` to deploy confidential VMs on all nodes.

Enable confidential VMs.

Enable secure boot. For more information, see the Azure documentation about secure boot.

Enable the virtualized Trusted Platform Module. For more information, see the Azure documentation about virtualized Trusted Platform Modules.

Specify `VMGuestStateOnly` to encrypt the VM guest state.

### 7.8.7.6. Sample customized install-config.yaml file for Azure

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

**IMPORTANT**

This sample YAML file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program and modify it.

```yaml
apiVersion: v1
baseDomain: example.com
controlPlane:
  hyperthreading: Enabled
  name: master
  platform:
    azure:
      encryptionAtHost: true
      ultraSSDCapability: Enabled
  osDisk:
    diskSizeGB: 1024
    diskType: Premium_LRS
    diskEncryptionSet:
      resourceGroup: disk_encryption_set_resource_group
      name: disk_encryption_set_name
      subscriptionId: secondary_subscription_id
  osImage:
    publisher: example_publisher_name
    offer: example_image_offer
    sku: example_offerSKU
    version: example_image_version
    type: Standard_D8s_v3
  replicas: 3
compute:
- hyperthreading: Enabled
  name: worker
  platform:
    azure:
      ultraSSDCapability: Enabled
```
type: Standard_D2s_v3
encryptionAtHost: true
osDisk:
diskSizeGB: 512
diskType: Standard_LRS
diskEncryptionSet:
  resourceGroup: disk_encryption_set_resource_group
  name: disk_encryption_set_name
  subscriptionId: secondary_subscription_id
osImage:
publisher: example_publisher_name
offer: example_image_offer
sku: example_offer_sku
version: example_image_version
zones:
  - "1"
  - "2"
  - "3"
replicas: 5
metadata:
  name: test-cluster
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
    hostPrefix: 23
  machineNetwork:
    - cidr: 10.0.0.0/16
  networkType: OVNKubernetes
  serviceNetwork:
    - 172.30.0.0/16
platform:
  azure:
    defaultMachinePlatform:
      osImage:
        publisher: example_publisher_name
        offer: example_image_offer
        sku: example_offer_sku
        version: example_image_version
    ultraSSDCapability: Enabled
baseDomainResourceGroupName: resource_group
region: centralus
resourceGroupName: existing_resource_group
networkResourceGroupName: vnet_resource_group
virtualNetwork: vnet
controlPlaneSubnet: control_plane_subnet
computeSubnet: compute_subnet
outboundType: UserDefinedRouting
cloudName: AzurePublicCloud
pullSecret: '"auths": {}'
fips: false
sshKey: ssh-ed25519 AAAA...
publish: Internal
Required. The installation program prompts you for this value.

If you do not provide these parameters and values, the installation program provides the default value.

The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, -, and the first line of the controlPlane section must not. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading, or hyperthreading. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores. You can disable it by setting the parameter value to Disabled. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

IMPORTANT

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger virtual machine types, such as Standard_D8s_v3, for your machines if you disable simultaneous multithreading.

You can specify the size of the disk to use in GB. Minimum recommendation for control plane nodes is 1024 GB.

Specify a list of zones to deploy your machines to. For high availability, specify at least two zones.

The cluster network plugin to install. The supported values are OVNKubernetes and OpenShiftSDN. The default value is OVNKubernetes.

Optional: A custom Red Hat Enterprise Linux CoreOS (RHCOS) image that should be used to boot control plane and compute machines. The publisher, offer, sku, and version parameters under platform.azure.defaultMachinePlatform.osImage apply to both control plane and compute machines. If the parameters under controlPlane.platform.azure.osImage or compute.platform.azure.osImage are set, they override the platform.azure.defaultMachinePlatform.osImage parameters.

Specify the name of the resource group that contains the DNS zone for your base domain.

Specify the name of an already existing resource group to install your cluster to. If undefined, a new resource group is created for the cluster.

If you use an existing VNet, specify the name of the resource group that contains it.

If you use an existing VNet, specify its name.

If you use an existing VNet, specify the name of the subnet to host the control plane machines.

If you use an existing VNet, specify the name of the subnet to host the compute machines.

You can customize your own outbound routing. Configuring user-defined routing prevents exposing external endpoints in your cluster. User-defined routing for egress requires deploying your cluster to an existing VNet.
Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container

**IMPORTANT**

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see Installing the system in FIPS mode. When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures.

You can optionally provide the `sshKey` value that you use to access the machines in your cluster.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

How to publish the user-facing endpoints of your cluster. Set `publish` to `Internal` to deploy a private cluster, which cannot be accessed from the internet. The default value is `External`.

### 7.8.7.7. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**Prerequisites**

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

**Procedure**
1. Edit your `install-config.yaml` file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port>  # 1
  httpsProxy: https://<username>:<pswd>@<ip>:<port>  # 2
  noProxy: example.com  # 3
additionalTrustBundle: |
  -----BEGIN CERTIFICATE-----
  <MY_TRUSTED_CA_CERT>
  -----END CERTIFICATE-----
  additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle>  # 5
```

1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.

2. A proxy URL to use for creating HTTPS connections outside the cluster.

3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, `.y.com` matches `x.y.com`, but not `y.com`. Use `*` to bypass the proxy for all destinations.

4. If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the `trustedCA` field of the `Proxy` object. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

5. Optional: The policy to determine the configuration of the `Proxy` object to reference the `user-ca-bundle` config map in the `trustedCA` field. The allowed values are `Proxyonly` and `Always`. Use `Proxyonly` to reference the `user-ca-bundle` config map only when `http/https` proxy is configured. Use `Always` to always reference the `user-ca-bundle` config map. The default value is `Proxyonly`.

**NOTE**

The installation program does not support the proxy `readinessEndpoints` field.

**NOTE**

If the installer times out, restart and then complete the deployment by using the `wait-for` command of the installer. For example:

```
$ ./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.
The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

**NOTE**

Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

Additional resources

- For more details about Accelerated Networking, see *Accelerated Networking for Microsoft Azure VMs*.

**7.8.8. Installing the OpenShift CLI by downloading the binary**

You can install the OpenShift CLI (`oc`) to interact with OpenShift Container Platform from a command-line interface. You can install `oc` on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of `oc`, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of `oc`.

**Installing the OpenShift CLI on Linux**

You can install the OpenShift CLI (`oc`) binary on Linux by using the following procedure.

**Procedure**

2. Select the architecture from the Product Variant drop-down list.

3. Select the appropriate version from the Version drop-down list.

4. Click Download Now next to the OpenShift v4.14 Linux Client entry and save the file.

5. Unpack the archive:

   ```
   $ tar xvf <file>
   ```

6. Place the `oc` binary in a directory that is on your `PATH`. To check your `PATH`, execute the following command:

   ```
   $ echo $PATH
   ```

**Verification**

- After you install the OpenShift CLI, it is available using the `oc` command:

  ```
  $ oc <command>
  ```
Installing the OpenShift CLI on Windows
You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

Procedure
2. Select the appropriate version from the Version drop-down list.
3. Click Download Now next to the OpenShift v4.14 Windows Client entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the oc binary to a directory that is on your PATH. To check your PATH, open the command prompt and execute the following command:

```
C:\> path
```

Verification
- After you install the OpenShift CLI, it is available using the oc command:

```
C:\> oc <command>
```

Installing the OpenShift CLI on macOS
You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.

Procedure
2. Select the appropriate version from the Version drop-down list.
3. Click Download Now next to the OpenShift v4.14 macOS Client entry and save the file.
   NOTE
   For macOS arm64, choose the OpenShift v4.14 macOS arm64 Client entry.
4. Unpack and unzip the archive.
5. Move the oc binary to a directory on your PATH. To check your PATH, open a terminal and execute the following command:

```
$ echo $PATH
```

Verification
- After you install the OpenShift CLI, it is available using the oc command:

```
$ oc <command>
```
7.8.9. Alternatives to storing administrator-level secrets in the kube-system project

By default, administrator secrets are stored in the **kube-system** project. If you configured the `credentialsMode` parameter in the `install-config.yaml` file to **Manual**, you must use one of the following alternatives:

- To manage long-term cloud credentials manually, follow the procedure in **Manually creating long-term credentials**.

- To implement short-term credentials that are managed outside the cluster for individual components, follow the procedures in **Configuring an Azure cluster to use short-term credentials**.

7.8.9.1. Manually creating long-term credentials

The Cloud Credential Operator (CCO) can be put into manual mode prior to installation in environments where the cloud identity and access management (IAM) APIs are not reachable, or the administrator prefers not to store an administrator-level credential secret in the cluster **kube-system** namespace.

**Procedure**

1. If you did not set the `credentialsMode` parameter in the `install-config.yaml` configuration file to **Manual**, modify the value as shown:

   **Sample configuration file snippet**

   ```yaml
   apiVersion: v1
   baseDomain: example.com
   credentialsMode: Manual
   # ...
   ```

2. If you have not previously created installation manifest files, do so by running the following command:

   ```
   $ openshift-install create manifests --dir <installation_directory>
   
   where `<installation_directory>` is the directory in which the installation program creates files.
   ```

3. Set a `$RELEASE_IMAGE` variable with the release image from your installation file by running the following command:

   ```
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
   ```

4. Extract the list of `CredentialsRequest` custom resources (CRs) from the OpenShift Container Platform release image by running the following command:

   ```
   $ oc adm release extract \
   --from=$RELEASE_IMAGE \
   --credentials-requests \
   --included 1 \
   --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml 2 \
   --to=<path_to_directory_for_credentials_requests> 3
   ```
The --included parameter includes only the manifests that your specific cluster configuration requires.

Specify the location of the install-config.yaml file.

Specify the path to the directory where you want to store the CredentialsRequest objects. If the specified directory does not exist, this command creates it.

This command creates a YAML file for each CredentialsRequest object.

Sample CredentialsRequest object

```yaml
apiVersion: cloudcredential.openshift.io/v1
class: CredentialsRequest
metadata:
  name: <component_credentials_request>
  namespace: openshift-cloud-credential-operator
...
spec:
  providerSpec:
    apiVersion: cloudcredential.openshift.io/v1
    class: AzureProviderSpec
    roleBindings:
    - role: Contributor
...
```

5. Create YAML files for secrets in the openshift-install manifests directory that you generated previously. The secrets must be stored using the namespace and secret name defined in the spec.secretRef for each CredentialsRequest object.

Sample CredentialsRequest object with secrets

```yaml
apiVersion: cloudcredential.openshift.io/v1
class: CredentialsRequest
metadata:
  name: <component_credentials_request>
  namespace: openshift-cloud-credential-operator
...
spec:
  providerSpec:
    apiVersion: cloudcredential.openshift.io/v1
    class: AzureProviderSpec
    roleBindings:
    - role: Contributor
...
    secretRef:
      name: <component_secret>
      namespace: <component_namespace>
...
```

Sample Secret object

```yaml
apiVersion: v1
class: Secret
```
Before upgrading a cluster that uses manually maintained credentials, you must ensure that the CCO is in an upgradeable state.

7.8.9.2. Configuring an Azure cluster to use short-term credentials

To install a cluster that uses Azure AD Workload Identity, you must configure the Cloud Credential Operator utility and create the required Azure resources for your cluster.

7.8.9.2.1. Configuring the Cloud Credential Operator utility

To create and manage cloud credentials from outside of the cluster when the Cloud Credential Operator (CCO) is operating in manual mode, extract and prepare the CCO utility (ccoctl) binary.

NOTE

The ccoctl utility is a Linux binary that must run in a Linux environment.

Prerequisites

- You have access to an OpenShift Container Platform account with cluster administrator access.
- You have installed the OpenShift CLI (oc).
- You have created a global Microsoft Azure account for the ccoctl utility to use with the following permissions:

Example 7.34. Required Azure permissions

- Microsoft/Resources/subscriptions/resourceGroups/read
- Microsoft/Resources/subscriptions/resourceGroups/write
- Microsoft/Resources/subscriptions/resourceGroups/delete
- Microsoft/Authorization/roleAssignments/read
- Microsoft/Authorization/roleAssignments/delete
- Microsoft/Authorization/roleAssignments/write
- Microsoft/Authorization/roleDefinitions/read
Procedure

1. Obtain the OpenShift Container Platform release image by running the following command:

   ```
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
   ```

2. Obtain the CCO container image from the OpenShift Container Platform release image by running the following command:

   ```
   $ CCO_IMAGE=$(oc adm release info --image-for='cloud-credential-operator' $RELEASE_IMAGE -a ~/.pull-secret)
   ```

   **NOTE**

   Ensure that the architecture of the $RELEASE_IMAGE matches the architecture of the environment in which you will use the ccoctl tool.

3. Extract the ccoctl binary from the CCO container image within the OpenShift Container Platform release image by running the following command:
$ oc image extract $CCO_IMAGE --file="/usr/bin/ccoctl" -a ~/.pull-secret

4. Change the permissions to make `ccoctl` executable by running the following command:

   $ chmod 775 ccoctl

**Verification**

- To verify that `ccoctl` is ready to use, display the help file by running the following command:

   $ ccoctl --help

**Output of ccoctl --help**

OpenShift credentials provisioning tool

Usage:

ccoclt [command]

Available Commands:

- alibabacloud Manage credentials objects for alibaba cloud
- aws Manage credentials objects for AWS cloud
- azure Manage credentials objects for Azure
- gcp Manage credentials objects for Google cloud
- help Help about any command
- ibmcloud Manage credentials objects for IBM Cloud
- nutanix Manage credentials objects for Nutanix

Flags:

- -h, --help help for ccoctl

Use "ccoctl [command] --help" for more information about a command.

7.8.9.2.2. Creating Azure resources with the Cloud Credential Operator utility

You can use the `ccoclt azure create-all` command to automate the creation of Azure resources.

**NOTE**

By default, `ccoclt` creates objects in the directory in which the commands are run. To create the objects in a different directory, use the `--output-dir` flag. This procedure uses `<path_to_ccoclt_output_dir>` to refer to this directory.

**Prerequisites**

You must have:

- Extracted and prepared the `ccoclt` binary.
- Access to your Microsoft Azure account by using the Azure CLI.

**Procedure**
1. Set a `$RELEASE_IMAGE` variable with the release image from your installation file by running the following command:

   ```bash
   $ RELEASE_IMAGE=$(./openshift-install version | awk '/release image/ {print $3}')
   ```

2. Extract the list of `CredentialsRequest` objects from the OpenShift Container Platform release image by running the following command:

   ```bash
   $ oc adm release extract \
   --from=$RELEASE_IMAGE \
   --credentials-requests \
   --included \
   --install-config=<path_to_directory_with_installation_configuration>/install-config.yaml \
   --to=<path_to_directory_for_credentials_requests>
   ```

   - The `--included` parameter includes only the manifests that your specific cluster configuration requires.
   - Specify the location of the `install-config.yaml` file.
   - Specify the path to the directory where you want to store the `CredentialsRequest` objects. If the specified directory does not exist, this command creates it.

   **NOTE**
   This command might take a few moments to run.

3. To enable the `ccoctl` utility to detect your Azure credentials automatically, log in to the Azure CLI by running the following command:

   ```bash
   $ az login
   ```

4. Use the `ccoctl` tool to process all `CredentialsRequest` objects by running the following command:

   ```bash
   $ ccoctl azure create-all \
   --name=<azure_infra_name> \
   --output-dir=<ccoctl_output_dir> \
   --region=<azure_region> \
   --subscription-id=<azure_subscription_id> \
   --credentials-requests-dir=<path_to_credentials_requests_directory> \
   --tenant-id=<azure_tenant_id>
   ```

   - Specify the user-defined name for all created Azure resources used for tracking.
   - Optional: Specify the directory in which you want the `ccoctl` utility to create objects. By default, the utility creates objects in the directory in which the commands are run.
   - Specify the Azure region in which cloud resources will be created.
   - Specify the Azure subscription ID to use.
5. Specify the directory containing the files for the component `CredentialsRequest` objects.

6. Specify the name of the resource group containing the cluster’s base domain Azure DNS zone.

7. Specify the Azure tenant ID to use.

**NOTE**

If your cluster uses Technology Preview features that are enabled by the `TechPreviewNoUpgrade` feature set, you must include the `--enable-tech-preview` parameter.

To see additional optional parameters and explanations of how to use them, run the `azure create-all --help` command.

**Verification**

- To verify that the OpenShift Container Platform secrets are created, list the files in the `<path_to_ccoctl_output_dir>/manifests` directory:

  ```bash
  $ ls <path_to_ccoctl_output_dir>/manifests
  ```

**Example output**

- `azure-ad-pod-identity-webhook-config.yaml`
- `cluster-authentication-02-config.yaml`
- `openshift-cloud-controller-manager-azure-cloud-credentials-credentials.yaml`
- `openshift-cloud-network-config-controller-azure-cloud-credentials-credentials.yaml`
- `openshift-cluster-api-capz-manager-bootstrap-credentials-credentials.yaml`
- `openshift-cluster-csi-drivers-azure-disk-credentials-credentials.yaml`
- `openshift-cluster-csi-drivers-azure-file-credentials-credentials.yaml`
- `openshift-image-registry-installer-cloud-credentials-credentials.yaml`
- `openshift-ingress-operator-cloud-credentials-credentials.yaml`
- `openshift-machine-api-azure-cloud-credentials-credentials.yaml`

You can verify that the Azure AD service accounts are created by querying Azure. For more information, refer to Azure documentation on listing AD service accounts.

### 7.8.9.2.3. Incorporating the Cloud Credential Operator utility manifests

To implement short-term security credentials managed outside the cluster for individual components, you must move the manifest files that the Cloud Credential Operator utility (`ccoctl`) created to the correct directories for the installation program.

**Prerequisites**

- You have configured an account with the cloud platform that hosts your cluster.
- You have configured the Cloud Credential Operator utility (`ccoctl`).
- You have created the cloud provider resources that are required for your cluster with the `ccoctl` utility.
Procedure

1. If you did not set the `credentialsMode` parameter in the `install-config.yaml` configuration file to `Manual`, modify the value as shown:

   **Sample configuration file snippet**
   ```yaml
   apiVersion: v1
   baseDomain: example.com
   credentialsMode: Manual
   # ...
   ```

2. If you used the `ccoctl` utility to create a new Azure resource group instead of using an existing resource group, modify the `resourceGroupName` parameter in the `install-config.yaml` as shown:

   **Sample configuration file snippet**
   ```yaml
   apiVersion: v1
   baseDomain: example.com
   # ...
   platform:
      azure:
        resourceGroupName: `<azure_infra_name>`
   # ...
   ```
   
   *(1) This value must match the user-defined name for Azure resources that was specified with the `--name` argument of the `ccoctl azure create-all` command.*

3. If you have not previously created installation manifest files, do so by running the following command:

   ```bash
   $ openshift-install create manifests --dir <installation_directory>
   ```

   where `<installation_directory>` is the directory in which the installation program creates files.

4. Copy the manifests that the `ccoctl` utility generated to the `manifests` directory that the installation program created by running the following command:

   ```bash
   $ cp /<path_to_ccoctl_output_dir>/manifests/* ./manifests/
   ```

5. Copy the private key that the `ccoctl` utility generated in the `tls` directory to the installation directory by running the following command:

   ```bash
   $ cp -a /<path_to_ccoctl_output_dir>/tls .
   ```

### 7.8.10. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.
IMPORTANT

You can run the `create cluster` command of the installation program only once, during initial installation.

Prerequisites

- You have configured an account with the cloud platform that hosts your cluster.
- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have an Azure subscription ID and tenant ID.
- If you are installing the cluster using a service principal, you have its application ID and password.
- If you are installing the cluster using a system-assigned managed identity, you have enabled it on the virtual machine that you will run the installation program from.
- If you are installing the cluster using a user-assigned managed identity, you have met these prerequisites:
  - You have its client ID.
  - You have assigned it to the virtual machine that you will run the installation program from.

Procedure

1. Optional: If you have run the installation program on this computer before, and want to use an alternative service principal or managed identity, go to the `~/.azure/` directory and delete the `osServicePrincipal.json` configuration file. Deleting this file prevents the installation program from automatically reusing subscription and authentication values from a previous installation.

2. Change to the directory that contains the installation program and initialize the cluster deployment:

   ```
   $ ./openshift-install create cluster --dir <installation_directory> \
   --log-level=info
   ```

   For `<installation_directory>`, specify the location of your customized `./install-config.yaml` file.

   To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

   If the installation program cannot locate the `osServicePrincipal.json` configuration file from a previous installation, you are prompted for Azure subscription and authentication values.

3. Enter the following Azure parameter values for your subscription:

   - `azure subscription id` Enter the subscription ID to use for the cluster.
   - `azure tenant id` Enter the tenant ID.

4. Depending on the Azure identity you are using to deploy the cluster, do one of the following when prompted for the `azure service principal client id`
If you are using a service principal, enter its application ID.
If you are using a system-assigned managed identity, leave this value blank.
If you are using a user-assigned managed identity, specify its client ID.

5. Depending on the Azure identity you are using to deploy the cluster, do one of the following when prompted for the **azure service principal client secret**
   - If you are using a service principal, enter its password.
   - If you are using a system-assigned managed identity, leave this value blank.
   - If you are using a user-assigned managed identity, leave this value blank.

If previously not detected, the installation program creates an **osServicePrincipal.json** configuration file and stores this file in the `~/.azure/` directory on your computer. This ensures that the installation program can load the profile when it is creating an OpenShift Container Platform cluster on the target platform.

**Verification**

When the cluster deployment completes successfully:

- The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the **kubeadmin** user.
- Credential information also outputs to `<installation_directory>/.openshift_install.log`.

**IMPORTANT**

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

**Example output**

```
...  
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```
**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

### 7.8.11. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

   ```sh
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```sh
   $ oc whoami
   ```

   **Example output**

   ```shell
   system:admin
   ```

**Additional resources**

- See Accessing the web console for more details about accessing and understanding the OpenShift Container Platform web console.

### 7.8.12. Telemetry access for OpenShift Container Platform
In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager Hybrid Cloud Console.

After you confirm that your OpenShift Cluster Manager Hybrid Cloud Console inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service

7.8.13. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.

7.9. INSTALLING A CLUSTER ON AZURE INTO A GOVERNMENT REGION

In OpenShift Container Platform version 4.14, you can install a cluster on Microsoft Azure into a government region. To configure the government region, you modify parameters in the `install-config.yaml` file before you install the cluster.

7.9.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You configured an Azure account to host the cluster and determined the tested and validated government region to deploy the cluster to.
- If you use a firewall, you configured it to allow the sites that your cluster requires access to.
- If the cloud identity and access management (IAM) APIs are not accessible in your environment, or if you do not want to store an administrator-level credential secret in the `kube-system` namespace, you can manually create and maintain long-term credentials.
- If you use customer-managed encryption keys, you prepared your Azure environment for encryption.

7.9.2. Azure government regions

OpenShift Container Platform supports deploying a cluster to Microsoft Azure Government (MAG) regions. MAG is specifically designed for US government agencies at the federal, state, and local level, as well as contractors, educational institutions, and other US customers that must run sensitive workloads on Azure. MAG is composed of government-only data center regions, all granted an Impact Level 5 Provisional Authorization.
Installing to a MAG region requires manually configuring the Azure Government dedicated cloud instance and region in the `install-config.yaml` file. You must also update your service principal to reference the appropriate government environment.

**NOTE**

The Azure government region cannot be selected using the guided terminal prompts from the installation program. You must define the region manually in the `install-config.yaml` file. Remember to also set the dedicated cloud instance, like `AzureUSGovernmentCloud`, based on the region specified.

7.9.3. Private clusters

You can deploy a private OpenShift Container Platform cluster that does not expose external endpoints. Private clusters are accessible from only an internal network and are not visible to the internet.

By default, OpenShift Container Platform is provisioned to use publicly-accessible DNS and endpoints. A private cluster sets the DNS, Ingress Controller, and API server to private when you deploy your cluster. This means that the cluster resources are only accessible from your internal network and are not visible to the internet.

**IMPORTANT**

If the cluster has any public subnets, load balancer services created by administrators might be publicly accessible. To ensure cluster security, verify that these services are explicitly annotated as private.

To deploy a private cluster, you must:

- Use existing networking that meets your requirements. Your cluster resources might be shared between other clusters on the network.

- Deploy from a machine that has access to:
  - The API services for the cloud to which you provision.
  - The hosts on the network that you provision.
  - The internet to obtain installation media.

You can use any machine that meets these access requirements and follows your company’s guidelines. For example, this machine can be a bastion host on your cloud network or a machine that has access to the network through a VPN.

7.9.3.1. Private clusters in Azure

To create a private cluster on Microsoft Azure, you must provide an existing private VNet and subnets to host the cluster. The installation program must also be able to resolve the DNS records that the cluster requires. The installation program configures the Ingress Operator and API server for only internal traffic.

Depending how your network connects to the private VNET, you might need to use a DNS forwarder to resolve the cluster’s private DNS records. The cluster’s machines use **168.63.129.16** internally for DNS resolution. For more information, see [What is Azure Private DNS?](#) and [What is IP address 168.63.129.16?](#)
in the Azure documentation.

The cluster still requires access to internet to access the Azure APIs.

The following items are not required or created when you install a private cluster:

- A **BaseDomainResourceGroup**, since the cluster does not create public records
- Public IP addresses
- Public DNS records
- Public endpoints

The cluster is configured so that the Operators do not create public records for the cluster and all cluster machines are placed in the private subnets that you specify.

**7.9.3.1.1. Limitations**

Private clusters on Azure are subject to only the limitations that are associated with the use of an existing VNet.

**7.9.3.2. User-defined outbound routing**

In OpenShift Container Platform, you can choose your own outbound routing for a cluster to connect to the internet. This allows you to skip the creation of public IP addresses and the public load balancer.

You can configure user-defined routing by modifying parameters in the `install-config.yaml` file before installing your cluster. A pre-existing VNet is required to use outbound routing when installing a cluster; the installation program is not responsible for configuring this.

When configuring a cluster to use user-defined routing, the installation program does not create the following resources:

- Outbound rules for access to the internet.
- Public IPs for the public load balancer.
- Kubernetes Service object to add the cluster machines to the public load balancer for outbound requests.

You must ensure the following items are available before setting user-defined routing:

- Egress to the internet is possible to pull container images, unless using an OpenShift image registry mirror.
- The cluster can access Azure APIs.
- Various allowlist endpoints are configured. You can reference these endpoints in the *Configuring your firewall* section.

There are several pre-existing networking setups that are supported for internet access using user-defined routing.

**7.9.4. About reusing a VNet for your OpenShift Container Platform cluster**
In OpenShift Container Platform 4.14, you can deploy a cluster into an existing Azure Virtual Network (VNet) in Microsoft Azure. If you do, you must also use existing subnets within the VNet and routing rules.

By deploying OpenShift Container Platform into an existing Azure VNet, you might be able to avoid service limit constraints in new accounts or more easily abide by the operational constraints that your company’s guidelines set. This is a good option to use if you cannot obtain the infrastructure creation permissions that are required to create the VNet.

### 7.9.4.1. Requirements for using your VNet

When you deploy a cluster by using an existing VNet, you must perform additional network configuration before you install the cluster. In installer-provisioned infrastructure clusters, the installer usually creates the following components, but it does not create them when you install into an existing VNet:

- Subnets
- Route tables
- VNets
- Network Security Groups

**NOTE**

The installation program requires that you use the cloud-provided DNS server. Using a custom DNS server is not supported and causes the installation to fail.

If you use a custom VNet, you must correctly configure it and its subnets for the installation program and the cluster to use. The installation program cannot subdivide network ranges for the cluster to use, set route tables for the subnets, or set VNet options like DHCP, so you must do so before you install the cluster.

The cluster must be able to access the resource group that contains the existing VNet and subnets. While all of the resources that the cluster creates are placed in a separate resource group that it creates, some network resources are used from a separate group. Some cluster Operators must be able to access resources in both resource groups. For example, the Machine API controller attaches NICS for the virtual machines that it creates to subnets from the networking resource group.

Your VNet must meet the following characteristics:

- The VNet’s CIDR block must contain the `Networking.MachineCIDR` range, which is the IP address pool for cluster machines.

- The VNet and its subnets must belong to the same resource group, and the subnets must be configured to use Azure-assigned DHCP IP addresses instead of static IP addresses.

You must provide two subnets within your VNet, one for the control plane machines and one for the compute machines. Because Azure distributes machines in different availability zones within the region that you specify, your cluster will have high availability by default.
NOTE

By default, if you specify availability zones in the `install-config.yaml` file, the installation program distributes the control plane machines and the compute machines across these availability zones within a region. To ensure high availability for your cluster, select a region with at least three availability zones. If your region contains fewer than three availability zones, the installation program places more than one control plane machine in the available zones.

To ensure that the subnets that you provide are suitable, the installation program confirms the following data:

- All the specified subnets exist.
- There are two private subnets, one for the control plane machines and one for the compute machines.
- The subnet CIDRs belong to the machine CIDR that you specified. Machines are not provisioned in availability zones that you do not provide private subnets for. If required, the installation program creates public load balancers that manage the control plane and worker nodes, and Azure allocates a public IP address to them.

NOTE

If you destroy a cluster that uses an existing VNet, the VNet is not deleted.

7.9.4.1.1. Network security group requirements

The network security groups for the subnets that host the compute and control plane machines require specific access to ensure that the cluster communication is correct. You must create rules to allow access to the required cluster communication ports.

IMPORTANT

The network security group rules must be in place before you install the cluster. If you attempt to install a cluster without the required access, the installation program cannot reach the Azure APIs, and installation fails.

Table 7.14. Required ports

<table>
<thead>
<tr>
<th>Port</th>
<th>Description</th>
<th>Control plane</th>
<th>Compute</th>
</tr>
</thead>
<tbody>
<tr>
<td>80</td>
<td>Allows HTTP traffic</td>
<td></td>
<td>x</td>
</tr>
<tr>
<td>443</td>
<td>Allows HTTPS traffic</td>
<td></td>
<td>x</td>
</tr>
<tr>
<td>6443</td>
<td>Allows communication to the control plane machines</td>
<td>x</td>
<td></td>
</tr>
<tr>
<td>22623</td>
<td>Allows internal communication to the machine config server for provisioning machines</td>
<td></td>
<td>x</td>
</tr>
</tbody>
</table>
1. If you are using Azure Firewall to restrict the internet access, then you can configure Azure Firewall to allow the Azure APIs. A network security group rule is not needed.

**IMPORTANT**

Currently, there is no supported way to block or restrict the machine config server endpoint. The machine config server must be exposed to the network so that newly-provisioned machines, which have no existing configuration or state, are able to fetch their configuration. In this model, the root of trust is the certificate signing requests (CSR) endpoint, which is where the kubelet sends its certificate signing request for approval to join the cluster. Because of this, machine configs should not be used to distribute sensitive information, such as secrets and certificates.

To ensure that the machine config server endpoints, ports 22623 and 22624, are secured in bare metal scenarios, customers must configure proper network policies.

Because cluster components do not modify the user-provided network security groups, which the Kubernetes controllers update, a pseudo-network security group is created for the Kubernetes controller to modify without impacting the rest of the environment.

**Additional resources**

- About the OpenShift SDN network plugin
- Configuring your firewall

**7.9.4.2. Division of permissions**

Starting with OpenShift Container Platform 4.3, you do not need all of the permissions that are required for an installation program-provisioned infrastructure cluster to deploy a cluster. This change mimics the division of permissions that you might have at your company: some individuals can create different resources in your clouds than others. For example, you might be able to create application-specific items, like instances, storage, and load balancers, but not networking-related components such as VNets, subnet, or ingress rules.

The Azure credentials that you use when you create your cluster do not need the networking permissions that are required to make VNets and core networking components within the VNet, such as subnets, routing tables, internet gateways, NAT, and VPN. You still need permission to make the application resources that the machines within the cluster require, such as load balancers, security groups, storage accounts, and nodes.

**7.9.4.3. Isolation between clusters**

Because the cluster is unable to modify network security groups in an existing subnet, there is no way to isolate clusters from each other on the VNet.

**7.9.5. Internet access for OpenShift Container Platform**

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access [OpenShift Cluster Manager Hybrid Cloud Console](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
• Access Quay.io to obtain the packages that are required to install your cluster.

• Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

### 7.9.6. Generating a key pair for cluster node SSH access

During an OpenShift Container Platform installation, you can provide an SSH public key to the installation program. The key is passed to the Red Hat Enterprise Linux CoreOS (RHCOS) nodes through their Ignition config files and is used to authenticate SSH access to the nodes. The key is added to the ~/.ssh/authorized_keys list for the core user on each node, which enables password-less authentication.

After the key is passed to the nodes, you can use the key pair to SSH in to the RHCOS nodes as the user core. To access the nodes through SSH, the private key identity must be managed by SSH for your local user.

If you want to SSH in to your cluster nodes to perform installation debugging or disaster recovery, you must provide the SSH public key during the installation process. The ./openshift-install gather command also requires the SSH public key to be in place on the cluster nodes.

**IMPORTANT**

Do not skip this procedure in production environments, where disaster recovery and debugging is required.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

**Procedure**

1. If you do not have an existing SSH key pair on your local machine to use for authentication onto your cluster nodes, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>
   ```

   Specify the path and file name, such as ~/.ssh/id_ed25519, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.
NOTE

If you plan to install an OpenShift Container Platform cluster that uses the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. View the public SSH key:

   $ cat <path>/<file_name>.pub

   For example, run the following to view the ~/.ssh/id_ed25519.pub public key:

   $ cat ~/.ssh/id_ed25519.pub

3. Add the SSH private key identity to the SSH agent for your local user, if it has not already been added. SSH agent management of the key is required for password-less SSH authentication onto your cluster nodes, or if you want to use the ./openshift-install gather command.

   NOTE

   On some distributions, default SSH private key identities such as ~/.ssh/id_rsa and ~/.ssh/id_dsa are managed automatically.

   a. If the ssh-agent process is not already running for your local user, start it as a background task:

      $ eval "$(ssh-agent -s)"

      Example output

      Agent pid 31874

   NOTE

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

4. Add your SSH private key to the ssh-agent:

   $ ssh-add <path>/<file_name> 1

   1 Specify the path and file name for your SSH private key, such as ~/.ssh/id_ed25519

   Example output

   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

Next steps
When you install OpenShift Container Platform, provide the SSH public key to the installation program.

7.9.7. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on the host you are using for installation.

Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space.

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program that corresponds with your host operating system and architecture, and place the file in the directory where you will store the installation configuration files.

   **IMPORTANT**

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   **IMPORTANT**

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ tar -xvf openshift-install-linux.tar.gz
   ```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

7.9.8. Manually creating the installation configuration file

When installing OpenShift Container Platform on Microsoft Azure into a government region, you must manually generate your installation configuration file.

Prerequisites
You have an SSH public key on your local machine to provide to the installation program. The key will be used for SSH authentication onto your cluster nodes for debugging and disaster recovery.

You have obtained the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Create an installation directory to store your required installation assets in:

   ```bash
   $ mkdir <installation_directory>
   ```

   **IMPORTANT**

   You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the sample `install-config.yaml` file template that is provided and save it in the `<installation_directory>`.

   **NOTE**

   You must name this configuration file `install-config.yaml`.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

   **IMPORTANT**

   The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.

Additional resources

- Installation configuration parameters for Azure

7.9.8.1. Minimum resource requirements for cluster installation

Each cluster machine must meet the following minimum requirements:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>-----------</td>
<td>------------------</td>
<td>----------</td>
<td>-------------</td>
<td>---------</td>
<td>----------------------------------</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS, RHEL 8.6 and later [3]</td>
<td>2</td>
<td>8 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
</tbody>
</table>

1. One vCPU is equivalent to one physical core when simultaneous multithreading (SMT), or hyperthreading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: (threads per core × cores) × sockets = vCPUs.

2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.

3. As with all user-provisioned installations, if you choose to use RHEL compute machines in your cluster, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and has been removed in OpenShift Container Platform 4.10 and later.

**IMPORTANT**

You are required to use Azure virtual machines that have the `premiumIO` parameter set to `true`.

If an instance type for your platform meets the minimum requirements for cluster machines, it is supported to use in OpenShift Container Platform.

Additional resources

- Optimizing storage

### 7.9.8.2. Tested instance types for Azure

The following Microsoft Azure instance types have been tested with OpenShift Container Platform.

**Example 7.35. Machine types based on 64-bit x86 architecture**

- c4.*
- c5.*
- c5a.*
- i3.*
- m4.*
7.9.8.3. Enabling trusted launch for Azure VMs

You can enable two trusted launch features when installing your cluster on Azure: secure boot and virtualized Trusted Platform Modules.

See the Azure documentation about virtual machine sizes to learn what sizes of virtual machines support these features.

**IMPORTANT**

Trusted launch is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see Technology Preview Features Support Scope.

**Prerequisites**

- You have created an install-config.yaml file.

**Procedure**

- Use a text editor to edit the install-config.yaml file prior to deploying your cluster and add the following stanza:

```yaml
controlPlane: 1
  platform:
    azure:
      settings:
        securityType: TrustedLaunch 2
        trustedLaunch:
```
Specify `controlPlane.platform.azure` or `compute.platform.azure` to enable trusted launch on only control plane or compute nodes respectively. Specify `platform.azure.defaultMachinePlatform` to enable trusted launch on all nodes.

Enable trusted launch features.

Enable secure boot. For more information, see the Azure documentation about secure boot.

Enable the virtualized Trusted Platform Module. For more information, see the Azure documentation about virtualized Trusted Platform Modules.

7.9.8.4. Enabling confidential VMs

You can enable confidential VMs when installing your cluster. You can enable confidential VMs for compute nodes, control plane nodes, or all nodes.

**IMPORTANT**

Using confidential VMs is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see Technology Preview Features Support Scope.

You can use confidential VMs with the following VM sizes:

- DCasv5-series
- DCadsv5-series
- ECasv5-series
- ECadsv5-series

**IMPORTANT**

Confidential VMs are currently not supported on 64-bit ARM architectures.

**Prerequisites**

- You have created an `install-config.yaml` file.

**Procedure**

- Use a text editor to edit the `install-config.yaml` file prior to deploying your cluster and add the following stanza:
Specify `controlPlane.platform.azure` or `compute.platform.azure` to deploy confidential VMs on only control plane or compute nodes respectively. Specify `platform.azure.defaultMachinePlatform` to deploy confidential VMs on all nodes.

Enable confidential VMs.

Enable secure boot. For more information, see the Azure documentation about secure boot.

Enable the virtualized Trusted Platform Module. For more information, see the Azure documentation about virtualized Trusted Platform Modules.

Specify `VMGuestStateOnly` to encrypt the VM guest state.

### 7.9.8.5. Sample customized install-config.yaml file for Azure

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

**IMPORTANT**

This sample YAML file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program and modify it.

The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, -, and the first line of the controlPlane section must not. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading, or hyperthreading. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to Disabled. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

## IMPORTANT

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger virtual machine types, such as Standard_D8s_v3, for your machines if you disable simultaneous multithreading.

You can specify the size of the disk to use in GB. Minimum recommendation for control plane nodes is 1024 GB.

Specify a list of zones to deploy your machines to. For high availability, specify at least two zones.

The cluster network plugin to install. The supported values are OVNKubernetes and OpenShiftSDN. The default value is OVNKubernetes.

Optional: A custom Red Hat Enterprise Linux CoreOS (RHCOS) image that should be used to boot control plane and compute machines. The publisher, offer, sku, and version parameters under platform.azure.defaultMachinePlatform.osImage apply to both control plane and compute machines. If the parameters under controlPlane.platform.azure.osImage or compute.platform.azure.osImage are set, they override the platform.azure.defaultMachinePlatform.osImage parameters.

Specify the name of the resource group that contains the DNS zone for your base domain.

Specify the name of an already existing resource group to install your cluster to. If undefined, a new resource group is created for the cluster.
If you use an existing VNet, specify the name of the resource group that contains it.

If you use an existing VNet, specify its name.

If you use an existing VNet, specify the name of the subnet to host the control plane machines.

If you use an existing VNet, specify the name of the subnet to host the compute machines.

You can customize your own outbound routing. Configuring user-defined routing prevents exposing external endpoints in your cluster. User-defined routing for egress requires deploying your cluster to an existing VNet.

Specify the name of the Azure cloud environment to deploy your cluster to. Set AzureUSGovernmentCloud to deploy to a Microsoft Azure Government (MAG) region. The default value is AzurePublicCloud.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

To enable FIPS mode for your cluster, you must run the installation program from a Red Hat Enterprise Linux (RHEL) computer configured to operate in FIPS mode. For more information about configuring FIPS mode on RHEL, see Installing the system in FIPS mode. When running Red Hat Enterprise Linux (RHEL) or Red Hat Enterprise Linux CoreOS (RHCOS) booted in FIPS mode, OpenShift Container Platform core components use the RHEL cryptographic libraries that have been submitted to NIST for FIPS 140-2/140-3 Validation on only the x86_64, ppc64le, and s390x architectures.

You can optionally provide the sshKey value that you use to access the machines in your cluster.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

How to publish the user-facing endpoints of your cluster. Set publish to Internal to deploy a private cluster, which cannot be accessed from the internet. The default value is External.

### 7.9.8.6. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the install-config.yaml file.

**Prerequisites**

- You have an existing install-config.yaml file.
- You reviewed the sites that your cluster requires access to and determined whether any of
them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The **Proxy** object’s `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the **Proxy** object’s `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

**Procedure**

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port>  
  httpsProxy: https://<username>:<pswd>@<ip>:<port> 
  noProxy: example.com
  additionalTrustBundle: | 
    -----BEGIN CERTIFICATE-----
    <MY_TRUSTED_CA_CERT>
    -----END CERTIFICATE-----
  additionalTrustBundlePolicy: <policy_to_add_additionalTrustBundle>
```

1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.

2. A proxy URL to use for creating HTTPS connections outside the cluster.

3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, `.y.com` matches `x.y.com`, but not `y.com`. Use `*` to bypass the proxy for all destinations.

4. If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace that contains one or more additional CA certificates that are required for proxying HTTPS connections. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges these contents with the Red Hat Enterprise Linux CoreOS (RHCOS) trust bundle, and this config map is referenced in the `trustedCA` field of the **Proxy** object. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

5. Optional: The policy to determine the configuration of the **Proxy** object to reference the `user-ca-bundle` config map in the `trustedCA` field. The allowed values are `Proxyonly` and `Always`. Use `Proxyonly` to reference the `user-ca-bundle` config map only when `http/https` proxy is configured. Use `Always` to always reference the `user-ca-bundle` config map. The default value is `Proxyonly`.  

---

OpenShift Container Platform 4.14 Installing
**NOTE**

The installation program does not support the proxy `readinessEndpoints` field.

**NOTE**

If the installer times out, restart and then complete the deployment by using the `wait-for` command of the installer. For example:

```
$ ./openshift-install wait-for install-complete --log-level debug
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

**NOTE**

Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

**Additional resources**

- For more details about Accelerated Networking, see [Accelerated Networking for Microsoft Azure VMs](#).

## 7.9.9. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

**Prerequisites**

- You have configured an account with the cloud platform that hosts your cluster.
- You have the OpenShift Container Platform installation program and the pull secret for your cluster.
- You have an Azure subscription ID and tenant ID.
- If you are installing the cluster using a service principal, you have its application ID and password.
- If you are installing the cluster using a system-assigned managed identity, you have enabled it on the virtual machine that you will run the installation program from.
- If you are installing the cluster using a user-assigned managed identity, you have met these prerequisites:
  - You have its client ID.
You have assigned it to the virtual machine that you will run the installation program from.

Procedure

1. Optional: If you have run the installation program on this computer before, and want to use an alternative service principal or managed identity, go to the ~/.azure/ directory and delete the osServicePrincipal.json configuration file.
   Deleting this file prevents the installation program from automatically reusing subscription and authentication values from a previous installation.

2. Change to the directory that contains the installation program and initialize the cluster deployment:

   $ ./openshift-install create cluster --dir <installation_directory> \ 1
   --log-level=info 2

   1 For <installation_directory>, specify the location of your customized .install-config.yaml file.

   2 To view different installation details, specify warn, debug, or error instead of info.

   If the installation program cannot locate the osServicePrincipal.json configuration file from a previous installation, you are prompted for Azure subscription and authentication values.

3. Enter the following Azure parameter values for your subscription:

   - **azure subscription id** Enter the subscription ID to use for the cluster.

   - **azure tenant id** Enter the tenant ID.

4. Depending on the Azure identity you are using to deploy the cluster, do one of the following when prompted for the azure service principal client id

   - If you are using a service principal, enter its application ID.

   - If you are using a system-assigned managed identity, leave this value blank.

   - If you are using a user-assigned managed identity, specify its client ID.

5. Depending on the Azure identity you are using to deploy the cluster, do one of the following when prompted for the azure service principal client secret

   - If you are using a service principal, enter its password.

   - If you are using a system-assigned managed identity, leave this value blank.

   - If you are using a user-assigned managed identity, leave this value blank.

   If previously not detected, the installation program creates an osServicePrincipal.json configuration file and stores this file in the ~/.azure/ directory on your computer. This ensures that the installation program can load the profile when it is creating an OpenShift Container Platform cluster on the target platform.

Verification

When the cluster deployment completes successfully:
The terminal displays directions for accessing your cluster, including a link to the web console and credentials for the kubeadmin user.

Credential information also outputs to `<installation_directory>/.openshift_install.log`.

**IMPORTANT**

Do not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

Example output

```plaintext
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "password"
INFO Time elapsed: 36m22s
```

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

7.9.10. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.14. Download and install the new version of oc.

Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

**Procedure**

2. Select the architecture from the Product Variant drop-down list.

3. Select the appropriate version from the Version drop-down list.

4. Click Download Now next to the OpenShift v4.14 Linux Client entry and save the file.

5. Unpack the archive:

   ```
   $ tar xvf <file>
   ```

6. Place the `oc` binary in a directory that is on your PATH.
   To check your PATH, execute the following command:

   ```
   $ echo $PATH
   ```

**Verification**

- After you install the OpenShift CLI, it is available using the `oc` command:

   ```
   $ oc <command>
   ```

**Installing the OpenShift CLI on Windows**

You can install the OpenShift CLI (`oc`) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version from the Version drop-down list.

3. Click Download Now next to the OpenShift v4.14 Windows Client entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the `oc` binary to a directory that is on your PATH.
   To check your PATH, open the command prompt and execute the following command:

   ```
   C:\> path
   ```

**Verification**

- After you install the OpenShift CLI, it is available using the `oc` command:

   ```
   C:\> oc <command>
   ```

**Installing the OpenShift CLI on macOS**

You can install the OpenShift CLI (`oc`) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version from the Version drop-down list.

3. Click Download Now next to the OpenShift v4.14 macOS Client entry and save the file.

   **NOTE**
   For macOS arm64, choose the OpenShift v4.14 macOS arm64 Client entry.

4. Unpack and unzip the archive.

5. Move the oc binary to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:
   ```
   $ echo $PATH
   ```

**Verification**

- After you install the OpenShift CLI, it is available using the oc command:
  ```
  $ oc <command>
  ```

**7.9.11. Logging in to the cluster by using the CLI**

You can log in to your cluster as a default system user by exporting the cluster kubeconfig file. The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the oc CLI.

**Procedure**

1. Export the kubeadmin credentials:

   ```
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   **Example output**
   -

2. Verify you can run oc commands successfully using the exported configuration:

   ```
   $ oc whoami
   ```

   **Example output**
   -
7.9.12. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.14, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager Hybrid Cloud Console.

After you confirm that your OpenShift Cluster Manager Hybrid Cloud Console inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

7.9.13. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.

7.10. INSTALLING A CLUSTER ON AZURE IN A RESTRICTED NETWORK WITH USER-PROVISIONED INFRASTRUCTURE

In OpenShift Container Platform, you can install a cluster on Microsoft Azure by using infrastructure that you provide.

Several Azure Resource Manager (ARM) templates are provided to assist in completing these steps or to help model your own.

**IMPORTANT**

The steps for performing a user-provisioned infrastructure installation are provided as an example only. Installing a cluster with infrastructure you provide requires knowledge of the cloud provider and the installation process of OpenShift Container Platform. Several ARM templates are provided to assist in completing these steps or to help model your own. You are also free to create the required resources through other methods.

**Prerequisites**

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You read the documentation on selecting a cluster installation method and preparing it for users.
- You configured an Azure account to host the cluster and determined the tested and validated region to deploy the cluster to.

- You mirrored the images for a disconnected installation to your registry and obtained the imageContentSources data for your version of OpenShift Container Platform.

**IMPORTANT**

Because the installation media is on the mirror host, you must use that computer to complete all installation steps.

- If you use a firewall, you configured it to allow the sites that your cluster requires access to.

- If the cloud identity and access management (IAM) APIs are not accessible in your environment, or if you do not want to store an administrator-level credential secret in the kube-system namespace, you have manually created long-term credentials.

- If you use customer-managed encryption keys, you prepared your Azure environment for encryption.

### 7.10.1. About installations in restricted networks

In OpenShift Container Platform 4.14, you can perform an installation that does not require an active connection to the internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service’s Route 53 DNS and IAM services, require internet access. Depending on your network, you might require less internet access for an installation on bare metal hardware, Nutanix, or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift image registry and contains the installation media. You can create this registry on a mirror host, which can access both the internet and your closed network, or by using other methods that meet your restrictions.

**IMPORTANT**

Because of the complexity of the configuration for user-provisioned installations, consider completing a standard user-provisioned infrastructure installation before you attempt a restricted network installation using user-provisioned infrastructure. Completing this test installation might make it easier to isolate and troubleshoot any issues that might arise during your installation in a restricted network.

### 7.10.1.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The ClusterVersion status includes an Unable to retrieve available updates error.

- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.
7.10.1.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.14, you require access to the internet to install your cluster.

You must have internet access to:

- Access OpenShift Cluster Manager Hybrid Cloud Console to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- Access Quay.io to obtain the packages that are required to install your cluster.

- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the required content and use it to populate a mirror registry with the installation packages. With some installation types, the environment that you install your cluster in will not require internet access. Before you update the cluster, you update the content of the mirror registry.

7.10.2. Configuring your Azure project

Before you can install OpenShift Container Platform, you must configure an Azure project to host it.

**IMPORTANT**

All Azure resources that are available through public endpoints are subject to resource name restrictions, and you cannot create resources that use certain terms. For a list of terms that Azure restricts, see Resolve reserved resource name errors in the Azure documentation.

7.10.2.1. Azure account limits

The OpenShift Container Platform cluster uses a number of Microsoft Azure components, and the default Azure subscription and service limits, quotas, and constraints affect your ability to install OpenShift Container Platform clusters.

**IMPORTANT**

Default limits vary by offer category types, such as Free Trial and Pay-As-You-Go, and by series, such as Dv2, F, and G. For example, the default for Enterprise Agreement subscriptions is 350 cores.

Check the limits for your subscription type and if necessary, increase quota limits for your account before you install a default cluster on Azure.

The following table summarizes the Azure components whose limits can impact your ability to install and run OpenShift Container Platform clusters.
<table>
<thead>
<tr>
<th>Component</th>
<th>Number of components required by default</th>
<th>Default Azure limit</th>
<th>Description</th>
</tr>
</thead>
</table>
| vCPU               | 44                                       | 20 per region      | A default cluster requires 44 vCPUs, so you must increase the account limit. By default, each cluster creates the following instances:  
  - One bootstrap machine, which is removed after installation  
  - Three control plane machines  
  - Three compute machines  
  Because the bootstrap and control plane machines use **Standard_D8s_v3** virtual machines, which use 8 vCPUs, and the compute machines use **Standard_D4s_v3** virtual machines, which use 4 vCPUs, a default cluster requires 44 vCPUs. The bootstrap node VM, which uses 8 vCPUs, is used only during installation.  
  To deploy more worker nodes, enable autoscaling, deploy large workloads, or use a different instance type, you must further increase the vCPU limit for your account to ensure that your cluster can deploy the machines that you require. |
<p>| OS Disk            | 7                                        |                    | Each cluster machine must have a minimum of 100 GB of storage and 300 IOPS. While these are the minimum supported values, faster storage is recommended for production clusters and clusters with intensive workloads. For more information about optimizing storage for performance, see the page titled &quot;Optimizing storage&quot; in the &quot;Scalability and performance&quot; section. |
| VNet               | 1                                        | 1000 per region    | Each default cluster requires one Virtual Network (VNet), which contains two subnets.                                                                                                                                                                                                                                                      |
