OpenShift Container Platform 4.15

Monitoring

Configuring and using the monitoring stack in OpenShift Container Platform
Configuring and using the monitoring stack in OpenShift Container Platform
Abstract

This document provides instructions for configuring and using the Prometheus monitoring stack in OpenShift Container Platform.

1.1. ABOUT OPENSHIFT CONTAINER PLATFORM MONITORING

OpenShift Container Platform includes a preconfigured, preinstalled, and self-updating monitoring stack that provides monitoring for core platform components. You also have the option to enable monitoring for user-defined projects.

A cluster administrator can configure the monitoring stack with the supported configurations. OpenShift Container Platform delivers monitoring best practices out of the box.

A set of alerts are included by default that immediately notify administrators about issues with a cluster. Default dashboards in the OpenShift Container Platform web console include visual representations of cluster metrics to help you to quickly understand the state of your cluster. With the OpenShift Container Platform web console, you can view and manage metrics, alerts, and review monitoring dashboards.

In the Observe section of OpenShift Container Platform web console, you can access and manage monitoring features such as metrics, alerts, monitoring dashboards, and metrics targets.

After installing OpenShift Container Platform, cluster administrators can optionally enable monitoring for user-defined projects. By using this feature, cluster administrators, developers, and other users can specify how services and pods are monitored in their own projects. As a cluster administrator, you can find answers to common problems such as user metrics unavailability and high consumption of disk space by Prometheus in Troubleshooting monitoring issues.

1.2. UNDERSTANDING THE MONITORING STACK

The OpenShift Container Platform monitoring stack is based on the Prometheus open source project and its wider ecosystem. The monitoring stack includes the following:

- **Default platform monitoring components.** A set of platform monitoring components are installed in the openshift-monitoring project by default during an OpenShift Container Platform installation. This provides monitoring for core cluster components including Kubernetes services. The default monitoring stack also enables remote health monitoring for clusters.
  These components are illustrated in the Installed by default section in the following diagram.

- **Components for monitoring user-defined projects** After optionally enabling monitoring for user-defined projects, additional monitoring components are installed in the openshift-user-workload-monitoring project. This provides monitoring for user-defined projects. These components are illustrated in the User section in the following diagram.
1.2.1. Default monitoring components

By default, the OpenShift Container Platform 4.15 monitoring stack includes these components:

**Table 1.1. Default monitoring stack components**

<table>
<thead>
<tr>
<th>Component</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cluster Monitoring Operator</td>
<td>The Cluster Monitoring Operator (CMO) is a central component of the monitoring stack. It deploys, manages, and automatically updates Prometheus and Alertmanager instances, Thanos Querier, Telemeter Client, and metrics targets. The CMO is deployed by the Cluster Version Operator (CVO).</td>
</tr>
<tr>
<td>Component</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td>Prometheus Operator</td>
<td>The Prometheus Operator (PO) in the openshift-monitoring project creates, configures, and manages platform Prometheus instances and Alertmanager instances. It also automatically generates monitoring target configurations based on Kubernetes label queries.</td>
</tr>
<tr>
<td>Prometheus</td>
<td>Prometheus is the monitoring system on which the OpenShift Container Platform monitoring stack is based. Prometheus is a time-series database and a rule evaluation engine for metrics. Prometheus sends alerts to Alertmanager for processing.</td>
</tr>
<tr>
<td>Prometheus Adapter</td>
<td>The Prometheus Adapter (PA in the preceding diagram) translates Kubernetes node and pod queries for use in Prometheus. The resource metrics that are translated include CPU and memory utilization metrics. The Prometheus Adapter exposes the cluster resource metrics API for horizontal pod autoscaling. The Prometheus Adapter is also used by the <code>oc adm top nodes</code> and <code>oc adm top pods</code> commands.</td>
</tr>
<tr>
<td>Metrics Server (Technology Preview)</td>
<td>If enabled, the Metrics Server component collects resource metrics and exposes them in the <code>metrics.k8s.io</code> Metrics API service for use by other tools and APIs, which frees the core platform Prometheus stack from handling this functionality. The Technology Preview of the Metrics Server component is automatically installed instead of Prometheus Adapter if you configure the <code>FeatureGate</code> custom resource with the <code>TechPreviewNoUpgrade</code> option. For more information about the support scope of Red Hat Technology Preview features, see Technology Preview Features Support Scope.</td>
</tr>
<tr>
<td>Alertmanager</td>
<td>The Alertmanager service handles alerts received from Prometheus. Alertmanager is also responsible for sending the alerts to external notification systems.</td>
</tr>
<tr>
<td>kube-state-metrics agent</td>
<td>The kube-state-metrics exporter agent (KSM in the preceding diagram) converts Kubernetes objects to metrics that Prometheus can use.</td>
</tr>
</tbody>
</table>
The monitoring-plugin dynamic plugin component deploys the monitoring pages in the **Observe** section of the OpenShift Container Platform web console. You can use Cluster Monitoring Operator (CMO) config map settings to manage monitoring-plugin resources for the web console pages.

The openshift-state-metrics exporter (OSM in the preceding diagram) expands upon kube-state-metrics by adding metrics for OpenShift Container Platform-specific resources.

The node-exporter agent (NE in the preceding diagram) collects metrics about every node in a cluster. The node-exporter agent is deployed on every node.

Thanos Querier aggregates and optionally deduplicates core OpenShift Container Platform metrics and metrics for user-defined projects under a single, multi-tenant interface.

Telemeter Client sends a subsection of the data from platform Prometheus instances to Red Hat to facilitate Remote Health Monitoring for clusters.

All of the components in the monitoring stack are monitored by the stack and are automatically updated when OpenShift Container Platform is updated.

**NOTE**

All components of the monitoring stack use the TLS security profile settings that are centrally configured by a cluster administrator. If you configure a monitoring stack component that uses TLS security settings, the component uses the TLS security profile settings that already exist in the `tlsSecurityProfile` field in the global OpenShift Container Platform `apiservers.config.openshift.io/cluster` resource.

### 1.2.2. Default monitoring targets

In addition to the components of the stack itself, the default monitoring stack monitors:

- CoreDNS
- Elasticsearch (if Logging is installed)
- etcd
- Fluentd (if Logging is installed)
• HAProxy
• Image registry
• Kubelets
• Kubernetes API server
• Kubernetes controller manager
• Kubernetes scheduler
• OpenShift API server
• OpenShift Controller Manager
• Operator Lifecycle Manager (OLM)
• Vector (if Logging is installed)

**NOTE**

Each OpenShift Container Platform component is responsible for its monitoring configuration. For problems with the monitoring of an OpenShift Container Platform component, open a Jira issue against that component, not against the general monitoring component.

Other OpenShift Container Platform framework components might be exposing metrics as well. For details, see their respective documentation.

### 1.2.3. Components for monitoring user-defined projects

OpenShift Container Platform includes an optional enhancement to the monitoring stack that enables you to monitor services and pods in user-defined projects. This feature includes the following components:

**Table 1.2. Components for monitoring user-defined projects**

<table>
<thead>
<tr>
<th>Component</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Prometheus Operator</td>
<td>The Prometheus Operator (PO) in the <code>openshift-user-workload-monitoring</code> project creates, configures, and manages Prometheus and Thanos Ruler instances in the same project.</td>
</tr>
<tr>
<td>Prometheus</td>
<td>Prometheus is the monitoring system through which monitoring is provided for user-defined projects. Prometheus sends alerts to Alertmanager for processing.</td>
</tr>
<tr>
<td>Component</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Thanos Ruler</td>
<td>The Thanos Ruler is a rule evaluation engine for Prometheus that is deployed as a separate process. In OpenShift Container Platform, Thanos Ruler provides rule and alerting evaluation for the monitoring of user-defined projects.</td>
</tr>
<tr>
<td>Alertmanager</td>
<td>The Alertmanager service handles alerts received from Prometheus and Thanos Ruler. Alertmanager is also responsible for sending user-defined alerts to external notification systems. Deploying this service is optional.</td>
</tr>
</tbody>
</table>

**NOTE**

The components in the preceding table are deployed after monitoring is enabled for user-defined projects.

All of these components are monitored by the stack and are automatically updated when OpenShift Container Platform is updated.

### 1.2.4. Monitoring targets for user-defined projects

When monitoring is enabled for user-defined projects, you can monitor:

- Metrics provided through service endpoints in user-defined projects.
- Pods running in user-defined projects.

### 1.3. GLOSSARY OF COMMON TERMS FOR OPENSIFT CONTAINER PLATFORM MONITORING

This glossary defines common terms that are used in OpenShift Container Platform architecture.

**Alertmanager**

Alertmanager handles alerts received from Prometheus. Alertmanager is also responsible for sending the alerts to external notification systems.

**Alerting rules**

Alerting rules contain a set of conditions that outline a particular state within a cluster. Alerts are triggered when those conditions are true. An alerting rule can be assigned a severity that defines how the alerts are routed.

**Cluster Monitoring Operator**

The Cluster Monitoring Operator (CMO) is a central component of the monitoring stack. It deploys and manages Prometheus instances such as, the Thanos Querier, the Telemeter Client, and metrics targets to ensure that they are up to date. The CMO is deployed by the Cluster Version Operator (CVO).

**Cluster Version Operator**

The Cluster Version Operator (CVO) manages the lifecycle of cluster Operators, many of which are installed in OpenShift Container Platform by default.
config map

A config map provides a way to inject configuration data into pods. You can reference the data stored in a config map in a volume of type ConfigMap. Applications running in a pod can use this data.

Container

A container is a lightweight and executable image that includes software and all its dependencies. Containers virtualize the operating system. As a result, you can run containers anywhere from a data center to a public or private cloud as well as a developer’s laptop.

custom resource (CR)

A CR is an extension of the Kubernetes API. You can create custom resources.

etcd

etcd is the key-value store for OpenShift Container Platform, which stores the state of all resource objects.

Fluentd

Fluentd gathers logs from nodes and feeds them to Elasticsearch.

Kubelets

Runs on nodes and reads the container manifests. Ensures that the defined containers have started and are running.

Kubernetes API server

Kubernetes API server validates and configures data for the API objects.

Kubernetes controller manager

Kubernetes controller manager governs the state of the cluster.

Kubernetes scheduler

Kubernetes scheduler allocates pods to nodes.

labels

Labels are key-value pairs that you can use to organize and select subsets of objects such as a pod.

node

A worker machine in the OpenShift Container Platform cluster. A node is either a virtual machine (VM) or a physical machine.

Operator

The preferred method of packaging, deploying, and managing a Kubernetes application in an OpenShift Container Platform cluster. An Operator takes human operational knowledge and encodes it into software that is packaged and shared with customers.

Operator Lifecycle Manager (OLM)

OLM helps you install, update, and manage the lifecycle of Kubernetes native applications. OLM is an open source toolkit designed to manage Operators in an effective, automated, and scalable way.

Persistent storage

Stores the data even after the device is shut down. Kubernetes uses persistent volumes to store the application data.

Persistent volume claim (PVC)

You can use a PVC to mount a PersistentVolume into a Pod. You can access the storage without knowing the details of the cloud environment.

pod

The pod is the smallest logical unit in Kubernetes. A pod is comprised of one or more containers to run in a worker node.
Prometheus

Prometheus is the monitoring system on which the OpenShift Container Platform monitoring stack is based. Prometheus is a time-series database and a rule evaluation engine for metrics. Prometheus sends alerts to Alertmanager for processing.

Prometheus adapter

The Prometheus Adapter translates Kubernetes node and pod queries for use in Prometheus. The resource metrics that are translated include CPU and memory utilization. The Prometheus Adapter exposes the cluster resource metrics API for horizontal pod autoscaling.

Prometheus Operator

The Prometheus Operator (PO) in the openshift-monitoring project creates, configures, and manages platform Prometheus and Alertmanager instances. It also automatically generates monitoring target configurations based on Kubernetes label queries.

Silences

A silence can be applied to an alert to prevent notifications from being sent when the conditions for an alert are true. You can mute an alert after the initial notification, while you work on resolving the underlying issue.

storage

OpenShift Container Platform supports many types of storage, both for on-premise and cloud providers. You can manage container storage for persistent and non-persistent data in an OpenShift Container Platform cluster.

Thanos Ruler

The Thanos Ruler is a rule evaluation engine for Prometheus that is deployed as a separate process. In OpenShift Container Platform, Thanos Ruler provides rule and alerting evaluation for the monitoring of user-defined projects.

web console

A user interface (UI) to manage OpenShift Container Platform.

1.4. ADDITIONAL RESOURCES

- [About remote health monitoring](#)
- [Granting users permission to monitor user-defined projects](#)
- [Configuring TLS security profiles](#)

1.5. NEXT STEPS

- [Configuring the monitoring stack](#)
CHAPTER 2. CONFIGURING THE MONITORING STACK

The OpenShift Container Platform 4 installation program provides only a low number of configuration options before installation. Configuring most OpenShift Container Platform framework components, including the cluster monitoring stack, happens postinstallation.

This section explains what configuration is supported, shows how to configure the monitoring stack, and demonstrates several common configuration scenarios.

2.1. PREREQUISITES

- The monitoring stack imposes additional resource requirements. Consult the computing resources recommendations in Scaling the Cluster Monitoring Operator and verify that you have sufficient resources.

2.2. MAINTENANCE AND SUPPORT FOR MONITORING

The supported way of configuring OpenShift Container Platform Monitoring is by configuring it using the options described in this document. Do not use other configurations, as they are unsupported. Configuration paradigms might change across Prometheus releases, and such cases can only be handled gracefully if all configuration possibilities are controlled. If you use configurations other than those described in this section, your changes will disappear because the cluster-monitoring-operator reconciles any differences. The Operator resets everything to the defined state by default and by design.

2.2.1. Support considerations for monitoring

The following modifications are explicitly not supported:

- Creating additional ServiceMonitor, PodMonitor, and PrometheusRule objects in the openshift-* and kube-* projects.

- Modifying any resources or objects deployed in the openshift-monitoring or openshift-user-workload-monitoring projects. The resources created by the OpenShift Container Platform monitoring stack are not meant to be used by any other resources, as there are no guarantees about their backward compatibility.

**NOTE**

The Alertmanager configuration is deployed as a secret resource in the openshift-monitoring namespace. If you have enabled a separate Alertmanager instance for user-defined alert routing, an Alertmanager configuration is also deployed as a secret resource in the openshift-user-workload-monitoring namespace. To configure additional routes for any instance of Alertmanager, you need to decode, modify, and then encode that secret. This procedure is a supported exception to the preceding statement.

- Modifying resources of the stack. The OpenShift Container Platform monitoring stack ensures its resources are always in the state it expects them to be. If they are modified, the stack will reset them.

- Deploying user-defined workloads to openshift-* and kube-* projects. These projects are reserved for Red Hat provided components and they should not be used for user-defined workloads.
- Enabling symptom based monitoring by using the **Probe** custom resource definition (CRD) in Prometheus Operator.

**NOTE**

Backward compatibility for metrics, recording rules, or alerting rules is not guaranteed.

- Installing custom Prometheus instances on OpenShift Container Platform. A custom instance is a Prometheus custom resource (CR) managed by the Prometheus Operator.

### 2.2.2. Support policy for monitoring Operators

Monitoring Operators ensure that OpenShift Container Platform monitoring resources function as designed and tested. If Cluster Version Operator (CVO) control of an Operator is overridden, the Operator does not respond to configuration changes, reconcile the intended state of cluster objects, or receive updates.

While overriding CVO control for an Operator can be helpful during debugging, this is unsupported and the cluster administrator assumes full control of the individual component configurations and upgrades.

**Overriding the Cluster Version Operator**

The `spec.overrides` parameter can be added to the configuration for the CVO to allow administrators to provide a list of overrides to the behavior of the CVO for a component. Setting the `spec.overrides[].unmanaged` parameter to `true` for a component blocks cluster upgrades and alerts the administrator after a CVO override has been set:

```plaintext
Disabling ownership via cluster version overrides prevents upgrades. Please remove overrides before continuing.
```

**WARNING**

Setting a CVO override puts the entire cluster in an unsupported state and prevents the monitoring stack from being reconciled to its intended state. This impacts the reliability features built into Operators and prevents updates from being received. Reported issues must be reproduced after removing any overrides for support to proceed.

### 2.3. PREPARING TO CONFIGURE THE MONITORING STACK

You can configure the monitoring stack by creating and updating monitoring config maps.

#### 2.3.1. Creating a cluster monitoring config map

To configure core OpenShift Container Platform monitoring components, you must create the `cluster-monitoring-config ConfigMap` object in the `openshift-monitoring` project.
When you save your changes to the `cluster-monitoring-config` ConfigMap object, some or all of the pods in the `openshift-monitoring` project might be redeployed. It can sometimes take a while for these components to redeploy.

**Prerequisites**

- You have access to the cluster as a user with the `cluster-admin` cluster role.
- You have installed the OpenShift CLI (`oc`).

**Procedure**

1. Check whether the `cluster-monitoring-config` ConfigMap object exists:

   ```bash
   $ oc -n openshift-monitoring get configmap cluster-monitoring-config
   ```

2. If the ConfigMap object does not exist:
   
   a. Create the following YAML manifest. In this example the file is called `cluster-monitoring-config.yaml`:

   ```yaml
   apiVersion: v1
   kind: ConfigMap
   metadata:
     name: cluster-monitoring-config
     namespace: openshift-monitoring
   data:
     config.yaml: |
   ```

   b. Apply the configuration to create the ConfigMap object:

   ```bash
   $ oc apply -f cluster-monitoring-config.yaml
   ```

### 2.3.2. Creating a user-defined workload monitoring config map

To configure the components that monitor user-defined projects, you must create the `user-workload-monitoring-config` ConfigMap object in the `openshift-user-workload-monitoring` project.

**NOTE**

When you save your changes to the `user-workload-monitoring-config` ConfigMap object, some or all of the pods in the `openshift-user-workload-monitoring` project might be redeployed. It can sometimes take a while for these components to redeploy. You can create and configure the config map before you first enable monitoring for user-defined projects, to prevent having to redeploy the pods often.

**Prerequisites**

- You have access to the cluster as a user with the `cluster-admin` cluster role.
- You have installed the OpenShift CLI (`oc`).
Procedure

1. Check whether the `user-workload-monitoring-config ConfigMap` object exists:

   ```
   $ oc -n openshift-user-workload-monitoring get configmap user-workload-monitoring-config
   ```

2. If the `user-workload-monitoring-config ConfigMap` object does not exist:
   a. Create the following YAML manifest. In this example the file is called `user-workload-monitoring-config.yaml`:
   ```yaml
   apiVersion: v1
   kind: ConfigMap
   metadata:
     name: user-workload-monitoring-config
     namespace: openshift-user-workload-monitoring
   data:
     config.yaml:
   ```
   b. Apply the configuration to create the `ConfigMap` object:
   ```
   $ oc apply -f user-workload-monitoring-config.yaml
   ```

   **NOTE**
   Configurations applied to the `user-workload-monitoring-config ConfigMap` object are not activated unless a cluster administrator has enabled monitoring for user-defined projects.

Additional resources

- [Enabling monitoring for user-defined projects](#)

2.4. CONFIGURING THE MONITORING STACK

In OpenShift Container Platform 4.15, you can configure the monitoring stack using the `cluster-monitoring-config` or `user-workload-monitoring-config ConfigMap` objects. Config maps configure the Cluster Monitoring Operator (CMO), which in turn configures the components of the stack.

Prerequisites

- **If you are configuring core OpenShift Container Platform monitoring components**
  - You have access to the cluster as a user with the `cluster-admin` cluster role.
  - You have created the `cluster-monitoring-config ConfigMap` object.

- **If you are configuring components that monitor user-defined projects**
  - You have access to the cluster as a user with the `cluster-admin` cluster role, or as a user with the `user-workload-monitoring-config-edit` role in the `openshift-user-workload-monitoring` project.
  - You have created the `user-workload-monitoring-config ConfigMap` object.
• You have installed the OpenShift CLI (oc).

Procedure

1. Edit the ConfigMap object.

   • To configure core OpenShift Container Platform monitoring components
      a. Edit the cluster-monitoring-config ConfigMap object in the openshift-monitoring project:

         $ oc -n openshift-monitoring edit configmap cluster-monitoring-config

      b. Add your configuration under data/config.yaml as a key-value pair
         <component_name>: <component_configuration>:

         apiVersion: v1
         kind: ConfigMap
         metadata:
          name: cluster-monitoring-config
          namespace: openshift-monitoring
         data:
          config.yaml: |
          <component>
           <configuration_for_the_component>

         Substitute <component> and <configuration_for_the_component> accordingly.

         The following example ConfigMap object configures a persistent volume claim (PVC) for Prometheus. This relates to the Prometheus instance that monitors core OpenShift Container Platform components only:

         apiVersion: v1
         kind: ConfigMap
         metadata:
          name: cluster-monitoring-config
          namespace: openshift-monitoring
         data:
          config.yaml: |
          prometheusK8s: 1
           volumeClaimTemplate:
            spec:
             storageClassName: fast
             volumeMode: Filesystem
             resources:
              requests:
               storage: 40Gi

         1 Defines the Prometheus component and the subsequent lines define its configuration.

   • To configure components that monitor user-defined projects
a. Edit the `user-workload-monitoring-config` **ConfigMap** object in the `openshift-user-workload-monitoring` project:

```
$ oc -n openshift-user-workload-monitoring edit configmap user-workload-monitoring-config
```

b. Add your configuration under `data/config.yaml` as a key-value pair `<component_name>: <component_configuration>`:

```yaml
apiVersion: v1
kind: ConfigMap
metadata:
  name: user-workload-monitoring-config
  namespace: openshift-user-workload-monitoring
data:
  config.yaml: |
    <component>: <configuration_for_the_component>
```

Substitute `<component>` and `<configuration_for_the_component>` accordingly.

The following example **ConfigMap** object configures a data retention period and minimum container resource requests for Prometheus. This relates to the Prometheus instance that monitors user-defined projects only:

```yaml
apiVersion: v1
kind: ConfigMap
metadata:
  name: user-workload-monitoring-config
  namespace: openshift-user-workload-monitoring
data:
  config.yaml: |
    prometheus:  
      retention: 24h  
      resources:  
        requests:  
          cpu: 200m  
          memory: 2Gi
```

1. Defines the Prometheus component and the subsequent lines define its configuration.

2. Configures a twenty-four hour data retention period for the Prometheus instance that monitors user-defined projects.

3. Defines a minimum resource request of 200 millicores for the Prometheus container.

4. Defines a minimum pod resource request of 2 GiB of memory for the Prometheus container.
The Prometheus config map component is called `prometheusK8s` in the `cluster-monitoring-config` ConfigMap object and `prometheus` in the `user-workload-monitoring-config` ConfigMap object.

2. Save the file to apply the changes to the ConfigMap object. The pods affected by the new configuration are restarted automatically.

**NOTE**

Configurations applied to the `user-workload-monitoring-config` ConfigMap object are not activated unless a cluster administrator has enabled monitoring for user-defined projects.

**WARNING**

When changes are saved to a monitoring config map, the pods and other resources in the related project might be redeployed. The running monitoring processes in that project might also be restarted.

Additional resources

- Configuration reference for the `cluster-monitoring-config` config map
- Configuration reference for the `user-workload-monitoring-config` config map
- See [Preparing to configure the monitoring stack](#) for steps to create monitoring config maps
- Enabling monitoring for user-defined projects

### 2.5. CONFIGURABLE MONITORING COMPONENTS

This table shows the monitoring components you can configure and the keys used to specify the components in the `cluster-monitoring-config` and `user-workload-monitoring-config` ConfigMap objects.

<table>
<thead>
<tr>
<th>Component</th>
<th>cluster-monitoring-config config map key</th>
<th>user-workload-monitoring-config config map key</th>
</tr>
</thead>
<tbody>
<tr>
<td>Prometheus Operator</td>
<td><code>prometheusOperator</code></td>
<td><code>prometheusOperator</code></td>
</tr>
<tr>
<td>Prometheus</td>
<td><code>prometheusK8s</code></td>
<td><code>prometheus</code></td>
</tr>
<tr>
<td>Alertmanager</td>
<td><code>alertmanagerMain</code></td>
<td><code>alertmanager</code></td>
</tr>
</tbody>
</table>
### 2.6. USING NODE SELECTORS TO MOVE MONITORING COMPONENTS

By using the `nodeSelector` constraint with labeled nodes, you can move any of the monitoring stack components to specific nodes. By doing so, you can control the placement and distribution of the monitoring components across a cluster.

By controlling placement and distribution of monitoring components, you can optimize system resource use, improve performance, and segregate workloads based on specific requirements or policies.

#### 2.6.1. How node selectors work with other constraints

If you move monitoring components by using node selector constraints, be aware that other constraints to control pod scheduling might exist for a cluster:

- Topology spread constraints might be in place to control pod placement.
- Hard anti-affinity rules are in place for Prometheus, Thanos Querier, Alertmanager, and other monitoring components to ensure that multiple pods for these components are always spread across different nodes and are therefore always highly available.

When scheduling pods onto nodes, the pod scheduler tries to satisfy all existing constraints when determining pod placement. That is, all constraints compound when the pod scheduler determines which pods will be placed on which nodes.

Therefore, if you configure a node selector constraint but existing constraints cannot all be satisfied, the pod scheduler cannot match all constraints and will not schedule a pod for placement onto a node.
To maintain resilience and high availability for monitoring components, ensure that enough nodes are available and match all constraints when you configure a node selector constraint to move a component.

Additional resources

- Understanding how to update labels on nodes
- Placing pods on specific nodes using node selectors
- Placing pods relative to other pods using affinity and anti-affinity rules
- Controlling pod placement by using pod topology spread constraints
- Configuring pod topology spread constraints for monitoring
- Kubernetes documentation about node selectors

2.6.2. Moving monitoring components to different nodes

To specify the nodes in your cluster on which monitoring stack components will run, configure the `nodeSelector` constraint in the component’s `ConfigMap` object to match labels assigned to the nodes.

NOTE

You cannot add a node selector constraint directly to an existing scheduled pod.

Prerequisites

- If you are configuring core OpenShift Container Platform monitoring components
  - You have access to the cluster as a user with the `cluster-admin` cluster role.
  - You have created the `cluster-monitoring-config` ConfigMap object.
- If you are configuring components that monitor user-defined projects
  - You have access to the cluster as a user with the `cluster-admin` cluster role or as a user with the `user-workload-monitoring-config-edit` role in the `openshift-user-workload-monitoring` project.
  - You have created the `user-workload-monitoring-config` ConfigMap object.
- You have installed the OpenShift CLI (`oc`).

Procedure

1. If you have not done so yet, add a label to the nodes on which you want to run the monitoring components:

   ```
   $ oc label nodes <node-name> <node-label>
   ```

2. Edit the `ConfigMap` object:

   - To move a component that monitors core OpenShift Container Platform projects
a. Edit the `cluster-monitoring-config ConfigMap` object in the `openshift-monitoring` project:

```
$ oc -n openshift-monitoring edit configmap cluster-monitoring-config
```

b. Specify the node labels for the `nodeSelector` constraint for the component under `data/config.yaml`:

```
apiVersion: v1
kind: ConfigMap
metadata:
  name: cluster-monitoring-config
  namespace: openshift-monitoring
data:
  config.yaml: |
    <component>: 1
    nodeSelector:
      <node-label-1>: 2
      <node-label-2>: 3
      ...
```

1. Substitute `<component>` with the appropriate monitoring stack component name.
2. Substitute `<node-label>` with the label you added to the node.
3. Optional: Specify additional labels. If you specify additional labels, the pods for the component are only scheduled on the nodes that contain all of the specified labels.

**NOTE**

If monitoring components remain in a `Pending` state after configuring the `nodeSelector` constraint, check the pod events for errors relating to taints and tolerations.

- **To move a component that monitors user-defined projects**

a. Edit the `user-workload-monitoring-config ConfigMap` object in the `openshift-user-workload-monitoring` project:

```
$ oc -n openshift-user-workload-monitoring edit configmap user-workload-monitoring-config
```

b. Specify the node labels for the `nodeSelector` constraint for the component under `data/config.yaml`:

```
apiVersion: v1
kind: ConfigMap
metadata:
  name: user-workload-monitoring-config
  namespace: openshift-user-workload-monitoring
data:
  config.yaml: |
    <component>: 1
```

1. Substitute `<component>` with the appropriate monitoring stack component name.
nodeSelector:
  <node-label-1> 2
  <node-label-2> 3
  <...>

1. Substitute <component> with the appropriate monitoring stack component name.
2. Substitute <node-label-1> with the label you added to the node.
3. Optional: Specify additional labels. If you specify additional labels, the pods for the component are only scheduled on the nodes that contain all of the specified labels.

**NOTE**

If monitoring components remain in a Pending state after configuring the nodeSelector constraint, check the pod events for errors relating to taints and tolerations.

3. Save the file to apply the changes. The components specified in the new configuration are moved to the new nodes automatically.

**NOTE**

Configurations applied to the user-workload-monitoring-config ConfigMap object are not activated unless a cluster administrator has enabled monitoring for user-defined projects.

**WARNING**

When you save changes to a monitoring config map, the pods and other resources in the project might be redeployed. The running monitoring processes in that project might also restart.

Additional resources

- See Preparing to configure the monitoring stack for steps to create monitoring config maps
- Enabling monitoring for user-defined projects
- Understanding how to update labels on nodes
- Placing pods on specific nodes using node selectors
- See the Kubernetes documentation for details on the nodeSelector constraint

2.7. ASSIGNING TOLERATIONS TO MONITORING COMPONENTS
You can assign tolerations to any of the monitoring stack components to enable moving them to tainted nodes.

Prerequisites

- **If you are configuring core OpenShift Container Platform monitoring components**
  - You have access to the cluster as a user with the `cluster-admin` cluster role.
  - You have created the `cluster-monitoring-config` ConfigMap object.

- **If you are configuring components that monitor user-defined projects**
  - You have access to the cluster as a user with the `cluster-admin` cluster role, or as a user with the `user-workload-monitoring-config-edit` role in the `openshift-user-workload-monitoring` project.
  - You have created the `user-workload-monitoring-config` ConfigMap object.

- You have installed the OpenShift CLI (oc).

Procedure

1. Edit the ConfigMap object:

   - **To assign tolerations to a component that monitors core OpenShift Container Platform projects:**
     a. Edit the `cluster-monitoring-config` ConfigMap object in the `openshift-monitoring` project:

        ```bash
        $ oc -n openshift-monitoring edit configmap cluster-monitoring-config
        ```

     b. Specify `tolerations` for the component:

        ```yaml
        apiVersion: v1
        kind: ConfigMap
        metadata:
          name: cluster-monitoring-config
          namespace: openshift-monitoring
        data:
          config.yaml: |
          <component>:
            tolerations:
              <toleration_specification>
        ```

        Substitute `<component>` and `<toleration_specification>` accordingly.

        For example, `oc adm taint nodes node1 key1=value1:NoSchedule` adds a taint to `node1` with the key `key1` and the value `value1`. This prevents monitoring components from deploying pods on `node1` unless a toleration is configured for that taint. The following example configures the `alertmanagerMain` component to tolerate the example taint:

        ```yaml
        apiVersion: v1
        kind: ConfigMap
        ```
To assign tolerations to a component that monitors user-defined projects:

a. Edit the `user-workload-monitoring-config ConfigMap` object in the `openshift-user-workload-monitoring` project:

   ```bash
   $ oc -n openshift-user-workload-monitoring edit configmap user-workload-monitoring-config
   ``

b. Specify `tolerations` for the component:

   ```yaml
   apiVersion: v1
   kind: ConfigMap
   metadata:
     name: user-workload-monitoring-config
     namespace: openshift-user-workload-monitoring
   data:
     config.yaml: |
     <component>:
       tolerations:<toleration_specification>
   ```

Substitute `<component>` and `<toleration_specification>` accordingly.

For example, `oc adm taint nodes node1 key1=value1:NoSchedule` adds a taint to `node1` with the key `key1` and the value `value1`. This prevents monitoring components from deploying pods on `node1` unless a toleration is configured for that taint. The following example configures the `thanosRuler` component to tolerate the example taint:

```yaml
apiVersion: v1
kind: ConfigMap
metadata:
  name: user-workload-monitoring-config
  namespace: openshift-user-workload-monitoring
data:
  config.yaml: |
  thanosRuler:
    tolerations:
      - key: "key1"
        operator: "Equal"
        value: "value1"
        effect: "NoSchedule"
```
2. Save the file to apply the changes. The new component placement configuration is applied automatically.

**NOTE**

Configurations applied to the `user-workload-monitoring-config ConfigMap` object are not activated unless a cluster administrator has enabled monitoring for user-defined projects.

**WARNING**

When changes are saved to a monitoring config map, the pods and other resources in the related project might be redeployed. The running monitoring processes in that project might also be restarted.

### Additional resources

- See [Preparing to configure the monitoring stack](#) for steps to create monitoring config maps
- [Enabling monitoring for user-defined projects](#)
- See the [OpenShift Container Platform documentation](#) on taints and tolerations
- See the [Kubernetes documentation](#) on taints and tolerations

### 2.8. SETTING THE BODY SIZE LIMIT FOR METRICS SCRAPING

By default, no limit exists for the uncompressed body size for data returned from scraped metrics targets. You can set a body size limit to help avoid situations in which Prometheus consumes excessive amounts of memory when scraped targets return a response that contains a large amount of data. In addition, by setting a body size limit, you can reduce the impact that a malicious target might have on Prometheus and on the cluster as a whole.

After you set a value for `enforcedBodySizeLimit`, the alert `PrometheusScrapeBodySizeLimitHit` fires when at least one Prometheus scrape target replies with a response body larger than the configured value.

**NOTE**

If metrics data scraped from a target has an uncompressed body size exceeding the configured size limit, the scrape fails. Prometheus then considers this target to be down and sets its `up` metric value to 0, which can trigger the `TargetDown` alert.

### Prerequisites

- You have access to the cluster as a user with the `cluster-admin` cluster role.
- You have installed the OpenShift CLI (oc).
Procedure

1. Edit the `cluster-monitoring-config` ConfigMap object in the `openshift-monitoring` namespace:

   ```bash
   $ oc -n openshift-monitoring edit configmap cluster-monitoring-config
   ```

2. Add a value for `enforcedBodySizeLimit` to `data/config.yaml/prometheusK8s` to limit the body size that can be accepted per target scrape:

   ```yaml
   apiVersion: v1
   kind: ConfigMap
   metadata:
     name: cluster-monitoring-config
     namespace: openshift-monitoring
   data:
     config.yaml: |
       prometheusK8s:
         enforcedBodySizeLimit: 40MB
   ```

   Specify the maximum body size for scraped metrics targets. This `enforcedBodySizeLimit` example limits the uncompressed size per target scrape to 40 megabytes. Valid numeric values use the Prometheus data size format: B (bytes), KB (kilobytes), MB (megabytes), GB (gigabytes), TB (terabytes), PB (petabytes), and EB (exabytes). The default value is 0, which specifies no limit. You can also set the value to `automatic` to calculate the limit automatically based on cluster capacity.

3. Save the file to apply the changes automatically.

   **WARNING**

   When you save changes to a `cluster-monitoring-config` config map, the pods and other resources in the `openshift-monitoring` project might be redeployed. The running monitoring processes in that project might also restart.

Additional resources

- Prometheus scrape configuration documentation

2.9. MANAGING CPU AND MEMORY RESOURCES FOR MONITORING COMPONENTS

You can ensure that the containers that run monitoring components have enough CPU and memory resources by specifying values for resource limits and requests for those components.

You can configure these limits and requests for core platform monitoring components in the `openshift-monitoring` namespace and for the components that monitor user-defined projects in the `openshift-user-workload-monitoring` namespace.
2.9.1. About specifying limits and requests for monitoring components

You can configure resource limits and request settings for core platform monitoring components and for the components that monitor user-defined projects, including the following components:

- Alertmanager (for core platform monitoring and for user-defined projects)
- kube-state-metrics
- monitoring-plugin
- node-exporter
- openshift-state-metrics
- Prometheus (for core platform monitoring and for user-defined projects)
- Prometheus Adapter
- Prometheus Operator and its admission webhook service
- Telemeter Client
- Thanos Querier
- Thanos Ruler

By defining resource limits, you limit a container’s resource usage, which prevents the container from exceeding the specified maximum values for CPU and memory resources.

By defining resource requests, you specify that a container can be scheduled only on a node that has enough CPU and memory resources available to match the requested resources.

2.9.2. Specifying limits and requests for monitoring components

To configure CPU and memory resources, specify values for resource limits and requests in the appropriate ConfigMap object for the namespace in which the monitoring component is located:

- The cluster-monitoring-config config map in the openshift-monitoring namespace for core platform monitoring
- The user-workload-monitoring-config config map in the openshift-user-workload-monitoring namespace for components that monitor user-defined projects

Prerequisites

- If you are configuring core platform monitoring components
  - You have access to the cluster as a user with the cluster-admin cluster role.
  - You have created a ConfigMap object named cluster-monitoring-config.
- If you are configuring components that monitor user-defined projects
  - You have access to the cluster as a user with the cluster-admin cluster role, or as a user with the user-workload-monitoring-config-edit role in the openshift-user-workload-monitoring project.
You have installed the OpenShift CLI (oc).

Procedure

1. To configure core platform monitoring components, edit the `cluster-monitoring-config` config map object in the `openshift-monitoring` namespace:

   ```bash
   $ oc -n openshift-monitoring edit configmap cluster-monitoring-config
   ```

2. Add values to define resource limits and requests for each core platform monitoring component you want to configure.

   **IMPORTANT**

   Make sure that the value set for a limit is always higher than the value set for a request. Otherwise, an error will occur, and the container will not run.

Example

```yaml
apiVersion: v1
kind: ConfigMap
metadata:
  name: cluster-monitoring-config
  namespace: openshift-monitoring
data:
config.yaml: |
  alertmanagerMain:
    resources:
      limits:
        cpu: 500m
        memory: 1Gi
      requests:
        cpu: 200m
        memory: 500Mi

  prometheusK8s:
    resources:
      limits:
        cpu: 500m
        memory: 3Gi
      requests:
        cpu: 200m
        memory: 500Mi

  prometheusOperator:
    resources:
      limits:
        cpu: 500m
        memory: 1Gi
      requests:
        cpu: 200m
        memory: 500Mi

  k8sPrometheusAdapter:
    resources:
      limits:
        cpu: 500m
```
memory: 1Gi
requests:
cpu: 200m
memory: 500Mi
kubeStateMetrics:
resources:
limits:
cpu: 500m
memory: 1Gi
requests:
cpu: 200m
memory: 500Mi
telemeterClient:
resources:
limits:
cpu: 500m
memory: 1Gi
requests:
cpu: 200m
memory: 500Mi
openshiftStateMetrics:
resources:
limits:
cpu: 500m
memory: 1Gi
requests:
cpu: 200m
memory: 500Mi
thanosQuerier:
resources:
limits:
cpu: 500m
memory: 1Gi
requests:
cpu: 200m
memory: 500Mi
nodeExporter:
resources:
limits:
cpu: 50m
memory: 150Mi
requests:
cpu: 20m
memory: 50Mi
monitoringPlugin:
resources:
limits:
cpu: 500m
memory: 1Gi
requests:
cpu: 200m
memory: 500Mi
prometheusOperatorAdmissionWebhook:
resources:
limits:
cpu: 50m
3. Save the file to apply the changes automatically.

**IMPORTANT**

When you save changes to the `cluster-monitoring-config` config map, the pods and other resources in the `openshift-monitoring` project might be redeployed. The running monitoring processes in that project might also restart.

Additional resources

- Kubernetes requests and limits documentation

### 2.10. CONFIGURING PERSISTENT STORAGE

Running cluster monitoring with persistent storage means that your metrics are stored to a persistent volume (PV) and can survive a pod being restarted or recreated. This is ideal if you require your metrics or alerting data to be guarded from data loss. For production environments, it is highly recommended to configure persistent storage. Because of the high IO demands, it is advantageous to use local storage.

#### 2.10.1. Persistent storage prerequisites

- Dedicate sufficient local persistent storage to ensure that the disk does not become full. How much storage you need depends on the number of pods.

- Verify that you have a persistent volume (PV) ready to be claimed by the persistent volume claim (PVC), one PV for each replica. Because Prometheus and Alertmanager both have two replicas, you need four PVs to support the entire monitoring stack. The PVs are available from the Local Storage Operator, but not if you have enabled dynamically provisioned storage.

- Use **Filesystem** as the storage type value for the `volumeMode` parameter when you configure the persistent volume.

**NOTE**

If you use a local volume for persistent storage, do not use a raw block volume, which is described with `volumeMode: Block` in the `LocalVolume` object. Prometheus cannot use raw block volumes.

**IMPORTANT**

Prometheus does not support file systems that are not POSIX compliant. For example, some NFS file system implementations are not POSIX compliant. If you want to use an NFS file system for storage, verify with the vendor that their NFS implementation is fully POSIX compliant.

#### 2.10.2. Configuring a local persistent volume claim
For monitoring components to use a persistent volume (PV), you must configure a persistent volume claim (PVC).

**Prerequisites**

- **If you are configuring core OpenShift Container Platform monitoring components**
  - You have access to the cluster as a user with the `cluster-admin` cluster role.
  - You have created the `cluster-monitoring-config` ConfigMap object.

- **If you are configuring components that monitor user-defined projects**
  - You have access to the cluster as a user with the `cluster-admin` cluster role, or as a user with the `user-workload-monitoring-config-edit` role in the `openshift-user-workload-monitoring` project.
  - You have created the `user-workload-monitoring-config` ConfigMap object.
  - You have installed the OpenShift CLI (`oc`).

**Procedure**

1. Edit the ConfigMap object:

   - **To configure a PVC for a component that monitors core OpenShift Container Platform projects:**
     - a. Edit the `cluster-monitoring-config` ConfigMap object in the `openshift-monitoring` project:

       ```
       $ oc -n openshift-monitoring edit configmap cluster-monitoring-config
       ```

     - b. Add your PVC configuration for the component under `data/config.yaml`:

       ```
       apiVersion: v1
kind: ConfigMap
metadata:
  name: cluster-monitoring-config
  namespace: openshift-monitoring
data:
  config.yaml: |
  <component>:
    volumeClaimTemplate:
      spec:
        storageClassName: <storage_class>
        resources:
          requests:
            storage: <amount_of_storage>

See the Kubernetes documentation on PersistentVolumeClaims for information on how to specify `volumeClaimTemplate`.

The following example configures a PVC that claims local persistent storage for the Prometheus instance that monitors core OpenShift Container Platform components:
In the above example, the storage class created by the Local Storage Operator is called `local-storage`.

The following example configures a PVC that claims local persistent storage for Alertmanager:

```yaml
apiVersion: v1
kind: ConfigMap
metadata:
  name: cluster-monitoring-config
namespace: openshift-monitoring
data:
  config.yaml: |
    prometheusK8s:
      volumeClaimTemplate:
        spec:
          storageClassName: local-storage
          resources:
            requests:
              storage: 40Gi
```

In the above example, the storage class created by the Local Storage Operator is called `local-storage`.

The following example configures a PVC that claims local persistent storage for Alertmanager:

```yaml
apiVersion: v1
kind: ConfigMap
metadata:
  name: cluster-monitoring-config
namespace: openshift-monitoring
data:
  config.yaml: |
    alertmanagerMain:
      volumeClaimTemplate:
        spec:
          storageClassName: local-storage
          resources:
            requests:
              storage: 10Gi
```

- **To configure a PVC for a component that monitors user-defined projects**
  
  a. Edit the `user-workload-monitoring-config` ConfigMap object in the `openshift-user-workload-monitoring` project:

  ```bash
  $ oc -n openshift-user-workload-monitoring edit configmap user-workload-monitoring-config
  ```

  b. Add your PVC configuration for the component under `data/config.yaml`:

  ```yaml
  apiVersion: v1
  kind: ConfigMap
  metadata:
    name: user-workload-monitoring-config
  namespace: openshift-user-workload-monitoring
  data:
    config.yaml: |
    <component>:
      volumeClaimTemplate:
  ```
See the Kubernetes documentation on PersistentVolumeClaims for information on how to specify `volumeClaimTemplate`.

The following example configures a PVC that claims local persistent storage for the Prometheus instance that monitors user-defined projects:

```yaml
apiVersion: v1
kind: ConfigMap
metadata:
  name: user-workload-monitoring-config
  namespace: openshift-user-workload-monitoring
data:
  config.yaml: |
    prometheus:
      volumeClaimTemplate:
        spec:
          storageClassName: local-storage
          resources:
            requests:
              storage: 40Gi
```

In the above example, the storage class created by the Local Storage Operator is called `local-storage`.

The following example configures a PVC that claims local persistent storage for Thanos Ruler:

```yaml
apiVersion: v1
kind: ConfigMap
metadata:
  name: user-workload-monitoring-config
  namespace: openshift-user-workload-monitoring
data:
  config.yaml: |
    thanosRuler:
      volumeClaimTemplate:
        spec:
          storageClassName: local-storage
          resources:
            requests:
              storage: 10Gi
```

**NOTE**

Storage requirements for the `thanosRuler` component depend on the number of rules that are evaluated and how many samples each rule generates.
2. Save the file to apply the changes. The pods affected by the new configuration are restarted automatically and the new storage configuration is applied.

**NOTE**
Configurations applied to the `user-workload-monitoring-config` ConfigMap object are not activated unless a cluster administrator has enabled monitoring for user-defined projects.

### 2.10.3. Resizing a persistent storage volume

OpenShift Container Platform does not support resizing an existing persistent storage volume used by `StatefulSet` resources, even if the underlying `StorageClass` resource used supports persistent volume sizing. Therefore, even if you update the `storage` field for an existing persistent volume claim (PVC) with a larger size, this setting will not be propagated to the associated persistent volume (PV).

However, resizing a PV is still possible by using a manual process. If you want to resize a PV for a monitoring component such as Prometheus, Thanos Ruler, or Alertmanager, you can update the appropriate config map in which the component is configured. Then, patch the PVC, and delete and orphan the pods. Orphaning the pods recreates the `StatefulSet` resource immediately and automatically updates the size of the volumes mounted in the pods with the new PVC settings. No service disruption occurs during this process.

**Prerequisites**

- You have installed the OpenShift CLI (`oc`).
- **If you are configuring core OpenShift Container Platform monitoring components**
  - You have access to the cluster as a user with the `cluster-admin` cluster role.
  - You have created the `cluster-monitoring-config` ConfigMap object.
  - You have configured at least one PVC for core OpenShift Container Platform monitoring components.
- **If you are configuring components that monitor user-defined projects**
  - You have access to the cluster as a user with the `cluster-admin` cluster role, or as a user with the `user-workload-monitoring-config-edit` role in the `openshift-user-workload-monitoring` project.
  - You have created the `user-workload-monitoring-config` ConfigMap object.
  - You have configured at least one PVC for components that monitor user-defined projects.

**Procedure**

1. Edit the `ConfigMap` object:
   - To resize a PVC for a component that monitors core OpenShift Container Platform projects:
     a. Edit the `cluster-monitoring-config` ConfigMap object in the `openshift-monitoring` project:
b. Add a new storage size for the PVC configuration for the component under `data/config.yaml`:

```
apiVersion: v1
kind: ConfigMap
metadata:
  name: cluster-monitoring-config
  namespace: openshift-monitoring
data:
  config.yaml: |
    <component>:
      volumeClaimTemplate:
        spec:
          storageClassName: <storage_class>
          resources:
            requests:
              storage: <amount_of_storage>
```

1. Specify the core monitoring component.
2. Specify the storage class.
3. Specify the new size for the storage volume.

The following example configures a PVC that sets the local persistent storage to 100 gigabytes for the Prometheus instance that monitors core OpenShift Container Platform components:

```
apiVersion: v1
kind: ConfigMap
metadata:
  name: cluster-monitoring-config
  namespace: openshift-monitoring
data:
  config.yaml: |
    prometheusK8s:
      volumeClaimTemplate:
        spec:
          storageClassName: local-storage
          resources:
            requests:
              storage: 100Gi
```

The following example configures a PVC that sets the local persistent storage for Alertmanager to 40 gigabytes:

```
apiVersion: v1
kind: ConfigMap
metadata:
  name: cluster-monitoring-config
  namespace: openshift-monitoring
data:
```
To resize a PVC for a component that monitors user-defined projects:

**NOTE**

You can resize the volumes for the Thanos Ruler and Prometheus instances that monitor user-defined projects.

a. Edit the `user-workload-monitoring-config` ConfigMap object in the `openshift-user-workload-monitoring` project:

```bash
$ oc -n openshift-user-workload-monitoring edit configmap user-workload-monitoring-config
```

b. Update the PVC configuration for the monitoring component under `data/config.yaml`:

```yaml
apiVersion: v1
kind: ConfigMap
metadata:
  name: user-workload-monitoring-config
  namespace: openshift-user-workload-monitoring
data:
  config.yaml:
    <component>:
      volumeClaimTemplate:
        spec:
          storageClassName: <storage_class>
          resources:
            requests:
              storage: <amount_of_storage>
```

1. Specify the core monitoring component.
2. Specify the storage class.
3. Specify the new size for the storage volume.

The following example configures the PVC size to 100 gigabytes for the Prometheus instance that monitors user-defined projects:

```yaml
apiVersion: v1
kind: ConfigMap
metadata:
  name: user-workload-monitoring-config
  namespace: openshift-user-workload-monitoring
```

CHAPTER 2. CONFIGURING THE MONITORING STACK

39
The following example sets the PVC size to 20 gigabytes for Thanos Ruler:

```yaml
apiVersion: v1
kind: ConfigMap
metadata:
  name: user-workload-monitoring-config
  namespace: openshift-user-workload-monitoring
data:
  config.yaml: |
    thanosRuler:
      volumeClaimTemplate:
        spec:
          storageClassName: local-storage
          resources:
            requests:
              storage: 20Gi
```

The following example sets the PVC to 20 gigabytes for Thanos Ruler:

```yaml
apiVersion: v1
kind: ConfigMap
metadata:
  name: user-workload-monitoring-config
  namespace: openshift-user-workload-monitoring
data:
  config.yaml: |
    prometheus:
      volumeClaimTemplate:
        spec:
          storageClassName: local-storage
          resources:
            requests:
              storage: 100Gi
```

2. Save the file to apply the changes. The pods affected by the new configuration restart automatically.

WARNING

When you save changes to a monitoring config map, the pods and other resources in the related project might be redeployed. The monitoring processes running in that project might also be restarted.

3. Manually patch every PVC with the updated storage request. The following example resizes the storage size for the Prometheus component in the `openshift-monitoring` namespace to 100Gi:

```bash
$ for p in $(oc -n openshift-monitoring get pvc -l app.kubernetes.io/name=prometheus -o jsonpath='{range .items[*]}{.metadata.name} {end}'); do \
oc -n openshift-monitoring patch pvc/$p --patch '"{}":{"resources":{"requests":
```
4. Delete the underlying StatefulSet with the `--cascade=orphan` parameter:

```
$ oc delete statefulset -l app.kubernetes.io/name=prometheus --cascade=orphan
```

### 2.10.4. Modifying the retention time and size for Prometheus metrics data

By default, Prometheus retains metrics data for the following durations:

- **Core platform monitoring**: 15 days
- **Monitoring for user-defined projects**: 24 hours

You can modify the retention time for Prometheus to change how soon the data is deleted. You can also set the maximum amount of disk space the retained metrics data uses. If the data reaches this size limit, Prometheus deletes the oldest data first until the disk space used is again below the limit.

Note the following behaviors of these data retention settings:

- The size-based retention policy applies to all data block directories in the `/prometheus` directory, including persistent blocks, write-ahead log (WAL) data, and m-mapped chunks.

- Data in the `/wal` and `/head_chunks` directories counts toward the retention size limit, but Prometheus never purges data from these directories based on size- or time-based retention policies. Thus, if you set a retention size limit lower than the maximum size set for the `/wal` and `/head_chunks` directories, you have configured the system not to retain any data blocks in the `/prometheus` data directories.

- The size-based retention policy is applied only when Prometheus cuts a new data block, which occurs every two hours after the WAL contains at least three hours of data.

- If you do not explicitly define values for either `retention` or `retentionSize`, retention time defaults to 15 days for core platform monitoring and 24 hours for user-defined project monitoring. Retention size is not set.

- If you define values for both `retention` and `retentionSize`, both values apply. If any data blocks exceed the defined retention time or the defined size limit, Prometheus purges these data blocks.

- If you define a value for `retentionSize` and do not define `retention`, only the `retentionSize` value applies.

- If you do not define a value for `retentionSize` and only define a value for `retention`, only the `retention` value applies.

- If you set the `retentionSize` or `retention` value to 0, the default settings apply. The default settings set retention time to 15 days for core platform monitoring and 24 hours for user-defined project monitoring. By default, retention size is not set.
NOTE

Data compaction occurs every two hours. Therefore, a persistent volume (PV) might fill up before compaction, potentially exceeding the retentionSize limit. In such cases, the KubePersistentVolumeFillingUp alert fires until the space on a PV is lower than the retentionSize limit.

Prerequisites

- If you are configuring core OpenShift Container Platform monitoring components
  - You have access to the cluster as a user with the cluster-admin cluster role.
  - You have created the cluster-monitoring-config ConfigMap object.
- If you are configuring components that monitor user-defined projects
  - A cluster administrator has enabled monitoring for user-defined projects.
  - You have access to the cluster as a user with the cluster-admin cluster role, or as a user with the user-workload-monitoring-config-edit role in the openshift-user-workload-monitoring project.
  - You have created the user-workload-monitoring-config ConfigMap object.
- You have installed the OpenShift CLI (oc).

Procedure

1. Edit the ConfigMap object:
   - To modify the retention time and size for the Prometheus instance that monitors core OpenShift Container Platform projects:
     a. Edit the cluster-monitoring-config ConfigMap object in the openshift-monitoring project:

     ```bash
     $ oc -n openshift-monitoring edit configmap cluster-monitoring-config
     ```

     b. Add the retention time and size configuration under data/config.yaml:

     ```yaml
     apiVersion: v1
     kind: ConfigMap
     metadata:
       name: cluster-monitoring-config
       namespace: openshift-monitoring
     data:
       config.yaml: |
       prometheusK8s:
         retention: <time_specification> ①
date: <size_specification> ②

     ① The retention time: a number directly followed by ms (milliseconds), s (seconds), m (minutes), h (hours), d (days), w (weeks), or y (years). You can also combine time values for specific times, such as 1h30m15s.
     ```
The retention size: a number directly followed by \( \text{B} \) (bytes), \( \text{KB} \) (kilobytes), \( \text{MB} \) (megabytes), \( \text{GB} \) (gigabytes), \( \text{TB} \) (terabytes), \( \text{PB} \) (petabytes), and \( \text{EB} \) (exabytes).

The following example sets the retention time to 24 hours and the retention size to 10 gigabytes for the Prometheus instance that monitors core OpenShift Container Platform components:

```yaml
apiVersion: v1
kind: ConfigMap
metadata:
  name: cluster-monitoring-config
  namespace: openshift-monitoring
data:
  config.yaml:
  prometheusK8s:
    retention: 24h
    retentionSize: 10GB
```

To modify the retention time and size for the Prometheus instance that monitors user-defined projects:

a. Edit the \textit{user-workload-monitoring-config} ConfigMap object in the \textit{openshift-user-workload-monitoring} project:

```bash
$ oc -n openshift-user-workload-monitoring edit configmap user-workload-monitoring-config
```

b. Add the retention time and size configuration under \texttt{data/config.yaml}:

```yaml
apiVersion: v1
kind: ConfigMap
metadata:
  name: user-workload-monitoring-config
  namespace: openshift-user-workload-monitoring
data:
  config.yaml:
  prometheus:
    retention: <time_specification>
    retentionSize: <size_specification>
```

1 The retention time: a number directly followed by \( \text{ms} \) (milliseconds), \( \text{s} \) (seconds), \( \text{m} \) (minutes), \( \text{h} \) (hours), \( \text{d} \) (days), \( \text{w} \) (weeks), or \( \text{y} \) (years). You can also combine time values for specific times, such as \( 1\text{h}30\text{m}15\text{s} \).

2 The retention size: a number directly followed by \( \text{B} \) (bytes), \( \text{KB} \) (kilobytes), \( \text{MB} \) (megabytes), \( \text{GB} \) (gigabytes), \( \text{TB} \) (terabytes), \( \text{PB} \) (petabytes), or \( \text{EB} \) (exabytes).

The following example sets the retention time to 24 hours and the retention size to 10 gigabytes for the Prometheus instance that monitors user-defined projects:

```yaml
apiVersion: v1
kind: ConfigMap
metadata:
```
Save the file to apply the changes. The pods affected by the new configuration restart automatically.

---

### WARNING

When changes are saved to a monitoring config map, the pods and other resources in the related project might be redeployed. The running monitoring processes in that project might also be restarted.

---

2.10.5. Modifying the retention time for Thanos Ruler metrics data

By default, for user-defined projects, Thanos Ruler automatically retains metrics data for 24 hours. You can modify the retention time to change how long this data is retained by specifying a time value in the `user-workload-monitoring-config` config map in the `openshift-user-workload-monitoring` namespace.

**Prerequisites**

- You have access to the cluster as a user with the `cluster-admin` cluster role or as a user with the `user-workload-monitoring-config-edit` role in the `openshift-user-workload-monitoring` project.
- A cluster administrator has enabled monitoring for user-defined projects.
- You have created the `user-workload-monitoring-config ConfigMap` object.
- You have installed the OpenShift CLI (`oc`).

**Procedure**

1. Edit the `user-workload-monitoring-config ConfigMap` object in the `openshift-user-workload-monitoring` project:

   ```bash
   $ oc -n openshift-user-workload-monitoring edit configmap user-workload-monitoring-config
   
   ```

2. Add the retention time configuration under `data/config.yaml`:

   ```yaml
   data:
     config.yaml:
       prometheus:
         retention: 24h
         retentionSize: 10GB
   ```
data:
  config.yaml:
    thanosRuler:
      retention: <time_specification>  

1 Specify the retention time in the following format: a number directly followed by ms (milliseconds), s (seconds), m (minutes), h (hours), d (days), w (weeks), or y (years). You can also combine time values for specific times, such as 1h30m15s. The default is 24h.

The following example sets the retention time to 10 days for Thanos Ruler data:

```yaml
apiVersion: v1
kind: ConfigMap
metadata:
  name: user-workload-monitoring-config
  namespace: openshift-user-workload-monitoring
data:
  config.yaml:
    thanosRuler:
      retention: 10d
```

3. Save the file to apply the changes. The pods affected by the new configuration automatically restart.

**WARNING**

Saving changes to a monitoring config map might restart monitoring processes and redeploy the pods and other resources in the related project. The running monitoring processes in that project might also restart.

Additional resources

- Creating a cluster monitoring config map

- Recommended configurable storage technology
- Understanding persistent storage
- Optimizing storage
- Configure local persistent storage
- Enabling monitoring for user-defined projects

### 2.11. Configuring Remote Write Storage
You can configure remote write storage to enable Prometheus to send ingested metrics to remote systems for long-term storage. Doing so has no impact on how or for how long Prometheus stores metrics.

**Prerequisites**

- **If you are configuring core OpenShift Container Platform monitoring components:**
  - You have access to the cluster as a user with the `cluster-admin` cluster role.
  - You have created the `cluster-monitoring-config` ConfigMap object.

- **If you are configuring components that monitor user-defined projects:**
  - You have access to the cluster as a user with the `cluster-admin` cluster role or as a user with the `user-workload-monitoring-config-edit` role in the `openshift-user-workload-monitoring` project.
  - You have created the `user-workload-monitoring-config` ConfigMap object.

- You have installed the OpenShift CLI (``oc``).

- You have set up a remote write compatible endpoint (such as Thanos) and know the endpoint URL. See the [Prometheus remote endpoints and storage documentation](#) for information about endpoints that are compatible with the remote write feature.

**IMPORTANT**

Red Hat only provides information for configuring remote write senders and does not offer guidance on configuring receiver endpoints. Customers are responsible for setting up their own endpoints that are remote-write compatible. Issues with endpoint receiver configurations are not included in Red Hat production support.

- You have set up authentication credentials in a `Secret` object for the remote write endpoint. You must create the secret in the same namespace as the Prometheus object for which you configure remote write: the `openshift-monitoring` namespace for default platform monitoring or the `openshift-user-workload-monitoring` namespace for user workload monitoring.

**WARNING**

To reduce security risks, use HTTPS and authentication to send metrics to an endpoint.

**Procedure**

1. Edit the ConfigMap object:

   - To configure remote write for the Prometheus instance that monitors core OpenShift Container Platform projects:
a. Edit the `cluster-monitoring-config ConfigMap` object in the `openshift-monitoring` project:

```
$ oc -n openshift-monitoring edit configmap cluster-monitoring-config
```

b. Add a `remoteWrite:` section under `data/config.yaml/prometheusK8s`.

c. Add an endpoint URL and authentication credentials in this section:

```yaml
apiVersion: v1
kind: ConfigMap
metadata:
  name: cluster-monitoring-config
  namespace: openshift-monitoring
data:
  config.yaml: |
    prometheusK8s: |
      remoteWrite: |
        - url: "https://remote-write-endpoint.example.com"  # 1
          <endpoint_authentication_credentials>  # 2
```

1. The URL of the remote write endpoint.

2. The authentication method and credentials for the endpoint. Currently supported authentication methods are AWS Signature Version 4, authentication using HTTP in an `Authorization` request header, Basic authentication, OAuth 2.0, and TLS client. See `Supported remote write authentication settings` for sample configurations of supported authentication methods.

d. Add write relabel configuration values after the authentication credentials:

```yaml
apiVersion: v1
kind: ConfigMap
metadata:
  name: cluster-monitoring-config
  namespace: openshift-monitoring
data:
  config.yaml: |
    prometheusK8s: |
      remoteWrite: |
        - url: "https://remote-write-endpoint.example.com"
          <endpoint_authentication_credentials>
          <your_write_relabel_configs>  # 1
```

1. The write relabel configuration settings.

For `<your_write_relabel_configs>` substitute a list of write relabel configurations for metrics that you want to send to the remote endpoint.

The following sample shows how to forward a single metric called `my_metric`:
To configure remote write for the Prometheus instance that monitors user-defined projects:

1. Edit the `user-workload-monitoring-config ConfigMap` object in the `openshift-user-workload-monitoring` project:

   ```
   $ oc -n openshift-user-workload-monitoring edit configmap user-workload-monitoring-config
   ```

2. Add a `remoteWrite:` section under `data/config.yaml/prometheus`.

3. Add an endpoint URL and authentication credentials in this section:

   ```yaml
   apiVersion: v1
   kind: ConfigMap
   metadata:
     name: user-workload-monitoring-config
     namespace: openshift-user-workload-monitoring
   data:
     config.yaml: |
     prometheusK8s:
       remoteWrite:
         - url: "https://remote-write-endpoint.example.com"
   ```

   1. The URL of the remote write endpoint.

   2. The authentication method and credentials for the endpoint. Currently supported authentication methods are AWS Signature Version 4, authentication using HTTP an `Authorization` request header, basic authentication, OAuth 2.0, and TLS client. See Supported remote write authentication settings below for sample configurations of supported authentication methods.

4. Add write relabel configuration values after the authentication credentials:

   ```yaml
   data:
     config.yaml: |
     prometheusK8s:
       remoteWrite:
         - sourceLabels: [__name__]
           regex: 'my_metric'
           action: keep
   ```
name: user-workload-monitoring-config
namespace: openshift-user-workload-monitoring
data:
  config.yaml: |
  prometheus:
    remoteWrite:
    - url: "https://remote-write-endpoint.example.com"
      <endpoint_authentication_credentials>
      <your_write_relabel_configs> 1

1 The write relabel configuration settings.

For `<your_write_relabel_configs>` substitute a list of write relabel configurations for metrics that you want to send to the remote endpoint.

The following sample shows how to forward a single metric called `my_metric`:

```yaml
apiVersion: v1
kind: ConfigMap
metadata:
  name: user-workload-monitoring-config
  namespace: openshift-user-workload-monitoring
data:
  config.yaml: |
  prometheus:
    remoteWrite:
    - url: "https://remote-write-endpoint.example.com"
      writeRelabelConfigs:
      - sourceLabels: [__name__]
        regex: 'my_metric'
        action: keep
```

See the Prometheus relabel_config documentation for information about write relabel configuration options.

2. Save the file to apply the changes. The pods affected by the new configuration restart automatically.

**NOTE**

Configurations applied to the **user-workload-monitoring-config** ConfigMap object are not activated unless a cluster administrator has enabled monitoring for user-defined projects.

**WARNING**

Saving changes to a monitoring **ConfigMap** object might redeploy the pods and other resources in the related project. Saving changes might also restart the running monitoring processes in that project.
2.11.1. Supported remote write authentication settings

You can use different methods to authenticate with a remote write endpoint. Currently supported authentication methods are AWS Signature Version 4, basic authentication, authorization, OAuth 2.0, and TLS client. The following table provides details about supported authentication methods for use with remote write.

<table>
<thead>
<tr>
<th>Authentication method</th>
<th>Config map field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWS Signature Version 4</td>
<td>sigv4</td>
<td>This method uses AWS Signature Version 4 authentication to sign requests. You cannot use this method simultaneously with authorization, OAuth 2.0, or Basic authentication.</td>
</tr>
<tr>
<td>Basic authentication</td>
<td>basicAuth</td>
<td>Basic authentication sets the authorization header on every remote write request with the configured username and password.</td>
</tr>
<tr>
<td>authorization</td>
<td>authorization</td>
<td>Authorization sets the Authorization header on every remote write request using the configured token.</td>
</tr>
<tr>
<td>OAuth 2.0</td>
<td>oauth2</td>
<td>An OAuth 2.0 configuration uses the client credentials grant type. Prometheus fetches an access token from <code>tokenUrl</code> with the specified client ID and client secret to access the remote write endpoint. You cannot use this method simultaneously with authorization, AWS Signature Version 4, or Basic authentication.</td>
</tr>
<tr>
<td>TLS client</td>
<td>tlsConfig</td>
<td>A TLS client configuration specifies the CA certificate, the client certificate, and the client key file information used to authenticate with the remote write endpoint server using TLS. The sample configuration assumes that you have already created a CA certificate file, a client certificate file, and a client key file.</td>
</tr>
</tbody>
</table>

2.11.2. Example remote write authentication settings

The following samples show different authentication settings you can use to connect to a remote write
Each sample also shows how to configure a corresponding Secret object that contains authentication credentials and other relevant settings. Each sample configures authentication for use with default platform monitoring in the openshift-monitoring namespace.

**Example 2.1. Sample YAML for AWS Signature Version 4 authentication**

The following shows the settings for a sigv4 secret named sigv4-credentials in the openshift-monitoring namespace.

```yaml
apiVersion: v1
kind: Secret
metadata:
  name: sigv4-credentials
  namespace: openshift-monitoring
stringData:
  accessKey: <AWS_access_key>
  secretKey: <AWS_secret_key>
type: Opaque
```

1. The AWS API access key.
2. The AWS API secret key.

The following shows sample AWS Signature Version 4 remote write authentication settings that use a Secret object named sigv4-credentials in the openshift-monitoring namespace:

```yaml
apiVersion: v1
kind: ConfigMap
metadata:
  name: cluster-monitoring-config
  namespace: openshift-monitoring
data:
  config.yaml: |
    prometheusK8s:
      remoteWrite:
        - url: "https://authorization.example.com/api/write"
          sigv4:
            region: <AWS_region>
            accessKey:
              name: sigv4-credentials
              key: accessKey
            secretKey:
              name: sigv4-credentials
              key: secretKey
            profile: <AWS_profile_name>
            roleArn: <AWS_role_arn>
```

1. The AWS region.
2, 4. The name of the Secret object containing the AWS API access credentials.
3. The key that contains the AWS API access key in the specified Secret object.
The key that contains the AWS API secret key in the specified Secret object.

The name of the AWS profile that is being used to authenticate.

The unique identifier for the Amazon Resource Name (ARN) assigned to your role.

Example 2.2. Sample YAML for basic authentication

The following shows sample basic authentication settings for a Secret object named rw-basic-auth in the openshift-monitoring namespace:

```yaml
apiVersion: v1
kind: Secret
metadata:
  name: rw-basic-auth
  namespace: openshift-monitoring
stringData:
  user: <basic_username>  # 1
  password: <basic_password>  # 2
type: Opaque
```

1. The username.
2. The password.

The following sample shows a basicAuth remote write configuration that uses a Secret object named rw-basic-auth in the openshift-monitoring namespace. It assumes that you have already set up authentication credentials for the endpoint.

```yaml
apiVersion: v1
kind: ConfigMap
metadata:
  name: cluster-monitoring-config
  namespace: openshift-monitoring
data:
  config.yaml: |
    prometheusK8s:
      remoteWrite:
        - url: "https://basicauth.example.com/api/write"
          basicAuth:
            username:
              name: rw-basic-auth  # 1
              key: user  # 2
            password:
              name: rw-basic-auth  # 3
              key: password  # 4
```

1. The name of the Secret object that contains the authentication credentials.
2. The key that contains the username in the specified Secret object.
3. The key that contains the password in the specified Secret object.
Example 2.3. Sample YAML for authentication with a bearer token using a Secret Object

The following shows bearer token settings for a Secret object named `rw-bearer-auth` in the `openshift-monitoring` namespace:

```yaml
apiVersion: v1
kind: Secret
metadata:
  name: rw-bearer-auth
  namespace: openshift-monitoring
stringData:
  token: <authentication_token>  
  type: Opaque
```

1. The authentication token.

The following shows sample bearer token config map settings that use a Secret object named `rw-bearer-auth` in the `openshift-monitoring` namespace:

```yaml
apiVersion: v1
kind: ConfigMap
metadata:
  name: cluster-monitoring-config
  namespace: openshift-monitoring
data:
  config.yaml: |
    enableUserWorkload: true
    prometheusK8s:
      remoteWrite:
        - url: "https://authorization.example.com/api/write"
      authorization:
        type: Bearer  
        credentials:
          name: rw-bearer-auth  
          key: token
```

1. The authentication type of the request. The default value is Bearer.
2. The name of the Secret object that contains the authentication credentials.
3. The key that contains the authentication token in the specified Secret object.

Example 2.4. Sample YAML for OAuth 2.0 authentication

The following shows sample OAuth 2.0 settings for a Secret object named `oauth2-credentials` in the `openshift-monitoring` namespace:

```yaml
apiVersion: v1
kind: Secret
```
The following shows an oauth2 remote write authentication sample configuration that uses a Secret object named oauth2-credentials in the openshift-monitoring namespace:

```yaml
metadata:
  name: oauth2-credentials
  namespace: openshift-monitoring
stringData:
  id: <oauth2_id>  
  secret: <oauth2_secret>  
  token: <oauth2_authentication_token>  
  type: Opaque
```

1. The Oauth 2.0 ID.
2. The OAuth 2.0 secret.
3. The OAuth 2.0 token.

The name of the corresponding Secret object. Note that ClientId can alternatively refer to a ConfigMap object, although clientSecret must refer to a Secret object.

The key that contains the OAuth 2.0 credentials in the specified Secret object.

The URL used to fetch a token with the specified clientId and clientSecret.

The OAuth 2.0 scopes for the authorization request. These scopes limit what data the tokens can access.
The OAuth 2.0 authorization request parameters required for the authorization server.

Example 2.5. Sample YAML for TLS client authentication

The following shows sample TLS client settings for a **tls Secret** object named **mtls-bundle** in the **openshift-monitoring** namespace.

```yaml
apiVersion: v1
kind: Secret
metadata:
  name: mtls-bundle
  namespace: openshift-monitoring
data:
  ca.crt: <ca_cert>  # 1
  client.crt: <client_cert>  # 2
  client.key: <client_key>  # 3
  type: tls
```

1. The CA certificate in the Prometheus container with which to validate the server certificate.
2. The client certificate for authentication with the server.
3. The client key.

The following sample shows a **tlsConfig** remote write authentication configuration that uses a TLS **Secret** object named **mtls-bundle**.

```yaml
apiVersion: v1
kind: ConfigMap
metadata:
  name: cluster-monitoring-config
  namespace: openshift-monitoring
data:
  config.yaml: |
    prometheusK8s:
      remoteWrite:
        - url: "https://remote-write-endpoint.example.com"
      tlsConfig:
        ca:
          secret:
            name: mtls-bundle  # 1
            key: ca.crt  # 2
cert:
          secret:
            name: mtls-bundle  # 3
            key: client.crt  # 4
        keySecret:
          name: mtls-bundle  # 5
          key: client.key  # 6
```
The name of the corresponding Secret object that contains the TLS authentication credentials. Note that ca and cert can alternatively refer to a ConfigMap object, though

The key in the specified Secret object that contains the CA certificate for the endpoint.

The key in the specified Secret object that contains the client certificate for the endpoint.

The key in the specified Secret object that contains the client key secret.

Additional resources

- See Setting up remote write compatible endpoints for steps to create a remote write compatible endpoint (such as Thanos).
- See Tuning remote write settings for information about how to optimize remote write settings for different use cases.
- See Understanding secrets for steps to create and configure Secret objects in OpenShift Container Platform.
- See the Prometheus REST API reference for remote write for information about additional optional fields.

2.12. ADDING CLUSTER ID LABELS TO METRICS

If you manage multiple OpenShift Container Platform clusters and use the remote write feature to send metrics data from these clusters to an external storage location, you can add cluster ID labels to identify the metrics data coming from different clusters. You can then query these labels to identify the source cluster for a metric and distinguish that data from similar metrics data sent by other clusters.

This way, if you manage many clusters for multiple customers and send metrics data to a single centralized storage system, you can use cluster ID labels to query metrics for a particular cluster or customer.

Creating and using cluster ID labels involves three general steps:

- Configuring the write relabel settings for remote write storage.
- Adding cluster ID labels to the metrics.
- Querying these labels to identify the source cluster or customer for a metric.

2.12.1. Creating cluster ID labels for metrics

You can create cluster ID labels for metrics for default platform monitoring and for user workload monitoring.

For default platform monitoring, you add cluster ID labels for metrics in the write_relabel settings for remote write storage in the cluster-monitoring-config config map in the openshift-monitoring namespace.

For user workload monitoring, you edit the settings in the user-workload-monitoring-config config map in the openshift-user-workload-monitoring namespace.
NOTE

When Prometheus scrapes user workload targets that expose a namespace label, the system stores this label as exported_namespace. This behavior ensures that the final namespace label value is equal to the namespace of the target pod. You cannot override this default configuration by setting the value of the honorLabels field to true for PodMonitor or ServiceMonitor objects.

Prerequisites

- If you are configuring default platform monitoring components:
  - You have access to the cluster as a user with the cluster-admin cluster role.
  - You have created the cluster-monitoring-config ConfigMap object.

- If you are configuring components that monitor user-defined projects:
  - You have access to the cluster as a user with the cluster-admin cluster role or as a user with the user-workload-monitoring-config-edit role in the openshift-user-workload-monitoring project.
  - You have created the user-workload-monitoring-config ConfigMap object.

- You have installed the OpenShift CLI (oc).
- You have configured remote write storage.

Procedure

1. Edit the ConfigMap object:
   - To create cluster ID labels for core OpenShift Container Platform metrics:
     - Edit the cluster-monitoring-config ConfigMap object in the openshift-monitoring project:
       ```
       $ oc -n openshift-monitoring edit configmap cluster-monitoring-config
       ```
     - In the writeRelabelConfigs: section under data/config.yaml/prometheusK8s/remoteWrite, add cluster ID relabel configuration values:
       ```yaml
       apiVersion: v1
       kind: ConfigMap
       metadata:
         name: cluster-monitoring-config
         namespace: openshift-monitoring
       data:
         config.yaml: |
         | prometheusK8s:
         |   remoteWrite:
         |   - url: "https://remote-write-endpoint.example.com"
         |   <endpoint_authentication_credentials>
         |   writeRelabelConfigs: 1
         |     - <relabel_config> 2
       ```
1. Add a list of write relabel configurations for metrics that you want to send to the remote endpoint.

2. Substitute the label configuration for the metrics sent to the remote write endpoint.

The following sample shows how to forward a metric with the cluster ID label `cluster_id` in default platform monitoring:

```yaml
apiVersion: v1
group: ConfigMap
metadata:
  name: cluster-monitoring-config
  namespace: openshift-monitoring
data:
  config.yaml: |
    prometheusK8s:
      remoteWrite:
        - url: "https://remote-write-endpoint.example.com"
          writeRelabelConfigs:
            - sourceLabels:
              - __tmp_openshift_cluster_id__
            targetLabel: cluster_id
            action: replace
```

1. The system initially applies a temporary cluster ID source label named `__tmp_openshift_cluster_id__`. This temporary label gets replaced by the cluster ID label name that you specify.

2. Specify the name of the cluster ID label for metrics sent to remote write storage. If you use a label name that already exists for a metric, that value is overwritten with the name of this cluster ID label. For the label name, do not use `__tmp_openshift_cluster_id__`. The final relabeling step removes labels that use this name.

3. The `replace` write relabel action replaces the temporary label with the target label for outgoing metrics. This action is the default and is applied if no action is specified.

- To create cluster ID labels for user-defined project metrics:
  
  a. Edit the `user-workload-monitoring-config ConfigMap` object in the `openshift-user-workload-monitoring` project:

```bash
$ oc -n openshift-user-workload-monitoring edit configmap user-workload-monitoring-config
```

  b. In the `writeRelabelConfigs` section under `data/config.yaml/prometheus/remoteWrite`, add cluster ID relabel configuration values:

```yaml
apiVersion: v1
kind: ConfigMap
metadata:
```
Add a list of write relabel configurations for metrics that you want to send to the remote endpoint.

Substitute the label configuration for the metrics sent to the remote write endpoint.

The following sample shows how to forward a metric with the cluster ID label `cluster_id` in user-workload monitoring:

```yaml
apiVersion: v1
da: ConfigMap
metadata:
  name: user-workload-monitoring-config
  namespace: openshift-user-workload-monitoring
data:
  config.yaml: |
    prometheus:
      remoteWrite:
        - url: "https://remote-write-endpoint.example.com"
          writeRelabelConfigs:
            - sourceLabels:
                - __tmp_openshift_cluster_id__
            targetLabel: cluster_id
            action: replace
```

1. The system initially applies a temporary cluster ID source label named `__tmp_openshift_cluster_id__`. This temporary label gets replaced by the cluster ID label name that you specify.

2. Specify the name of the cluster ID label for metrics sent to remote write storage. If you use a label name that already exists for a metric, that value is overwritten with the name of this cluster ID label. For the label name, do not use `__tmp_openshift_cluster_id__`. The final relabeling step removes labels that use this name.

3. The `replace` write relabel action replaces the temporary label with the target label for outgoing metrics. This action is the default and is applied if no action is specified.

2. Save the file to apply the changes to the ConfigMap object. The pods affected by the updated configuration automatically restart.
## WARNING

Saving changes to a monitoring ConfigMap object might redeploy the pods and other resources in the related project. Saving changes might also restart the running monitoring processes in that project.

### Additional resources
- For details about write relabel configuration, see Configuring remote write storage.
- For information about how to get your cluster ID, see Obtaining your cluster ID.

### 2.13. CONFIGURING METRICS COLLECTION PROFILES

#### IMPORTANT

Using a metrics collection profile is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see https://access.redhat.com/support/offerings/techpreview.

By default, Prometheus collects metrics exposed by all default metrics targets in OpenShift Container Platform components. However, you might want Prometheus to collect fewer metrics from a cluster in certain scenarios:

- **If cluster administrators require only alert, telemetry, and console metrics and do not require other metrics to be available.**
- **If a cluster increases in size, and the increased size of the default metrics data collected now requires a significant increase in CPU and memory resources.**

You can use a metrics collection profile to collect either the default amount of metrics data or a minimal amount of metrics data. When you collect minimal metrics data, basic monitoring features such as alerting continue to work. At the same time, the CPU and memory resources required by Prometheus decrease.

#### 2.13.1. About metrics collection profiles

You can enable one of two metrics collection profiles:

- **full**: Prometheus collects metrics data exposed by all platform components. This setting is the default.
- **minimal**: Prometheus collects only the metrics data required for platform alerts, recording rules, telemetry, and console dashboards.
2.13.2. Choosing a metrics collection profile

To choose a metrics collection profile for core OpenShift Container Platform monitoring components, edit the `cluster-monitoring-config ConfigMap` object.

Prerequisites

- You have installed the OpenShift CLI (`oc`).
- You have enabled Technology Preview features by using the `FeatureGate` custom resource (CR).
- You have created the `cluster-monitoring-config ConfigMap` object.
- You have access to the cluster as a user with the `cluster-admin` cluster role.

**WARNING**

Saving changes to a monitoring config map might restart monitoring processes and redeploy the pods and other resources in the related project. The running monitoring processes in that project might also restart.

Procedure

1. Edit the `cluster-monitoring-config ConfigMap` object in the `openshift-monitoring` project:

   ```bash
   $ oc -n openshift-monitoring edit configmap cluster-monitoring-config
   ```

2. Add the metrics collection profile setting under `data/config.yaml/prometheusK8s`:

   ```yaml
   apiVersion: v1
   kind: ConfigMap
   metadata:
     name: cluster-monitoring-config
     namespace: openshift-monitoring
   data:
     config.yaml:
       prometheusK8s:
         collectionProfile: <metrics_collection_profile_name>  
   
   1 The name of the metrics collection profile. The available values are `full` or `minimal`. If you do not specify a value or if the `collectionProfile` key name does not exist in the config map, the default setting of `full` is used.
   ```

The following example sets the metrics collection profile to `minimal` for the core platform instance of Prometheus:

```yaml
apiVersion: v1
kind: ConfigMap
```
Save the file to apply the changes. The pods affected by the new configuration restart automatically.

Additional resources

- See Viewing a list of available metrics for steps to view a list of metrics being collected for a cluster.
- See Enabling features using feature gates for steps to enable Technology Preview features.

2.14. CONTROLLING THE IMPACT OF UNBOUND METRICS ATTRIBUTES IN USER-DEFINED PROJECTS

Developers can create labels to define attributes for metrics in the form of key-value pairs. The number of potential key-value pairs corresponds to the number of possible values for an attribute. An attribute that has an unlimited number of potential values is called an unbound attribute. For example, a `customer_id` attribute is unbound because it has an infinite number of possible values.

Every assigned key-value pair has a unique time series. The use of many unbound attributes in labels can result in an exponential increase in the number of time series created. This can impact Prometheus performance and can consume a lot of disk space.

Cluster administrators can use the following measures to control the impact of unbound metrics attributes in user-defined projects:

- Limit the number of samples that can be accepted per target scrape in user-defined projects
- Limit the number of scraped labels, the length of label names, and the length of label values
- Create alerts that fire when a scrape sample threshold is reached or when the target cannot be scraped

**NOTE**

Limiting scrape samples can help prevent the issues caused by adding many unbound attributes to labels. Developers can also prevent the underlying cause by limiting the number of unbound attributes that they define for metrics. Using attributes that are bound to a limited set of possible values reduces the number of potential key-value pair combinations.

2.14.1. Setting scrape sample and label limits for user-defined projects

You can limit the number of samples that can be accepted per target scrape in user-defined projects. You can also limit the number of scraped labels, the length of label names, and the length of label values.
WARNING
If you set sample or label limits, no further sample data is ingested for that target scrape after the limit is reached.

Prerequisites

- You have access to the cluster as a user with the `cluster-admin` cluster role, or as a user with the `user-workload-monitoring-config-edit` role in the `openshift-user-workload-monitoring` project.
- You have enabled monitoring for user-defined projects.
- You have installed the OpenShift CLI (`oc`).

Procedure

1. Edit the `user-workload-monitoring-config ConfigMap` object in the `openshift-user-workload-monitoring` project:

   ```bash
   $ oc -n openshift-user-workload-monitoring edit configmap user-workload-monitoring-config
   ```

2. Add the `enforcedSampleLimit` configuration to `data/config.yaml` to limit the number of samples that can be accepted per target scrape in user-defined projects:

   ```yaml
   apiVersion: v1
   kind: ConfigMap
   metadata:
     name: user-workload-monitoring-config
     namespace: openshift-user-workload-monitoring
   data:
     config.yaml: |
       prometheus:
         enforcedSampleLimit: 50000
   
   1 A value is required if this parameter is specified. This `enforcedSampleLimit` example limits the number of samples that can be accepted per target scrape in user-defined projects to 50,000.

3. Add the `enforcedLabelLimit`, `enforcedLabelNameLengthLimit`, and `enforcedLabelValueLengthLimit` configurations to `data/config.yaml` to limit the number of scraped labels, the length of label names, and the length of label values in user-defined projects:

   ```yaml
   apiVersion: v1
   kind: ConfigMap
   metadata:
     name: user-workload-monitoring-config
     namespace: openshift-user-workload-monitoring
   data:
   ```
Specifies the maximum number of labels per scrape. The default value is 0, which specifies no limit.

2. Specifies the maximum length in characters of a label name. The default value is 0, which specifies no limit.

3. Specifies the maximum length in characters of a label value. The default value is 0, which specifies no limit.

4. Save the file to apply the changes. The limits are applied automatically.

NOTE
Configurations applied to the user-workload-monitoring-config ConfigMap object are not activated unless a cluster administrator has enabled monitoring for user-defined projects.

WARNING
When changes are saved to the user-workload-monitoring-config ConfigMap object, the pods and other resources in the openshift-user-workload-monitoring project might be redeployed. The running monitoring processes in that project might also be restarted.

2.14.2. Creating scrape sample alerts
You can create alerts that notify you when:

- The target cannot be scraped or is not available for the specified for duration
- A scrape sample threshold is reached or is exceeded for the specified for duration

Prerequisites

- You have access to the cluster as a user with the cluster-admin cluster role, or as a user with the user-workload-monitoring-config-edit role in the openshift-user-workload-monitoring project.

- You have enabled monitoring for user-defined projects.

- You have created the user-workload-monitoring-config ConfigMap object.
You have limited the number of samples that can be accepted per target scrape in user-defined projects, by using enforcedSampleLimit.

You have installed the OpenShift CLI (oc).

Procedure

1. Create a YAML file with alerts that inform you when the targets are down and when the enforced sample limit is approaching. The file in this example is called monitoring-stack-alerts.yaml:

```yaml
apiVersion: monitoring.coreos.com/v1
kind: PrometheusRule
metadata:
  labels:
    prometheus: k8s
    role: alert-rules
  name: monitoring-stack-alerts
  namespace: ns1
spec:
groups:
  - name: general.rules
    rules:
      - alert: TargetDown
        annotations:
          message: '{{ printf \"%.4g\" $value }\% of the {{ $labels.job }}/{{ $labels.service }} targets in {{ $labels.namespace }} namespace are down.'
        expr: 100 * (count(up == 0) BY (job, namespace, service)) / count(up) BY (job, namespace, service)) > 10
        for: 10m
        labels:
          severity: warning
      - alert: ApproachingEnforcedSamplesLimit
        annotations:
          message: '{{ $labels.container }} container of the {{ $labels.pod }} pod in the {{ $labels.namespace }} namespace consumes {{ $value | humanizePercentage }} of the samples limit budget.'
        expr: scrape_samples_scraped/50000 > 0.8
        for: 10m
        labels:
          severity: warning
```

1. Defines the name of the alerting rule.
2. Specifies the user-defined project where the alerting rule will be deployed.
3. The TargetDown alert will fire if the target cannot be scraped or is not available for the for duration.
4. The message that will be output when the TargetDown alert fires.
5. The conditions for the TargetDown alert must be true for this duration before the alert is fired.
Defines the severity for the **TargetDown** alert.

The **ApproachingEnforcedSamplesLimit** alert will fire when the defined scrape sample threshold is reached or exceeded for the specified **for** duration.

The message that will be output when the **ApproachingEnforcedSamplesLimit** alert fires.

The threshold for the **ApproachingEnforcedSamplesLimit** alert. In this example the alert will fire when the number of samples per target scrape has exceeded 80% of the enforced sample limit of **50000**. The **for** duration must also have passed before the alert will fire. The `<number>` in the expression `scrape_samples_scraped/<number> > <threshold>` must match the `enforcedSampleLimit` value defined in the user-workload-monitoring-config ConfigMap object.

The conditions for the **ApproachingEnforcedSamplesLimit** alert must be true for this duration before the alert is fired.

Defines the severity for the **ApproachingEnforcedSamplesLimit** alert.

2. Apply the configuration to the user-defined project:

```
$ oc apply -f monitoring-stack-alerts.yaml
```

**Additional resources**

- Creating a user-defined workload monitoring config map
- Enabling monitoring for user-defined projects
- See Determining why Prometheus is consuming a lot of disk space for steps to query which metrics have the highest number of scrape samples.
CHAPTER 3. CONFIGURING EXTERNAL ALERTMANAGER INSTANCES

The OpenShift Container Platform monitoring stack includes a local Alertmanager instance that routes alerts from Prometheus. You can add external Alertmanager instances to route alerts for core OpenShift Container Platform projects or user-defined projects.

If you add the same external Alertmanager configuration for multiple clusters and disable the local instance for each cluster, you can then manage alert routing for multiple clusters by using a single external Alertmanager instance.

Prerequisites

- **If you are configuring core OpenShift Container Platform monitoring components in the openshift-monitoring project:**
  - You have access to the cluster as a user with the `cluster-admin` cluster role.
  - You have created the `cluster-monitoring-config` config map.

- **If you are configuring components that monitor user-defined projects**
  - You have access to the cluster as a user with the `cluster-admin` cluster role, or as a user with the `user-workload-monitoring-config-edit` role in the `openshift-user-workload-monitoring` project.
  - You have created the `user-workload-monitoring-config` config map.
  - You have installed the OpenShift CLI (`oc`).

Procedure

1. Edit the **ConfigMap** object.

   - **To configure additional Alertmanagers for routing alerts from core OpenShift Container Platform projects:**
     a. Edit the `cluster-monitoring-config` config map in the `openshift-monitoring` project:

        ```bash
        $ oc -n openshift-monitoring edit configmap cluster-monitoring-config
        ```

     b. Add an **additionalAlertmanagerConfigs** section under `data/config.yaml/prometheusK8s`.

     c. Add the configuration details for additional Alertmanagers in this section:

        ```yaml
        apiVersion: v1
        kind: ConfigMap
        metadata:
          name: cluster-monitoring-config
          namespace: openshift-monitoring
        data:
          config.yaml: |
        ```
For `<alertmanager_specification>`, substitute authentication and other configuration details for additional Alertmanager instances. Currently supported authentication methods are bearer token (`bearerToken`) and client TLS (`tlsConfig`). The following sample config map configures an additional Alertmanager using a bearer token with client TLS authentication:

```yaml
apiVersion: v1
class: ConfigMap
metadata:
  name: cluster-monitoring-config
namespace: openshift-monitoring
data:
  config.yaml: |
    prometheusK8s:
      additionalAlertmanagerConfigs:
      - `<alertmanager_specification>`
```

- To configure additional Alertmanager instances for routing alerts from user-defined projects:

  a. Edit the `user-workload-monitoring-config` config map in the `openshift-user-workload-monitoring` project:

     ```bash
     $ oc -n openshift-user-workload-monitoring edit configmap user-workload-monitoring-config
     ```

  b. Add a `<component>/additionalAlertmanagerConfigs`: section under `data/config.yaml`.

  c. Add the configuration details for additional Alertmanagers in this section:

     ```yaml
     apiVersion: v1
     ```
For `<component>`, substitute one of two supported external Alertmanager components: `prometheus` or `thanosRuler`.

For `<alertmanager_specification>`, substitute authentication and other configuration details for additional Alertmanager instances. Currently supported authentication methods are bearer token (`bearerToken`) and client TLS (`tlsConfig`). The following sample config map configures an additional Alertmanager using Thanos Ruler with a bearer token and client TLS authentication:

```yaml
apiVersion: v1
kind: ConfigMap
metadata:
  name: user-workload-monitoring-config
  namespace: openshift-user-workload-monitoring
data:
  config.yaml: |
    thanosRuler:
      additionalAlertmanagerConfigs:
        - scheme: https
          pathPrefix: /
          timeout: "30s"
          apiVersion: v1
          bearerToken:
            name: alertmanager-bearer-token
            key: token
          tlsConfig:
            key:
              name: alertmanager-tls
              key: tls.key
            cert:
              name: alertmanager-tls
              key: tls.crt
            ca:
              name: alertmanager-tls
              key: tls.ca
          staticConfigs:
            - external-alertmanager1-remote.com
            - external-alertmanager1-remote2.com
```

2. Save the file to apply the changes to the `ConfigMap` object. The new component placement configuration is applied automatically.
NOTE

Configurations applied to the `user-workload-monitoring-config ConfigMap` object are not activated unless a cluster administrator has enabled monitoring for user-defined projects.

3. Save the file to apply the changes to the *ConfigMap* object. The new component placement configuration is applied automatically.
The OpenShift Container Platform monitoring stack includes Alertmanager, which routes alerts from Prometheus to endpoint receivers. If you need to authenticate with a receiver so that Alertmanager can send alerts to it, you can configure Alertmanager to use a secret that contains authentication credentials for the receiver.

For example, you can configure Alertmanager to use a secret to authenticate with an endpoint receiver that requires a certificate issued by a private Certificate Authority (CA). You can also configure Alertmanager to use a secret to authenticate with a receiver that requires a password file for Basic HTTP authentication. In either case, authentication details are contained in the Secret object rather than in the ConfigMap object.

4.1. ADDING A SECRET TO THE ALERTMANAGER CONFIGURATION

You can add secrets to the Alertmanager configuration for core platform monitoring components by editing the cluster-monitoring-config config map in the openshift-monitoring project.

After you add a secret to the config map, the secret is mounted as a volume at /etc/alertmanager/secrets/<secret_name> within the alertmanager container for the Alertmanager pods.

Prerequisites

- If you are configuring core OpenShift Container Platform monitoring components in the openshift-monitoring project:
  - You have access to the cluster as a user with the cluster-admin cluster role.
  - You have created the cluster-monitoring-config config map.
  - You have created the secret to be configured in Alertmanager in the openshift-monitoring project.

- If you are configuring components that monitor user-defined projects
  - A cluster administrator has enabled monitoring for user-defined projects.
  - You have access to the cluster as a user with the cluster-admin cluster role, or as a user with the user-workload-monitoring-config-edit role in the openshift-user-workload-monitoring project.
  - You have created the secret to be configured in Alertmanager in the openshift-user-workload-monitoring project.

- You have installed the OpenShift CLI (oc).

Procedure

1. Edit the ConfigMap object.

   • To add a secret configuration to Alertmanager for core platform monitoring
     a. Edit the cluster-monitoring-config config map in the openshift-monitoring project:

     $ oc -n openshift-monitoring edit configmap cluster-monitoring-config
b. Add a `secrets:` section under `data/config.yaml/alertmanagerMain` with the following configuration:

```yaml
apiVersion: v1
kind: ConfigMap
metadata:
  name: cluster-monitoring-config
  namespace: openshift-monitoring
data:
  config.yaml: |
    alertmanagerMain:
      secrets:  # 1
        - <secret_name_1>  # 2
        - <secret_name_2>
```

1. This section contains the secrets to be mounted into Alertmanager. The secrets must be located within the same namespace as the Alertmanager object.

2. The name of the `Secret` object that contains authentication credentials for the receiver. If you add multiple secrets, place each one on a new line.

The following sample config map settings configure Alertmanager to use two `Secret` objects named `test-secret-basic-auth` and `test-secret-api-token`:

```yaml
apiVersion: v1
kind: ConfigMap
metadata:
  name: cluster-monitoring-config
  namespace: openshift-monitoring
data:
  config.yaml: |
    alertmanagerMain:
      secrets:
        - test-secret-basic-auth
        - test-secret-api-token
```

- To add a secret configuration to Alertmanager for user-defined project monitoring
  a. Edit the `user-workload-monitoring-config` config map in the `openshift-user-workload-monitoring` project:

    ```bash
    $ oc -n openshift-user-workload-monitoring edit configmap user-workload-monitoring-config
    ```

  b. Add a `secrets:` section under `data/config.yaml/alertmanager/secrets` with the following configuration:

    ```yaml
    apiVersion: v1
    kind: ConfigMap
    metadata:
      name: user-workload-monitoring-config
      namespace: openshift-user-workload-monitoring
data:
      config.yaml: |
    ```
This section contains the secrets to be mounted into Alertmanager. The secrets must be located within the same namespace as the Alertmanager object.

The name of the Secret object that contains authentication credentials for the receiver. If you add multiple secrets, place each one on a new line.

The following sample config map settings configure Alertmanager to use two Secret objects named test-secret and test-secret-api-token:

```yaml
apiVersion: v1
type: ConfigMap
metadata:
  name: user-workload-monitoring-config
  namespace: openshift-user-workload-monitoring
data:
  config.yaml: |
    alertmanager:
      enabled: true
      secrets:
        - test-secret
        - test-api-receiver-token
```

**NOTE**

Configurations applied to the user-workload-monitoring-config ConfigMap object are not activated unless a cluster administrator has enabled monitoring for user-defined projects.

2. Save the file to apply the changes to the ConfigMap object. The new configuration is applied automatically.

### 4.2. ATTACHING ADDITIONAL LABELS TO YOUR TIME SERIES AND ALERTS

You can attach custom labels to all time series and alerts leaving Prometheus by using the external labels feature of Prometheus.

**Prerequisites**

- If you are configuring core OpenShift Container Platform monitoring components
  - You have access to the cluster as a user with the cluster-admin cluster role.
  - You have created the cluster-monitoring-config ConfigMap object.

- If you are configuring components that monitor user-defined projects
  - You have access to the cluster as a user with the cluster-admin cluster role, or as a user with the user-workload-monitoring-config-edit role in the openshift-user-workload-
With the `user-workload-monitoring-config-edit` role in the `openshift-user-workload-monitoring` project.

- You have created the `user-workload-monitoring-config` ConfigMap object.
- You have installed the OpenShift CLI (`oc`).

Procedure

1. Edit the ConfigMap object:

   - To attach custom labels to all time series and alerts leaving the Prometheus instance that monitors core OpenShift Container Platform projects:
     a. Edit the `cluster-monitoring-config` ConfigMap object in the `openshift-monitoring` project:

        ```
        $ oc -n openshift-monitoring edit configmap cluster-monitoring-config
        ```

     b. Define a map of labels you want to add for every metric under `data/config.yaml`:

        ```
        apiVersion: v1
        kind: ConfigMap
        metadata:
          name: cluster-monitoring-config
          namespace: openshift-monitoring
        data:
          config.yaml:
            | prometheusK8s:
            | externalLabels:
            | <key>: <value>  
        ```

        Substitute `<key>: <value>` with a map of key-value pairs where `<key>` is a unique name for the new label and `<value>` is its value.

        **WARNING**

        - Do not use `prometheus` or `prometheus_replica` as key names, because they are reserved and will be overwritten.
        - Do not use `cluster` or `managed_cluster` as key names. Using them can cause issues where you are unable to see data in the developer dashboards.

For example, to add metadata about the region and environment to all time series and alerts, use the following example:

```
apiVersion: v1
kind: ConfigMap
metadata:
```
• To attach custom labels to all time series and alerts leaving the Prometheus instance that monitors user-defined projects:

a. Edit the `user-workload-monitoring-config` ConfigMap object in the `openshift-user-workload-monitoring` project:

   ```shell
   $ oc -n openshift-user-workload-monitoring edit configmap user-workload-monitoring-config
   ``

b. Define a map of labels you want to add for every metric under `data/config.yaml`:

   ```yaml
   apiVersion: v1
   kind: ConfigMap
   metadata:
     name: user-workload-monitoring-config
     namespace: openshift-user-workload-monitoring
   data:
     config.yaml: |
     prometheus:
       externalLabels:
         <key>: <value>  # 1
   ```

   1 Substitute `<key>: <value>` with a map of key-value pairs where `<key>` is a unique name for the new label and `<value>` is its value.

**WARNING**

- Do not use `prometheus` or `prometheus_replica` as key names, because they are reserved and will be overwritten.

- Do not use `cluster` or `managed_cluster` as key names. Using them can cause issues where you are unable to see data in the developer dashboards.
In the `openshift-user-workload-monitoring` project, Prometheus handles metrics and Thanos Ruler handles alerting and recording rules. Setting `externalLabels` for `prometheus` in the `user-workload-monitoring-config ConfigMap` object will only configure external labels for metrics and not for any rules.

For example, to add metadata about the region and environment to all time series and alerts related to user-defined projects, use the following example:

```yaml
apiVersion: v1
kind: ConfigMap
metadata:
  name: user-workload-monitoring-config
  namespace: openshift-user-workload-monitoring
data:
  config.yaml: |
    prometheus:
      externalLabels:
        region: eu
        environment: prod
```

2. Save the file to apply the changes. The new configuration is applied automatically.

**NOTE**

Configurations applied to the `user-workload-monitoring-config ConfigMap` object are not activated unless a cluster administrator has enabled monitoring for user-defined projects.

**WARNING**

When changes are saved to a monitoring config map, the pods and other resources in the related project might be redeployed. The running monitoring processes in that project might also be restarted.

**Additional resources**

- See [Preparing to configure the monitoring stack](#) for steps to create monitoring config maps.
- [Enabling monitoring for user-defined projects](#)
CHAPTER 5. CONFIGURING POD TOPOLOGY SPREAD CONSTRAINTS FOR MONITORING

You can use pod topology spread constraints to control how Prometheus, Thanos Ruler, and Alertmanager pods are spread across a network topology when OpenShift Container Platform pods are deployed in multiple availability zones.

Pod topology spread constraints are suitable for controlling pod scheduling within hierarchical topologies in which nodes are spread across different infrastructure levels, such as regions and zones within those regions. Additionally, by being able to schedule pods in different zones, you can improve network latency in certain scenarios.

Additional resources
- Controlling pod placement by using pod topology spread constraints
- Kubernetes Pod Topology Spread Constraints documentation

5.1. SETTING UP POD TOPOLOGY SPREAD CONSTRAINTS FOR PROMETHEUS

For core OpenShift Container Platform platform monitoring, you can set up pod topology spread constraints for Prometheus to fine tune how pod replicas are scheduled to nodes across zones. Doing so helps ensure that Prometheus pods are highly available and run more efficiently, because workloads are spread across nodes in different data centers or hierarchical infrastructure zones.

You configure pod topology spread constraints for Prometheus in the `cluster-monitoring-config` ConfigMap.

Prerequisites
- You have access to the cluster as a user with the `cluster-admin` role.
- You have created the `cluster-monitoring-config` ConfigMap object.
- You have installed the OpenShift CLI (`oc`).

Procedure

1. Edit the `cluster-monitoring-config` ConfigMap object in the `openshift-monitoring` namespace:

   ```bash
   $ oc -n openshift-monitoring edit configmap cluster-monitoring-config
   ```

2. Add values for the following settings under `data/config.yaml/prometheusK8s` to configure pod topology spread constraints:

   ```yaml
   apiVersion: v1
   kind: ConfigMap
   metadata:
     name: cluster-monitoring-config
     namespace: openshift-monitoring
   data:
   ```
Specify a numeric value for `maxSkew`, which defines the degree to which pods are allowed to be unevenly distributed. This field is required, and the value must be greater than zero. The value specified has a different effect depending on what value you specify for `whenUnsatisfiable`.

Specify a key of node labels for `topologyKey`. This field is required. Nodes that have a label with this key and identical values are considered to be in the same topology. The scheduler will try to put a balanced number of pods into each domain.

Specify a value for `whenUnsatisfiable`. This field is required. Available options are `DoNotSchedule` and `ScheduleAnyway`. Specify `DoNotSchedule` if you want the `maxSkew` value to define the maximum difference allowed between the number of matching pods in the target topology and the global minimum. Specify `ScheduleAnyway` if you want the scheduler to still schedule the pod but to give higher priority to nodes that might reduce the skew.

Specify a value for `matchLabels`. This value is used to identify the set of matching pods to which to apply the constraints.

3. Save the file to apply the changes automatically.

**WARNING**

When you save changes to the `cluster-monitoring-config` config map, the pods and other resources in the `openshift-monitoring` project might be redeployed. The running monitoring processes in that project might also restart.

### 5.2. SETTING UP POD TOPOLOGY SPREAD CONSTRAINTS FOR ALERTMANAGER

For core OpenShift Container Platform platform monitoring, you can set up pod topology spread constraints for Alertmanager to fine tune how pod replicas are scheduled to nodes across zones. Doing so helps ensure that Alertmanager pods are highly available and run more efficiently, because workloads are spread across nodes in different data centers or hierarchical infrastructure zones.

You configure pod topology spread constraints for Alertmanager in the `cluster-monitoring-config` config map.
Prerequisites

- You have access to the cluster as a user with the `cluster-admin` cluster role.
- You have created the `cluster-monitoring-config` ConfigMap object.
- You have installed the OpenShift CLI (`oc`).

Procedure

1. Edit the `cluster-monitoring-config` ConfigMap object in the `openshift-monitoring` namespace:

   ```
   $ oc -n openshift-monitoring edit configmap cluster-monitoring-config
   ```

2. Add values for the following settings under `data/config.yaml/alertmanagermain` to configure pod topology spread constraints:

   ```yaml
   apiVersion: v1
   kind: ConfigMap
   metadata:
     name: cluster-monitoring-config
     namespace: openshift-monitoring
   data:
     config.yaml: |
       alertmanagerMain:
         topologySpreadConstraints:
           - maxSkew: 1
             topologyKey: monitoring
             whenUnsatisfiable: DoNotSchedule
       labelSelector:
         matchLabels:
           app.kubernetes.io/name: alertmanager
   ```

   **1** Specify a numeric value for **maxSkew**, which defines the degree to which pods are allowed to be unevenly distributed. This field is required, and the value must be greater than zero. The value specified has a different effect depending on what value you specify for **whenUnsatisfiable**.

   **2** Specify a key of node labels for **topologyKey**. This field is required. Nodes that have a label with this key and identical values are considered to be in the same topology. The scheduler will try to put a balanced number of pods into each domain.

   **3** Specify a value for **whenUnsatisfiable**. This field is required. Available options are `DoNotSchedule` and `ScheduleAnyway`. Specify `DoNotSchedule` if you want the `maxSkew` value to define the maximum difference allowed between the number of matching pods in the target topology and the global minimum. Specify `ScheduleAnyway` if you want the scheduler to still schedule the pod but to give higher priority to nodes that might reduce the skew.

   **4** Specify a value for **matchLabels**. This value is used to identify the set of matching pods to which to apply the constraints.

3. Save the file to apply the changes automatically.
5.3. SETTING UP POD TOPOLOGY SPREAD CONSTRAINTS FOR THANOS RULER

For user-defined monitoring, you can set up pod topology spread constraints for Thanos Ruler to fine tune how pod replicas are scheduled to nodes across zones. Doing so helps ensure that Thanos Ruler pods are highly available and run more efficiently, because workloads are spread across nodes in different data centers or hierarchical infrastructure zones.

You configure pod topology spread constraints for Thanos Ruler in the **user-workload-monitoring-config** config map.

Prerequisites

- A cluster administrator has enabled monitoring for user-defined projects.
- You have access to the cluster as a user with the **cluster-admin** cluster role, or as a user with the **user-workload-monitoring-config-edit** role in the **openshift-user-workload-monitoring** project.
- You have created the **user-workload-monitoring-config ConfigMap** object.
- You have installed the OpenShift CLI (**oc**).

Procedure

1. Edit the **user-workload-monitoring-config** config map in the **openshift-user-workload-monitoring** namespace:

   ```bash
   $ oc -n openshift-user-workload-monitoring edit configmap user-workload-monitoring-config
   ```

2. Add values for the following settings under **data/config.yaml/thanosRuler** to configure pod topology spread constraints:

   ```yaml
   apiVersion: v1
   kind: ConfigMap
   metadata:
     name: user-workload-monitoring-config
   namespace: openshift-user-workload-monitoring
   data:
     config.yaml: |
     thanosRuler:
       topologySpreadConstraints:
         - maxSkew: 1
   ```
Specify a numeric value for `maxSkew`, which defines the degree to which pods are allowed to be unevenly distributed. This field is required, and the value must be greater than zero. The value specified has a different effect depending on what value you specify for `whenUnsatisfiable`.

Specify a key of node labels for `topologyKey`. This field is required. Nodes that have a label with this key and identical values are considered to be in the same topology. The scheduler will try to put a balanced number of pods into each domain.

Specify a value for `whenUnsatisfiable`. This field is required. Available options are `DoNotSchedule` and `ScheduleAnyway`. Specify `DoNotSchedule` if you want the `maxSkew` value to define the maximum difference allowed between the number of matching pods in the target topology and the global minimum. Specify `ScheduleAnyway` if you want the scheduler to still schedule the pod but to give higher priority to nodes that might reduce the skew.

Specify a value for `matchLabels`. This value is used to identify the set of matching pods to which to apply the constraints.

3. Save the file to apply the changes automatically.

**WARNING**

When you save changes to the `user-workload-monitoring-config` config map, the pods and other resources in the `openshift-user-workload-monitoring` project might be redeployed. The running monitoring processes in that project might also restart.

### 5.4. SETTING LOG LEVELS FOR MONITORING COMPONENTS

You can configure the log level for Alertmanager, Prometheus Operator, Prometheus, Thanos Querier, and Thanos Ruler.

The following log levels can be applied to the relevant component in the `cluster-monitoring-config` and `user-workload-monitoring-config` ConfigMap objects:

- **debug**: Log debug, informational, warning, and error messages.
- **info**: Log informational, warning, and error messages.
- **warn**: Log warning and error messages only.
- **error**: Log error messages only.
The default log level is **info**.

**Prerequisites**

- **If you are setting a log level for Alertmanager, Prometheus Operator, Prometheus, or Thanos Querier in the `openshift-monitoring` project:**
  - You have access to the cluster as a user with the `cluster-admin` cluster role.
  - You have created the `cluster-monitoring-config` ConfigMap object.

- **If you are setting a log level for Prometheus Operator, Prometheus, or Thanos Ruler in the `openshift-user-workload-monitoring` project:**
  - You have access to the cluster as a user with the `cluster-admin` cluster role, or as a user with the `user-workload-monitoring-config-edit` role in the `openshift-user-workload-monitoring` project.
  - You have created the `user-workload-monitoring-config` ConfigMap object.

- You have installed the OpenShift CLI (`oc`).

**Procedure**

1. Edit the **ConfigMap** object:

   - **To set a log level for a component in the `openshift-monitoring` project:**
     a. Edit the `cluster-monitoring-config` ConfigMap object in the `openshift-monitoring` project:

        ```
        $ oc -n openshift-monitoring edit configmap cluster-monitoring-config
        ```

     b. Add `logLevel: <log_level>` for a component under `data/config.yaml`:

        ```yaml
        apiVersion: v1
        kind: ConfigMap
        metadata:
          name: cluster-monitoring-config
        namespace: openshift-monitoring
        data:
          config.yaml: |
          <component>:
            logLevel: <log_level>
        ```

        **1** The monitoring stack component for which you are setting a log level. For default platform monitoring, available component values are `prometheusK8s`, `alertmanagerMain`, `prometheusOperator`, and `thanosQuerier`.

        **2** The log level to set for the component. The available values are `error`, `warn`, `info`, and `debug`. The default value is `info`.

   - **To set a log level for a component in the `openshift-user-workload-monitoring` project:**
a. Edit the `user-workload-monitoring-config ConfigMap` object in the `openshift-user-workload-monitoring` project:

```
$ oc -n openshift-user-workload-monitoring edit configmap user-workload-monitoring-config
```

b. Add `logLevel: <log_level>` for a component under `data/config.yaml`:

```
apiVersion: v1
kind: ConfigMap
metadata:
  name: user-workload-monitoring-config
  namespace: openshift-user-workload-monitoring
data:
  config.yaml: |
    <component>: 1  
      logLevel: <log_level> 2
```

1. The monitoring stack component for which you are setting a log level. For user workload monitoring, available component values are `alertmanager`, `prometheus`, `prometheusOperator`, and `thanosRuler`.

2. The log level to apply to the component. The available values are `error`, `warn`, `info`, and `debug`. The default value is `info`.

2. Save the file to apply the changes. The pods for the component restart automatically when you apply the log-level change.

**NOTE**

Configurations applied to the `user-workload-monitoring-config ConfigMap` object are not activated unless a cluster administrator has enabled monitoring for user-defined projects.

**WARNING**

When changes are saved to a monitoring config map, the pods and other resources in the related project might be redeployed. The running monitoring processes in that project might also be restarted.

3. Confirm that the log-level has been applied by reviewing the deployment or pod configuration in the related project. The following example checks the log level in the `prometheus-operator` deployment in the `openshift-user-workload-monitoring` project:

```
$ oc -n openshift-user-workload-monitoring get deploy prometheus-operator -o yaml | grep "log-level"
```

**Example output**
4. Check that the pods for the component are running. The following example lists the status of pods in the `openshift-user-workload-monitoring` project:

```bash
$ oc -n openshift-user-workload-monitoring get pods
```

**NOTE**

If an unrecognized `logLevel` value is included in the `ConfigMap` object, the pods for the component might not restart successfully.

### 5.5. Enabling the Query Log File for Prometheus

You can configure Prometheus to write all queries that have been run by the engine to a log file. You can do so for default platform monitoring and for user-defined workload monitoring.

**IMPORTANT**

Because log rotation is not supported, only enable this feature temporarily when you need to troubleshoot an issue. After you finish troubleshooting, disable query logging by reverting the changes you made to the `ConfigMap` object to enable the feature.

**Prerequisites**

- If you are enabling the query log file feature for Prometheus in the `openshift-monitoring` project:
  - You have access to the cluster as a user with the `cluster-admin` cluster role.
  - You have created the `cluster-monitoring-config ConfigMap` object.

- If you are enabling the query log file feature for Prometheus in the `openshift-user-workload-monitoring` project:
  - You have access to the cluster as a user with the `cluster-admin` cluster role, or as a user with the `user-workload-monitoring-config-edit` role in the `openshift-user-workload-monitoring` project.
  - You have created the `user-workload-monitoring-config ConfigMap` object.

- You have installed the OpenShift CLI (`oc`).

**Procedure**

- To set the query log file for Prometheus in the `openshift-monitoring` project:
  1. Edit the `cluster-monitoring-config ConfigMap` object in the `openshift-monitoring` project:
     ```bash
     $ oc -n openshift-monitoring edit configmap cluster-monitoring-config
     ```
  2. Add `queryLogFile: <path>` for `prometheusK8s` under `data/config.yaml`:
The full path to the file in which queries will be logged.

3. Save the file to apply the changes.

**WARNING**

When you save changes to a monitoring config map, pods and other resources in the related project might be redeployed. The running monitoring processes in that project might also be restarted.

4. Verify that the pods for the component are running. The following sample command lists the status of pods in the *openshift-monitoring* project:

   ```bash
   $ oc -n openshift-monitoring get pods
   ```

5. Read the query log:

   ```bash
   $ oc -n openshift-monitoring exec prometheus-k8s-0 -- cat <path>
   ```

**IMPORTANT**

Revert the setting in the config map after you have examined the logged query information.

- To set the query log file for Prometheus in the *openshift-user-workload-monitoring* project:

  1. Edit the *user-workload-monitoring-config ConfigMap* object in the *openshift-user-workload-monitoring* project:

     ```bash
     $ oc -n openshift-user-workload-monitoring edit configmap user-workload-monitoring-config
     ```

  2. Add `queryLogFile: <path>` for `prometheus` under `data/config.yaml`:

     ```yaml
     apiVersion: v1
     kind: ConfigMap
     ```
The full path to the file in which queries will be logged.

3. Save the file to apply the changes.

**NOTE**
Configurations applied to the `user-workload-monitoring-config` ConfigMap object are not activated unless a cluster administrator has enabled monitoring for user-defined projects.

**WARNING**
When you save changes to a monitoring config map, pods and other resources in the related project might be redeployed. The running monitoring processes in that project might also be restarted.

4. Verify that the pods for the component are running. The following example command lists the status of pods in the `openshift-user-workload-monitoring` project:

```
$ oc -n openshift-user-workload-monitoring get pods
```

5. Read the query log:

```
$ oc -n openshift-user-workload-monitoring exec prometheus-user-workload-0 -- cat <path>
```

**IMPORTANT**
Revert the setting in the config map after you have examined the logged query information.

Additional resources
- See [Preparing to configure the monitoring stack](#) for steps to create monitoring config maps
- See [Enabling monitoring for user-defined projects](#) for steps to enable user-defined monitoring.

### 5.6. ENABLING QUERY LOGGING FOR THANOS QUERIER
For default platform monitoring in the openshift-monitoring project, you can enable the Cluster Monitoring Operator to log all queries run by Thanos Querier.

**IMPORTANT**

Because log rotation is not supported, only enable this feature temporarily when you need to troubleshoot an issue. After you finish troubleshooting, disable query logging by reverting the changes you made to the ConfigMap object to enable the feature.

**Prerequisites**

- You have installed the OpenShift CLI (oc).
- You have access to the cluster as a user with the cluster-admin cluster role.
- You have created the cluster-monitoring-config ConfigMap object.

**Procedure**

You can enable query logging for Thanos Querier in the openshift-monitoring project:

1. Edit the cluster-monitoring-config ConfigMap object in the openshift-monitoring project:

   ```bash
   $ oc -n openshift-monitoring edit configmap cluster-monitoring-config
   ```

2. Add a thanosQuerier section under data/config.yaml and add values as shown in the following example:

   ```yaml
   apiVersion: v1
   kind: ConfigMap
   metadata:
     name: cluster-monitoring-config
     namespace: openshift-monitoring
   data:
     config.yaml: |
       thanosQuerier:
         enableRequestLogging: <value> 1
         logLevel: <value> 2
   ```

   1. Set the value to `true` to enable logging and `false` to disable logging. The default value is `false`.

   2. Set the value to `debug, info, warn`, or `error`. If no value exists for `logLevel`, the log level defaults to `error`.

3. Save the file to apply the changes.
WARNING

When you save changes to a monitoring config map, pods and other resources in the related project might be redeployed. The running monitoring processes in that project might also be restarted.

Verification

1. Verify that the Thanos Querier pods are running. The following sample command lists the status of pods in the openshift-monitoring project:

   $ oc -n openshift-monitoring get pods

2. Run a test query using the following sample commands as a model:

   $ token=`oc create token prometheus-k8s -n openshift-monitoring`

3. Run the following command to read the query log:

   $ oc -n openshift-monitoring logs <thanos_querier_pod_name> -c thanos-query

   **NOTE**

   Because the thanos-querier pods are highly available (HA) pods, you might be able to see logs in only one pod.

4. After you examine the logged query information, disable query logging by changing the enableRequestLogging value to false in the config map.

Additional resources

- See [Preparing to configure the monitoring stack](#) for steps to create monitoring config maps.
CHAPTER 6. SETTING AUDIT LOG LEVELS FOR THE PROMETHEUS ADAPTER

In default platform monitoring, you can configure the audit log level for the Prometheus Adapter.

Prerequisites

- You have installed the OpenShift CLI (oc).
- You have access to the cluster as a user with the cluster-admin cluster role.
- You have created the cluster-monitoring-config ConfigMap object.

Procedure

You can set an audit log level for the Prometheus Adapter in the default openshift-monitoring project:

1. Edit the cluster-monitoring-config ConfigMap object in the openshift-monitoring project:

   $ oc -n openshift-monitoring edit configmap cluster-monitoring-config

2. Add profile: in the k8sPrometheusAdapter/audit section under data/config.yaml:

   ```yaml
   apiVersion: v1
   kind: ConfigMap
   metadata:
     name: cluster-monitoring-config
     namespace: openshift-monitoring
   data:
     config.yaml:
       k8sPrometheusAdapter:
         audit:
           profile: <audit_log_level>  
   
   1 The audit log level to apply to the Prometheus Adapter.

3. Set the audit log level by using one of the following values for the profile: parameter:

   - **None**: Do not log events.
   - **Metadata**: Log only the metadata for the request, such as user, timestamp, and so forth. Do not log the request text and the response text. **Metadata** is the default audit log level.
   - **Request**: Log only the metadata and the request text but not the response text. This option does not apply for non-resource requests.
   - **RequestResponse**: Log event metadata, request text, and response text. This option does not apply for non-resource requests.

4. Save the file to apply the changes. The pods for the Prometheus Adapter restart automatically when you apply the change.
WARNING

When changes are saved to a monitoring config map, the pods and other resources in the related project might be redeployed. The running monitoring processes in that project might also be restarted.

Verification

1. In the config map, under `k8sPrometheusAdapter/audit/profile`, set the log level to `Request` and save the file.

2. Confirm that the pods for the Prometheus Adapter are running. The following example lists the status of pods in the `openshift-monitoring` project:

   ```bash
   $ oc -n openshift-monitoring get pods
   ```

3. Confirm that the audit log level and audit log file path are correctly configured:

   ```bash
   $ oc -n openshift-monitoring get deploy prometheus-adapter -o yaml
   ```

Example output

   ```yaml
   ...  
   - --audit-policy-file=/etc/audit/request-profile.yaml  
   - --audit-log-path=/var/log/adapter/audit.log
   ```

4. Confirm that the correct log level has been applied in the `prometheus-adapter` deployment in the `openshift-monitoring` project:

   ```bash
   $ oc -n openshift-monitoring exec deploy/prometheus-adapter -c prometheus-adapter -- cat /etc/audit/request-profile.yaml
   ```

Example output

   ```json
   "apiVersion": "audit.k8s.io/v1"  
   "kind": "Policy"  
   "metadata":  
   "name": "Request"  
   "omitStages":  
   - "RequestReceived"  
   "rules":  
   - "level": "Request"
   ```

NOTE

If you enter an unrecognized `profile` value for the Prometheus Adapter in the `ConfigMap` object, no changes are made to the Prometheus Adapter, and an error is logged by the Cluster Monitoring Operator.
5. Review the audit log for the Prometheus Adapter:

```
$ oc -n openshift-monitoring exec -c <prometheus_adapter_pod_name> -- cat /var/log/adapter/audit.log
```

Additional resources

- See [Preparing to configure the monitoring stack](#) for steps to create monitoring config maps.

### 6.1. DISABLING THE LOCAL ALERTMANAGER

A local Alertmanager that routes alerts from Prometheus instances is enabled by default in the `openshift-monitoring` project of the OpenShift Container Platform monitoring stack.

If you do not need the local Alertmanager, you can disable it by configuring the `cluster-monitoring-config` config map in the `openshift-monitoring` project.

**Prerequisites**

- You have access to the cluster as a user with the `cluster-admin` cluster role.
- You have created the `cluster-monitoring-config` config map.
- You have installed the OpenShift CLI (`oc`).

**Procedure**

1. Edit the `cluster-monitoring-config` config map in the `openshift-monitoring` project:

   ```
   $ oc -n openshift-monitoring edit configmap cluster-monitoring-config
   ```

2. Add `enabled: false` for the `alertmanagerMain` component under `data/config.yaml`:

   ```json
   apiVersion: v1
   kind: ConfigMap
   metadata:
     name: cluster-monitoring-config
     namespace: openshift-monitoring
   data:
     config.yaml: |
     alertmanagerMain:
       enabled: false
   ```

3. Save the file to apply the changes. The Alertmanager instance is disabled automatically when you apply the change.

**Additional resources**

### 6.2. NEXT STEPS
- Enabling monitoring for user-defined projects
- Learn about remote health reporting and, if necessary, opt out of it.
CHAPTER 7. ENABLING MONITORING FOR USER-DEFINED PROJECTS

In OpenShift Container Platform 4.15, you can enable monitoring for user-defined projects in addition to the default platform monitoring. You can monitor your own projects in OpenShift Container Platform without the need for an additional monitoring solution. Using this feature centralizes monitoring for core platform components and user-defined projects.

NOTE

Versions of Prometheus Operator installed using Operator Lifecycle Manager (OLM) are not compatible with user-defined monitoring. Therefore, custom Prometheus instances installed as a Prometheus custom resource (CR) managed by the OLM Prometheus Operator are not supported in OpenShift Container Platform.

7.1. ENABLING MONITORING FOR USER-DEFINED PROJECTS

Cluster administrators can enable monitoring for user-defined projects by setting the `enableUserWorkload: true` field in the cluster monitoring ConfigMap object.

IMPORTANT

In OpenShift Container Platform 4.15 you must remove any custom Prometheus instances before enabling monitoring for user-defined projects.

NOTE

You must have access to the cluster as a user with the cluster-admin cluster role to enable monitoring for user-defined projects in OpenShift Container Platform. Cluster administrators can then optionally grant users permission to configure the components that are responsible for monitoring user-defined projects.

Prerequisites

- You have access to the cluster as a user with the cluster-admin cluster role.
- You have installed the OpenShift CLI (oc).
- You have created the cluster-monitoring-config ConfigMap object.
- You have optionally created and configured the user-workload-monitoring-config ConfigMap object in the openshift-user-workload-monitoring project. You can add configuration options to this ConfigMap object for the components that monitor user-defined projects.

NOTE

Every time you save configuration changes to the user-workload-monitoring-config ConfigMap object, the pods in the openshift-user-workload-monitoring project are redeployed. It can sometimes take a while for these components to redeploy. You can create and configure the ConfigMap object before you first enable monitoring for user-defined projects, to prevent having to redeploy the pods often.
Procedure

1. Edit the `cluster-monitoring-config` ConfigMap object:
   
   ```bash
   $ oc -n openshift-monitoring edit configmap cluster-monitoring-config
   ```

2. Add `enableUserWorkload: true` under `data/config.yaml`:
   
   ```yaml
   apiVersion: v1
   kind: ConfigMap
   metadata:
     name: cluster-monitoring-config
     namespace: openshift-monitoring
   data:
     config.yaml:
       enableUserWorkload: true
   ```
   
   When set to `true`, the `enableUserWorkload` parameter enables monitoring for user-defined projects in a cluster.

3. Save the file to apply the changes. Monitoring for user-defined projects is then enabled automatically.

   **WARNING**

   When changes are saved to the `cluster-monitoring-config` ConfigMap object, the pods and other resources in the `openshift-monitoring` project might be redeployed. The running monitoring processes in that project might also be restarted.

4. Check that the `prometheus-operator`, `prometheus-user-workload` and `thanos-ruler-user-workload` pods are running in the `openshift-user-workload-monitoring` project. It might take a short while for the pods to start:
   
   ```bash
   $ oc -n openshift-user-workload-monitoring get pod
   ```

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>prometheus-operator-6f7b748d5b-t7nbg</td>
<td>2/2</td>
<td>Running</td>
<td>0</td>
<td>3h</td>
</tr>
<tr>
<td>prometheus-user-workload-0</td>
<td>4/4</td>
<td>Running</td>
<td>1</td>
<td>3h</td>
</tr>
<tr>
<td>prometheus-user-workload-1</td>
<td>4/4</td>
<td>Running</td>
<td>1</td>
<td>3h</td>
</tr>
<tr>
<td>thanos-ruler-user-workload-0</td>
<td>3/3</td>
<td>Running</td>
<td>0</td>
<td>3h</td>
</tr>
<tr>
<td>thanos-ruler-user-workload-1</td>
<td>3/3</td>
<td>Running</td>
<td>0</td>
<td>3h</td>
</tr>
</tbody>
</table>

   **Additional resources**

   - Creating a user-defined workload monitoring config map
7.2. GRANTING USERS PERMISSION TO MONITOR USER-DEFINED PROJECTS

Cluster administrators can monitor all core OpenShift Container Platform and user-defined projects.

Cluster administrators can grant developers and other users permission to monitor their own projects. Privileges are granted by assigning one of the following monitoring roles:

- The `monitoring-rules-view` cluster role provides read access to `PrometheusRule` custom resources for a project.

- The `monitoring-rules-edit` cluster role grants a user permission to create, modify, and delete `PrometheusRule` custom resources for a project. It also grants a user the ability to silence alerts.

- The `monitoring-edit` cluster role grants the same privileges as the `monitoring-rules-edit` cluster role. Additionally, it enables a user to create new scrape targets for services or pods. With this role, you can also create, modify, and delete `ServiceMonitor` and `PodMonitor` resources.

You can also grant users permission to configure the components that are responsible for monitoring user-defined projects:

- The `user-workload-monitoring-config-edit` role in the `openshift-user-workload-monitoring` project enables you to edit the `user-workload-monitoring-config` ConfigMap object. With this role, you can edit the ConfigMap object to configure Prometheus, Prometheus Operator, and Thanos Ruler for user-defined workload monitoring.

You can also grant users permission to configure alert routing for user-defined projects:

- The `alert-routing-edit` cluster role grants a user permission to create, update, and delete `AlertmanagerConfig` custom resources for a project.

This section provides details on how to assign these roles by using the OpenShift Container Platform web console or the CLI.

7.2.1. Granting user permissions by using the web console

You can grant users permissions to monitor their own projects, by using the OpenShift Container Platform web console.

**Prerequisites**

- You have access to the cluster as a user with the `cluster-admin` cluster role.

- The user account that you are assigning the role to already exists.

**Procedure**

1. In the Administrator perspective within the OpenShift Container Platform web console, navigate to User Management → RoleBindings → Create binding.
2. In the **Binding Type** section, select the "Namespace Role Binding" type.

3. In the **Name** field, enter a name for the role binding.

4. In the **Namespace** field, select the user-defined project where you want to grant the access.

    **IMPORTANT**

    The monitoring role will be bound to the project that you apply in the **Namespace** field. The permissions that you grant to a user by using this procedure will apply only to the selected project.

5. Select **monitoring-rules-view**, **monitoring-rules-edit**, or **monitoring-edit** in the **Role Name** list.

6. In the **Subject** section, select **User**.

7. In the **Subject Name** field, enter the name of the user.

8. Select **Create** to apply the role binding.

### 7.2.2. Granting user permissions by using the CLI

You can grant users permissions to monitor their own projects, by using the OpenShift CLI (`oc`).

**Prerequisites**

- You have access to the cluster as a user with the `cluster-admin` cluster role.
- The user account that you are assigning the role to already exists.
- You have installed the OpenShift CLI (`oc`).

**Procedure**

- Assign a monitoring role to a user for a project:

  ```
  $ oc policy add-role-to-user <role> <user> -n <namespace>
  ```

  **1** Substitute `<role>` with **monitoring-rules-view**, **monitoring-rules-edit**, or **monitoring-edit**.

    **IMPORTANT**

    Whichever role you choose, you must bind it against a specific project as a cluster administrator.

    As an example, substitute `<role>` with **monitoring-edit**, `<user>` with **johnsmith**, and `<namespace>` with **ns1**. This assigns the user **johnsmith** permission to set up metrics collection and to create alerting rules in the **ns1** namespace.
7.3. GRANTING USERS PERMISSION TO CONFIGURE MONITORING FOR USER-DEFINED PROJECTS

As a cluster administrator, you can assign the `user-workload-monitoring-config-edit` role to a user. This grants permission to configure and manage monitoring for user-defined projects without giving them permission to configure and manage core OpenShift Container Platform monitoring components.

**Prerequisites**

- You have access to the cluster as a user with the `cluster-admin` cluster role.
- The user account that you are assigning the role to already exists.
- You have installed the OpenShift CLI (`oc`).

**Procedure**

1. Assign the `user-workload-monitoring-config-edit` role to a user in the `openshift-user-workload-monitoring` project:

   ```
   $ oc -n openshift-user-workload-monitoring adm policy add-role-to-user \ 
   user-workload-monitoring-config-edit <user> \ 
   --role-namespace openshift-user-workload-monitoring
   ```

2. Verify that the user is correctly assigned to the `user-workload-monitoring-config-edit` role by displaying the related role binding:

   ```
   $ oc describe rolebinding <role_binding_name> -n openshift-user-workload-monitoring
   ``

**Example command**

```
$ oc describe rolebinding user-workload-monitoring-config-edit -n openshift-user-workload-monitoring
```

**Example output**

```
Name:         user-workload-monitoring-config-edit
Labels:       <none>
Annotations:  <none>
Role:         
  Kind:  Role
  Name:  user-workload-monitoring-config-edit
Subjects:     
  Kind:  Name  Namespace
  ----  -----  --------
    User user1
```

1. In this example, `user1` is assigned to the `user-workload-monitoring-config-edit` role.

7.4. ACCESSING METRICS FROM OUTSIDE THE CLUSTER FOR CUSTOM APPLICATIONS
You can query Prometheus metrics from outside the cluster when monitoring your own services with user-defined projects. Access this data from outside the cluster by using the `thanos-querier` route.

This access only supports using a Bearer Token for authentication.

**Prerequisites**

- You have deployed your own service, following the "Enabling monitoring for user-defined projects" procedure.
- You are logged in to an account with the `cluster-monitoring-view` cluster role, which provides permission to access the Thanos Querier API.
- You are logged in to an account that has permission to get the Thanos Querier API route.

**NOTE**

If your account does not have permission to get the Thanos Querier API route, a cluster administrator can provide the URL for the route.

**Procedure**

1. Extract an authentication token to connect to Prometheus by running the following command:

   ```bash
   $ TOKEN=$(oc whoami -t)
   ```

2. Extract the `thanos-querier` API route URL by running the following command:

   ```bash
   $ HOST=$(oc -n openshift-monitoring get route thanos-querier -ojsonpath={.spec.host})
   ```

3. Set the namespace to the namespace in which your service is running by using the following command:

   ```bash
   $ NAMESPACE=ns1
   ```

4. Query the metrics of your own services in the command line by running the following command:

   ```bash
   ```

   The output shows the status for each application pod that Prometheus is scraping:

   ```json
   
   
   
   
   
   
   
   
   ```

**Additional resources**

- [Enabling monitoring for user-defined projects](#)
7.5. EXCLUDING A USER-DEFINED PROJECT FROM MONITORING

Individual user-defined projects can be excluded from user workload monitoring. To do so, add the `openshift.io/user-monitoring` label to the project’s namespace with a value of `false`.

**Procedure**

1. Add the label to the project namespace:

   ```$ oc label namespace my-project 'openshift.io/user-monitoring=false'```

2. To re-enable monitoring, remove the label from the namespace:

   ```$ oc label namespace my-project 'openshift.io/user-monitoring'```

   **NOTE**

   If there were any active monitoring targets for the project, it may take a few minutes for Prometheus to stop scraping them after adding the label.

7.6. DISABLING MONITORING FOR USER-DEFINED PROJECTS

After enabling monitoring for user-defined projects, you can disable it again by setting `enableUserWorkload: false` in the cluster monitoring `ConfigMap` object.

**NOTE**

Alternatively, you can remove `enableUserWorkload: true` to disable monitoring for user-defined projects.

**Procedure**

1. Edit the `cluster-monitoring-config ConfigMap` object:

   ```$ oc -n openshift-monitoring edit configmap cluster-monitoring-config```

   a. Set `enableUserWorkload:` to `false` under `data/config.yaml`:

   ```
   apiVersion: v1
   kind: ConfigMap
   metadata:
     name: cluster-monitoring-config
   namespace: openshift-monitoring
   data:
     config.yaml:
       enableUserWorkload: false
   ```

2. Save the file to apply the changes. Monitoring for user-defined projects is then disabled automatically.

3. Check that the `prometheus-operator`, `prometheus-user-workload` and `thanos-ruler-user-workload` pods are terminated in the `openshift-user-workload-monitoring` project. This might take a short while:
$ oc -n openshift-user-workload-monitoring get pod

Example output

No resources found in openshift-user-workload-monitoring project.

NOTE

The `user-workload-monitoring-config ConfigMap` object in the `openshift-user-workload-monitoring` project is not automatically deleted when monitoring for user-defined projects is disabled. This is to preserve any custom configurations that you may have created in the `ConfigMap` object.

7.7. NEXT STEPS

- Managing metrics
CHAPTER 8. ENABLING ALERT ROUTING FOR USER-DEFINED PROJECTS

In OpenShift Container Platform 4.15, a cluster administrator can enable alert routing for user-defined projects. This process consists of two general steps:

- Enable alert routing for user-defined projects to use the default platform Alertmanager instance or, optionally, a separate Alertmanager instance only for user-defined projects.

- Grant users permission to configure alert routing for user-defined projects.

After you complete these steps, developers and other users can configure custom alerts and alert routing for their user-defined projects.

8.1. UNDERSTANDING ALERT ROUTING FOR USER-DEFINED PROJECTS

As a cluster administrator, you can enable alert routing for user-defined projects. With this feature, you can allow users with the `alert-routing-edit` role to configure alert notification routing and receivers for user-defined projects. These notifications are routed by the default Alertmanager instance or, if enabled, an optional Alertmanager instance dedicated to user-defined monitoring.

Users can then create and configure user-defined alert routing by creating or editing the `AlertmanagerConfig` objects for their user-defined projects without the help of an administrator.

After a user has defined alert routing for a user-defined project, user-defined alert notifications are routed as follows:

- To the `alertmanager-main` pods in the `openshift-monitoring` namespace if using the default platform Alertmanager instance.

- To the `alertmanager-user-workload` pods in the `openshift-user-workload-monitoring` namespace if you have enabled a separate instance of Alertmanager for user-defined projects.

**NOTE**

The following are limitations of alert routing for user-defined projects:

- For user-defined alerting rules, user-defined routing is scoped to the namespace in which the resource is defined. For example, a routing configuration in namespace `ns1` only applies to `PrometheusRules` resources in the same namespace.

- When a namespace is excluded from user-defined monitoring, `AlertmanagerConfig` resources in the namespace cease to be part of the Alertmanager configuration.

8.2. ENABLING THE PLATFORM ALERTMANAGER INSTANCE FOR USER-DEFINED ALERT ROUTING

You can allow users to create user-defined alert routing configurations that use the main platform instance of Alertmanager.

Prerequisites
Prerequisites

- You have access to the cluster as a user with the `cluster-admin` cluster role.
- You have installed the OpenShift CLI (`oc`).

Procedure

1. Edit the `cluster-monitoring-config` ConfigMap object:

   ```bash
   $ oc -n openshift-monitoring edit configmap cluster-monitoring-config
   ```

2. Add `enableUserAlertmanagerConfig: true` in the `alertmanagerMain` section under `data/config.yaml`:

   ```yaml
   apiVersion: v1
   kind: ConfigMap
   metadata:
     name: cluster-monitoring-config
     namespace: openshift-monitoring
   data:
     config.yaml:
       alertmanagerMain:
         enableUserAlertmanagerConfig: true
   ```

   Set the `enableUserAlertmanagerConfig` value to `true` to allow users to create user-defined alert routing configurations that use the main platform instance of Alertmanager.

3. Save the file to apply the changes.

8.3. ENABLING A SEPARATE ALERTMANAGER INSTANCE FOR USER-DEFINED ALERT ROUTING

In some clusters, you might want to deploy a dedicated Alertmanager instance for user-defined projects, which can help reduce the load on the default platform Alertmanager instance and can better separate user-defined alerts from default platform alerts. In these cases, you can optionally enable a separate instance of Alertmanager to send alerts for user-defined projects only.

Prerequisites

- You have access to the cluster as a user with the `cluster-admin` cluster role.
- You have enabled monitoring for user-defined projects in the `cluster-monitoring-config` config map for the `openshift-monitoring` namespace.
- You have installed the OpenShift CLI (`oc`).

Procedure

1. Edit the `user-workload-monitoring-config` ConfigMap object:

   ```bash
   $ oc -n openshift-user-workload-monitoring edit configmap user-workload-monitoring-config
   ```
2. Add `enabled: true` and `enableAlertmanagerConfig: true` in the `alertmanager` section under `data/config.yaml`:

```yaml
apiVersion: v1
kind: ConfigMap
metadata:
  name: user-workload-monitoring-config
  namespace: openshift-user-workload-monitoring
data:
  config.yaml: |
    alertmanager:
      enabled: true
      enableAlertmanagerConfig: true
```

1. Set the `enabled` value to `true` to enable a dedicated instance of the Alertmanager for user-defined projects in a cluster. Set the value to `false` or omit the key entirely to disable the Alertmanager for user-defined projects. If you set this value to `false` or if the key is omitted, user-defined alerts are routed to the default platform Alertmanager instance.

2. Set the `enableAlertmanagerConfig` value to `true` to enable users to define their own alert routing configurations with `AlertmanagerConfig` objects.

3. Save the file to apply the changes. The dedicated instance of Alertmanager for user-defined projects starts automatically.

**Verification**

- Verify that the `user-workload` Alertmanager instance has started:

  ```bash
  # oc -n openshift-user-workload-monitoring get alertmanager
  ```

  **Example output**

  ```
  NAME            VERSION   REPLICAS   AGE
  user-workload   0.24.0    2          100s
  ```

### 8.4. Granting Users Permission to Configure Alert Routing for User-Defined Projects

You can grant users permission to configure alert routing for user-defined projects.

**Prerequisites**

- You have access to the cluster as a user with the `cluster-admin` cluster role.

- You have enabled monitoring for user-defined projects in the `cluster-monitoring-config` config map for the `openshift-monitoring` namespace.

- The user account that you are assigning the role to already exists.

- You have installed the OpenShift CLI (`oc`).
Procedure

- Assign the `alert-routing-edit` cluster role to a user in the user-defined project:

  ```bash
  $ oc -n <namespace> adm policy add-role-to-user alert-routing-edit <user>
  ```

  For `<namespace>`, substitute the namespace for the user-defined project, such as `ns1`. For `<user>`, substitute the username for the account to which you want to assign the role.

Additional resources

- Enabling monitoring for user defined projects
- Creating alert routing for user-defined projects

8.5. NEXT STEPS

- Managing alerts
CHAPTER 9. MANAGING METRICS

You can collect metrics to monitor how cluster components and your own workloads are performing.

9.1. UNDERSTANDING METRICS

In OpenShift Container Platform 4.15, cluster components are monitored by scraping metrics exposed through service endpoints. You can also configure metrics collection for user-defined projects. Metrics enable you to monitor how cluster components and your own workloads are performing.

You can define the metrics that you want to provide for your own workloads by using Prometheus client libraries at the application level.

In OpenShift Container Platform, metrics are exposed through an HTTP service endpoint under the /metrics canonical name. You can list all available metrics for a service by running a curl query against http://<endpoint>/metrics. For instance, you can expose a route to the prometheus-example-app example application and then run the following to view all of its available metrics:

```bash
$ curl http://<example_app_endpoint>/metrics
```

Example output

```
# HELP http_requests_total Count of all HTTP requests
# TYPE http_requests_total counter
http_requests_total{code="200",method="get"} 4
http_requests_total{code="404",method="get"} 2
# HELP version Version information about this binary
# TYPE version gauge
version{version="v0.1.0"} 1
```

Additional resources

- Prometheus client library documentation

9.2. SETTING UP METRICS COLLECTION FOR USER-DEFINED PROJECTS

You can create a ServiceMonitor resource to scrape metrics from a service endpoint in a user-defined project. This assumes that your application uses a Prometheus client library to expose metrics to the /metrics canonical name.

This section describes how to deploy a sample service in a user-defined project and then create a ServiceMonitor resource that defines how that service should be monitored.

9.2.1. Deploying a sample service

To test monitoring of a service in a user-defined project, you can deploy a sample service.

Procedure

1. Create a YAML file for the service configuration. In this example, it is called prometheus-example-app.yaml.
2. Add the following deployment and service configuration details to the file:

```yaml
apiVersion: v1
kind: Namespace
metadata:
  name: ns1
---
apiVersion: apps/v1
kind: Deployment
metadata:
  labels:
    app: prometheus-example-app
name: prometheus-example-app
namespace: ns1
spec:
  replicas: 1
selector:
  matchLabels:
    app: prometheus-example-app
template:
  metadata:
    labels:
      app: prometheus-example-app
spec:
  containers:
  - image: ghcr.io/rhobs/prometheus-example-app:0.4.2
    imagePullPolicy: IfNotPresent
    name: prometheus-example-app
---
apiVersion: v1
kind: Service
metadata:
  labels:
    app: prometheus-example-app
name: prometheus-example-app
namespace: ns1
spec:
  ports:
  - port: 8080
    protocol: TCP
    targetPort: 8080
    name: web
  selector:
    app: prometheus-example-app
  type: ClusterIP
```

This configuration deploys a service named `prometheus-example-app` in the user-defined `ns1` project. This service exposes the custom `version` metric.

3. Apply the configuration to the cluster:

```bash
$ oc apply -f prometheus-example-app.yaml
```

It takes some time to deploy the service.

4. You can check that the pod is running:
9.2.2. Specifying how a service is monitored

To use the metrics exposed by your service, you must configure OpenShift Container Platform monitoring to scrape metrics from the /metrics endpoint. You can do this using a ServiceMonitor custom resource definition (CRD) that specifies how a service should be monitored, or a PodMonitor CRD that specifies how a pod should be monitored. The former requires a Service object, while the latter does not, allowing Prometheus to directly scrape metrics from the metrics endpoint exposed by a pod.

This procedure shows you how to create a ServiceMonitor resource for a service in a user-defined project.

Prerequisites

- You have access to the cluster as a user with the cluster-admin cluster role or the monitoring-edit cluster role.
- You have enabled monitoring for user-defined projects.
- For this example, you have deployed the prometheus-example-app sample service in the ns1 project.

NOTE

The prometheus-example-app sample service does not support TLS authentication.

Procedure

1. Create a YAML file for the ServiceMonitor resource configuration. In this example, the file is called example-app-service-monitor.yaml.

2. Add the following ServiceMonitor resource configuration details:

   ```yaml
   apiVersion: monitoring.coreos.com/v1
   kind: ServiceMonitor
   metadata:
     labels:
       k8s-app: prometheus-example-monitor
   spec:
     endpoints:
     - interval: 30s
       port: web
       scheme: http
   ```
This defines a ServiceMonitor resource that scrapes the metrics exposed by the prometheus-example-app sample service, which includes the version metric.

NOTE

A ServiceMonitor resource in a user-defined namespace can only discover services in the same namespace. That is, the namespaceSelector field of the ServiceMonitor resource is always ignored.

3. Apply the configuration to the cluster:

   $ oc apply -f example-app-service-monitor.yaml

   It takes some time to deploy the ServiceMonitor resource.

4. You can check that the ServiceMonitor resource is running:

   $ oc -n ns1 get servicemonitor

Example output

   NAME          AGE
   prometheus-example-monitor  81m

Additional resources

- Enabling monitoring for user-defined projects
- How to scrape metrics using TLS in a ServiceMonitor configuration in a user-defined project
- PodMonitor API
- ServiceMonitor API

9.3. VIEWING A LIST OF AVAILABLE METRICS

As a cluster administrator or as a user with view permissions for all projects, you can view a list of metrics available in a cluster and output the list in JSON format.

Prerequisites

- You are a cluster administrator, or you have access to the cluster as a user with the cluster-monitoring-view cluster role.
- You have installed the OpenShift Container Platform CLI (oc).
- You have obtained the OpenShift Container Platform API route for Thanos Querier.
- You are able to get a bearer token by using the oc whoami -t command.
IMPORTANT

You can only use bearer token authentication to access the Thanos Querier API route.

Procedure

1. If you have not obtained the OpenShift Container Platform API route for Thanos Querier, run the following command:

   $$\text{oc get routes -n openshift-monitoring thanos-querier -o jsonpath=\'{.status.ingress[0].host}\'}$$

2. Retrieve a list of metrics in JSON format from the Thanos Querier API route by running the following command. This command uses oc to authenticate with a bearer token.

   $$\text{curl -k -H "Authorization: Bearer $(oc whoami -t)" https://<thanos_querier_route>/api/v1/metadata}$$

   Replace `<thanos_querier_route>` with the OpenShift Container Platform API route for Thanos Querier.

9.4. QUERYING METRICS

The OpenShift Container Platform monitoring dashboard enables you to run Prometheus Query Language (PromQL) queries to examine metrics visualized on a plot. This functionality provides information about the state of a cluster and any user-defined workloads that you are monitoring.

As a cluster administrator, you can query metrics for all core OpenShift Container Platform and user-defined projects.

As a developer, you must specify a project name when querying metrics. You must have the required privileges to view metrics for the selected project.

9.4.1. Querying metrics for all projects as a cluster administrator

As a cluster administrator or as a user with view permissions for all projects, you can access metrics for all default OpenShift Container Platform and user-defined projects in the Metrics UI.

Prerequisites

- You have access to the cluster as a user with the `cluster-admin` cluster role or with view permissions for all projects.
- You have installed the OpenShift CLI (oc).

Procedure

1. From the Administrator perspective in the OpenShift Container Platform web console, select Observe → Metrics.

2. To add one or more queries, do any of the following:
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a custom query.</td>
<td>Add your Prometheus Query Language (PromQL) query to the <strong>Expression</strong> field. As you type a PromQL expression, autocomplete suggestions appear in a drop-down list. These suggestions include functions, metrics, labels, and time tokens. You can use the keyboard arrows to select one of these suggested items and then press Enter to add the item to your expression. You can also move your mouse pointer over a suggested item to view a brief description of that item.</td>
</tr>
<tr>
<td>Add multiple queries.</td>
<td>Select <strong>Add query</strong>.</td>
</tr>
<tr>
<td>Duplicate an existing query.</td>
<td>Select the Options menu next to the query, then choose <strong>Duplicate query</strong>.</td>
</tr>
<tr>
<td>Disable a query from being run.</td>
<td>Select the Options menu next to the query and choose <strong>Disable query</strong>.</td>
</tr>
</tbody>
</table>

3. To run queries that you created, select **Run queries**. The metrics from the queries are visualized on the plot. If a query is invalid, the UI shows an error message.

**NOTE**

Queries that operate on large amounts of data might time out or overload the browser when drawing time series graphs. To avoid this, select **Hide graph** and calibrate your query using only the metrics table. Then, after finding a feasible query, enable the plot to draw the graphs.

**NOTE**

By default, the query table shows an expanded view that lists every metric and its current value. You can select ℹ️ to minimize the expanded view for a query.

4. Optional: The page URL now contains the queries you ran. To use this set of queries again in the future, save this URL.

5. Explore the visualized metrics. Initially, all metrics from all enabled queries are shown on the plot. You can select which metrics are shown by doing any of the following:

<table>
<thead>

<tbody>
<tr>
<td>OpenShift Container Platform 4.15 Monitoring</td>
<td>110</td>
</tr>
</tbody>
</table>
**Hide all metrics from a query.**

Click the Options menu for the query and click **Hide all series**.

**Hide a specific metric.**

Go to the query table and click the colored square near the metric name.

**Zoom into the plot and change the time range.**

Either:

- Visually select the time range by clicking and dragging on the plot horizontally.
- Use the menu in the left upper corner to select the time range.

**Reset the time range.**

Select **Reset zoom**.

**Display outputs for all queries at a specific point in time.**

Hold the mouse cursor on the plot at that point. The query outputs will appear in a pop-up box.

**Hide the plot.**

Select **Hide graph**.

### Additional resources

- For more information about creating PromQL queries, see the Prometheus query documentation.

### 9.4.2. Querying metrics for user-defined projects as a developer

You can access metrics for a user-defined project as a developer or as a user with view permissions for the project.

In the **Developer** perspective, the Metrics UI includes some predefined CPU, memory, bandwidth, and network packet queries for the selected project. You can also run custom Prometheus Query Language (PromQL) queries for CPU, memory, bandwidth, network packet and application metrics for the project.

**NOTE**

Developers can only use the **Developer** perspective and not the **Administrator** perspective. As a developer, you can only query metrics for one project at a time.

### Prerequisites

- You have access to the cluster as a developer or as a user with view permissions for the project that you are viewing metrics for.

- You have enabled monitoring for user-defined projects.
• You have deployed a service in a user-defined project.

• You have created a **ServiceMonitor** custom resource definition (CRD) for the service to define how the service is monitored.

**Procedure**

1. From the **Developer** perspective in the OpenShift Container Platform web console, select **Observe → Metrics**.

2. Select the project that you want to view metrics for in the **Project** list.

3. Select a query from the **Select query** list, or create a custom PromQL query based on the selected query by selecting **Show PromQL**. The metrics from the queries are visualized on the plot.

**NOTE**

In the Developer perspective, you can only run one query at a time.

4. Explore the visualized metrics by doing any of the following:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
</table>
| Zoom into the plot and change the time range. | Either:  
  1. Visually select the time range by clicking and dragging on the plot horizontally.  
  2. Use the menu in the left upper corner to select the time range. |
| Reset the time range.                | Select **Reset zoom**.                                                     |
| Display outputs for all queries at a specific point in time. | Hold the mouse cursor on the plot at that point. The query outputs appear in a pop-up box. |

**Additional resources**

- For more information about creating PromQL queries, see the **Prometheus query documentation**.

**9.5. GETTING DETAILED INFORMATION ABOUT A METRICS TARGET**

In the **Administrator** perspective in the OpenShift Container Platform web console, you can use the **Metrics targets** page to view, search, and filter the endpoints that are currently targeted for scraping, which helps you to identify and troubleshoot problems. For example, you can view the current status of targeted endpoints to see when OpenShift Container Platform Monitoring is not able to scrape metrics from a targeted component.

The **Metrics targets** page shows targets for default OpenShift Container Platform projects and for user-defined projects.
Prerequisites

- You have access to the cluster as an administrator for the project for which you want to view metrics targets.

Procedure

1. In the Administrator perspective, select Observe $\rightarrow$ Targets. The Metrics targets page opens with a list of all service endpoint targets that are being scraped for metrics. This page shows details about targets for default OpenShift Container Platform and user-defined projects. This page lists the following information for each target:
   - Service endpoint URL being scraped
   - ServiceMonitor component being monitored
   - The up or down status of the target
   - Namespace
   - Last scrape time
   - Duration of the last scrape

2. Optional: The list of metrics targets can be long. To find a specific target, do any of the following:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Filter the targets by status and source.</td>
<td>Select filters in the Filter list. The following filtering options are available:</td>
</tr>
<tr>
<td></td>
<td>- <strong>Status filters:</strong></td>
</tr>
<tr>
<td></td>
<td>- <strong>Up.</strong> The target is currently up and being actively scraped for metrics.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Down.</strong> The target is currently down and not being scraped for metrics.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Source filters:</strong></td>
</tr>
<tr>
<td></td>
<td>- <strong>Platform.</strong> Platform-level targets relate only to default Red Hat OpenShift Service on AWS projects. These projects provide core Red Hat OpenShift Service on AWS functionality.</td>
</tr>
<tr>
<td></td>
<td>- <strong>User.</strong> User targets relate to user-defined projects. These projects are user-created and can be customized.</td>
</tr>
<tr>
<td>Search for a target by name or label.</td>
<td>Enter a search term in the Text or Label field next to the search box.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Sort the targets.</td>
<td>Click one or more of the <strong>Endpoint Status</strong>, <strong>Namespace</strong>, <strong>Last Scrape</strong>, and <strong>Scrape Duration</strong> column headers.</td>
</tr>
</tbody>
</table>

3. Click the URL in the **Endpoint** column for a target to navigate to its **Target details** page. This page provides information about the target, including the following:

- The endpoint URL being scraped for metrics
- The current **Up** or **Down** status of the target
- A link to the namespace
- A link to the ServiceMonitor details
- Labels attached to the target
- The most recent time that the target was scraped for metrics
In OpenShift Container Platform 4.15, the Alerting UI enables you to manage alerts, silences, and alerting rules.

- **Alerting rules.** Alerting rules contain a set of conditions that outline a particular state within a cluster. Alerts are triggered when those conditions are true. An alerting rule can be assigned a severity that defines how the alerts are routed.

- **Alerts.** An alert is fired when the conditions defined in an alerting rule are true. Alerts provide a notification that a set of circumstances are apparent within an OpenShift Container Platform cluster.

- **Silences.** A silence can be applied to an alert to prevent notifications from being sent when the conditions for an alert are true. You can mute an alert after the initial notification, while you work on resolving the underlying issue.

**NOTE**

The alerts, silences, and alerting rules that are available in the Alerting UI relate to the projects that you have access to. For example, if you are logged in as a user with the `cluster-admin` role, you can access all alerts, silences, and alerting rules.

If you are a non-administrator user, you can create and silence alerts if you are assigned the following user roles:

- The `cluster-monitoring-view` cluster role, which allows you to access Alertmanager
- The `monitoring-alertmanager-edit` role, which permits you to create and silence alerts in the Administrator perspective in the web console
- The `monitoring-rules-edit` cluster role, which permits you to create and silence alerts in the Developer perspective in the web console

### 10.1. ACCESSING THE ALERTING UI IN THE ADMINISTRATOR AND DEVELOPER PERSPECTIVES

The Alerting UI is accessible through the Administrator perspective and the Developer perspective of the OpenShift Container Platform web console.

- In the Administrator perspective, go to **Observe → Alerting.** The three main pages in the Alerting UI in this perspective are the **Alerts, Silences,** and **Alerting rules** pages.

- In the Developer perspective, go to **Observe → `<project_name>` → Alerts.** In this perspective, alerts, silences, and alerting rules are all managed from the **Alerts** page. The results shown in the **Alerts** page are specific to the selected project.

**NOTE**

In the Developer perspective, you can select from core OpenShift Container Platform and user-defined projects that you have access to in the **Project: `<project_name>`** list. However, alerts, silences, and alerting rules relating to core OpenShift Container Platform projects are not displayed if you are not logged in as a cluster administrator.
10.2. SEARCHING AND FILTERING ALERTS, SILENCES, AND ALERTING RULES

You can filter the alerts, silences, and alerting rules that are displayed in the Alerting UI. This section provides a description of each of the available filtering options.

Understanding alert filters
In the Administrator perspective, the Alerts page in the Alerting UI provides details about alerts relating to default OpenShift Container Platform and user-defined projects. The page includes a summary of severity, state, and source for each alert. The time at which an alert went into its current state is also shown.

You can filter by alert state, severity, and source. By default, only Platform alerts that are Firing are displayed. The following describes each alert filtering option:

- **State** filters:
  - **Firing**: The alert is firing because the alert condition is true and the optional for duration has passed. The alert continues to fire while the condition remains true.
  - **Pending**: The alert is active but is waiting for the duration that is specified in the alerting rule before it fires.
  - **Silenced**: The alert is now silenced for a defined time period. Silences temporarily mute alerts based on a set of label selectors that you define. Notifications are not sent for alerts that match all the listed values or regular expressions.

- **Severity** filters:
  - **Critical**: The condition that triggered the alert could have a critical impact. The alert requires immediate attention when fired and is typically paged to an individual or to a critical response team.
  - **Warning**: The alert provides a warning notification about something that might require attention to prevent a problem from occurring. Warnings are typically routed to a ticketing system for non-immediate review.
  - **Info**: The alert is provided for informational purposes only.
  - **None**: The alert has no defined severity.

You can also create custom severity definitions for alerts relating to user-defined projects.

- **Source** filters:
  - **Platform**: Platform-level alerts relate only to default OpenShift Container Platform projects. These projects provide core OpenShift Container Platform functionality.
  - **User**: User alerts relate to user-defined projects. These alerts are user-created and are customizable. User-defined workload monitoring can be enabled postinstallation to provide observability into your own workloads.

Understanding silence filters
In the Administrator perspective, the Silences page in the Alerting UI provides details about silences applied to alerts in default OpenShift Container Platform and user-defined projects. The page includes a summary of the state of each silence and the time at which a silence ends.
You can filter by silence state. By default, only **Active** and **Pending** silences are displayed. The following describes each silence state filter option:

- **State** filters:
  - **Active**. The silence is active and the alert will be muted until the silence is expired.
  - **Pending**. The silence has been scheduled and it is not yet active.
  - **Expired**. The silence has expired and notifications will be sent if the conditions for an alert are true.

**Understanding alerting rule filters**

In the **Administrator** perspective, the **Alerting rules** page in the Alerting UI provides details about alerting rules relating to default OpenShift Container Platform and user-defined projects. The page includes a summary of the state, severity, and source for each alerting rule.

You can filter alerting rules by alert state, severity, and source. By default, only **Platform** alerting rules are displayed. The following describes each alerting rule filtering option:

- **Alert state** filters:
  - **Firing**. The alert is firing because the alert condition is true and the optional **for** duration has passed. The alert continues to fire while the condition remains true.
  - **Pending**. The alert is active but is waiting for the duration that is specified in the alerting rule before it fires.
  - **Silenced**. The alert is now silenced for a defined time period. Silences temporarily mute alerts based on a set of label selectors that you define. Notifications are not sent for alerts that match all the listed values or regular expressions.
  - **Not Firing**. The alert is not firing.

- **Severity** filters:
  - **Critical**. The conditions defined in the alerting rule could have a critical impact. When true, these conditions require immediate attention. Alerts relating to the rule are typically paged to an individual or to a critical response team.
  - **Warning**. The conditions defined in the alerting rule might require attention to prevent a problem from occurring. Alerts relating to the rule are typically routed to a ticketing system for non-immediate review.
  - **Info**. The alerting rule provides informational alerts only.
  - **None**. The alerting rule has no defined severity.

- **Source** filters:
  - **Platform**. Platform-level alerting rules relate only to default OpenShift Container Platform projects. These projects provide core OpenShift Container Platform functionality.
User-defined workload alerting rules relate to user-defined projects. These alerting rules are user-created and are customizable. User-defined workload monitoring can be enabled postinstallation to provide observability into your own workloads.

Searching and filtering alerts, silences, and alerting rules in the Developer perspective

In the Developer perspective, the Alerts page in the Alerting UI provides a combined view of alerts and silences relating to the selected project. A link to the governing alerting rule is provided for each displayed alert.

In this view, you can filter by alert state and severity. By default, all alerts in the selected project are displayed if you have permission to access the project. These filters are the same as those described for the Administrator perspective.

10.3. GETTING INFORMATION ABOUT ALERTS, SILENCES, AND ALERTING RULES

The Alerting UI provides detailed information about alerts and their governing alerting rules and silences.

Prerequisites

- You have access to the cluster as a developer or as a user with view permissions for the project that you are viewing alerts for.

Procedure

To obtain information about alerts in the Administrator perspective

1. Open the OpenShift Container Platform web console and go to the Observe → Alerting → Alerts page.

2. Optional: Search for alerts by name by using the Name field in the search list.

3. Optional: Filter alerts by state, severity, and source by selecting filters in the Filter list.

4. Optional: Sort the alerts by clicking one or more of the Name, Severity, State, and Source column headers.

5. Click the name of an alert to view its Alert details page. The page includes a graph that illustrates alert time series data. It also provides the following information about the alert:
   - A description of the alert
   - Messages associated with the alert
   - Labels attached to the alert
   - A link to its governing alerting rule
   - Silences for the alert, if any exist

To obtain information about silences in the Administrator perspective

1. Go to the Observe → Alerting → Silences page.

2. Optional: Filter the silences by name using the Search by name field.
3. Optional: Filter silences by state by selecting filters in the Filter list. By default, Active and Pending filters are applied.

4. Optional: Sort the silences by clicking one or more of the Name, Firing alerts, State, and Creator column headers.

5. Select the name of a silence to view its Silence details page. The page includes the following details:
   - Alert specification
   - Start time
   - End time
   - Silence state
   - Number and list of firing alerts

To obtain information about alerting rules in the Administrator perspective

1. Go to the Observe → Alerting → Alerting rules page.

2. Optional: Filter alerting rules by state, severity, and source by selecting filters in the Filter list.

3. Optional: Sort the alerting rules by clicking one or more of the Name, Severity, Alert state, and Source column headers.

4. Select the name of an alerting rule to view its Alerting rule details page. The page provides the following details about the alerting rule:
   - Alerting rule name, severity, and description.
   - The expression that defines the condition for firing the alert.
   - The time for which the condition should be true for an alert to fire.
   - A graph for each alert governed by the alerting rule, showing the value with which the alert is firing.
   - A table of all alerts governed by the alerting rule.

To obtain information about alerts, silences, and alerting rules in the Developer perspective

1. Go to the Observe → <project_name> → Alerts page.

2. View details for an alert, silence, or an alerting rule:
   - Alert details can be viewed by clicking a greater than symbol (>) next to an alert name and then selecting the alert from the list.
   - Silence details can be viewed by clicking a silence in the Silenced by section of the Alert details page. The Silence details page includes the following information:
     - Alert specification
     - Start time
     - End time
10.4. MANAGING SILENCES

You can create a silence for an alert in the OpenShift Container Platform web console in both the Administrator and Developer perspectives. After you create a silence, you will not receive notifications about an alert when the alert fires.

Creating silences is useful in scenarios where you have received an initial alert notification, and you do not want to receive further notifications during the time in which you resolve the underlying issue causing the alert to fire.

When creating a silence, you must specify whether it becomes active immediately or at a later time. You must also set a duration period after which the silence expires.

After you create silences, you can view, edit, and expire them.

10.4.1. Silencing alerts

You can silence a specific alert or silence alerts that match a specification that you define.

Prerequisites

- If you are a cluster administrator, you have access to the cluster as a user with the `cluster-admin` role.

- If you are a non-administrator user, you have access to the cluster as a user with the following user roles:
  - The `cluster-monitoring-view` cluster role, which allows you to access Alertmanager.
  - The `monitoring-alertmanager-edit` role, which permits you to create and silence alerts in the Administrator perspective in the web console.
  - The `monitoring-rules-edit` cluster role, which permits you to create and silence alerts in the Developer perspective in the web console.

Procedure
To silence a specific alert in the **Administrator** perspective:

1. Go to **Observe** → **Alerting** → **Alerts** in the OpenShift Container Platform web console.

2. For the alert that you want to silence, click **Silence alert** to open the **Silence alert** page with a default configuration for the chosen alert.

3. Optional: Change the default configuration details for the silence.

   **NOTE**
   
   You must add a comment before saving a silence.

4. To save the silence, click **Silence**.

To silence a specific alert in the **Developer** perspective:

1. Go to **Observe** → `<project_name>` → **Alerts** in the OpenShift Container Platform web console.

2. If necessary, expand the details for the alert by selecting a greater than symbol (>) next to the alert name.

3. Click the alert message in the expanded view to open the **Alert details** page for the alert.

4. Click **Silence alert** to open the **Silence alert** page with a default configuration for the alert.

5. Optional: Change the default configuration details for the silence.

   **NOTE**
   
   You must add a comment before saving a silence.

6. To save the silence, click **Silence**.

To silence a set of alerts by creating a silence configuration in the **Administrator** perspective:

1. Go to **Observe** → **Alerting** → **Silences** in the OpenShift Container Platform web console.

2. Click **Create silence**.

3. On the **Create silence** page, set the schedule, duration, and label details for an alert.

   **NOTE**
   
   You must add a comment before saving a silence.

4. To create silences for alerts that match the labels that you entered, click **Silence**.

To silence a set of alerts by creating a silence configuration in the **Developer** perspective:

1. Go to **Observe** → `<project_name>` → **Silences** in the OpenShift Container Platform web console.
2. Click **Create silence**.

3. On the **Create silence** page, set the duration and label details for an alert.

   **NOTE**

   You must add a comment before saving a silence.

4. To create silences for alerts that match the labels that you entered, click **Silence**.

### 10.4.2. Editing silences

You can edit a silence, which expires the existing silence and creates a new one with the changed configuration.

**Prerequisites**

- If you are a cluster administrator, you have access to the cluster as a user with the **cluster-admin** role.

- If you are a non-administrator user, you have access to the cluster as a user with the following user roles:
  - The **cluster-monitoring-view** cluster role, which allows you to access Alertmanager.
  - The **monitoring-alertmanager-edit** role, which permits you to create and silence alerts in the **Administrator** perspective in the web console.
  - The **monitoring-rules-edit** cluster role, which permits you to create and silence alerts in the **Developer** perspective in the web console.

**Procedure**

To edit a silence in the **Administrator** perspective:

1. Go to **Observe** → **Alerting** → **Silences**.

2. For the silence you want to modify, click **Edit silence** and select **Edit silence**. Alternatively, you can click **Actions** and select **Edit silence** on the **Silence details** page for a silence.

3. On the **Edit silence** page, make changes and click **Silence**. Doing so expires the existing silence and creates one with the updated configuration.

To edit a silence in the **Developer** perspective:

1. Go to **Observe** → **<project_name>** → **Silences**.

2. For the silence you want to modify, click **Edit silence** and select **Edit silence**. Alternatively, you can click **Actions** and select **Edit silence** on the **Silence details** page for a silence.
3. On the Edit silence page, make changes and click Silence. Doing so expires the existing silence and creates one with the updated configuration.

10.4.3. Expiring silences

You can expire a single silence or multiple silences. Expiring a silence deactivates it permanently.

NOTE

You cannot delete expired, silenced alerts. Expired silences older than 120 hours are garbage collected.

Prerequisites

- If you are a cluster administrator, you have access to the cluster as a user with the cluster-admin role.
- If you are a non-administrator user, you have access to the cluster as a user with the following user roles:
  - The cluster-monitoring-view cluster role, which allows you to access Alertmanager.
  - The monitoring-alertmanager-edit role, which permits you to create and silence alerts in the Administrator perspective in the web console.
  - The monitoring-rules-edit cluster role, which permits you to create and silence alerts in the Developer perspective in the web console.

Procedure

To expire a silence or silences in the Administrator perspective:

1. Go to Observe → Alerting → Silences.
2. For the silence or silences you want to expire, select the checkbox in the corresponding row.
3. Click Expire 1 silence to expire a single selected silence or Expire <n> silences to expire multiple selected silences, where <n> is the number of silences you selected. Alternatively, to expire a single silence you can click Actions and select Expire silence on the Silence details page for a silence.

To expire a silence in the Developer perspective:

1. Go to Observe → <project_name> → Silences.
2. For the silence or silences you want to expire, select the checkbox in the corresponding row.
3. Click Expire 1 silence to expire a single selected silence or Expire <n> silences to expire multiple selected silences, where <n> is the number of silences you selected. Alternatively, to expire a single silence you can click Actions and select Expire silence on the Silence details page for a silence.

10.5. MANAGING ALERTING RULES FOR CORE PLATFORM MONITORING
OpenShift Container Platform 4.15 monitoring ships with a large set of default alerting rules for platform metrics. As a cluster administrator, you can customize this set of rules in two ways:

- Modify the settings for existing platform alerting rules by adjusting thresholds or by adding and modifying labels. For example, you can change the severity label for an alert from warning to critical to help you route and triage issues flagged by an alert.
- Define and add new custom alerting rules by constructing a query expression based on core platform metrics in the openshift-monitoring namespace.

Core platform alerting rule considerations

- New alerting rules must be based on the default OpenShift Container Platform monitoring metrics.
- You can only add and modify alerting rules. You cannot create new recording rules or modify existing recording rules.
- If you modify existing platform alerting rules by using an AlertRelabelConfig object, your modifications are not reflected in the Prometheus alerts API. Therefore, any dropped alerts still appear in the OpenShift Container Platform web console even though they are no longer forwarded to Alertmanager. Additionally, any modifications to alerts, such as a changed severity label, do not appear in the web console.

10.5.1. Tips for optimizing alerting rules for core platform monitoring

If you customize core platform alerting rules to meet your organization’s specific needs, follow these guidelines to help ensure that the customized rules are efficient and effective.

- **Minimize the number of new rules** Create only rules that are essential to your specific requirements. By minimizing the number of rules, you create a more manageable and focused alerting system in your monitoring environment.
- **Focus on symptoms rather than causes** Create rules that notify users of symptoms instead of underlying causes. This approach ensures that users are promptly notified of a relevant symptom so that they can investigate the root cause after an alert has triggered. This tactic also significantly reduces the overall number of rules you need to create.
- **Plan and assess your needs before implementing changes** First, decide what symptoms are important and what actions you want users to take if these symptoms occur. Then, assess existing rules and decide if you can modify any of them to meet your needs instead of creating entirely new rules for each symptom. By modifying existing rules and creating new ones judiciously, you help to streamline your alerting system.
- **Provide clear alert messaging** When you create alert messages, describe the symptom, possible causes, and recommended actions. Include unambiguous, concise explanations along with troubleshooting steps or links to more information. Doing so helps users quickly assess the situation and respond appropriately.
- **Include severity levels** Assign severity levels to your rules to indicate how a user needs to react when a symptom occurs and triggers an alert. For example, classifying an alert as Critical signals that an individual or a critical response team needs to respond immediately. By defining severity levels, you help users know how to respond to an alert and help ensure that the most urgent issues receive prompt attention.

10.5.2. Creating new alerting rules
As a cluster administrator, you can create new alerting rules based on platform metrics. These alerting rules trigger alerts based on the values of chosen metrics.

**NOTE**

If you create a customized `AlertingRule` resource based on an existing platform alerting rule, silence the original alert to avoid receiving conflicting alerts.

**Prerequisites**

- You have access to the cluster as a user that has the `cluster-admin` cluster role.
- You have installed the OpenShift CLI (`oc`).

**Procedure**

1. Create a new YAML configuration file named `example-alerting-rule.yaml` in the `openshift-monitoring` namespace.

2. Add an `AlertingRule` resource to the YAML file. The following example creates a new alerting rule named `example`, similar to the default `watchdog` alert:

   ```yaml
   apiVersion: monitoring.openshift.io/v1
   kind: AlertingRule
   metadata:
     name: example
     namespace: openshift-monitoring
   spec:
     groups:
       - name: example-rules
         rules:
           - alert: ExampleAlert
             expr: vector(1)
   
   $ oc apply -f example-alerting-rule.yaml
   ```

   1. The name of the alerting rule you want to create.
   2. The PromQL query expression that defines the new rule.

3. Apply the configuration file to the cluster:

   ```bash
   $ oc apply -f example-alerting-rule.yaml
   ```

**10.5.3. Modifying core platform alerting rules**

As a cluster administrator, you can modify core platform alerts before Alertmanager routes them to a receiver. For example, you can change the severity label of an alert, add a custom label, or exclude an alert from being sent to Alertmanager.

**Prerequisites**

- You have access to the cluster as a user with the `cluster-admin` cluster role.
- You have installed the OpenShift CLI (`oc`).
Procedure

1. Create a new YAML configuration file named `example-modified-alerting-rule.yaml` in the `openshift-monitoring` namespace.

2. Add an `AlertRelabelConfig` resource to the YAML file. The following example modifies the `severity` setting to `critical` for the default platform `watchdog` alerting rule:

   ```yaml
   apiVersion: monitoring.openshift.io/v1
   kind: AlertRelabelConfig
   metadata:
     name: watchdog
     namespace: openshift-monitoring
   spec:
     configs:
       - sourceLabels: [alertname,severity]  
         regex: "Watchdog;none"  
         targetLabel: severity 
         replacement: critical 
         action: Replace
   
   1. The source labels for the values you want to modify.
   2. The regular expression against which the value of `sourceLabels` is matched.
   3. The target label of the value you want to modify.
   4. The new value to replace the target label.
   5. The relabel action that replaces the old value based on regex matching. The default action is `Replace`. Other possible values are `Keep`, `Drop`, `HashMod`, `LabelMap`, `LabelDrop`, and `LabelKeep`.

3. Apply the configuration file to the cluster:

   ```bash
   $ oc apply -f example-modified-alerting-rule.yaml
   ```

Additional resources

- See Monitoring overview for details about OpenShift Container Platform 4.15 monitoring architecture.
- See the Alertmanager documentation for information about alerting rules.
- See the Prometheus relabeling documentation for information about how relabeling works.
- See the Prometheus alerting documentation for further guidelines on optimizing alerts.

10.6. MANAGING ALERTING RULES FOR USER-DEFINED PROJECTS

OpenShift Container Platform monitoring ships with a set of default alerting rules. As a cluster administrator, you can view the default alerting rules.
In OpenShift Container Platform 4.15, you can create, view, edit, and remove alerting rules in user-defined projects.

Alerting rule considerations

- The default alerting rules are used specifically for the OpenShift Container Platform cluster.
- Some alerting rules intentionally have identical names. They send alerts about the same event with different thresholds, different severity, or both.
- Inhibition rules prevent notifications for lower severity alerts that are firing when a higher severity alert is also firing.

10.6.1. Optimizing alerting for user-defined projects

You can optimize alerting for your own projects by considering the following recommendations when creating alerting rules:

- **Minimize the number of alerting rules that you create for your project** Create alerting rules that notify you of conditions that impact you. It is more difficult to notice relevant alerts if you generate many alerts for conditions that do not impact you.

- **Create alerting rules for symptoms instead of causes** Create alerting rules that notify you of conditions regardless of the underlying cause. The cause can then be investigated. You will need many more alerting rules if each relates only to a specific cause. Some causes are then likely to be missed.

- **Plan before you write your alerting rules** Determine what symptoms are important to you and what actions you want to take if they occur. Then build an alerting rule for each symptom.

- **Provide clear alert messaging** State the symptom and recommended actions in the alert message.

- **Include severity levels in your alerting rules** The severity of an alert depends on how you need to react if the reported symptom occurs. For example, a critical alert should be triggered if a symptom requires immediate attention by an individual or a critical response team.

Additional resources

- See the [Prometheus alerting documentation](#) for further guidelines on optimizing alerts
- See [Monitoring overview](#) for details about OpenShift Container Platform 4.15 monitoring architecture

10.6.2. About creating alerting rules for user-defined projects

If you create alerting rules for a user-defined project, consider the following key behaviors and important limitations when you define the new rules:

- A user-defined alerting rule can include metrics exposed by its own project in addition to the default metrics from core platform monitoring. You cannot include metrics from another user-defined project.

  For example, an alerting rule for the `ns1` user-defined project can use metrics exposed by the `ns1` project in addition to core platform metrics, such as CPU and memory metrics. However, the rule cannot include metrics from a different `ns2` user-defined project.
To reduce latency and to minimize the load on core platform monitoring components, you can add the `openshift.io/prometheus-rule-evaluation-scope: leaf-prometheus` label to a rule. This label forces only the Prometheus instance deployed in the `openshift-user-workload-monitoring` project to evaluate the alerting rule and prevents the Thanos Ruler instance from doing so.

**IMPORTANT**

If an alerting rule has this label, your alerting rule can use only those metrics exposed by your user-defined project. Alerting rules you create based on default platform metrics might not trigger alerts.

### 10.6.3. Creating alerting rules for user-defined projects

You can create alerting rules for user-defined projects. Those alerting rules will trigger alerts based on the values of the chosen metrics.

**Prerequisites**

- You have enabled monitoring for user-defined projects.
- You are logged in as a user that has the `monitoring-rules-edit` cluster role for the project where you want to create an alerting rule.
- You have installed the OpenShift CLI (`oc`).

**Procedure**

1. Create a YAML file for alerting rules. In this example, it is called `example-app-alerting-rule.yaml`.

2. Add an alerting rule configuration to the YAML file. For example:

   ```yaml
   apiVersion: monitoring.coreos.com/v1
   kind: PrometheusRule
   metadata:
     name: example-alert
     namespace: ns1
   spec:
     groups:
     - name: example
       rules:
       - alert: VersionAlert
         expr: version{job= "prometheus-example-app"} == 0
   ```

   This configuration creates an alerting rule named `example-alert`. The alerting rule fires an alert when the `version` metric exposed by the sample service becomes 0.

3. Apply the configuration file to the cluster:
$ oc apply -f example-app-alerting-rule.yaml

Additional resources

- See Monitoring overview for details about OpenShift Container Platform 4.15 monitoring architecture.

10.6.4. Accessing alerting rules for user-defined projects

To list alerting rules for a user-defined project, you must have been assigned the `monitoring-rules-view` cluster role for the project.

Prerequisites

- You have enabled monitoring for user-defined projects.
- You are logged in as a user that has the `monitoring-rules-view` cluster role for your project.
- You have installed the OpenShift CLI (`oc`).

Procedure

1. To list alerting rules in `<project>`:

   $ oc -n <project> get prometheusrule

2. To list the configuration of an alerting rule, run the following:

   $ oc -n <project> get prometheusrule <rule> -o yaml

10.6.5. Listing alerting rules for all projects in a single view

As a cluster administrator, you can list alerting rules for core OpenShift Container Platform and user-defined projects together in a single view.

Prerequisites

- You have access to the cluster as a user with the `cluster-admin` role.
- You have installed the OpenShift CLI (`oc`).

Procedure

1. In the Administrator perspective, navigate to Observe → Alerting → Alerting rules.

2. Select the Platform and User sources in the Filter drop-down menu.

   NOTE

   The Platform source is selected by default.

10.6.6. Removing alerting rules for user-defined projects
You can remove alerting rules for user-defined projects.

Prerequisites

- You have enabled monitoring for user-defined projects.
- You are logged in as a user that has the `monitoring-rules-edit` cluster role for the project where you want to create an alerting rule.
- You have installed the OpenShift CLI (`oc`).

Procedure

- To remove rule `<foo>` in `<namespace>`, run the following:

  ```
  $ oc -n <namespace> delete prometheusrule <foo>
  ```

Additional resources

- See the Alertmanager documentation

10.7. SENDING NOTIFICATIONS TO EXTERNAL SYSTEMS

In OpenShift Container Platform 4.15, firing alerts can be viewed in the Alerting UI. Alerts are not configured by default to be sent to any notification systems. You can configure OpenShift Container Platform to send alerts to the following receiver types:

- PagerDuty
- Webhook
- Email
- Slack

Routing alerts to receivers enables you to send timely notifications to the appropriate teams when failures occur. For example, critical alerts require immediate attention and are typically paged to an individual or a critical response team. Alerts that provide non-critical warning notifications might instead be routed to a ticketing system for non-immediate review.

Checking that alerting is operational by using the watchdog alert

OpenShift Container Platform monitoring includes a watchdog alert that fires continuously. Alertmanager repeatedly sends watchdog alert notifications to configured notification providers. The provider is usually configured to notify an administrator when it stops receiving the watchdog alert. This mechanism helps you quickly identify any communication issues between Alertmanager and the notification provider.

10.7.1. Configuring alert receivers

You can configure alert receivers to ensure that you learn about important issues with your cluster.

Prerequisites

- You have access to the cluster as a user with the `cluster-admin` cluster role.
Procedure

1. In the Administrator perspective, go to Administration → Cluster Settings → Configuration → Alertmanager.

   NOTE
   Alternatively, you can go to the same page through the notification drawer. Select the bell icon at the top right of the OpenShift Container Platform web console and choose Configure in the AlertmanagerReceiverNotConfigured alert.

2. Click Create Receiver in the Receivers section of the page.

3. In the Create Receiver form, add a Receiver name and choose a Receiver type from the list.

4. Edit the receiver configuration:
   - For PagerDuty receivers:
     a. Choose an integration type and add a PagerDuty integration key.
     b. Add the URL of your PagerDuty installation.
     c. Click Show advanced configuration if you want to edit the client and incident details or the severity specification.
   - For webhook receivers:
     a. Add the endpoint to send HTTP POST requests to.
     b. Click Show advanced configuration if you want to edit the default option to send resolved alerts to the receiver.
   - For email receivers:
     a. Add the email address to send notifications to.
     b. Add SMTP configuration details, including the address to send notifications from, the smarthost and port number used for sending emails, the hostname of the SMTP server, and authentication details.
     c. Select whether TLS is required.
     d. Click Show advanced configuration if you want to edit the default option not to send resolved alerts to the receiver or edit the body of email notifications configuration.
   - For Slack receivers:
     a. Add the URL of the Slack webhook.
     b. Add the Slack channel or user name to send notifications to.
     c. Select Show advanced configuration if you want to edit the default option not to send resolved alerts to the receiver or edit the icon and username configuration. You can also choose whether to find and link channel names and usernames.
5. By default, firing alerts with labels that match all of the selectors are sent to the receiver. If you want label values for firing alerts to be matched exactly before they are sent to the receiver, perform the following steps:

   a. Add routing label names and values in the **Routing labels** section of the form.
   
   b. Click **Add label** to add further routing labels.

6. Click **Create** to create the receiver.

10.7.2. Creating alert routing for user-defined projects

If you are a non-administrator user who has been given the **alert-routing-edit** cluster role, you can create or edit alert routing for user-defined projects.

**Prerequisites**

- A cluster administrator has enabled monitoring for user-defined projects.
- A cluster administrator has enabled alert routing for user-defined projects.
- You are logged in as a user that has the **alert-routing-edit** cluster role for the project for which you want to create alert routing.
- You have installed the OpenShift CLI (**oc**).

**Procedure**

1. Create a YAML file for alert routing. The example in this procedure uses a file called **example-app-alert-routing.yaml**.

2. Add an **AlertmanagerConfig** YAML definition to the file. For example:

   ```yaml
   apiVersion: monitoring.coreos.com/v1beta1
   kind: AlertmanagerConfig
   metadata:
     name: example-routing
     namespace: ns1
   spec:
     route:
       receiver: default
      groupBy: [job]
       receivers:
         - name: default
           webhookConfigs:
             - url: https://example.org/post
   ```

   **NOTE**

   For user-defined alerting rules, user-defined routing is scoped to the namespace in which the resource is defined. For example, a routing configuration defined in the **AlertmanagerConfig** object for namespace **ns1** only applies to **PrometheusRules** resources in the same namespace.

3. Save the file.
4. Apply the resource to the cluster:

   $ oc apply -f example-app-alert-routing.yaml

   The configuration is automatically applied to the Alertmanager pods.

### 10.8. APPLYING A CUSTOM ALERTMANAGER CONFIGURATION

You can overwrite the default Alertmanager configuration by editing the `alertmanager-main` secret in the `openshift-monitoring` namespace for the platform instance of Alertmanager.

**Prerequisites**

- You have access to the cluster as a user with the `cluster-admin` cluster role.

**Procedure**

To change the Alertmanager configuration from the CLI:

1. Print the currently active Alertmanager configuration into file `alertmanager.yaml`:

   $ oc -n openshift-monitoring get secret alertmanager-main --template='{{ index .data "alertmanager.yaml" }}' | base64 --decode > alertmanager.yaml

2. Edit the configuration in `alertmanager.yaml`:

   ```yaml
   global:
     resolve_timeout: 5m
   route:
     group_wait: 30s
     group_interval: 5m
     repeat_interval: 12h
     receiver: default
   routes:
     - matchers:
       - "alertname=Watchdog"
       repeat_interval: 2m
       receiver: watchdog
     - matchers:
       - "service=<your_service>"
       routes:
       - <your_matching_rules>
       receiver: <receiver>
   receivers:
     - name: default
     - name: watchdog
     - name: <receiver>
   # <receiver_configuration>
   ``

   **The `group_wait` value** specifies how long Alertmanager waits before sending an initial notification for a group of alerts. This value controls how long Alertmanager waits while collecting initial alerts for the same group before sending a notification.
The `group_interval` value specifies how much time must elapse before Alertmanager sends a notification about new alerts added to a group of alerts for which an initial

The `repeat_interval` value specifies the minimum amount of time that must pass before an alert notification is repeated. If you want a notification to repeat at each group interval, set the `repeat_interval` value to less than the `group_interval` value. However, the repeated notification can still be delayed, for example, when certain Alertmanager pods are restarted or rescheduled.

The `service` value specifies the service that fires the alerts.

The `<your_matching_rules>` value specifies the target alerts.

The `receiver` value specifies the receiver to use for the alert.

**NOTE**

Use the `matchers` key name to indicate the matchers that an alert has to fulfill to match the node. Do not use the `match` or `match_re` key names, which are both deprecated and planned for removal in a future release.

In addition, if you define inhibition rules, use the `target_matchers` key name to indicate the target matchers and the `source_matchers` key name to indicate the source matchers. Do not use the `target_match`, `target_match_re`, `source_match`, or `source_match_re` key names, which are deprecated and planned for removal in a future release.

The following Alertmanager configuration example configures PagerDuty as an alert receiver:

```yaml
global:
  resolve_timeout: 5m
route:
  group_wait: 30s
  group_interval: 5m
  repeat_interval: 12h
receiver: default
routes:
  - matchers:
      - "alertname=Watchdog"
    repeat_interval: 2m
    receiver: watchdog
  - matchers:
      - "service=example-app"
    routes:
      - matchers:
          - "severity=critical"
          receiver: team-frontend-page
receivers:
  - name: default
  - name: watchdog
  - name: team-frontend-page
pagerduty_configs:
  - service_key: "_your-key_"
```
With this configuration, alerts of critical severity that are fired by the example-app service are sent using the team-frontend-page receiver. Typically these types of alerts would be paged to an individual or a critical response team.

3. Apply the new configuration in the file:

```bash
$ oc -n openshift-monitoring create secret generic alertmanager-main --from-file=alertmanager.yaml --dry-run=client -o=yaml | oc -n openshift-monitoring replace secret -filename=-
```

To change the Alertmanager configuration from the OpenShift Container Platform web console:

1. Go to the Administration → Cluster Settings → Configuration → Alertmanager → YAML page of the web console.
2. Modify the YAML configuration file.
3. Click Save.

### 10.9. APPLYING A CUSTOM CONFIGURATION TO ALERTMANAGER FOR USER-DEFINED ALERT ROUTING

If you have enabled a separate instance of Alertmanager dedicated to user-defined alert routing, you can overwrite the configuration for this instance of Alertmanager by editing the alertmanager-user-workload secret in the openshift-user-workload-monitoring namespace.

**Prerequisites**

- You have access to the cluster as a user with the cluster-admin cluster role.
- You have installed the OpenShift CLI (oc).

**Procedure**

1. Print the currently active Alertmanager configuration into the file alertmanager.yaml:

   ```bash
   $ oc -n openshift-user-workload-monitoring get secret alertmanager-user-workload --template='{{ index .data "alertmanager.yaml" }}' | base64 --decode > alertmanager.yaml
   ```

2. Edit the configuration in alertmanager.yaml:

   ```yaml
   route:
     receiver: Default
     group_by:
       - name: Default
     routes:
       - matchers:
         - "service = prometheus-example-monitor"
           receiver: <receiver> 1
     receivers:
       - name: Default
         - name: <receiver> 2
       # <receiver_configuration>
   ```
1. Specifies which alerts match the route. This example shows all alerts that have the `service="prometheus-example-monitor"` label.

2. Specifies the receiver to use for the alerts group.

3. Apply the new configuration in the file:

   ```
   $ oc -n openshift-user-workload-monitoring create secret generic alertmanager-user-workload --from-file=alertmanager.yaml --dry-run=client -o=yaml | oc -n openshift-user-workload-monitoring replace secret --filename=-
   ```

Additional resources

- See the [PagerDuty official site](https://www.pagerduty.com) for more information on PagerDuty.
- See the [PagerDuty Prometheus Integration Guide](https://docs.pagerduty.com/docs/prometheus-integration) to learn how to retrieve the `service_key`.
- See [Alertmanager configuration](https://prometheus.io/docs/prometheus/latest/configuration/configuration/#alertmanager) for configuring alerting through different alert receivers.
- See [Enabling alert routing for user-defined projects](https://prometheus.io/docs/prometheus/latest/configuration/configuration/#enabling-alert-routing) to learn how to enable a dedicated instance of Alertmanager for user-defined alert routing.

### 10.10. NEXT STEPS

- Reviewing monitoring dashboards
CHAPTER 11. REVIEWING MONITORING DASHBOARDS

OpenShift Container Platform 4.15 provides a comprehensive set of monitoring dashboards that help you understand the state of cluster components and user-defined workloads.

Use the Administrator perspective to access dashboards for the core OpenShift Container Platform components, including the following items:

- API performance
- etcd
- Kubernetes compute resources
- Kubernetes network resources
- Prometheus
- USE method dashboards relating to cluster and node performance
- Node performance metrics

Figure 11.1. Example dashboard in the Administrator perspective

Use the Developer perspective to access Kubernetes compute resources dashboards that provide the following application metrics for a selected project:

- CPU usage
- Memory usage
- Bandwidth information
Packet rate information

Figure 11.2. Example dashboard in the Developer perspective

![Dashboard Preview]

NOTE

In the **Developer** perspective, you can view dashboards for only one project at a time.

11.1. REVIEWING MONITORING DASHBOARDS AS A CLUSTER ADMINISTRATOR

In the **Administrator** perspective, you can view dashboards relating to core OpenShift Container Platform cluster components.

Prerequisites

- You have access to the cluster as a user with the **cluster-admin** cluster role.

Procedure

1. In the **Administrator** perspective in the OpenShift Container Platform web console, navigate to **Observe → Dashboards**.

2. Choose a dashboard in the **Dashboard** list. Some dashboards, such as **etcd** and **Prometheus** dashboards, produce additional sub-menus when selected.

3. Optional: Select a time range for the graphs in the **Time Range** list.
   - Select a pre-defined time period.
• Set a custom time range by selecting Custom time range in the Time Range list.
  a. Input or select the From and To dates and times.
  b. Click Save to save the custom time range.

4. Optional: Select a Refresh Interval

5. Hover over each of the graphs within a dashboard to display detailed information about specific items.

11.2. REVIEWING MONITORING DASHBOARDS AS A DEVELOPER

In the Developer perspective, you can view dashboards relating to a selected project. You must have access to monitor a project to view dashboard information for it.

Prerequisites

• You have access to the cluster as a developer or as a user.
• You have view permissions for the project that you are viewing the dashboard for.

Procedure

1. In the Developer perspective in the OpenShift Container Platform web console, navigate to Observe → Dashboard.

2. Select a project from the Project: drop-down list.

3. Select a dashboard from the Dashboard drop-down list to see the filtered metrics.

   NOTE

   All dashboards produce additional sub-menus when selected, except Kubernetes / Compute Resources / Namespace (Pods)

4. Optional: Select a time range for the graphs in the Time Range list.
   • Select a pre-defined time period.
   • Set a custom time range by selecting Custom time range in the Time Range list.
     a. Input or select the From and To dates and times.
     b. Click Save to save the custom time range.

5. Optional: Select a Refresh Interval

6. Hover over each of the graphs within a dashboard to display detailed information about specific items.

Additional resources

• Monitoring project and application metrics using the Developer perspective
11.3. NEXT STEPS

- Accessing third-party monitoring APIs
CHAPTER 12. ACCESSING THIRD-PARTY MONITORING APIS

In OpenShift Container Platform 4.15, you can access web service APIs for some third-party monitoring components from the command line interface (CLI).

IMPORTANT

In certain situations, accessing API endpoints can degrade the performance and scalability of your cluster, especially if you use endpoints to retrieve, send, or query large amounts of metrics data.

To avoid these issues, follow these recommendations:

- Avoid querying endpoints frequently. Limit queries to a maximum of one every 30 seconds.
- Do not try to retrieve all metrics data via the `/federate` endpoint for Prometheus. Query it only when you want to retrieve a limited, aggregated data set. For example, retrieving fewer than 1,000 samples for each request helps minimize the risk of performance degradation.

12.1. ABOUT ACCESSING MONITORING WEB SERVICE APIS

You can directly access web service API endpoints from the command line for the following monitoring stack components:

- Prometheus
- Alertmanager
- Thanos Ruler
- Thanos Querier

NOTE

To access Thanos Ruler and Thanos Querier service APIs, the requesting account must have `get` permission on the namespaces resource, which can be granted by binding the `cluster-monitoring-view` cluster role to the account.

When you access web service API endpoints for monitoring components, be aware of the following limitations:

- You can only use Bearer Token authentication to access API endpoints.
- You can only access endpoints in the `/api` path for a route. If you try to access an API endpoint in a web browser, an Application is not available error occurs. To access monitoring features in a web browser, use the OpenShift Container Platform web console to review monitoring dashboards.

Additional resources

- Reviewing monitoring dashboards
12.2. ACCESSING A MONITORING WEB SERVICE API

The following example shows how to query the service API receivers for the Alertmanager service used in core platform monitoring. You can use a similar method to access the prometheus-k8s service for core platform Prometheus and the thanos-ruler service for Thanos Ruler.

Prerequisites

- You are logged in to an account that is bound against the monitoring-alertmanager-edit role in the openshift-monitoring namespace.
- You are logged in to an account that has permission to get the Alertmanager API route.

**NOTE**

If your account does not have permission to get the Alertmanager API route, a cluster administrator can provide the URL for the route.

Procedure

1. Extract an authentication token by running the following command:

   ```bash
   $ TOKEN=$(oc whoami -t)
   ```

2. Extract the alertmanager-main API route URL by running the following command:

   ```bash
   $ HOST=$(oc -n openshift-monitoring get route alertmanager-main -ojsonpath={.spec.host})
   ```

3. Query the service API receivers for Alertmanager by running the following command:

   ```bash
   ```

12.3. QUERYING METRICS BY USING THE FEDERATION ENDPOINT FOR PROMETHEUS

You can use the federation endpoint for Prometheus to scrape platform and user-defined metrics from a network location outside the cluster. To do so, access the Prometheus /federate endpoint for the cluster via an OpenShift Container Platform route.
IMPORTANT

A delay in retrieving metrics data occurs when you use federation. This delay can affect the accuracy and timeliness of the scraped metrics.

Using the federation endpoint can also degrade the performance and scalability of your cluster, especially if you use the federation endpoint to retrieve large amounts of metrics data. To avoid these issues, follow these recommendations:

- Do not try to retrieve all metrics data via the federation endpoint for Prometheus. Query it only when you want to retrieve a limited, aggregated data set. For example, retrieving fewer than 1,000 samples for each request helps minimize the risk of performance degradation.

- Avoid frequent querying of the federation endpoint for Prometheus. Limit queries to a maximum of one every 30 seconds.

If you need to forward large amounts of data outside the cluster, use remote write instead. For more information, see the Configuring remote write storage section.

Prerequisites

- You have installed the OpenShift CLI (oc).

- You have access to the cluster as a user with the cluster-monitoring-view cluster role or have obtained a bearer token with get permission on the namespaces resource.

NOTE

You can only use bearer token authentication to access the Prometheus federation endpoint.

- You are logged in to an account that has permission to get the Prometheus federation route.

NOTE

If your account does not have permission to get the Prometheus federation route, a cluster administrator can provide the URL for the route.

Procedure

1. Retrieve the bearer token by running the following the command:

   ```
   $ TOKEN=$(oc whoami -t)
   ```

2. Get the Prometheus federation route URL by running the following command:

   ```
   $ HOST=$(oc -n openshift-monitoring get route prometheus-k8s-federate -o jsonpath={.spec.host})
   ```

3. Query metrics from the /federate route. The following example command queries up metrics:

   ```
   ```
Example output

```
# TYPE up untyped
up{apiserver="kube-apiserver",endpoint="https",instance="10.0.143.148:6443",job="apiserver",namespace="default",service="kubernetes",prometheus="openshift-monitoring/k8s",prometheus_replica="prometheus-k8s-0"} 1 1657035322214
up{apiserver="kube-apiserver",endpoint="https",instance="10.0.148.166:6443",job="apiserver",namespace="default",service="kubernetes",prometheus="openshift-monitoring/k8s",prometheus_replica="prometheus-k8s-0"} 1 1657035338597
up{apiserver="kube-apiserver",endpoint="https",instance="10.0.173.16:6443",job="apiserver",namespace="default",service="kubernetes",prometheus="openshift-monitoring/k8s",prometheus_replica="prometheus-k8s-0"} 1 1657035343834
...
```

12.4. ACCESSING METRICS FROM OUTSIDE THE CLUSTER FOR CUSTOM APPLICATIONS

You can query Prometheus metrics from outside the cluster when monitoring your own services with user-defined projects. Access this data from outside the cluster by using the `thanos-querier` route.

This access only supports using a Bearer Token for authentication.

Prerequisites

- You have deployed your own service, following the "Enabling monitoring for user-defined projects" procedure.
- You are logged in to an account with the `cluster-monitoring-view` cluster role, which provides permission to access the Thanos Querier API.
- You are logged in to an account that has permission to get the Thanos Querier API route.

**NOTE**

If your account does not have permission to get the Thanos Querier API route, a cluster administrator can provide the URL for the route.

Procedure

1. Extract an authentication token to connect to Prometheus by running the following command:

```
$ TOKEN=$(oc whoami -t)
```

2. Extract the `thanos-querier` API route URL by running the following command:

```
$ HOST=$(oc -n openshift-monitoring get route thanos-querier -ojsonpath={.spec.host})
```

3. Set the namespace to the namespace in which your service is running by using the following command:
4. Query the metrics of your own services in the command line by running the following command:

```bash
$ NAMESPACE=ns1

```

The output shows the status for each application pod that Prometheus is scraping:

**Example output**

```
{"status":"success","data":{"resultType":"vector","result":[{"metric":{"__name__":"up","endpoint":"web","instance":"10.129.0.46:8080","job":"prometheus-example-app","namespace":"ns1","pod":"prometheus-example-app-68d47c4fb6-jztp2","service":"prometheus-example-app"},"value":[1591881154.748,1]}}}
```

### 12.5. ADDITIONAL RESOURCES

- Enabling monitoring for user-defined projects
- Configuring remote write storage
- Managing metrics
- Managing alerts
CHAPTER 13. TROUBLESHOOTING MONITORING ISSUES

Find troubleshooting steps for common issues with core platform and user-defined project monitoring.

13.1. INVESTIGATING WHY USER-DEFINED PROJECT METRICS ARE UNAVAILABLE

ServiceMonitor resources enable you to determine how to use the metrics exposed by a service in user-defined projects. Follow the steps outlined in this procedure if you have created a ServiceMonitor resource but cannot see any corresponding metrics in the Metrics UI.

Prerequisites

- You have access to the cluster as a user with the cluster-admin role.
- You have installed the OpenShift CLI (oc).
- You have enabled and configured monitoring for user-defined workloads.
- You have created the user-workload-monitoring-config ConfigMap object.
- You have created a ServiceMonitor resource.

Procedure

1. Check that the corresponding labels match in the service and ServiceMonitor resource configurations.
   a. Obtain the label defined in the service. The following example queries the prometheus-example-app service in the ns1 project:

      ```
      $ oc -n ns1 get service prometheus-example-app -o yaml
      
      labels:
      app: prometheus-example-app
      ```

      Example output

      
      ```
      labels:
      app: prometheus-example-app
      ```

   b. Check that the matchLabels definition in the ServiceMonitor resource configuration matches the label output in the preceding step. The following example queries the prometheus-example-monitor service monitor in the ns1 project:

      ```
      $ oc -n ns1 get servicemonitor prometheus-example-monitor -o yaml
      
      apiVersion: v1
      kind: ServiceMonitor
      metadata:
      name: prometheus-example-monitor
      namespace: ns1
      spec:
      endpoints:
      ```

      Example output

      ```
      apiVersion: v1
      kind: ServiceMonitor
      metadata:
      name: prometheus-example-monitor
      namespace: ns1
      spec:
      endpoints:
      ```
You can check service and ServiceMonitor resource labels as a developer with view permissions for the project.

2. Inspect the logs for the Prometheus Operator in the openshift-user-workload-monitoring project.
   a. List the pods in the openshift-user-workload-monitoring project:

   ```
   $ oc -n openshift-user-workload-monitoring get pods
   ``

   **Example output**

   ```
   NAME                                   READY   STATUS    RESTARTS   AGE
   prometheus-operator-776fcbbd56-2nbfm   2/2     Running   0          132m
   prometheus-user-workload-0             5/5     Running   1          132m
   prometheus-user-workload-1             5/5     Running   1          132m
   thanos-ruler-user-workload-0           3/3     Running   0          132m
   thanos-ruler-user-workload-1           3/3     Running   0          132m
   ``

   b. Obtain the logs from the prometheus-operator container in the prometheus-operator pod. In the following example, the pod is called prometheus-operator-776fcbbd56-2nbfm:

   ```
   $ oc -n openshift-user-workload-monitoring logs prometheus-operator-776fcbbd56-2nbfm -c prometheus-operator
   ``

   If there is an issue with the service monitor, the logs might include an error similar to this example:

   ```
   level=warn ts=2020-08-10T11:48:20.906739623Z caller=operator.go:1829 component=prometheusoperator msg="skipping servicemonitor" error="it accesses file system via bearer token file which Prometheus specification prohibits"
   servicemonitor=eagle/eagle namespace=openshift-user-workload-monitoring prometheus=user-workload
   ```

3. **Review the target status for your endpoint** on the Metrics targets page in the OpenShift Container Platform web console UI.
   a. Log in to the OpenShift Container Platform web console and navigate to **Observe → Targets** in the Administrator perspective.

   b. Locate the metrics endpoint in the list, and review the status of the target in the **Status** column.

   c. If the **Status** is **Down**, click the URL for the endpoint to view more information on the **Target Details** page for that metrics target.
4. Configure debug level logging for the Prometheus Operator in the `openshift-user-workload-monitoring` project.

   a. Edit the `user-workload-monitoring-config` ConfigMap object in the `openshift-user-workload-monitoring` project:

   ```bash
   $ oc -n openshift-user-workload-monitoring edit configmap user-workload-monitoring-config
   ``

   b. Add `logLevel: debug` for `prometheusOperator` under `data/config.yaml` to set the log level to `debug`:

   ```yaml
   apiVersion: v1
   kind: ConfigMap
   metadata:
     name: user-workload-monitoring-config
     namespace: openshift-user-workload-monitoring
   data:
     config.yaml: |
       prometheusOperator:
         logLevel: debug
   # ...
   ```

   c. Save the file to apply the changes.

   **NOTE**

   The `prometheus-operator` in the `openshift-user-workload-monitoring` project restarts automatically when you apply the log-level change.

   d. Confirm that the `debug` log-level has been applied to the `prometheus-operator` deployment in the `openshift-user-workload-monitoring` project:

   ```bash
   $ oc -n openshift-user-workload-monitoring get deploy prometheus-operator -o yaml | grep "log-level"
   ``

   **Example output**

   ```yaml
   - --log-level=debug
   ```

   Debug level logging will show all calls made by the Prometheus Operator.

   e. Check that the `prometheus-operator` pod is running:

   ```bash
   $ oc -n openshift-user-workload-monitoring get pods
   ``

   **NOTE**

   If an unrecognized Prometheus Operator loglevel value is included in the config map, the `prometheus-operator` pod might not restart successfully.
Review the debug logs to see if the Prometheus Operator is using the `ServiceMonitor` resource. Review the logs for other related errors.

### 13.2. Determining Why Prometheus Is Consuming A Lot Of Disk Space

Developers can create labels to define attributes for metrics in the form of key-value pairs. The number of potential key-value pairs corresponds to the number of possible values for an attribute. An attribute that has an unlimited number of potential values is called an unbound attribute. For example, a `customer_id` attribute is unbound because it has an infinite number of possible values.

Every assigned key-value pair has a unique time series. The use of many unbound attributes in labels can result in an exponential increase in the number of time series created. This can impact Prometheus performance and can consume a lot of disk space.

You can use the following measures when Prometheus consumes a lot of disk:

- **Check the number of scrape samples** that are being collected.
- **Check the time series database (TSDB) status using the Prometheus HTTP API** for more information about which labels are creating the most time series. Doing so requires cluster administrator privileges.
- **Reduce the number of unique time series that are created** by reducing the number of unbound attributes that are assigned to user-defined metrics.

  **NOTE**

  Using attributes that are bound to a limited set of possible values reduces the number of potential key-value pair combinations.

- **Enforce limits on the number of samples that can be scraped** across user-defined projects. This requires cluster administrator privileges.

**Prerequisites**

- You have access to the cluster as a user with the `cluster-admin` cluster role.
- You have installed the OpenShift CLI (`oc`).

**Procedure**

1. In the Administrator perspective, navigate to Observe → Metrics.

2. Run the following Prometheus Query Language (PromQL) query in the Expression field. This returns the ten metrics that have the highest number of scrape samples:
3. Investigate the number of unbound label values assigned to metrics with higher than expected scrape sample counts.

- **If the metrics relate to a user-defined project** review the metrics key-value pairs assigned to your workload. These are implemented through Prometheus client libraries at the application level. Try to limit the number of unbound attributes referenced in your labels.

- **If the metrics relate to a core OpenShift Container Platform project** create a Red Hat support case on the [Red Hat Customer Portal](https://customer.redhat.com).

4. Review the TSDB status using the Prometheus HTTP API by running the following commands as a cluster administrator:

```bash
$ oc login -u <username> -p <password>
$ host=$(oc -n openshift-monitoring get route prometheus-k8s -ojsonpath={.spec.host})
$ token=$(oc whoami -t)
$ curl -H "Authorization: Bearer $token" -k "https://$host/api/v1/status/tsdb"
```

**Example output**

```
"status": "success",
```

**Additional resources**

- See [Setting a scrape sample limit for user-defined projects](https://example.com) for details on how to set a scrape sample limit and create related alerting rules

- [Submitting a support case](https://customer.redhat.com)
CHAPTER 14. CONFIG MAP REFERENCE FOR THE CLUSTER MONITORING OPERATOR

14.1. CLUSTER MONITORING OPERATOR CONFIGURATION REFERENCE

Parts of OpenShift Container Platform cluster monitoring are configurable. The API is accessible by setting parameters defined in various config maps.

- To configure monitoring components, edit the `ConfigMap` object named `cluster-monitoring-config` in the `openshift-monitoring` namespace. These configurations are defined by `ClusterMonitoringConfiguration`.

- To configure monitoring components that monitor user-defined projects, edit the `ConfigMap` object named `user-workload-monitoring-config` in the `openshift-user-workload-monitoring` namespace. These configurations are defined by `UserWorkloadConfiguration`.

The configuration file is always defined under the `config.yaml` key in the config map data.

NOTE

- Not all configuration parameters are exposed.
- Configuring cluster monitoring is optional.
- If a configuration does not exist or is empty, default values are used.
- If the configuration is invalid YAML data, the Cluster Monitoring Operator stops reconciling the resources and reports `Degraded=True` in the status conditions of the Operator.

14.2. ADDITIONALALERTMANAGERCONFIG

14.2.1. Description

The `AdditionalAlertmanagerConfig` resource defines settings for how a component communicates with additional Alertmanager instances.

14.2.2. Required

- apiVersion

Appears in: `PrometheusK8sConfig`, `PrometheusRestrictedConfig`, `ThanosRulerConfig`

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>string</td>
<td>Defines the API version of Alertmanager. Possible values are v1 or v2. The default is v2.</td>
</tr>
<tr>
<td>Property</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>---------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>bearerToken</td>
<td>*v1.SecretKeySelector</td>
<td>Defines the secret key reference containing the bearer token to use when authenticating to Alertmanager.</td>
</tr>
<tr>
<td>pathPrefix</td>
<td>string</td>
<td>Defines the path prefix to add in front of the push endpoint path.</td>
</tr>
<tr>
<td>scheme</td>
<td>string</td>
<td>Defines the URL scheme to use when communicating with Alertmanager instances. Possible values are http or https. The default value is http.</td>
</tr>
<tr>
<td>staticConfigs</td>
<td>[]string</td>
<td>A list of statically configured Alertmanager endpoints in the form of &lt;hosts&gt;:&lt;port&gt;.</td>
</tr>
<tr>
<td>timeout</td>
<td>*string</td>
<td>Defines the timeout value used when sending alerts.</td>
</tr>
<tr>
<td>tlsConfig</td>
<td>TLSConfig</td>
<td>Defines the TLS settings to use for Alertmanager connections.</td>
</tr>
</tbody>
</table>

### 14.3. ALERTMANAGERMAINCONFIG

#### 14.3.1. Description

The AlertmanagerMainConfig resource defines settings for the Alertmanager component in the openshift-monitoring namespace.

Appears in: ClusterMonitoringConfiguration

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>enabled</td>
<td>*bool</td>
<td>A Boolean flag that enables or disables the main Alertmanager instance in the openshift-monitoring namespace. The default value is true.</td>
</tr>
<tr>
<td>Property</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>-----------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>enableUserAlertmanagerConfig</td>
<td>bool</td>
<td>A Boolean flag that enables or disables user-defined namespaces to be selected for <code>AlertmanagerConfig</code> lookups. This setting only applies if the user workload monitoring instance of Alertmanager is not enabled. The default value is <code>false</code>.</td>
</tr>
<tr>
<td>logLevel</td>
<td>string</td>
<td>Defines the log level setting for Alertmanager. The possible values are: <code>error</code>, <code>warn</code>, <code>info</code>, <code>debug</code>. The default value is <code>info</code>.</td>
</tr>
<tr>
<td>nodeSelector</td>
<td>map[string]string</td>
<td>Defines the nodes on which the Pods are scheduled.</td>
</tr>
<tr>
<td>resources</td>
<td>*v1.ResourceRequirements</td>
<td>Defines resource requests and limits for the Alertmanager container.</td>
</tr>
<tr>
<td>secrets</td>
<td>[]string</td>
<td>Defines a list of secrets to be mounted into Alertmanager. The secrets must reside within the same namespace as the Alertmanager object. They are added as volumes named <code>secret-&lt;secret-name&gt;</code> and mounted at <code>/etc/alertmanager/secrets/&lt;secret-name&gt;</code> in the <code>alertmanager</code> container of the Alertmanager pods.</td>
</tr>
<tr>
<td>tolerations</td>
<td>[]v1.Toleration</td>
<td>Defines tolerations for the pods.</td>
</tr>
<tr>
<td>volumeClaimTemplate</td>
<td>*monv1.EmbeddedPersistentVolumeClaim</td>
<td>Defines persistent storage for Alertmanager. Use this setting to configure the persistent volume claim, including storage class, volume size, and name.</td>
</tr>
</tbody>
</table>

### 14.4. ALERTMANAGERUSERWORKLOADCONFIG

#### 14.4.1. Description
The **AlertmanagerUserWorkloadConfig** resource defines the settings for the Alertmanager instance used for user-defined projects.

**Appears in:** UserWorkloadConfiguration

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>enabled</td>
<td>bool</td>
<td>A Boolean flag that enables or disables a dedicated instance of Alertmanager for user-defined alerts in the <code>openshift-user-workload-monitoring</code> namespace. The default value is <strong>false</strong>.</td>
</tr>
<tr>
<td>enableAlertmanagerConfig</td>
<td>bool</td>
<td>A Boolean flag to enable or disable user-defined namespaces to be selected for <code>AlertmanagerConfig</code> lookup. The default value is <strong>false</strong>.</td>
</tr>
<tr>
<td>logLevel</td>
<td>string</td>
<td>Defines the log level setting for Alertmanager for user workload monitoring. The possible values are <code>error</code>, <code>warn</code>, <code>info</code>, and <code>debug</code>. The default value is <strong>info</strong>.</td>
</tr>
<tr>
<td>resources</td>
<td>*v1.ResourceRequirements</td>
<td>Defines resource requests and limits for the Alertmanager container.</td>
</tr>
<tr>
<td>secrets</td>
<td>[]string</td>
<td>Defines a list of secrets to be mounted into Alertmanager. The secrets must be located within the same namespace as the Alertmanager object. They are added as volumes named <code>secret-&lt;secret-name&gt;</code> and mounted at <code>/etc/alertmanager/secrets/&lt;secret-name&gt;</code> in the <code>alertmanager</code> container of the Alertmanager pods.</td>
</tr>
<tr>
<td>nodeSelector</td>
<td>map[string]string</td>
<td>Defines the nodes on which the pods are scheduled.</td>
</tr>
<tr>
<td>tolerations</td>
<td>[]v1.Toleration</td>
<td>Defines tolerations for the pods.</td>
</tr>
<tr>
<td>topologySpreadConstraints</td>
<td>[]v1.TopologySpreadConstraint</td>
<td>Defines a pod’s topology spread constraints.</td>
</tr>
</tbody>
</table>
### 14.5. CLUSTERMONITORINGCONFIGURATION

#### 14.5.1. Description

The **ClusterMonitoringConfiguration** resource defines settings that customize the default platform monitoring stack through the `cluster-monitoring-config` config map in the `openshift-monitoring` namespace.

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>alertmanagerMain</td>
<td>*AlertmanagerMainConfig</td>
<td><strong>AlertmanagerMainConfig</strong> defines settings for the Alertmanager component in the <code>openshift-monitoring</code> namespace.</td>
</tr>
<tr>
<td>enableUserWorkload</td>
<td>*bool</td>
<td><strong>UserWorkloadEnabled</strong> is a Boolean flag that enables monitoring for user-defined projects.</td>
</tr>
<tr>
<td>k8sPrometheusAdapter</td>
<td>*K8sPrometheusAdapter</td>
<td><strong>K8sPrometheusAdapter</strong> defines settings for the Prometheus Adapter component.</td>
</tr>
<tr>
<td>kubeStateMetrics</td>
<td>*KubeStateMetricsConfig</td>
<td><strong>KubeStateMetricsConfig</strong> defines settings for the <code>kube-state-metrics</code> agent.</td>
</tr>
<tr>
<td>metricsServer</td>
<td>*MetricsServerConfig</td>
<td><strong>MetricsServer</strong> defines settings for the Metrics Server component.</td>
</tr>
<tr>
<td>prometheusK8s</td>
<td>*PrometheusK8sConfig</td>
<td><strong>PrometheusK8sConfig</strong> defines settings for the Prometheus component.</td>
</tr>
<tr>
<td>Property</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>------</td>
<td>-------------</td>
</tr>
<tr>
<td>openshiftStateMetrics</td>
<td>*OpenShiftStateMetricsConfig</td>
<td>OpenShiftMetricsConfig defines settings for the openshift-state-metrics agent.</td>
</tr>
<tr>
<td>telemeterClient</td>
<td>*TelemeterClientConfig</td>
<td>TelemeterClientConfig defines settings for the Telemeter Client component.</td>
</tr>
<tr>
<td>thanosQuerier</td>
<td>*ThanosQuerierConfig</td>
<td>ThanosQuerierConfig defines settings for the Thanos Querier component.</td>
</tr>
<tr>
<td>nodeExporter</td>
<td>NodeExporterConfig</td>
<td>NodeExporterConfig defines settings for the node-exporter agent.</td>
</tr>
<tr>
<td>monitoringPlugin</td>
<td>*MonitoringPluginConfig</td>
<td>MonitoringPluginConfig defines settings for the monitoring console-plugin component.</td>
</tr>
</tbody>
</table>

14.6. DEDICATEDSERVICEMONITORS

14.6.1. Description

**IMPORTANT**

This setting is deprecated and is planned to be removed in a future OpenShift Container Platform version. In the current version, this setting still exists but has no effect.

You can use the DedicatedServiceMonitors resource to configure dedicated Service Monitors for the Prometheus Adapter

Appears in: K8sPrometheusAdapter
When `enabled` is set to `true`, the Cluster Monitoring Operator (CMO) deploys a dedicated Service Monitor that exposes the kubelet `/metrics/resource` endpoint. This Service Monitor sets `honorTimestamps: true` and only keeps metrics that are relevant for the pod resource queries of Prometheus Adapter. Additionally, Prometheus Adapter is configured to use these dedicated metrics. Overall, this feature improves the consistency of Prometheus Adapter-based CPU usage measurements used by, for example, the `oc adm top pod` command or the Horizontal Pod Autoscaler.

### 14.7. K8SPROMETHEUSADAPTER

#### 14.7.1. Description

The `K8sPrometheusAdapter` resource defines settings for the Prometheus Adapter component.

Appears in: `ClusterMonitoringConfiguration`

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>audit</code></td>
<td>*Audit</td>
<td>Defines the audit configuration used by the Prometheus Adapter instance. Possible profile values are: <code>metadata</code>, <code>request</code>, <code>requestresponse</code>, and <code>none</code>. The default value is <code>metadata</code>.</td>
</tr>
<tr>
<td><code>nodeSelector</code></td>
<td>map[string]string</td>
<td>Defines the nodes on which the pods are scheduled.</td>
</tr>
<tr>
<td><code>resources</code></td>
<td>*v1.ResourceRequirements</td>
<td>Defines resource requests and limits for the PrometheusAdapter container.</td>
</tr>
<tr>
<td><code>tolerations</code></td>
<td>[]v1.Toleration</td>
<td>Defines tolerations for the pods.</td>
</tr>
</tbody>
</table>
### 14.8. KUBESTATEMETRICSCONFIG

#### 14.8.1. Description

The `KubeStateMetricsConfig` resource defines settings for the `kube-state-metrics` agent.

Appears in: `ClusterMonitoringConfiguration`

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nodeSelector</td>
<td>map[string]string</td>
<td>Defines the nodes on which the pods are scheduled.</td>
</tr>
<tr>
<td>resources</td>
<td>*v1.ResourceRequirements</td>
<td>Defines resource requests and limits for the <code>KubeStateMetrics</code> container.</td>
</tr>
<tr>
<td>tolerations</td>
<td>[]v1.Toleration</td>
<td>Defines tolerations for the pods.</td>
</tr>
<tr>
<td>topologySpreadConstraints</td>
<td>[]v1.TopologySpreadConstraint</td>
<td>Defines a pod’s topology spread constraints.</td>
</tr>
</tbody>
</table>

### 14.9. METRICSSERVERCONFIG

#### 14.9.1. Description

**IMPORTANT**

Metrics Server is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see [Technology Preview Features Support Scope](#).

The `MetricsServerConfig` resource defines settings for the Metrics Server component. Note that this setting only applies when the `TechPreviewNoUpgrade` feature gate is enabled.

Appears in: `ClusterMonitoringConfiguration`
<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nodeSelector</td>
<td>map[string]string</td>
<td>Defines the nodes on which the pods are scheduled.</td>
</tr>
<tr>
<td>tolerations</td>
<td>[]v1.Toleration</td>
<td>Defines tolerations for the pods.</td>
</tr>
<tr>
<td>resources</td>
<td>*v1.ResourceRequirements</td>
<td>Defines resource requests and limits for the Metrics Server container.</td>
</tr>
<tr>
<td>topologySpreadConstraints</td>
<td>[]v1.TopologySpreadConstraint</td>
<td>Defines a pod’s topology spread constraints.</td>
</tr>
</tbody>
</table>

**14.10. PROMETHEUSOPERATORADMISSIONWEBHOOKCONFIG**

**14.10.1. Description**

The `PrometheusOperatorAdmissionWebhookConfig` resource defines settings for the admission webhook workload for Prometheus Operator.

Appears in: `ClusterMonitoringConfiguration`

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>resources</td>
<td>*v1.ResourceRequirements</td>
<td>Defines resource requests and limits for the <code>prometheus-operator-admission-webhook</code> container.</td>
</tr>
<tr>
<td>topologySpreadConstraints</td>
<td>[]v1.TopologySpreadConstraint</td>
<td>Defines a pod’s topology spread constraints.</td>
</tr>
</tbody>
</table>

**14.11. MONITORINGPLUGINCONFIG**

**14.11.1. Description**

The `MonitoringPluginConfig` resource defines settings for the web console plugin component in the `openshift-monitoring` namespace.

Appears in: `ClusterMonitoringConfiguration`

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nodeSelector</td>
<td>map[string]string</td>
<td>Defines the nodes on which the pods are scheduled.</td>
</tr>
</tbody>
</table>
### 14.12. NODEEXPORTERCOLLECTORBUDDYINFOCONFIG

#### 14.12.1. Description

The `NodeExporterCollectorBuddyInfoConfig` resource works as an on/off switch for the *buddyinfo* collector of the *node-exporter* agent. By default, the *buddyinfo* collector is disabled.

Appears in: `NodeExporterCollectorConfig`

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>enabled</td>
<td>bool</td>
<td>A Boolean flag that enables or disables the <em>buddyinfo</em> collector.</td>
</tr>
</tbody>
</table>

### 14.13. NODEEXPORTERCOLLECTORCONFIG

#### 14.13.1. Description

The `NodeExporterCollectorConfig` resource defines settings for individual collectors of the *node-exporter* agent.

Appears in: `NodeExporterConfig`

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cpufreq</td>
<td><code>NodeExporterCollectorCpufreqConfig</code></td>
<td>Defines the configuration of the <em>cpufreq</em> collector, which collects CPU frequency statistics. Disabled by default.</td>
</tr>
<tr>
<td>tcpstat</td>
<td><code>NodeExporterCollectorTcpStatConfig</code></td>
<td>Defines the configuration of the <em>tcpstat</em> collector, which collects TCP connection statistics. Disabled by default.</td>
</tr>
<tr>
<td>Property</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>------------------------------------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>netdev</td>
<td>NodeExporterCollectorNetDevConfig</td>
<td>Defines the configuration of the netdev collector, which collects network devices statistics. Enabled by default.</td>
</tr>
<tr>
<td>netclass</td>
<td>NodeExporterCollectorNetClassConfig</td>
<td>Defines the configuration of the netclass collector, which collects information about network devices. Enabled by default.</td>
</tr>
<tr>
<td>buddyinfo</td>
<td>NodeExporterCollectorBuddyInfoConfig</td>
<td>Defines the configuration of the buddyinfo collector, which collects statistics about memory fragmentation from the node_buddyinfo_blocks metric. This metric collects data from /proc/buddyinfo. Disabled by default.</td>
</tr>
<tr>
<td>mountstats</td>
<td>NodeExporterCollectorMountStatsConfig</td>
<td>Defines the configuration of the mountstats collector, which collects statistics about NFS volume I/O activities. Disabled by default.</td>
</tr>
<tr>
<td>ksmd</td>
<td>NodeExporterCollectorKSMDCConfig</td>
<td>Defines the configuration of the ksmd collector, which collects statistics from the kernel same-page merger daemon. Disabled by default.</td>
</tr>
<tr>
<td>processes</td>
<td>NodeExporterCollectorProcessesConfig</td>
<td>Defines the configuration of the processes collector, which collects statistics from processes and threads running in the system. Disabled by default.</td>
</tr>
<tr>
<td>systemd</td>
<td>NodeExporterCollectorSystemdConfig</td>
<td>Defines the configuration of the systemd collector, which collects statistics on the systemd daemon and its managed services. Disabled by default.</td>
</tr>
</tbody>
</table>

## 14.14. NODEEXPORTERCOLLECTORCPUFREQCONFIG

### 14.14.1. Description
Use the `NodeExporterCollectorCpufreqConfig` resource to enable or disable the `cpufreq` collector of the `node-exporter` agent. By default, the `cpufreq` collector is disabled. Under certain circumstances, enabling the `cpufreq` collector increases CPU usage on machines with many cores. If you enable this collector and have machines with many cores, monitor your systems closely for excessive CPU usage.

Appears in: `NodeExporterCollectorConfig`

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>enabled</td>
<td>bool</td>
<td>A Boolean flag that enables or disables the <code>cpufreq</code> collector.</td>
</tr>
</tbody>
</table>

### 14.15. NODEEXPORTERCOLLECTORKSMDCONFIG

#### 14.15.1. Description

Use the `NodeExporterCollectorKSMDConfig` resource to enable or disable the `ksmd` collector of the `node-exporter` agent. By default, the `ksmd` collector is disabled.

Appears in: `NodeExporterCollectorConfig`

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>enabled</td>
<td>bool</td>
<td>A Boolean flag that enables or disables the <code>ksmd</code> collector.</td>
</tr>
</tbody>
</table>

### 14.16. NODEEXPORTERCOLLECTORMOUNTSTATSCONFIG

#### 14.16.1. Description

Use the `NodeExporterCollectorMountStatsConfig` resource to enable or disable the `mountstats` collector of the `node-exporter` agent. By default, the `mountstats` collector is disabled. If you enable the collector, the following metrics become available: `node_mountstats_nfs_read_bytes_total`, `node_mountstats_nfs_write_bytes_total`, and `node_mountstats_nfs_operations_requests_total`. Be aware that these metrics can have a high cardinality. If you enable this collector, closely monitor any increases in memory usage for the `prometheus-k8s` pods.

Appears in: `NodeExporterCollectorConfig`

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>enabled</td>
<td>bool</td>
<td>A Boolean flag that enables or disables the <code>mountstats</code> collector.</td>
</tr>
</tbody>
</table>

### 14.17. NODEEXPORTERCOLLECTORNETCLASSCONFIG

#### 14.17.1. Description
Use the `NodeExporterCollectorNetClassConfig` resource to enable or disable the `netclass` collector of the `node-exporter` agent. By default, the `netclass` collector is enabled. If you disable this collector, these metrics become unavailable: `node_network_info`, `node_network_address_assign_type`, `node_network_carrier`, `node_network_carrier_changes_total`, `node_network_carrier_up_changes_total`, `node_network_carrier_down_changes_total`, `node_network_device_id`, `node_network_dormant`, `node_network_flags`, `node_network_iface_id`, `node_network_iface_link`, `node_network_iface_link_mode`, `node_network_mtu_bytes`, `node_network_name_assign_type`, `node_network_net_dev_group`, `node_network_speed_bytes`, `node_network_transmit_queue_length`, and `node_network_protocol_type`.

Appears in: `NodeExporterCollectorConfig`

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>enabled</td>
<td>bool</td>
<td>A Boolean flag that enables or disables the <code>netclass</code> collector.</td>
</tr>
<tr>
<td>useNetlink</td>
<td>bool</td>
<td>A Boolean flag that activates the <code>netlink</code> implementation of the <code>netclass</code> collector. The default value is <code>true</code>, which activates the <code>netlink</code> mode. This implementation improves the performance of the <code>netclass</code> collector.</td>
</tr>
</tbody>
</table>

14.18. NODEEXPORTERCOLLECTORNETDEVCONFIG

14.18.1. Description

Use the `NodeExporterCollectorNetDevConfig` resource to enable or disable the `netdev` collector of the `node-exporter` agent. By default, the `netdev` collector is enabled. If disabled, these metrics become unavailable: `node_network_receive_bytes_total`, `node_network_receive_compressed_total`, `node_network_receive_drop_total`, `node_network_receive_errs_total`, `node_network_receive_fifo_total`, `node_network_receive_frame_total`, `node_network_receive_multicast_total`, `node_network_receive_nohandler_total`, `node_network_receive_packets_total`, `node_network_transmit_bytes_total`, `node_network_transmit_carrier_total`, `node_network_transmit_colls_total`, `node_network_transmit_compressed_total`, `node_network_transmit_drop_total`, `node_network_transmit_errs_total`, `node_network_transmit_fifo_total`, and `node_network_transmit_packets_total`.

Appears in: `NodeExporterCollectorConfig`

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>enabled</td>
<td>bool</td>
<td>A Boolean flag that enables or disables the <code>netdev</code> collector.</td>
</tr>
</tbody>
</table>

14.19. NODEEXPORTERCOLLECTORPROCESSESCONFIG
14.19.1. Description

Use the **NodeExporterCollectorProcessesConfig** resource to enable or disable the `processes` collector of the `node-exporter` agent. If the collector is enabled, the following metrics become available: `node_processes_max_processes`, `node_processes_pids`, `node_processes_state`, `node_processes_threads`, `node_processes_threads_state`. The metric `node_processes_state` and `node_processes_threads_state` can have up to five series each, depending on the state of the processes and threads. The possible states of a process or a thread are: `D` (UNINTERRUPTABLE_SLEEP), `R` (RUNNING & RUNNABLE), `S` (INTERRUPTABLE_SLEEP), `T` (STOPPED), or `Z` (ZOMBIE). By default, the `processes` collector is disabled.

Appears in: **NodeExporterCollectorConfig**

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>enabled</td>
<td>bool</td>
<td>A Boolean flag that enables or disables the <code>processes</code> collector.</td>
</tr>
</tbody>
</table>

14.20. NODEEXPORTERCOLLECTORSYSTEMDCONFIG

14.20.1. Description

Use the **NodeExporterCollectorSystemdConfig** resource to enable or disable the `systemd` collector of the `node-exporter` agent. By default, the `systemd` collector is disabled. If enabled, the following metrics become available: `node_systemd_system_running`, `node_systemd_units`, `node_systemd_version`. If the unit uses a socket, it also generates the following metrics: `node_systemd_socket_accepted_connections_total`, `node_systemd_socket_current_connections`, `node_systemd_socket_refused_connections_total`. You can use the `units` parameter to select the `systemd` units to be included by the `systemd` collector. The selected units are used to generate the `node_systemd_unit_state` metric, which shows the state of each `systemd` unit. However, this metric’s cardinality might be high (at least five series per unit per node). If you enable this collector with a long list of selected units, closely monitor the `prometheus-k8s` deployment for excessive memory usage. Note that the `node_systemd_timer_last_trigger_seconds` metric is only shown if you have configured the value of the `units` parameter as `logrotate.timer`.

Appears in: **NodeExporterCollectorConfig**

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>enabled</td>
<td>bool</td>
<td>A Boolean flag that enables or disables the <code>systemd</code> collector.</td>
</tr>
<tr>
<td>units</td>
<td>[]string</td>
<td>A list of regular expression (regex) patterns that match systemd units to be included by the <code>systemd</code> collector. By default, the list is empty, so the collector exposes no metrics for systemd units.</td>
</tr>
</tbody>
</table>
14.21. NODEEXPORTERCOLLECTORTCPSTATCONFIG

14.21.1. Description

The `NodeExporterCollectorTcpStatConfig` resource works as an on/off switch for the `tcpstat` collector of the `node-exporter` agent. By default, the `tcpstat` collector is disabled.

Appears in: `NodeExporterCollectorConfig`

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>

14.22. NODEEXPORTERCONFIG

14.22.1. Description

The `NodeExporterConfig` resource defines settings for the `node-exporter` agent.

Appears in: `ClusterMonitoringConfiguration`

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>collectors</td>
<td><code>NodeExporterCollectorConfig</code></td>
<td>Defines which collectors are enabled and their additional configuration parameters.</td>
</tr>
<tr>
<td>maxProcs</td>
<td><code>uint32</code></td>
<td>The target number of CPUs on which the node-exporter’s process will run. The default value is 0, which means that node-exporter runs on all CPUs. If a kernel deadlock occurs or if performance degrades when reading from <code>sysfs</code> concurrently, you can change this value to 1, which limits node-exporter to running on one CPU. For nodes with a high CPU count, you can set the limit to a low number, which saves resources by preventing Go routines from being scheduled to run on all CPUs. However, I/O performance degrades if the <code>maxProcs</code> value is set too low and there are many metrics to collect.</td>
</tr>
</tbody>
</table>
14.23. OPENSHTSTATEMETRICSCONFIG

14.23.1. Description

The **OpenShiftStateMetricsConfig** resource defines settings for the *openshift-state-metrics* agent.

Appears in: **ClusterMonitoringConfiguration**

<table>
<thead>
<tr>

<tr>
<td>retention</td>
<td>string</td>
<td>Defines the duration for which Prometheus retains data. This definition must be specified using the following regular expression pattern: [0-9]+(ms</td>
</tr>
<tr>
<td>retentionSize</td>
<td>string</td>
<td>Defines the maximum amount of disk space used by data blocks plus the write-ahead log (WAL). Supported values are B, KB, KiB, MB, MiB, GB, GiB, TB, TiB, PB, PiB, EB, and EiB. The default value is nil.</td>
</tr>
<tr>
<td>tolerations</td>
<td>[]v1.Toleration</td>
<td>Defines tolerations for the pods.</td>
</tr>
<tr>
<td>topologySpreadConstraints</td>
<td>[]v1.TopologySpreadConstraint</td>
<td>Defines the pod’s topology spread constraints.</td>
</tr>
</tbody>
</table>
**volumeClaimTemplate**

*monv1.EmbeddedPersistentVolumeClaim

Defines persistent storage for Prometheus. Use this setting to configure the storage class and size of a volume.

### 14.27. REMOTEWritespec

#### 14.27.1. Description

The **RemoteWriteSpec** resource defines the settings for remote write storage.

#### 14.27.2. Required

- url

Appears in: PrometheusK8sConfig, PrometheusRestrictedConfig

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>authorization</td>
<td>*monv1.SafeAuthorization</td>
<td>Defines the authorization settings for remote write storage.</td>

<tr>
<td>sigv4</td>
<td>*monv1.Sigv4</td>
<td>Defines AWS Signature Version 4 authentication settings.</td>
</tr>
<tr>
<td>tlsConfig</td>
<td>*monv1.SafeTLSConfig</td>
<td>Defines TLS authentication settings for the remote write endpoint.</td>
</tr>
<tr>
<td>url</td>
<td>string</td>
<td>Defines the URL of the remote write endpoint to which samples will be sent.</td>
</tr>
<tr>
<td>writeRelabelConfigs</td>
<td>[]monv1.RelabelConfig</td>
<td>Defines the list of remote write relabel configurations.</td>
</tr>
</tbody>
</table>

### 14.28. TLSCONFIG

#### 14.28.1. Description

The **TLSCONFIG** resource configures the settings for TLS connections.

#### 14.28.2. Required

- insecureSkipVerify

Appears in: AdditionalAlertmanagerConfig
<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ca</td>
<td>*v1.SecretKeySelector</td>
<td>Defines the secret key reference containing the Certificate Authority (CA) to use for the remote host.</td>
</tr>
<tr>
<td>cert</td>
<td>*v1.SecretKeySelector</td>
<td>Defines the secret key reference containing the public certificate to use for the remote host.</td>
</tr>
<tr>
<td>key</td>
<td>*v1.SecretKeySelector</td>
<td>Defines the secret key reference containing the private key to use for the remote host.</td>
</tr>
<tr>
<td>serverName</td>
<td>string</td>
<td>Used to verify the hostname on the returned certificate.</td>
</tr>
<tr>
<td>insecureSkipVerify</td>
<td>bool</td>
<td>When set to <code>true</code>, disables the verification of the remote host’s certificate and name.</td>
</tr>
</tbody>
</table>

### 14.29. TELEMETERCLIENTCONFIG

#### 14.29.1. Description

`TelemeterClientConfig` defines settings for the Telemeter Client component.

#### 14.29.2. Required

- `nodeSelector`
- `tolerations`

Appears in: `ClusterMonitoringConfiguration`

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nodeSelector</td>
<td>map[string]string</td>
<td>Defines the nodes on which the pods are scheduled.</td>
</tr>
<tr>
<td>resources</td>
<td>*v1.ResourceRequirements</td>
<td>Defines resource requests and limits for the <code>TelemeterClient</code> container.</td>
</tr>
<tr>
<td>tolerations</td>
<td>[]v1.Toleration</td>
<td>Defines tolerations for the pods.</td>
</tr>
<tr>
<td>topologySpreadConstraints</td>
<td>[]v1.TopologySpreadConstraint</td>
<td>Defines the pod’s topology spread constraints.</td>

</tbody>
</table>
The Cluster Observability Operator (COO) is an optional OpenShift Container Platform Operator that enables administrators to create standalone monitoring stacks that are independently configurable for use by different services and users.

The COO complements the built-in monitoring capabilities of OpenShift Container Platform. You can deploy it in parallel with the default platform and user workload monitoring stacks managed by the Cluster Monitoring Operator (CMO).

These release notes track the development of the Cluster Observability Operator in OpenShift Container Platform.

15.1.1. Cluster Observability Operator 0.1.1

This release updates the Cluster Observability Operator to support installing the Operator in restricted networks or disconnected environments.

15.1.2. Cluster Observability Operator 0.1

This release makes a Technology Preview version of the Cluster Observability Operator available on OperatorHub.

15.2. CLUSTER OBSERVABILITY OPERATOR OVERVIEW

The Cluster Observability Operator is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see Technology Preview Features Support Scope.
The Cluster Observability Operator (COO) is an optional component of the OpenShift Container Platform. You can deploy it to create standalone monitoring stacks that are independently configurable for use by different services and users.

The COO deploys the following monitoring components:

- Prometheus
- Thanos Querier (optional)
- Alertmanager (optional)

The COO components function independently of the default in-cluster monitoring stack, which is deployed and managed by the Cluster Monitoring Operator (CMO). Monitoring stacks deployed by the two Operators do not conflict. You can use a COO monitoring stack in addition to the default platform monitoring components deployed by the CMO.

15.2.1. Understanding the Cluster Observability Operator

A default monitoring stack created by the Cluster Observability Operator (COO) includes a highly available Prometheus instance capable of sending metrics to an external endpoint by using remote write.

Each COO stack also includes an optional Thanos Querier component, which you can use to query a highly available Prometheus instance from a central location, and an optional Alertmanager component, which you can use to set up alert configurations for different services.

15.2.1.1. Advantages of using the Cluster Observability Operator

The MonitoringStack CRD used by the COO offers an opinionated default monitoring configuration for COO-deployed monitoring components, but you can customize it to suit more complex requirements.

Deploying a COO-managed monitoring stack can help meet monitoring needs that are difficult or impossible to address by using the core platform monitoring stack deployed by the Cluster Monitoring Operator (CMO). A monitoring stack deployed using COO has the following advantages over core platform and user workload monitoring:

- **Extendability**
  
  Users can add more metrics to a COO-deployed monitoring stack, which is not possible with core platform monitoring without losing support. In addition, COO-managed stacks can receive certain cluster-specific metrics from core platform monitoring by using federation.

- **Multi-tenancy support**
  
  The COO can create a monitoring stack per user namespace. You can also deploy multiple stacks per namespace or a single stack for multiple namespaces. For example, cluster administrators, SRE teams, and development teams can all deploy their own monitoring stacks on a single cluster, rather than having to use a single shared stack of monitoring components. Users on different teams can then independently configure features such as separate alerts, alert routing, and alert receivers for their applications and services.

- **Scalability**
  
  You can create COO-managed monitoring stacks as needed. Multiple monitoring stacks can run on a single cluster, which can facilitate the monitoring of very large clusters by using manual sharding. This ability addresses cases where the number of metrics exceeds the monitoring capabilities of a single Prometheus instance.

- **Flexibility**
Deploying the COO with Operator Lifecycle Manager (OLM) decouples COO releases from OpenShift Container Platform release cycles. This method of deployment enables faster release iterations and the ability to respond rapidly to changing requirements and issues. Additionally, by deploying a COO-managed monitoring stack, users can manage alerting rules independently of OpenShift Container Platform release cycles.

**Highly customizable**

The COO can delegate ownership of single configurable fields in custom resources to users by using Server-Side Apply (SSA), which enhances customization.

**Additional resources**

- Kubernetes documentation for Server-Side Apply (SSA)

### 15.3. INSTALLING THE CLUSTER OBSERVABILITY OPERATOR

**IMPORTANT**

The Cluster Observability Operator is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see [Technology Preview Features Support Scope](#).

As a cluster administrator, you can install the Cluster Observability Operator (COO) from OperatorHub by using the OpenShift Container Platform web console or CLI. OperatorHub is a user interface that works in conjunction with Operator Lifecycle Manager (OLM), which installs and manages Operators on a cluster.

To install the COO using OperatorHub, follow the procedure described in [Adding Operators to a cluster](#).

#### 15.3.1. Uninstalling the Cluster Observability Operator using the web console

If you have installed the Cluster Observability Operator (COO) by using OperatorHub, you can uninstall it in the OpenShift Container Platform web console.

**Prerequisites**

- You have access to the cluster as a user with the `cluster-admin` cluster role.
- You have logged in to the OpenShift Container Platform web console.

**Procedure**

1. Go to **Operators → Installed Operators**.
2. Locate the **Cluster Observability Operator** entry in the list.
3. Click for this entry and select **Uninstall Operator**.
15.4. CONFIGURING THE CLUSTER OBSERVABILITY OPERATOR TO MONITOR A SERVICE

IMPORTANT

The Cluster Observability Operator is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see Technology Preview Features Support Scope.

You can monitor metrics for a service by configuring monitoring stacks managed by the Cluster Observability Operator (COO).

To test monitoring a service, follow these steps:

1. Deploy a sample service that defines a service endpoint.
2. Create a `ServiceMonitor` object that specifies how the service is to be monitored by the COO.
3. Create a `MonitoringStack` object to discover the `ServiceMonitor` object.

15.4.1. Deploying a sample service for Cluster Observability Operator

This configuration deploys a sample service named `prometheus-coo-example-app` in the user-defined `ns1-coo` project. The service exposes the custom `version` metric.

Prerequisites

- You have access to the cluster as a user with the `cluster-admin` cluster role or as a user with administrative permissions for the namespace.

Procedure

1. Create a YAML file named `prometheus-coo-example-app.yaml` that contains the following configuration details for a namespace, deployment, and service:

```yaml
apiVersion: v1
kind: Namespace
metadata:
  name: ns1-coo
---
apiVersion: apps/v1
kind: Deployment
metadata:
  labels:
    app: prometheus-coo-example-app
namespace: ns1-coo
spec:
2. Save the file.

3. Apply the configuration to the cluster by running the following command:

   ```bash
   $ oc apply -f prometheus-coo-example-app.yaml
   ```

4. Verify that the pod is running by running the following command and observing the output:

   ```bash
   $ oc -n -ns1-coo get pod
   ```

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>prometheus-coo-example-app-0927545cb7-anskj</td>
<td>1/1</td>
<td>Running</td>
<td>0</td>
<td>81m</td>
</tr>
</tbody>
</table>

**15.4.2. Specifying how a service is monitored by Cluster Observability Operator**

To use the metrics exposed by the sample service you created in the "Deploying a sample service for Cluster Observability Operator" section, you must configure monitoring components to scrape metrics from the `/metrics` endpoint.

You can create this configuration by using a **ServiceMonitor** object that specifies how the service is to be monitored, or a **PodMonitor** object that specifies how a pod is to be monitored. The ServiceMonitor

```yaml
replicas: 1
selector:
  matchLabels:
    app: prometheus-coo-example-app
template:
  metadata:
    labels:
      app: prometheus-coo-example-app
  spec:
    containers:
      - image: ghcr.io/rhobs/prometheus-example-app:0.4.2
        imagePullPolicy: IfNotPresent
        name: prometheus-coo-example-app
---
apiVersion: v1
kind: Service
metadata:
  labels:
    app: prometheus-coo-example-app
  name: prometheus-coo-example-app
  namespace: ns1-coo
spec:
  ports:
  - port: 8080
    protocol: TCP
    targetPort: 8080
    name: web
  selector:
    app: prometheus-coo-example-app
  type: ClusterIP
```
object requires a Service object. The PodMonitor object does not, which enables the MonitoringStack object to scrape metrics directly from the metrics endpoint exposed by a pod.

This procedure shows how to create a ServiceMonitor object for a sample service named prometheus-coo-example-app in the ns1-coo namespace.

Prerequisites

- You have access to the cluster as a user with the cluster-admin cluster role or as a user with administrative permissions for the namespace.
- You have installed the Cluster Observability Operator.
- You have deployed the prometheus-coo-example-app sample service in the ns1-coo namespace.

NOTE

The prometheus-coo-example-app sample service does not support TLS authentication.

Procedure

1. Create a YAML file named example-coo-app-service-monitor.yaml that contains the following ServiceMonitor object configuration details:

   ```yaml
   apiVersion: monitoring.rhobs/v1alpha1
   kind: ServiceMonitor
   metadata:
     labels:
       k8s-app: prometheus-coo-example-monitor
     name: prometheus-coo-example-monitor
     namespace: ns1-coo
   spec:
     endpoints:
     - interval: 30s
       port: web
       scheme: http
     selector:
       matchLabels:
         app: prometheus-coo-example-app
   ```

   This configuration defines a ServiceMonitor object that the MonitoringStack object will reference to scrape the metrics data exposed by the prometheus-coo-example-app sample service.

2. Apply the configuration to the cluster by running the following command:

   ```bash
   $ oc apply -f example-app-service-monitor.yaml
   ```

3. Verify that the ServiceMonitor resource is created by running the following command and observing the output:

   ```bash
   $ oc -n ns1-coo get servicemonitor
   ```
15.4.3. Creating a MonitoringStack object for the Cluster Observability Operator

To scrape the metrics data exposed by the target `prometheus-coo-example-app` service, create a MonitoringStack object that references the ServiceMonitor object you created in the "Specifying how a service is monitored for Cluster Observability Operator" section. This MonitoringStack object can then discover the service and scrape the exposed metrics data from it.

Prerequisites

- You have access to the cluster as a user with the cluster-admin cluster role or as a user with administrative permissions for the namespace.
- You have installed the Cluster Observability Operator.
- You have deployed the `prometheus-coo-example-app` sample service in the `ns1-coo` namespace.
- You have created a ServiceMonitor object named `prometheus-coo-example-monitor` in the `ns1-coo` namespace.

Procedure

1. Create a YAML file for the MonitoringStack object configuration. For this example, name the file `example-coo-monitoring-stack.yaml`.

2. Add the following MonitoringStack object configuration details:

   Example MonitoringStack object

   ```yaml
   apiVersion: monitoring.rhobs/v1alpha1
   kind: MonitoringStack
   metadata:
     name: example-coo-monitoring-stack
     namespace: ns1-coo
   spec:
     logLevel: debug
     retention: 1d
     resourceSelector:
       matchLabels:
         k8s-app: prometheus-coo-example-monitor
   ```

3. Apply the MonitoringStack object by running the following command:

   ```bash
   $ oc apply -f example-coo-monitoring-stack.yaml
   ```

4. Verify that the MonitoringStack object is available by running the following command and inspecting the output:

   ```bash
   $ oc -n ns1-coo get monitoringstack
   ```

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>prometheus-coo-example-monitor</td>
<td>81m</td>
</tr>
</tbody>
</table>
Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>example-coo-monitoring-stack</td>
<td>81m</td>
</tr>
</tbody>
</table>
