OpenShift Container Platform 4.6

Backup and restore

Backing up and restoring your OpenShift Container Platform cluster
Backing up and restoring your OpenShift Container Platform cluster
Abstract

This document provides instructions for backing up your cluster’s data and for recovering from various disaster scenarios.
Table of Contents

CHAPTER 1. BACKUP AND RESTORE ................................................................. 5
1.1. OVERVIEW OF BACKUP AND RESTORE OPERATIONS IN OPENSHIFT CONTAINER PLATFORM 5

      4.2.4.4.1. Setting Velero CPU and memory resource allocations 36
      4.2.4.4.2. Enabling self-signed CA certificates 37
      4.2.4.5. Installing the Data Protection Application 38
      4.2.4.5.1. Enabling CSI in the DataProtectionApplication CR 40
   4.2.5. Installing and configuring the OpenShift API for Data Protection with Multicloud Object Gateway 41
4.2.5.1. Installing the OADP Operator
4.2.5.2. Configuring the Multicloud Object Gateway
4.2.5.3. Creating a secret for backup and snapshot locations
4.2.5.3.1. Configuring secrets for different backup and snapshot location credentials
4.2.5.4. Configuring the Data Protection Application
4.2.5.4.1. Setting Velero CPU and memory resource allocations
4.2.5.4.2. Enabling self-signed CA certificates
4.2.5.5. Installing the Data Protection Application
4.2.5.5.1. Enabling CSI in the DataProtectionApplication CR
4.2.6. Installing and configuring the OpenShift API for Data Protection with OpenShift Container Storage
4.2.6.1. Installing the OADP Operator
4.2.6.2. Creating a secret for backup and snapshot locations
4.2.6.2.1. Configuring secrets for different backup and snapshot location credentials
4.2.6.3. Configuring the Data Protection Application
4.2.6.3.1. Setting Velero CPU and memory resource allocations
4.2.6.3.2. Enabling self-signed CA certificates
4.2.6.4. Installing the Data Protection Application
4.2.6.4.1. Enabling CSI in the DataProtectionApplication CR
4.2.7. Uninstalling the OpenShift API for Data Protection
4.3. BACKING UP AND RESTORING
4.3.1. Backing up applications
4.3.1.1. Creating a Backup CR
4.3.1.2. Backing up persistent volumes with CSI snapshots
4.3.1.3. Backing up applications with Restic
4.3.1.4. Creating backup hooks
4.3.1.5. Scheduling backups
4.3.2. Restoring applications
4.3.2.1. Creating a Restore CR
4.3.2.2. Creating restore hooks
4.4. TROUBLESHOOTING
4.4.1. Debugging Velero resources with the OpenShift CLI tool
   Velero CRs
   Velero pod logs
   Velero pod debug logs
4.4.2. Debugging Velero resources with the Velero CLI tool
   Syntax
   Help option
   Describe command
   Logs command
4.4.3. Installation issues
   4.4.3.1. Backup storage contains invalid directories
   4.4.3.2. Incorrect AWS credentials
4.4.4. Backup and Restore CR issues
   4.4.4.1. Backup CR cannot retrieve volume
   4.4.4.2. Backup CR status remains in progress
4.4.5. Restic issues
   4.4.5.1. Restic permission error for NFS data volumes with root_squash enabled
   4.4.5.2. Restore CR of Restic backup is "PartiallyFailed", "Failed", or remains "InProgress"
   4.4.5.3. Restic Backup CR cannot be recreated after bucket is emptied
4.4.6. Using the must-gather tool
   Viewing metrics data with the Prometheus console

CHAPTER 5. CONTROL PLANE BACKUP AND RESTORE
5.1. BACKING UP ETCD
  5.1.1. Backing up etcd data
5.2. REPLACING AN UNHEALTHY ETCD MEMBER
  5.2.1. Prerequisites
  5.2.2. Identifying an unhealthy etcd member
  5.2.3. Determining the state of the unhealthy etcd member
  5.2.4. Replacing the unhealthy etcd member
    5.2.4.1. Replacing an unhealthy etcd member whose machine is not running or whose node is not ready
    5.2.4.2. Replacing an unhealthy etcd member whose etcd pod is crashlooping
5.3. DISASTER RECOVERY
  5.3.1. About disaster recovery
  5.3.2. Restoring to a previous cluster state
    5.3.2.1. About restoring cluster state
    5.3.2.2. Restoring to a previous cluster state
    5.3.2.3. Issues and workarounds for restoring a persistent storage state
  5.3.3. Recovering from expired control plane certificates
    5.3.3.1. Recovering from expired control plane certificates
1.1. OVERVIEW OF BACKUP AND RESTORE OPERATIONS IN OPENSHIFT CONTAINER PLATFORM

As a cluster administrator, you might need to stop an OpenShift Container Platform cluster for a period and restart it later. Some reasons for restarting a cluster are that you need to perform maintenance on a cluster or want to reduce resource costs. In OpenShift Container Platform, you can perform a **graceful shutdown of a cluster** so that you can easily restart the cluster later.

You must **back up etcd data** before shutting down a cluster; etcd is the key-value store for OpenShift Container Platform, which persists the state of all resource objects. An etcd backup plays a crucial role in disaster recovery. In OpenShift Container Platform, you can also **replace an unhealthy etcd member**.

When you want to get your cluster running again, **restart the cluster gracefully**.

**NOTE**

A cluster's certificates expire one year after the installation date. You can shut down a cluster and expect it to restart gracefully while the certificates are still valid. Although the cluster automatically retrieves the expired control plane certificates, you must still **approve the certificate signing requests (CSRs)**.

You might run into several situations where OpenShift Container Platform does not work as expected, such as:

- You have a cluster that is not functional after the restart because of unexpected conditions, such as node failure, or network connectivity issues.
- You have deleted something critical in the cluster by mistake.
- You have lost the majority of your control plane hosts, leading to etcd quorum loss.

You can always recover from a disaster situation by **restoring your cluster to its previous state** using the saved etcd snapshots.

1.2. APPLICATION BACKUP AND RESTORE OPERATIONS

As a cluster administrator, you can back up and restore applications running on OpenShift Container Platform by using the OpenShift API for Data Protection (OADP).

OADP backs up and restores Kubernetes resources and internal images, at the granularity of a namespace, by using **Velero 1.7**. OADP backs up and restores persistent volumes (PVs) by using snapshots or Restic. For details, see **OADP features**.

1.2.1. OADP requirements

OADP has the following requirements:

- You must be logged in as a user with a **cluster-admin** role.
- You must have object storage for storing backups, such as one of the following storage types:
  - Amazon Web Services
IMPORTANT

The CloudStorage API for S3 storage is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see https://access.redhat.com/support/offerings/techpreview/.

- To back up PVs with snapshots, you must have cloud storage that has a native snapshot API or supports Container Storage Interface (CSI) snapshots, such as the following providers:
  - Amazon Web Services
  - Microsoft Azure
  - Google Cloud Platform
  - CSI snapshot-enabled cloud storage, such as Ceph RBD or Ceph FS

NOTE

If you do not want to back up PVs by using snapshots, you can use Restic, which is installed by the OADP Operator by default.

1.2.2. Backing up and restoring applications

You back up applications by creating a Backup custom resource (CR). You can configure the following backup options:

- **Backup hooks** to run commands before or after the backup operation
- **Scheduled backups**
- **Restic backups**

You restore applications by creating a Restore CR. You can configure restore hooks to run commands in init containers or in the application container during the restore operation.
CHAPTER 2. SHUTTING DOWN THE CLUSTER GRACEFULLY

This document describes the process to gracefully shut down your cluster. You might need to temporarily shut down your cluster for maintenance reasons, or to save on resource costs.

2.1. PREREQUISITES

- Take an etcd backup prior to shutting down the cluster.

2.2. SHUTTING DOWN THE CLUSTER

You can shut down your cluster in a graceful manner so that it can be restarted at a later date.

NOTE

You can shut down a cluster until a year from the installation date and expect it to restart gracefully. After a year from the installation date, the cluster certificates expire.

Prerequisites

- You have access to the cluster as a user with the `cluster-admin` role.
- You have taken an etcd backup.

IMPORTANT

It is important to take an etcd backup before performing this procedure so that your cluster can be restored if you encounter any issues when restarting the cluster.

Procedure

1. If you are shutting the cluster down for an extended period, determine the date on which certificates expire.

   ```
   $ oc -n openshift-kube-apiserver-operator get secret kube-apiserver-to-kubelet-signer -o jsonpath='{.metadata.annotations.auth.openshift.io/certificate-not-after}'
   ```

   **Example output**

   ```
   2022-08-05T14:37:50Z
   ```

   To ensure that the cluster can restart gracefully, plan to restart it on or before the specified date. As the cluster restarts, the process might require you to manually approve the pending certificate signing requests (CSRs) to recover kubelet certificates.

2. Shut down all of the nodes in the cluster. You can do this from your cloud provider’s web console, or run the following loop:

   ```
   $ for node in $(oc get nodes -o jsonpath='{.items[*].metadata.name}'); do oc debug node/$node -- chroot /host shutdown -h 1 <1>; done
   ```
Indicates how long, in minutes, this process lasts before the control-plane nodes are shut down. For large-scale clusters with 10 nodes or more, set to 10 minutes or longer to make sure all the compute nodes have time to shut down first.

Example output

```
Starting pod/ip-10-0-130-169us-east-2computeinternal-debug ...
To use host binaries, run `chroot /host`
Shutdown scheduled for Mon 2021-09-13 09:36:17 UTC, use `shutdown -c` to cancel.

Removing debug pod ...
Starting pod/ip-10-0-150-116us-east-2computeinternal-debug ...
To use host binaries, run `chroot /host`
Shutdown scheduled for Mon 2021-09-13 09:36:29 UTC, use `shutdown -c` to cancel.
```

Indicates how long, in minutes, this process lasts before the control-plane nodes are shut down. For large-scale clusters with 10 nodes or more, set to 10 minutes or longer to make sure all the compute nodes have time to shut down first.

Shutting down the nodes using one of these methods allows pods to terminate gracefully, which reduces the chance for data corruption.

**NOTE**

Adjust the shut down time to be longer for large-scale clusters:

```
$ for node in $(oc get nodes -o jsonpath='{.items[*].metadata.name}'); do oc
ddebug node/$node -- chroot /host shutdown -h 10; done
```

**NOTE**

It is not necessary to drain control plane nodes (also known as the master nodes) of the standard pods that ship with OpenShift Container Platform prior to shutdown.

Cluster administrators are responsible for ensuring a clean restart of their own workloads after the cluster is restarted. If you drained control plane nodes prior to shutdown because of custom workloads, you must mark the control plane nodes as schedulable before the cluster will be functional again after restart.

3. Shut off any cluster dependencies that are no longer needed, such as external storage or an LDAP server. Be sure to consult your vendor’s documentation before doing so.

Additional resources

- [Restarting the cluster gracefully](#)
CHAPTER 3. RESTARTING THE CLUSTER GRACEFULLY

This document describes the process to restart your cluster after a graceful shutdown.

Even though the cluster is expected to be functional after the restart, the cluster might not recover due to unexpected conditions, for example:

- etcd data corruption during shutdown
- Node failure due to hardware
- Network connectivity issues

If your cluster fails to recover, follow the steps to restore to a previous cluster state.

3.1. PREREQUISITES

- You have gracefully shut down your cluster.

3.2. RESTARTING THE CLUSTER

You can restart your cluster after it has been shut down gracefully.

Prerequisites

- You have access to the cluster as a user with the cluster-admin role.
- This procedure assumes that you gracefully shut down the cluster.

Procedure

1. Power on any cluster dependencies, such as external storage or an LDAP server.

2. Start all cluster machines.
   Use the appropriate method for your cloud environment to start the machines, for example, from your cloud provider’s web console.
   Wait approximately 10 minutes before continuing to check the status of control plane nodes (also known as the master nodes).

3. Verify that all control plane nodes are ready.

   $ oc get nodes -l node-role.kubernetes.io/master

   The control plane nodes are ready if the status is Ready, as shown in the following output:

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>ip-10-0-168-251.ec2.internal</td>
<td>Ready</td>
<td>master</td>
<td>75m</td>
<td>v1.19.0</td>
</tr>
<tr>
<td>ip-10-0-170-223.ec2.internal</td>
<td>Ready</td>
<td>master</td>
<td>75m</td>
<td>v1.19.0</td>
</tr>
<tr>
<td>ip-10-0-211-16.ec2.internal</td>
<td>Ready</td>
<td>master</td>
<td>75m</td>
<td>v1.19.0</td>
</tr>
</tbody>
</table>

4. If the control plane nodes are not ready, then check whether there are any pending certificate signing requests (CSRs) that must be approved.
a. Get the list of current CSRs:

   $ oc get csr

b. Review the details of a CSR to verify that it is valid:

   $ oc describe csr <csr_name>  

   <csr_name> is the name of a CSR from the list of current CSRs.

c. Approve each valid CSR:

   $ oc adm certificate approve <csr_name>

5. After the control plane nodes are ready, verify that all worker nodes are ready.

   $ oc get nodes -l node-role.kubernetes.io/worker

   The worker nodes are ready if the status is Ready, as shown in the following output:

   NAME                           STATUS   ROLES    AGE   VERSION
   ip-10-0-179-95.ec2.internal    Ready    worker   64m   v1.19.0
   ip-10-0-182-134.ec2.internal   Ready    worker   64m   v1.19.0
   ip-10-0-250-100.ec2.internal   Ready    worker   64m   v1.19.0

6. If the worker nodes are not ready, then check whether there are any pending certificate signing requests (CSRs) that must be approved.

   a. Get the list of current CSRs:

      $ oc get csr

   b. Review the details of a CSR to verify that it is valid:

      $ oc describe csr <csr_name>  

      <csr_name> is the name of a CSR from the list of current CSRs.

c. Approve each valid CSR:

      $ oc adm certificate approve <csr_name>

7. Verify that the cluster started properly.

   a. Check that there are no degraded cluster Operators.

      $ oc get clusteroperators

      Check that there are no cluster Operators with the DEGRADED condition set to True.

      NAME                  VERSION  AVAILABLE  PROGRESSING  DEGRADED
b. Check that all nodes are in the **Ready** state:

```bash
$ oc get nodes
```

Check that the status for all nodes is **Ready**.

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>ip-10-0-168-251.ec2.internal</td>
<td>Ready</td>
<td>master</td>
<td>82m</td>
<td>v1.19.0</td>
</tr>
<tr>
<td>ip-10-0-170-223.ec2.internal</td>
<td>Ready</td>
<td>master</td>
<td>82m</td>
<td>v1.19.0</td>
</tr>
<tr>

</tr>
<tr>
<td>ip-10-0-250-100.ec2.internal</td>
<td>Ready</td>
<td>worker</td>
<td>69m</td>
<td>v1.19.0</td>
</tr>
</tbody>
</table>

If the cluster did not start properly, you might need to restore your cluster using an etcd backup.

**Additional resources**

- See [Restoring to a previous cluster state](#) for how to use an etcd backup to restore if your cluster failed to recover after restarting.
CHAPTER 4. APPLICATION BACKUP AND RESTORE

4.1. OADP FEATURES AND PLUG-INS

OpenShift API for Data Protection (OADP) features provide options for backing up and restoring applications.

The default plug-ins enable Velero to integrate with certain cloud providers and to back up and restore OpenShift Container Platform resources.

4.1.1. OADP features

OpenShift API for Data Protection (OADP) supports the following features:

**Backup**
- You can back up all resources in your cluster or you can filter the resources by type, namespace, or label.
- OADP backs up Kubernetes objects and internal images by saving them as an archive file on object storage. OADP backs up persistent volumes (PVs) by creating snapshots with the native cloud snapshot API or with the Container Storage Interface (CSI). For cloud providers that do not support snapshots, OADP backs up resources and PV data with Restic.

**Restore**
- You can restore resources and PVs from a backup. You can restore all objects in a backup or filter the restored objects by namespace, PV, or label.

**Schedule**
- You can schedule backups at specified intervals.

**Hooks**
- You can use hooks to run commands in a container on a pod, for example, `fsfreeze` to freeze a file system. You can configure a hook to run before or after a backup or restore. Restore hooks can run in an init container or in the application container.

4.1.2. OADP plug-ins

The OpenShift API for Data Protection (OADP) provides default Velero plug-ins that are integrated with storage providers to support backup and snapshot operations. You can create custom plug-ins based on the Velero plug-ins.

OADP also provides plug-ins for OpenShift Container Platform resource backups and Container Storage Interface (CSI) snapshots.

**Table 4.1. OADP plug-ins**

<table>

</tr>
</tbody>
</table>

1. Mandatory.

2. The **csi** plug-in uses the Velero CSI beta snapshot API.

### 4.2. INSTALLING AND CONFIGURING OADP

#### 4.2.1. About installing OADP

As a cluster administrator, you install the OpenShift API for Data Protection (OADP) by installing the OADP Operator. The OADP Operator installs Velero 1.7.

To back up Kubernetes resources and internal images, you must have object storage as a backup location, such as one of the following storage types:

- Amazon Web Services
- Microsoft Azure
- Google Cloud Platform
- Multicloud Object Gateway
- S3-compatible object storage, such as Noobaa or Minio
You can back up persistent volumes (PVs) by using snapshots or Restic.

To back up PVs with snapshots, you must have a cloud provider that supports either a native snapshot API or Container Storage Interface (CSI) snapshots, such as one of the following cloud providers:

- Amazon Web Services
- Microsoft Azure
- Google Cloud Platform
- CSI snapshot-enabled cloud provider, such as OpenShift Container Storage

If your cloud provider does not support snapshots or if your storage is NFS, you can back up applications with Restic.

You create a Secret object for your storage provider credentials and then you install the Data Protection Application.

Additional resources

- Overview of backup locations and snapshot locations in the Velero documentation.

4.2.2. Installing and configuring the OpenShift API for Data Protection with Amazon Web Services

You install the OpenShift API for Data Protection (OADP) with Amazon Web Services (AWS) by installing the OADP Operator, configuring AWS for Velero, and then installing the Data Protection Application.

IMPORTANT

The CloudStorage API for S3 storage is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see https://access.redhat.com/support/offerings/techpreview/.
To install the OADP Operator in a restricted network environment, you must first disable the default OperatorHub sources and mirror the Operator catalog. See Using Operator Lifecycle Manager on restricted networks for details.

4.2.2.1. Installing the OADP Operator

You install the OpenShift API for Data Protection (OADP) Operator on OpenShift Container Platform 4.6 by using Operator Lifecycle Manager (OLM).

The OADP Operator installs Velero 1.7.

Prerequisites

- You must be logged in as a user with cluster-admin privileges.

Procedure

1. In the OpenShift Container Platform web console, click Operators → OperatorHub.
2. Use the Filter by keyword field to find the OADP Operator.
3. Select the OADP Operator and click Install.
4. Click Install to install the Operator in the openshift-adp project.
5. Click Operators → Installed Operators to verify the installation.

4.2.2.2. Configuring Amazon Web Services S3

You can configure an Amazon Web Services (AWS) S3 storage bucket as a replication repository for the Migration Toolkit for Containers (MTC).

Prerequisites

- The AWS S3 storage bucket must be accessible to the source and target clusters.
- You must have the AWS CLI installed.
- If you are using the snapshot copy method:
  - You must have access to EC2 Elastic Block Storage (EBS).
  - The source and target clusters must be in the same region.
  - The source and target clusters must have the same storage class.
  - The storage class must be compatible with snapshots.

Procedure

1. Create an AWS S3 bucket:

   ```bash
   $ aws s3api create-bucket \
     --bucket <bucket> \ 1
     --region <bucket_region> 2
   ```
1. Specify your S3 bucket name.
2. Specify your S3 bucket region, for example, **us-east-1**.

2. Create the IAM user **velero**:

   ```bash
   $ aws iam create-user --user-name velero
   ```

3. Create an EC2 EBS snapshot policy:

   ```json
   $ cat > velero-ec2-snapshot-policy.json <<EOF
   {
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Action": [
           "ec2:DescribeVolumes",
           "ec2:DescribeSnapshots",
           "ec2:CreateTags",
           "ec2:CreateVolume",
           "ec2:CreateSnapshot",
           "ec2:DeleteSnapshot"
         ],
         "Resource": "*"
       }
     ]
   }
   EOF
   ```

4. Create an AWS S3 access policy for one or for all S3 buckets:

   ```json
   $ cat > velero-s3-policy.json <<EOF
   {
     "Version": "2012-10-17",
     "Statement": [
       {
         "Effect": "Allow",
         "Action": [
           "s3:GetObject",
           "s3:DeleteObject",
           "s3:PutObject",
           "s3:AbortMultipartUpload",
           "s3:ListMultipartUploadParts"
         ],
         "Resource": [
           "arn:aws:s3:::<bucket>/*"
         ]
       },
       {
         "Effect": "Allow",
         "Action": [
           "s3:ListBucket",
           "s3:GetBucketLocation",
           "s3:GetObject"
         ],
         "Resource": ["arn:aws:s3:::<bucket>"
       }
     ]
   }
   EOF
   ```
To grant access to a single S3 bucket, specify the bucket name. To grant access to all AWS S3 buckets, specify * instead of a bucket name as in the following example:

Example output

"Resource": [
    "arn:aws:s3:::*"
]

5. Attach the EC2 EBS policy to velero:

$ aws iam put-user-policy \n  --user-name velero \n  --policy-name velero-ebs \n  --policy-document file://velero-ec2-snapshot-policy.json

6. Attach the AWS S3 policy to velero:

$ aws iam put-user-policy \n  --user-name velero \n  --policy-name velero-s3 \n  --policy-document file://velero-s3-policy.json

7. Create an access key for velero:

$ aws iam create-access-key --user-name velero

8. Create a credentials-velero file:

$ cat << EOF > ./credentials-velero
[default]
aws_access_key_id=<AWS_ACCESS_KEY_ID>
aws_secret_access_key=<AWS_SECRET_ACCESS_KEY>
EOF
You use the credentials-velero file to create a Secret object for AWS before you install the Data Protection Application.

4.2.2.3. Creating a secret for backup and snapshot locations

You create a Secret object for the backup and snapshot locations if they use the same credentials.

The default name of the Secret is cloud-credentials.

Prerequisites

- Your object storage and cloud storage must use the same credentials.
- You must configure object storage for Velero.
- You must create a credentials-velero file for the object storage in the appropriate format.

NOTE

The DataProtectionApplication custom resource (CR) requires a Secret for installation. If no spec.backupLocations.credential.name value is specified, the default name is used.

If you do not want to specify the backup locations or the snapshot locations, you must create a Secret with the default name by using an empty credentials-velero file.

Procedure

1. Create a Secret with the default name:

   ```bash
   $ oc create secret generic cloud-credentials -n openshift-adp --from-file cloud=credentials-velero
   ```

   The Secret is referenced in the spec.backupLocations.credential block of the DataProtectionApplication CR when you install the Data Protection Application.

4.2.2.3.1. Configuring secrets for different backup and snapshot location credentials

If your backup and snapshot locations use different credentials, you create separate profiles in the credentials-velero file.

Then, you create a Secret object and specify the profiles in the DataProtectionApplication custom resource (CR).

Procedure

1. Create a credentials-velero file with separate profiles for the backup and snapshot locations, as in the following example:

   ```yaml
   [backupStorage]
   aws_access_key_id=<AWS_ACCESS_KEY_ID>
   aws_secret_access_key=<AWS_SECRET_ACCESS_KEY>
   ```
2. Create a Secret object with the credentials-velero file:

```
$ oc create secret generic cloud-credentials -n openshift-adp --from-file cloud=credentials-velero
```

3. Add the profiles to the DataProtectionApplication CR, as in the following example:

```yaml
apiVersion: oadp.openshift.io/v1alpha1
kind: DataProtectionApplication
metadata:
  name: <dpa_sample>
  namespace: openshift-adp
spec:
  ...
  backupLocations:
    - name: default
      velero:
        provider: aws
        default: true
        objectStorage:
          bucket: <bucket_name>
          prefix: <prefix>
          config:
            region: us-east-1
            profile: "backupStorage"
        credential:
          key: cloud
          name: cloud-credentials
  snapshotLocations:
    - name: default
      velero:
        provider: aws
        config:
          region: us-west-2
          profile: "volumeSnapshot"
```

### 4.2.2.4. Configuring the Data Protection Application

You can configure Velero resource allocations and enable self-signed CA certificates.

#### 4.2.2.4.1. Setting Velero CPU and memory resource allocations

You set the CPU and memory resource allocations for the Velero pod by editing the DataProtectionApplication custom resource (CR) manifest.

**Prerequisites**

- You must have the OpenShift API for Data Protection (OADP) Operator installed.

**Procedure**
- Edit the values in the `spec.configuration.velero.podConfig.ResourceAllocations` block of the `DataProtectionApplication` CR manifest, as in the following example:

```yaml
apiVersion: oadp.openshift.io/v1alpha1
kind: DataProtectionApplication
metadata:  
  name: <dpa_sample>
spec:  
  ...  
  configuration:  
    velero:  
      podConfig:  
        resourceAllocations:  
          limits:  
            cpu: "1"  
            memory: 512Mi
          requests:  
            cpu: 500m  
            memory: 256Mi
```

1. Specify the value in millicpus or CPU units. Default value is **500m** or **1 CPU unit**.
2. Default value is **512Mi**.
3. Default value is **500m** or **1 CPU unit**.
4. Default value is **256Mi**.

### 4.2.2.4.2. Enabling self-signed CA certificates

You must enable a self-signed CA certificate for object storage by editing the `DataProtectionApplication` custom resource (CR) manifest to prevent a **certificate signed by unknown authority** error.

**Prerequisites**

- You must have the OpenShift API for Data Protection (OADP) Operator installed.

**Procedure**

- Edit the `spec.backupLocations.velero.objectStorage.caCert` parameter and `spec.backupLocations.velero.config` parameters of the `DataProtectionApplication` CR manifest:

```yaml
apiVersion: oadp.openshift.io/v1alpha1
kind: DataProtectionApplication
metadata:  
  name: <dpa_sample>
spec:  
  ...  
  backupLocations:  
    - name: default  
      velero:  
        provider: aws
```
 Specify the Base46-encoded CA certificate string.

Must be `false` to disable SSL/TLS security.

4.2.2.5. Installing the Data Protection Application

You install the Data Protection Application (DPA) by creating an instance of the `DataProtectionApplication` API.

Prerequisites

- You must install the OADP Operator.
- You must configure object storage as a backup location.
- If you use snapshots to back up PVs, your cloud provider must support either a native snapshot API or Container Storage Interface (CSI) snapshots.
- If the backup and snapshot locations use the same credentials, you must create a `Secret` with the default name, `cloud-credentials`.
- If the backup and snapshot locations use different credentials, you must create a `Secret` with the default name, `cloud-credentials`, which contains separate profiles for the backup and snapshot location credentials.

**NOTE**

If you do not want to specify backup or snapshot locations during the installation, you can create a default `Secret` with an empty `credentials-velero` file. If there is no default `Secret`, the installation will fail.

Procedure

1. Click **Operators → Installed Operators** and select the OADP Operator.
2. Under **Provided APIs**, click **Create instance** in the `DataProtectionApplication` box.
3. Click **YAML View** and update the parameters of the `DataProtectionApplication` manifest:

```yaml
apiVersion: oadp.openshift.io/v1alpha1
kind: DataProtectionApplication
metadata:
  name: <dpa_sample>
  namespace: openshift-adp
spec:
  default: true
  objectStorage:
    bucket: <bucket>
    prefix: <prefix>
  caCert: <base64_encoded_cert_string> 1
  config:
    insecureSkipTLSVerify: "false" 2
...
```

1. Specify the Base46-encoded CA certificate string.
2. Must be `false` to disable SSL/TLS security.
The openshift plug-in is mandatory in order to back up and restore namespaces on an OpenShift Container Platform cluster. Set to false if you want to disable the Restic installation. Restic deploys a daemon set, which means that each worker node has Restic pods running. You configure Restic for backups by adding spec.defaultVolumesToRestic: true to the Backup CR. Specify a bucket as the backup storage location. If the bucket is not a dedicated bucket for Velero backups, you must specify a prefix. Specify a prefix for Velero backups, for example, velero, if the bucket is used for multiple purposes. Specify the name of the Secret object that you created. If you do not specify this value, the default name, cloud-credentials, is used. If you specify a custom name, the custom name is used for the backup location. You do not need to specify a snapshot location if you use CSI snapshots or Restic to back up PVs. The snapshot location must be in the same region as the PVs.

4. Click Create.

5. Verify the installation by viewing the OADP resources:

```bash
$ oc get all -n openshift-adp
```

**Example output**

```
NAME                                                     READY   STATUS    RESTARTS   AGE
pod/oadp-operator-controller-manager-67d9494d47-6l8z8    2/2     Running   0          2m8s
pod/oadp-velero-sample-1-aws-registry-5d6968cbdd-d5w9k   1/1     Running   0          95s
pod/restic-9cq4q                                         1/1     Running   0          94s
pod/restic-m4lts                                         1/1     Running   0          94s
pod/restic-pv4kr                                         1/1     Running   0          95s
```
4.2.2.5.1. Enabling CSI in the DataProtectionApplication CR

You enable the Container Storage Interface (CSI) in the DataProtectionApplication custom resource (CR) in order to back up persistent volumes with CSI snapshots.

Prerequisites

- The cloud provider must support CSI snapshots.

Procedure

- Edit the DataProtectionApplication CR, as in the following example:

```yaml
apiVersion: oadp.openshift.io/v1alpha1
class: DataProtectionApplication
...
spec:
configuration:
velero:
defaultPlugins:
- openshift
- csi
featureFlags:
- EnableCSI

1 Add the csi default plug-in.
2 Add the EnableCSI feature flag.
```
4.2.3. Installing and configuring the OpenShift API for Data Protection with Microsoft Azure

You install the OpenShift API for Data Protection (OADP) with Microsoft Azure by installing the OADP Operator, configuring Azure for Velero, and then installing the Data Protection Application.

**IMPORTANT**

The CloudStorage API for S3 storage is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see [https://access.redhat.com/support/offerings/techpreview/](https://access.redhat.com/support/offerings/techpreview/).

To install the OADP Operator in a restricted network environment, you must first disable the default OperatorHub sources and mirror the Operator catalog. See Using Operator Lifecycle Manager on restricted networks for details.

### 4.2.3.1. Installing the OADP Operator

You install the OpenShift API for Data Protection (OADP) Operator on OpenShift Container Platform 4.6 by using Operator Lifecycle Manager (OLM).

The OADP Operator installs Velero 1.7.

**Prerequisites**

- You must be logged in as a user with `cluster-admin` privileges.

**Procedure**

1. In the OpenShift Container Platform web console, click **Operators** → **OperatorHub**.

2. Use the **Filter by keyword** field to find the **OADP Operator**.

3. Select the **OADP Operator** and click **Install**.

4. Click **Install** to install the Operator in the **openshift-adp** project.

5. Click **Operators** → **Installed Operators** to verify the installation.

### 4.2.3.2. Configuring Microsoft Azure Blob

You can configure a Microsoft Azure Blob storage container as a replication repository for the Migration Toolkit for Containers (MTC).

**Prerequisites**

- You must have an Azure storage account.

- You must have the Azure CLI installed.
The Azure Blob storage container must be accessible to the source and target clusters.

If you are using the snapshot copy method:

- The source and target clusters must be in the same region.
- The source and target clusters must have the same storage class.
- The storage class must be compatible with snapshots.

**Procedure**

1. Set the `AZURE_RESOURCE_GROUP` variable:
   
   ```bash
   $ AZURE_RESOURCE_GROUP=Velero_Backups
   ```

2. Create an Azure resource group:

   ```bash
   $ az group create -n $AZURE_RESOURCE_GROUP --location <CentralUS>  
   ```

   Specify your location.

3. Set the `AZURE_STORAGE_ACCOUNT_ID` variable:

   ```bash
   $ AZURE_STORAGE_ACCOUNT_ID=velerobackups
   ```

4. Create an Azure storage account:

   ```bash
   $ az storage account create \
   --name $AZURE_STORAGE_ACCOUNT_ID \
   --resource-group $AZURE_RESOURCE_GROUP \
   --sku Standard_GRS \
   --encryption-services blob \
   --https-only true \
   --kind BlobStorage \
   --access-tier Hot
   ```

5. Set the `BLOB_CONTAINER` variable:

   ```bash
   $ BLOB_CONTAINER=velero
   ```

6. Create an Azure Blob storage container:

   ```bash
   $ az storage container create \
   -n $BLOB_CONTAINER \
   --public-access off \
   --account-name $AZURE_STORAGE_ACCOUNT_ID
   ```

7. Obtain the storage account access key:

   ```bash
   $ AZURE_STORAGE_ACCOUNT_ACCESS_KEY=`az storage account keys list \
   --account-name $AZURE_STORAGE_ACCOUNT_ID \
   --query "[?keyName == 'key1'].value" -o tsv`
   ```
8. Create a **credentials-velero** file:

```bash
$ cat << EOF > ./credentials-velero
AZURE_SUBSCRIPTION_ID=${AZURE_SUBSCRIPTION_ID}
AZURE_TENANT_ID=${AZURE_TENANT_ID}
AZURE_CLIENT_ID=${AZURE_CLIENT_ID}
AZURE_CLIENT_SECRET=${AZURE_CLIENT_SECRET}
AZURE_RESOURCE_GROUP=${AZURE_RESOURCE_GROUP}
AZURE_STORAGE_ACCOUNT_ACCESS_KEY=${AZURE_STORAGE_ACCOUNT_ACCESS_KEY}
AZURE_CLOUD_NAME=AzurePublicCloud
EOF
```

   Mandatory. You cannot back up internal images if the **credentials-velero** file contains only the service principal credentials.

You use the **credentials-velero** file to create a **Secret** object for Azure before you install the Data Protection Application.

### 4.2.3.3. Creating a secret for backup and snapshot locations

You create a **Secret** object for the backup and snapshot locations if they use the same credentials.

The default name of the **Secret** is **cloud-credentials-azure**.

**Prerequisites**

- Your object storage and cloud storage must use the same credentials.
- You must configure object storage for Velero.
- You must create a **credentials-velero** file for the object storage in the appropriate format.

**NOTE**

The **DataProtectionApplication** custom resource (CR) requires a **Secret** for installation. If no **spec.backupLocations.credential.name** value is specified, the default name is used.

If you do not want to specify the backup locations or the snapshot locations, you must create a **Secret** with the default name by using an empty **credentials-velero** file.

**Procedure**

- Create a **Secret** with the default name:

  ```bash
  $ oc create secret generic cloud-credentials-azure -n openshift-adp --from-file
cloud=credentials-velero
  ```

The **Secret** is referenced in the **spec.backupLocations.credential** block of the **DataProtectionApplication** CR when you install the Data Protection Application.
4.2.3.3.1. Configuring secrets for different backup and snapshot location credentials

If your backup and snapshot locations use different credentials, you create two `Secret` objects:

- Backup location `Secret` with a custom name. The custom name is specified in the `spec.backupLocations` block of the `DataProtectionApplication` custom resource (CR).
- Snapshot location `Secret` with the default name, `cloud-credentials-azure`. This `Secret` is not specified in the `DataProtectionApplication` CR.

**Procedure**

1. Create a `credentials-velero` file for the snapshot location in the appropriate format for your cloud provider.

2. Create a `Secret` for the snapshot location with the default name:

   ```
   $ oc create secret generic cloud-credentials-azure -n openshift-adp --from-file cloud=credentials-velero
   ```

3. Create a `credentials-velero` file for the backup location in the appropriate format for your object storage.

4. Create a `Secret` for the backup location with a custom name:

   ```
   $ oc create secret generic <custom_secret> -n openshift-adp --from-file cloud=credentials-velero
   ```

5. Add the `Secret` with the custom name to the `DataProtectionApplication` CR, as in the following example:

   ```yaml
   apiVersion: oadp.openshift.io/v1alpha1
   kind: DataProtectionApplication
   metadata:
     name: <dpa_sample>
     namespace: openshift-adp
   spec:
     ...
     backupLocations:
     - velero:
       config:
         resourceGroup: <azure_resource_group>
         storageAccount: <azure_storage_account_id>
         subscriptionId: <azure_subscription_id>
         storageAccountKeyEnvVar: AZURE_STORAGE_ACCOUNT_ACCESS_KEY
         credential:
           key: cloud
           name: <custom_secret>  # 1
         provider: azure
         default: true
         objectStorage:
           bucket: <bucket_name>
           prefix: <prefix>
     snapshotLocations:
     - velero:
   ```
4.2.3.4. Configuring the Data Protection Application

You can configure Velero resource allocations and enable self-signed CA certificates.

4.2.3.4.1. Setting Velero CPU and memory resource allocations

You set the CPU and memory resource allocations for the Velero pod by editing the DataProtectionApplication custom resource (CR) manifest.

Prerequisites

- You must have the OpenShift API for Data Protection (OADP) Operator installed.

Procedure

- Edit the values in the spec.configuration.velero.podConfig.ResourceAllocations block of the DataProtectionApplication CR manifest, as in the following example:

```yaml
apiVersion: oadp.openshift.io/v1alpha1
kind: DataProtectionApplication
metadata:
  name: <dpa_sample>
spec:
  ...
  configuration:
    velero:
      podConfig:
        resourceAllocations:
          limits:
            cpu: "1"  # Specify the value in millicpus or CPU units. Default value is 500m or 1 CPU unit.
            memory: 512Mi  # Default value is 512Mi.
          requests:
            cpu: 500m  # Default value is 500m or 1 CPU unit.
            memory: 256Mi  # Default value is 256Mi.
```

1. Backup location Secret with custom name.
4.2.3.4.2. Enabling self-signed CA certificates

You must enable a self-signed CA certificate for object storage by editing the DataProtectionApplication custom resource (CR) manifest to prevent a certificate signed by unknown authority error.

Prerequisites

- You must have the OpenShift API for Data Protection (OADP) Operator installed.

Procedure

- Edit the spec.backupLocations.velero.objectStorage.caCert parameter and spec.backupLocations.velero.config parameters of the DataProtectionApplication CR manifest:

```yaml
apiVersion: oadm.openshift.io/v1alpha1
kind: DataProtectionApplication
metadata:
  name: <dpa_sample>
spec:
  ...
  backupLocations:
    - name: default
      velero:
        provider: aws
        default: true
      objectStorage:
        bucket: <bucket>
        prefix: <prefix>
        caCert: <base64_encoded_cert_string> ①
cfg:
  insecureSkipTLSVerify: "false" ②
...
```

① Specify the Base46-encoded CA certificate string.

② Must be false to disable SSL/TLS security.

4.2.3.5. Installing the Data Protection Application

You install the Data Protection Application (DPA) by creating an instance of the DataProtectionApplication API.

Prerequisites

- You must install the OADP Operator.
- You must configure object storage as a backup location.
- If you use snapshots to back up PVs, your cloud provider must support either a native snapshot API or Container Storage Interface (CSI) snapshots.
If the backup and snapshot locations use the same credentials, you must create a **Secret** with the default name, `cloud-credentials-azure`.

If the backup and snapshot locations use different credentials, you must create two **Secrets**:

- **Secret** with a custom name for the backup location. You add this **Secret** to the `DataProtectionApplication` CR.
- **Secret** with the default name, `cloud-credentials-azure`, for the snapshot location. This **Secret** is not referenced in the `DataProtectionApplication` CR.

![NOTE]

If you do not want to specify backup or snapshot locations during the installation, you can create a default **Secret** with an empty `credentials-velero` file. If there is no default **Secret**, the installation will fail.

**Procedure**

1. Click **Operators → Installed Operators** and select the OADP Operator.

2. Under **Provided APIs**, click **Create instance** in the `DataProtectionApplication` box.

3. Click **YAML View** and update the parameters of the `DataProtectionApplication` manifest:

```yaml
apiVersion: oadp.openshift.io/v1alpha1
kind: DataProtectionApplication
metadata:
  name: <dpa_sample>
  namespace: openshift-adp
spec:
  configuration:
    velero:
      defaultPlugins:
      - azure
      - openshift <.>
    restic:
      enable: true <.>
    backupLocations:
    - velero:
      config:
        resourceGroup: <azure_resource_group> <.>
        storageAccount: <azure_storage_account_id> <.>
        subscriptionId: <azure_subscription_id> <.>
        storageAccountKeyEnvVar: AZURE_STORAGE_ACCOUNT_ACCESS_KEY
      credential:
        key: cloud
        name: cloud-credentials-azure <.>
      provider: azure
      default: true
      objectStorage:
        bucket: <bucket_name> <.>
        prefix: <prefix> <.>
    snapshotLocations: <.>
- velero:
  config:
```

---

OpenShift Container Platform 4.6 Backup and restore
The **openshift** plug-in is mandatory in order to back up and restore namespaces on an OpenShift Container Platform cluster. <> Set to **false** if you want to disable the Restic installation. Restic deploys a daemon set, which means that each worker node has Restic pods running. You configure Restic for backups by adding `spec.defaultVolumesToRestic: true` to the **Backup** CR. <> Specify the Azure resource group. <> Specify the Azure storage account ID. <> Specify the Azure subscription ID. <> If you do not specify this value, the default name, `cloud-credentials-azure`, is used. If you specify a custom name, the custom name is used for the backup location. <> Specify a bucket as the backup storage location. If the bucket is not a dedicated bucket for Velero backups, you must specify a prefix. <> Specify a prefix for Velero backups, for example, `velero`, if the bucket is used for multiple purposes. <> You do not need to specify a snapshot location if you use CSI snapshots or Restic to back up PVs.

4. Click **Create**.

5. Verify the installation by viewing the OADP resources:

   ```bash
   $ oc get all -n openshift-adp
   
   Example output
   
<table>
<thead>
<tr>

4.2.3.5.1. Enabling CSI in the DataProtectionApplication CR

You enable the Container Storage Interface (CSI) in the DataProtectionApplication custom resource (CR) in order to back up persistent volumes with CSI snapshots.

**Prerequisites**

- The cloud provider must support CSI snapshots.

**Procedure**

- Edit the DataProtectionApplication CR, as in the following example:

  ```yaml
  apiVersion: oadp.openshift.io/v1alpha1
  kind: DataProtectionApplication
  ...  
  spec:
    configuration:
      velero:
        defaultPlugins:
        - openshift
        - csi
        featureFlags:
          - EnableCSI
  
  1. Add the csi default plug-in.
  2. Add the EnableCSI feature flag.
  ```

4.2.4. Installing and configuring the OpenShift API for Data Protection with Google Cloud Platform

You install the OpenShift API for Data Protection (OADP) with Google Cloud Platform (GCP) by installing the OADP Operator, configuring GCP for Velero, and then installing the Data Protection Application.

**IMPORTANT**

The CloudStorage API for S3 storage is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see https://access.redhat.com/support/offerings/techpreview/.

To install the OADP Operator in a restricted network environment, you must first disable the default OperatorHub sources and mirror the Operator catalog. See Using Operator Lifecycle Manager on restricted networks for details.

4.2.4.1. Installing the OADP Operator
You install the OpenShift API for Data Protection (OADP) Operator on OpenShift Container Platform 4.6 by using Operator Lifecycle Manager (OLM).

The OADP Operator installs Velero 1.7.

Prerequisites

- You must be logged in as a user with `cluster-admin` privileges.

Procedure

1. In the OpenShift Container Platform web console, click **Operators** → **OperatorHub**.
2. Use the **Filter by keyword** field to find the **OADP Operator**.
3. Select the **OADP Operator** and click **Install**.
4. Click **Install** to install the Operator in the **openshift-adp** project.
5. Click **Operators** → **Installed Operators** to verify the installation.

4.2.4.2. Configuring Google Cloud Platform

You can configure a Google Cloud Platform (GCP) storage bucket as a replication repository for the Migration Toolkit for Containers (MTC).

Prerequisites

- The GCP storage bucket must be accessible to the source and target clusters.
- You must have **gsutil** installed.
- If you are using the snapshot copy method:
  - The source and target clusters must be in the same region.
  - The source and target clusters must have the same storage class.
  - The storage class must be compatible with snapshots.

Procedure

1. Log in to **gsutil**:

   ```
   $ gsutil init
   Welcome! This command will take you through the configuration of gcloud.
   Your current configuration has been set to: [default]
   To continue, you must login. Would you like to login (Y/n)?
   ```

2. Set the **BUCKET** variable:
3. Create a storage bucket:

```bash
$ gsutil mb gs://$BUCKET/
```

4. Set the `PROJECT_ID` variable to your active project:

```bash
$ PROJECT_ID=`gcloud config get-value project`
```

5. Create a `velero` IAM service account:

```bash
$ gcloud iam service-accounts create velero --display-name "Velero Storage"
```

6. Create the `SERVICE_ACCOUNT_EMAIL` variable:

```bash
$ SERVICE_ACCOUNT_EMAIL=`gcloud iam service-accounts list --filter="displayName:Velero Storage" --format 'value(email)"
```

7. Create the `ROLE_PERMISSIONS` variable:

```bash
$ ROLE_PERMISSIONS=(
  compute.disks.get
  compute.disks.create
  compute.disks.createSnapshot
  compute.snapshots.get
  compute.snapshots.create
  compute.snapshots.useReadOnly
  compute.snapshots.delete
  compute.zones.get
)
```

8. Create the `velero.server` custom role:

```bash
$ gcloud iam roles create velero.server --project $PROJECT_ID --title "Velero Server" --permissions "$\{(IFS=","; echo \"${ROLE_PERMISSIONS[*]}\")\}"
```

9. Add IAM policy binding to the project:

```bash
$ gcloud projects add-iam-policy-binding $PROJECT_ID --member serviceAccount:$SERVICE_ACCOUNT_EMAIL --role projects/$PROJECT_ID/roles/velero.server
```

10. Update the IAM service account:

```bash
$ gsutil iam ch serviceAccount:$SERVICE_ACCOUNT_EMAIL:objectAdmin gs://$BUCKET
```
11. Save the IAM service account keys to the `credentials-velero` file in the current directory:

   ```bash
   $ gcloud iam service-accounts keys create credentials-velero \
      --iam-account $SERVICE_ACCOUNT_EMAIL
   ``

   You use the `credentials-velero` file to create a `Secret` object for GCP before you install the Data Protection Application.

### 4.2.4.3. Creating a secret for backup and snapshot locations

You create a `Secret` object for the backup and snapshot locations if they use the same credentials.

The default name of the `Secret` is `cloud-credentials-gcp`.

**Prerequisites**

- Your object storage and cloud storage must use the same credentials.
- You must configure object storage for Velero.
- You must create a `credentials-velero` file for the object storage in the appropriate format.

**Procedure**

- Create a `Secret` with the default name:

  ```bash
  $ oc create secret generic cloud-credentials-gcp -n openshift-adp --from-file
  cloud=credentials-velero
  ```

The `Secret` is referenced in the `spec.backupLocations.credential` block of the `DataProtectionApplication` CR when you install the Data Protection Application.

#### 4.2.4.3.1. Configuring secrets for different backup and snapshot location credentials

If your backup and snapshot locations use different credentials, you create two `Secret` objects:

- Backup location `Secret` with a custom name. The custom name is specified in the `spec.backupLocations` block of the `DataProtectionApplication` custom resource (CR).
- Snapshot location `Secret` with the default name, `cloud-credentials-gcp`. This `Secret` is not specified in the `DataProtectionApplication` CR.

**Procedure**

1. Create a `credentials-velero` file for the snapshot location in the appropriate format for your cloud provider.

2. Create a `Secret` for the snapshot location with the default name:

   ```bash
   $ oc create secret generic cloud-credentials-gcp -n openshift-adp --from-file
   cloud=credentials-velero
   ```
3. Create a `credentials-velero` file for the backup location in the appropriate format for your object storage.

4. Create a **Secret** for the backup location with a custom name:

   ```
   $ oc create secret generic <custom_secret> -n openshift-adp --from-file cloud=credentials-velero
   ```

5. Add the **Secret** with the custom name to the **DataProtectionApplication** CR, as in the following example:

   ```
   apiVersion: oadp.openshift.io/v1alpha1
   kind: DataProtectionApplication
   metadata:
     name: <dpa_sample>
     namespace: openshift-adp
   spec:
     ...
     backupLocations:
     - velero:
       provider: gcp
       default: true
       credential:
         key: cloud
         name: <custom_secret>
       objectStorage:
         bucket: <bucket_name>
         prefix: <prefix>
     snapshotLocations:
     - velero:
       provider: gcp
       default: true
       config:
         project: <project>
         snapshotLocation: us-west1
   ```

   1 Backup location **Secret** with custom name.

**4.2.4.4. Configuring the Data Protection Application**

You can configure Velero resource allocations and enable self-signed CA certificates.

**4.2.4.4.1. Setting Velero CPU and memory resource allocations**

You set the CPU and memory resource allocations for the **Velero** pod by editing the **DataProtectionApplication** custom resource (CR) manifest.

**Prerequisites**

- You must have the OpenShift API for Data Protection (OADP) Operator installed.

**Procedure**

1. Edit the manifest according to the following example:

   ```
   apiVersion: oadp.openshift.io/v1alpha1
   kind: DataProtectionApplication
   metadata:
     name: <dpa_sample>
     namespace: openshift-adp
   spec:
     ...
     backupLocations:
     - velero:
       provider: gcp
       default: true
       credential:
         key: cloud
         name: <custom_secret>
       objectStorage:
         bucket: <bucket_name>
         prefix: <prefix>
     snapshotLocations:
     - velero:
       provider: gcp
       default: true
       config:
         project: <project>
         snapshotLocation: us-west1
   ```

   1 Backup location **Secret** with custom name.
Edit the values in the `spec.configuration.velero.podConfig.ResourceAllocations` block of the `DataProtectionApplication` CR manifest, as in the following example:

```yaml
apiVersion: oadp.openshift.io/v1alpha1
kind: DataProtectionApplication
metadata:
  name: <dpa_sample>
spec:
  ...
  configuration:
    velero:
      podConfig:
        resourceAllocations:
          limits:
            cpu: "1"  
            memory: 512Mi
          requests:
            cpu: 500m
            memory: 256Mi
```

1. Specify the value in milliCpus or CPU units. Default value is 500m or 1 CPU unit.
2. Default value is 512Mi.
3. Default value is 500m or 1 CPU unit.
4. Default value is 256Mi.

### 4.2.4.4.2. Enabling self-signed CA certificates

You must enable a self-signed CA certificate for object storage by editing the `DataProtectionApplication` custom resource (CR) manifest to prevent a `certificate signed by unknown authority` error.

**Prerequisites**

- You must have the OpenShift API for Data Protection (OADP) Operator installed.

**Procedure**

- Edit the `spec.backupLocations.velero.objectStorage.caCert` parameter and `spec.backupLocations.velero.config` parameters of the `DataProtectionApplication` CR manifest:

```yaml
apiVersion: oadp.openshift.io/v1alpha1
kind: DataProtectionApplication
metadata:
  name: <dpa_sample>
spec:
  ...
  backupLocations:
    - name: default
      velero:
        provider: aws
```
4.2.4.5. Installing the Data Protection Application

You install the Data Protection Application (DPA) by creating an instance of the **DataProtectionApplication** API.

**Prerequisites**

- You must install the OADP Operator.
- You must configure object storage as a backup location.
- If you use snapshots to back up PVs, your cloud provider must support either a native snapshot API or Container Storage Interface (CSI) snapshots.
- If the backup and snapshot locations use the same credentials, you must create a **Secret** with the default name, `cloud-credentials-gcp`.
- If the backup and snapshot locations use different credentials, you must create two **Secrets**:
  - **Secret** with a custom name for the backup location. You add this **Secret** to the **DataProtectionApplication** CR.
  - **Secret** with the default name, `cloud-credentials-gcp`, for the snapshot location. This **Secret** is not referenced in the **DataProtectionApplication** CR.

**NOTE**

If you do not want to specify backup or snapshot locations during the installation, you can create a default **Secret** with an empty `credentials-velero` file. If there is no default **Secret**, the installation will fail.

**Procedure**

1. Click **Operators → Installed Operators** and select the OADP Operator.
2. Under **Provided APIs**, click **Create instance** in the **DataProtectionApplication** box.
3. Click **YAML View** and update the parameters of the **DataProtectionApplication** manifest:

```yaml
apiVersion: oadp.openshift.io/v1alpha1
kind: DataProtectionApplication

default: true

objectStorage:
  bucket: <bucket>
  prefix: <prefix>
  caCert: <base64-encoded_cert_string>  # Specify the Base46-encoded CA certificate string.
  config:
    insecureSkipTLSVerify: "false"  # Must be false to disable SSL/TLS security.
```

The **openshift** plug-in is mandatory in order to back up and restore namespaces on an OpenShift Container Platform cluster. Set to **false** if you want to disable the Restic installation. Restic deploys a daemon set, which means that each worker node has Restic pods running. You configure Restic for backups by adding `spec.defaultVolumesToRestic: true` to the **Backup** CR. If you do not specify this value, the default name, **cloud-credentials-gcp**, is used. If you specify a custom name, the custom name is used for the backup location. Specify a bucket as the backup storage location. If the bucket is not a dedicated bucket for Velero backups, you must specify a prefix. Specify a prefix for Velero backups, for example, **velero**, if the bucket is used for multiple purposes. You do not need to specify a snapshot location if you use CSI snapshots or Restic to back up PVs. The snapshot location must be in the same region as the PVs.

4. Click **Create**.

5. Verify the installation by viewing the OADP resources:

```
$ oc get all -n openshift-adp
```

**Example output**

```
NAME                                                          READY STATUS  RESTARTS  AGE
pod/oadp-operator-controller-manager-67d9494d47-6l8z8          2/2    Running 0   2m8s
pod/oadp-velero-sample-1-aws-registry-5d6968cbdd-d5w9k         1/1    Running 0   95s
pod/restic-9cq4q                                              1/1    Running 0   94s
pod/restic-m4lts                                              1/1    Running 0   94s
pod/restic-pv4kr                                              1/1    Running 0   95s
```
4.2.4.5.1. Enabling CSI in the DataProtectionApplication CR

You enable the Container Storage Interface (CSI) in the DataProtectionApplication custom resource (CR) in order to back up persistent volumes with CSI snapshots.

Prerequisites

- The cloud provider must support CSI snapshots.

Procedure

- Edit the DataProtectionApplication CR, as in the following example:

```yaml
apiVersion: oadp.openshift.io/v1alpha1
class: DataProtectionApplication
...
spec:
  configuration:
    velero:
      defaultPlugins:
        - openshift
        - csi
      featureFlags:
        - EnableCSI
```

1. Add the csi default plug-in.
2. Add the EnableCSI feature flag.
4.2.5. Installing and configuring the OpenShift API for Data Protection with Multicloud Object Gateway

You install the OpenShift API for Data Protection (OADP) with Multicloud Object Gateway (MCG) by installing the OADP Operator, creating a Secret object, and then installing the Data Protection Application.

MCG is a component of OpenShift Container Storage (OCS). You configure MCG as a backup location in the DataProtectionApplication custom resource (CR).

**IMPORTANT**

The CloudStorage API for S3 storage is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see https://access.redhat.com/support/offerings/techpreview/.

If your cloud provider has a native snapshot API, configure a snapshot location. If your cloud provider does not support snapshots or if your storage is NFS, you can create backups with Restic.

You do not need to specify a snapshot location in the DataProtectionApplication CR for Restic or Container Storage Interface (CSI) snapshots.

To install the OADP Operator in a restricted network environment, you must first disable the default OperatorHub sources and mirror the Operator catalog. For details, see Using Operator Lifecycle Manager on restricted networks.

4.2.5.1. Installing the OADP Operator

You install the OpenShift API for Data Protection (OADP) Operator on OpenShift Container Platform 4.6 by using Operator Lifecycle Manager (OLM).

The OADP Operator installs Velero 1.7.

**Prerequisites**

- You must be logged in as a user with cluster-admin privileges.

**Procedure**

1. In the OpenShift Container Platform web console, click Operators → OperatorHub.
2. Use the Filter by keyword field to find the OADP Operator.
3. Select the OADP Operator and click Install.
4. Click Install to install the Operator in the openshift-adp project.
5. Click Operators → Installed Operators to verify the installation.
4.2.5.2. Configuring the Multicloud Object Gateway

You can configure the Multicloud Object Gateway (MCG) as a replication repository for the Migration Toolkit for Containers (MTC). MCG is a component of OpenShift Container Storage.

Procedure

1. Deploy OpenShift Container Storage by using the appropriate OpenShift Container Storage deployment guide.

2. Obtain the S3 endpoint, AWS_ACCESS_KEY_ID, and AWS_SECRET_ACCESS_KEY by running the describe command on the NooBaa custom resource. These values are required in order to add MCG as a replication repository to the MTC web console.

4.2.5.3. Creating a secret for backup and snapshot locations

You create a Secret object for the backup and snapshot locations if they use the same credentials.

The default name of the Secret is cloud-credentials.

Prerequisites

- Your object storage and cloud storage must use the same credentials.
- You must configure object storage for Velero.
- You must create a credentials-velero file for the object storage in the appropriate format.

Procedure

- Create a Secret with the default name:

  $ oc create secret generic cloud-credentials -n openshift-adp --from-file cloud=credentials-velero

The Secret is referenced in the spec.backupLocations.credential block of the DataProtectionApplication CR when you install the Data Protection Application.

4.2.5.3.1. Configuring secrets for different backup and snapshot location credentials

If your backup and snapshot locations use different credentials, you create two Secret objects:

- Backup location Secret with a custom name. The custom name is specified in the spec.backupLocations block of the DataProtectionApplication custom resource (CR).

- Snapshot location Secret with the default name, cloud-credentials. This Secret is not specified in the DataProtectionApplication CR.

Procedure

1. Create a credentials-velero file for the snapshot location in the appropriate format for your cloud provider.

2. Create a Secret for the snapshot location with the default name:
Create a credentials-velero file for the backup location in the appropriate format for your object storage.

Create a Secret for the backup location with a custom name:

Add the Secret with the custom name to the DataProtectionApplication CR, as in the following example:

```yaml
apiVersion: oadp.openshift.io/v1alpha1
kind: DataProtectionApplication
metadata:
  name: <dpa_sample>
  namespace: openshift-adp
spec:
  configuration:
    velero:
      defaultPlugins:
        - aws
        - openshift
    restic:
      enable: true
  backupLocations:
    - velero:
      config:
        profile: "default"
        region: minio
        s3Url: <url>
        insecureSkipTLSVerify: "true"
        s3ForcePathStyle: "true"
    provider: aws
      default: true
      credential:
        key: cloud
        name: <custom_secret>
    objectStorage:
      bucket: <bucket_name>
      prefix: <prefix>
```

Backup location Secret with custom name.

4.2.5.4. Configuring the Data Protection Application

You can configure Velero resource allocations and enable self-signed CA certificates.

4.2.5.4.1. Setting Velero CPU and memory resource allocations
You set the CPU and memory resource allocations for the Velero pod by editing the DataProtectionApplication custom resource (CR) manifest.

Prerequisites

- You must have the OpenShift API for Data Protection (OADP) Operator installed.

Procedure

- Edit the values in the spec.configuration.velero.podConfig.ResourceAllocations block of the DataProtectionApplication CR manifest, as in the following example:

```yaml
apiVersion: oadp.openshift.io/v1alpha1
kind: DataProtectionApplication
metadata:
  name: <dpa_sample>
spec: ...
configuration:
  velero:
    podConfig:
      resourceAllocations:
        limits:
          cpu: "1"  # 1
          memory: 512Mi  # 2
        requests:
          cpu: 500m  # 3
          memory: 256Mi  # 4
```

1. Specify the value in millicpus or CPU units. Default value is **500m** or 1 CPU unit.
2. Default value is **512Mi**.
3. Default value is **500m** or 1 CPU unit.
4. Default value is **256Mi**.

4.2.5.4.2. Enabling self-signed CA certificates

You must enable a self-signed CA certificate for object storage by editing the DataProtectionApplication custom resource (CR) manifest to prevent a certificate signed by unknown authority error.

Prerequisites

- You must have the OpenShift API for Data Protection (OADP) Operator installed.

Procedure

- Edit the spec.backupLocations.velero.objectStorage.caCert parameter and spec.backupLocations.velero.config parameters of the DataProtectionApplication CR manifest:

```yaml
apiVersion: oadp.openshift.io/v1alpha1
```
4.2.5.5. Installing the Data Protection Application

You install the Data Protection Application (DPA) by creating an instance of the `DataProtectionApplication` API.

**Prerequisites**

- You must install the OADP Operator.
- You must configure object storage as a backup location.
- If you use snapshots to back up PVs, your cloud provider must support either a native snapshot API or Container Storage Interface (CSI) snapshots.
- If the backup and snapshot locations use the same credentials, you must create a **Secret** with the default name, `cloud-credentials`.
- If the backup and snapshot locations use different credentials, you must create two **Secrets**:
  - **Secret** with a custom name for the backup location. You add this **Secret** to the `DataProtectionApplication` CR.
  - **Secret** with the default name, `cloud-credentials`, for the snapshot location. This **Secret** is not referenced in the `DataProtectionApplication` CR.

**NOTE**

If you do not want to specify backup or snapshot locations during the installation, you can create a default **Secret** with an empty `credentials-velero` file. If there is no default **Secret**, the installation will fail.

**Procedure**

```yaml
kind: DataProtectionApplication
metadata:
  name: <dpa_sample>
spec:
  ...
  backupLocations:
    - name: default
      velero:
        provider: aws
        default: true
      objectStorage:
        bucket: <bucket>
        prefix: <prefix>
        caCert: <base64_encoded_cert_string>  # Specify the Base46-encoded CA certificate string.
      config:
        insecureSkipTLSVerify: "false"  # Must be false to disable SSL/TLS security.
  ...
```
1. Click **Operators → Installed Operators** and select the OADP Operator.

2. Under **Provided APIs**, click **Create instance** in the **DataProtectionApplication** box.

3. Click **YAML View** and update the parameters of the **DataProtectionApplication** manifest:

   ```yaml
   apiVersion: oadm.openshift.io/v1alpha1
   kind: DataProtectionApplication
   metadata:
     name: <dpa_sample>
   namespace: openshift-adp
   spec:
     configuration:
       velero:
         defaultPlugins:
         - aws
         - openshift  
       restic:
         enable: true
         backupLocations:
         - velero:
             config:
               profile: "default"
               region: minio
               s3Url: <url>  
               insecureSkipTLSVerify: "true"
               s3ForcePathStyle: "true"
               provider: aws
             default: true
             credential:
               key: cloud
               name: cloud-credentials  
             objectStorage:
               bucket: <bucket_name>  
               prefix: <prefix>  
   
   <> The **openshift** plug-in is mandatory in order to back up and restore namespaces on an OpenShift Container Platform cluster. <> Set to **false** if you want to disable the Restic installation. Restic deploys a daemon set, which means that each worker node has **Restic** pods running. You configure Restic for backups by adding **spec.defaultVolumesToRestic: true** to the **Backup** CR. <> Specify the URL of the S3 endpoint. <> If you do not specify this value, the default name, **cloud-credentials**, is used. If you specify a custom name, the custom name is used for the backup location. <> Specify a bucket as the backup storage location. If the bucket is not a dedicated bucket for Velero backups, you must specify a prefix. <> Specify a prefix for Velero backups, for example, **velero**, if the bucket is used for multiple purposes.

4. Click **Create**.

5. Verify the installation by viewing the OADP resources:

   ```
   $ oc get all -n openshift-adp
   
   Example output
   ```

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### 4.2.5.5.1. Enabling CSI in the DataProtectionApplication CR

You enable the Container Storage Interface (CSI) in the **DataProtectionApplication** custom resource (CR) in order to back up persistent volumes with CSI snapshots.

**Prerequisites**

- The cloud provider must support CSI snapshots.

**Procedure**

- Edit the **DataProtectionApplication** CR, as in the following example:

```yaml
apiVersion: oadp.openshift.io/v1alpha1
kind: DataProtectionApplication
...
spec:
  configuration:
    velero:
      defaultPlugins:
        - openshift
        - csi
      featureFlags:
        - EnableCSI
```

1. Add the **csi** default plug-in.
Add the EnableCSI feature flag.

4.2.6. Installing and configuring the OpenShift API for Data Protection with OpenShift Container Storage

You install the OpenShift API for Data Protection (OADP) with OpenShift Container Storage (OCS) by installing the OADP Operator and configuring a backup location and a snapshot location. Then, you install the Data Protection Application.

You can configure Multicloud Object Gateway or any S3-compatible object storage as a backup location in the DataProtectionApplication custom resource (CR).

**IMPORTANT**

The CloudStorage API for S3 storage is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see [https://access.redhat.com/support/offerings/techpreview/](https://access.redhat.com/support/offerings/techpreview/).

If the cloud provider has a native snapshot API, you can configure cloud storage as a snapshot location in the DataProtectionApplication CR. You do not need to specify a snapshot location for Restic or Container Storage Interface (CSI) snapshots.

To install the OADP Operator in a restricted network environment, you must first disable the default OperatorHub sources and mirror the Operator catalog. For details, see Using Operator Lifecycle Manager on restricted networks.

4.2.6.1. Installing the OADP Operator

You install the OpenShift API for Data Protection (OADP) Operator on OpenShift Container Platform 4.6 by using Operator Lifecycle Manager (OLM).

The OADP Operator installs Velero 1.7.

**Prerequisites**

- You must be logged in as a user with cluster-admin privileges.

**Procedure**

1. In the OpenShift Container Platform web console, click Operators → OperatorHub.

2. Use the Filter by keyword field to find the OADP Operator.

3. Select the OADP Operator and click Install.

4. Click Install to install the Operator in the openshift-adp project.

5. Click Operators → Installed Operators to verify the installation.
NOTE

After you install the OADP Operator, you configure object storage as a backup location and cloud storage as a snapshot location, if the cloud provider supports a native snapshot API.

If the cloud provider does not support snapshots or if your storage is NFS, you can create backups with Restic. Restic does not require a snapshot location.

4.2.6.2. Creating a secret for backup and snapshot locations

You create a Secret object for the backup and snapshot locations if they use the same credentials.

The default name of the Secret is cloud-credentials, unless you specify a default plug-in for the backup storage provider.

Prerequisites

- Your object storage and cloud storage must use the same credentials.
- You must configure object storage for Velero.
- You must create a credentials-velero file for the object storage in the appropriate format.

Procedure

1. Create a Secret with the default name:

   ```bash
   $ oc create secret generic cloud-credentials -n openshift-adp --from-file cloud=credentials-velero
   ```

   The Secret is referenced in the spec.backupLocations.credential block of the DataProtectionApplication CR when you install the Data Protection Application.

4.2.6.2.1. Configuring secrets for different backup and snapshot location credentials

If your backup and snapshot locations use different credentials, you create two Secret objects:

- Backup location Secret with a custom name. The custom name is specified in the spec.backupLocations block of the DataProtectionApplication custom resource (CR).
- Snapshot location Secret with the default name, cloud-credentials. This Secret is not specified in the DataProtectionApplication CR.

Procedure

1. Create a credentials-velero file for the snapshot location in the appropriate format for your cloud provider.

2. Create a Secret for the snapshot location with the default name:

   ```bash
   $ oc create secret generic cloud-credentials -n openshift-adp --from-file cloud=credentials-velero
   ```
3. Create a credentials-velero file for the backup location in the appropriate format for your object storage.

4. Create a Secret for the backup location with a custom name:

```bash
$ oc create secret generic <custom_secret> -n openshift-adp --from-file cloud=credentials-velero
```

5. Add the Secret with the custom name to the DataProtectionApplication CR, as in the following example:

```yaml
apiVersion: oadp.openshift.io/v1alpha1
kind: DataProtectionApplication
metadata:
  name: <dpa_sample>
  namespace: openshift-adp
spec:
  configuration:
    velero:
      defaultPlugins:
      - csi
      - openshift
      featureFlags:
      - EnableCSI
      restic:
        enable: true
      backupLocations:
      - velero:
          provider: gcp
          default: true
          credential:
            key: cloud
            name: <custom_secret>
          objectStorage:
            bucket: <bucket_name>
            prefix: <prefix>
```

1. Backup location Secret with custom name.

4.2.6.3. Configuring the Data Protection Application

You can configure Velero resource allocations and enable self-signed CA certificates.

4.2.6.3.1. Setting Velero CPU and memory resource allocations

You set the CPU and memory resource allocations for the Velero pod by editing the DataProtectionApplication custom resource (CR) manifest.

Prerequisites

- You must have the OpenShift API for Data Protection (OADP) Operator installed.

Procedure
- Edit the values in the `spec.configuration.velero.podConfig.ResourceAllocations` block of the `DataProtectionApplication` CR manifest, as in the following example:

```yaml
apiVersion: oadp.openshift.io/v1alpha1
kind: DataProtectionApplication
metadata:
  name: <dpa_sample>
spec:
  ... configuration:
    velero:
      podConfig:
        resourceAllocations:
          limits:
            cpu: "1" 1
            memory: 512Mi 2
          requests:
            cpu: 500m 3
            memory: 256Mi 4
```

1. Specify the value in millicpus or CPU units. Default value is 500m or 1 CPU unit.
2. Default value is 512Mi.
3. Default value is 500m or 1 CPU unit.
4. Default value is 256Mi.

### 4.2.6.3.2. Enabling self-signed CA certificates

You must enable a self-signed CA certificate for object storage by editing the `DataProtectionApplication` custom resource (CR) manifest to prevent a `certificate signed by unknown authority` error.

**Prerequisites**

- You must have the OpenShift API for Data Protection (OADP) Operator installed.

**Procedure**

- Edit the `spec.backupLocations.velero.objectStorage.caCert` parameter and `spec.backupLocations.velero.config` parameters of the `DataProtectionApplication` CR manifest:

```yaml
apiVersion: oadp.openshift.io/v1alpha1
kind: DataProtectionApplication
metadata:
  name: <dpa_sample>
spec:
  ... backupLocations:
    - name: default
      velero:
        provider: aws
```
4.2.6.4. Installing the Data Protection Application

You install the Data Protection Application (DPA) by creating an instance of the DataProtectionApplication API.

Prerequisites

- You must install the OADP Operator.
- You must configure object storage as a backup location.
- If you use snapshots to back up PVs, your cloud provider must support either a native snapshot API or Container Storage Interface (CSI) snapshots.
- If the backup and snapshot locations use the same credentials, you must create a Secret with the default name, cloud-credentials.
- If the backup and snapshot locations use different credentials, you must create two Secrets:
  - Secret with a custom name for the backup location. You add this Secret to the DataProtectionApplication CR.
  - Secret with the default name, cloud-credentials, for the snapshot location. This Secret is not referenced in the DataProtectionApplication CR.

**NOTE**

If you do not want to specify backup or snapshot locations during the installation, you can create a default Secret with an empty credentials-velero file. If there is no default Secret, the installation will fail.

Procedure

1. Click Operators → Installed Operators and select the OADP Operator.
2. Under Provided APIs, click Create instance in the DataProtectionApplication box.
3. Click YAML View and update the parameters of the DataProtectionApplication manifest:

```yaml
apiVersion: oadp.openshift.io/v1alpha1
class: DataProtectionApplication
kind: DataProtectionApplication
spec:
  default: true
  objectStorage:
    bucket: <bucket>
    prefix: <prefix>
  caCert: <base64_encoded_cert_string>
  config:
    insecureSkipTLSVerify: "false"
...```

1. Specify the Base46-encoded CA certificate string.
2. Must be false to disable SSL/TLS security.
metadata:
  name: <dpa_sample>
  namespace: openshift-adp
spec:
  configuration:
    velero:
      defaultPlugins:
      - gcp
      - csi
      - openshift
    featureFlags:
      - EnableCSI
    restic:
      enable: true
    backupLocations:
      - velero:
        provider: gcp
data:
  default:
  credential:
    key: cloud
    name: <default_secret>
  objectStorage:
    bucket: <bucket_name>
    prefix: <prefix>

Specify the default plug-in for the backup provider, for example, gcp, if appropriate. Specify the csi default plug-in if you use CSI snapshots to back up PVs. The csi plug-in uses the Velero CSI beta snapshot APIs. You do not need to configure a snapshot location. The openshift plug-in is mandatory in order to back up and restore namespaces on an OpenShift Container Platform cluster. Mandatory for CSI. Set to false if you want to disable the Restic installation. Restic deploys a daemon set, which means that each worker node has Restic pods running. You configure Restic for backups by adding spec.defaultVolumesToRestic: true to the Backup CR. Specify the backup provider. If you use a default plug-in for the backup provider, you must specify the correct default name for the Secret, for example, cloud-credentials-gcp. If you specify a custom name, the custom name is used for the backup location. If you do not specify a Secret name, the default name is used. Specify a bucket as the backup storage location. If the bucket is not a dedicated bucket for Velero backups, you must specify a prefix. Specify a prefix for Velero backups, for example, velero, if the bucket is used for multiple purposes.

4. Click Create.

5. Verify the installation by viewing the OADP resources:

   $ oc get all -n openshift-adp

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>pod/oadp-operator-controller-manager-67d9494d47-61828</td>

<td>95s</td>
</tr>
</tbody>
</table>
4.2.6.4.1. Enabling CSI in the DataProtectionApplication CR

You enable the Container Storage Interface (CSI) in the **DataProtectionApplication** custom resource (CR) in order to back up persistent volumes with CSI snapshots.

**Prerequisites**

- The cloud provider must support CSI snapshots.

**Procedure**

- Edit the **DataProtectionApplication** CR, as in the following example:

```yaml
apiVersion: oadp.openshift.io/v1alpha1
kind: DataProtectionApplication
...
spec:
configuration:
velero:
defaultPlugins:
- openshift
- csi

featureFlags:
- EnableCSI
```

1. Add the **csi** default plug-in.
2. Add the **EnableCSI** feature flag.

### 4.2.7. Uninstalling the OpenShift API for Data Protection
4.3. BACKING UP AND RESTORING

4.3.1. Backing up applications

You back up applications by creating a **Backup** custom resource (CR).

The **Backup** CR creates backup files for Kubernetes resources and internal images, on S3 object storage, and snapshots for persistent volumes (PVs), if the cloud provider uses a native snapshot API or the **Container Storage Interface (CSI)** to create snapshots, such as OpenShift Container Storage 4. For more information, see **CSI volume snapshots**.

**IMPORTANT**

The **CloudStorage** API for S3 storage is a Technology Preview feature only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs) and might not be functionally complete. Red Hat does not recommend using them in production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

For more information about the support scope of Red Hat Technology Preview features, see [https://access.redhat.com/support/offerings/techpreview/](https://access.redhat.com/support/offerings/techpreview/).

If your cloud provider has a native snapshot API or supports **Container Storage Interface (CSI)** snapshots, the **Backup** CR backs up persistent volumes by creating snapshots. For more information, see the **Overview of CSI volume snapshots** in the OpenShift Container Platform documentation.

If your cloud provider does not support snapshots or if your applications are on NFS data volumes, you can create backups by using **Restic**.

You can create **backup hooks** to run commands before or after the backup operation.

You can schedule backups by creating a **Schedule CR** instead of a **Backup** CR.

4.3.1.1. Creating a Backup CR

You back up Kubernetes images, internal images, and persistent volumes (PVs) by creating a **Backup** custom resource (CR).

**Prerequisites**

- You must install the OpenShift API for Data Protection (OADP) Operator.
- The **DataProtectionApplication** CR must be in a **Ready** state.
- Backup location prerequisites:
  - You must have S3 object storage configured for Velero.
  - You must have a backup location configured in the **DataProtectionApplication** CR.
- Snapshot location prerequisites:
- Your cloud provider must have a native snapshot API or support Container Storage Interface (CSI) snapshots.

- For CSI snapshots, you must create a `VolumeSnapshotClass` CR to register the CSI driver.

- You must have a volume location configured in the `DataProtectionApplication` CR.

**Procedure**

1. Retrieve the `backupStorageLocations` CRs:

   ```bash
   $ oc get backupStorageLocations
   ```

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>PHASE</th>
<th>LAST VALIDATED</th>
<th>AGE</th>
<th>DEFAULT</th>
</tr>
</thead>
<tbody>
<tr>
<td>velero-sample-1</td>
<td>Available</td>
<td>11s</td>
<td>31m</td>
<td></td>
</tr>
</tbody>
</table>

2. Create a `Backup` CR, as in the following example:

   ```yaml
   apiVersion: velero.io/v1
   kind: Backup
   metadata:
     name: <backup>
   labels:
     velero.io/storage-location: default
   namespace: openshift-adp
   spec:
     hooks: {}
     includedNamespaces:
     - <namespace>
     includeClusterResources: true
     storageLocation: <velero-sample-1>
     ttl: 720h0m0s
   ```

   1. Specify an array of namespaces to back up.
   2. Specify the name of the `backupStorageLocations` CR.

3. Verify that the status of the `Backup` CR is `Completed`:

   ```bash
   $ oc get backup -n openshift-adp <backup> -o jsonpath='{.status.phase}'
   ```

**4.3.1.2. Backing up persistent volumes with CSI snapshots**

You back up persistent volumes with Container Storage Interface (CSI) snapshots by creating a `VolumeSnapshotClass` custom resource (CR) to register the CSI driver before you create the `Backup` CR.

**Prerequisites**

- The cloud provider must support CSI snapshots.
You must enable CSI in the **DataProtectionApplication** CR.

**Procedure**

- Create a **VolumeSnapshotClass** CR, as in the following examples:

  **Ceph RBD**

  ```yaml
  apiVersion: snapshot.storage.k8s.io/v1
  kind: VolumeSnapshotClass
  deletionPolicy: Retain
  metadata:
    name: <volume_snapshot_class_name>
    labels:
      velero.io/csi-volumesnapshot-class: "true"
      snapshotter: openshift-storage.rbd.csi.ceph.com
    driver: openshift-storage.rbd.csi.ceph.com
  parameters:
    clusterID: openshift-storage
    csi.storage.k8s.io/snapshotter-secret-name: rook-csi-rbd-provisioner
    csi.storage.k8s.io/snapshotter-secret-namespace: openshift-storage
  ```

  **Ceph FS**

  ```yaml
  apiVersion: snapshot.storage.k8s.io/v1
  kind: VolumeSnapshotClass
  metadata:
    name: <volume_snapshot_class_name>
    labels:
      velero.io/csi-volumesnapshot-class: "true"
    driver: openshift-storage.cephfs.csi.ceph.com
  deletionPolicy: Retain
  parameters:
    clusterID: openshift-storage
    csi.storage.k8s.io/snapshotter-secret-name: rook-csi-cephfs-provisioner
    csi.storage.k8s.io/snapshotter-secret-namespace: openshift-storage
  ```

  **Other cloud providers**

  ```yaml
  apiVersion: snapshot.storage.k8s.io/v1
  kind: VolumeSnapshotClass
  metadata:
    name: <volume_snapshot_class_name>
    labels:
      velero.io/csi-volumesnapshot-class: "true"
    driver: <csi_driver>
  deletionPolicy: Retain
  ```

You can now create a **Backup** CR.

**4.3.1.3. Backing up applications with Restic**

You back up Kubernetes resources, internal images, and persistent volumes with Restic by editing the **Backup** custom resource (CR).
You do not need to specify a snapshot location in the **DataProtectionApplication** CR.

**Prerequisites**

- You must install the OpenShift API for Data Protection (OADP) Operator.
- You must not disable the default Restic installation by setting `spec.configuration.restic.enable` to `false` in the **DataProtectionApplication** CR.
- The **DataProtectionApplication** CR must be in a **Ready** state.

**Procedure**

- Edit the **Backup** CR, as in the following example:

  ```yaml
  apiVersion: velero.io/v1
  kind: Backup
  metadata:
    name: <backup>
    labels:
      velero.io/storage-location: default
      namespace: openshift-adp
  spec:
    defaultVolumesToRestic: true
  ...
  
  1 Add `defaultVolumesToRestic: true` to the `spec` block.

4.3.1.4. Creating backup hooks

You create backup hooks to run commands in a container in a pod by editing the **Backup** custom resource (CR).

*Pre* hooks run before the pod is backed up. *Post* hooks run after the backup.

**Procedure**

- Add a hook to the `spec.hooks` block of the **Backup** CR, as in the following example:

  ```yaml
  apiVersion: velero.io/v1
  kind: Backup
  metadata:
    name: <backup>
    namespace: openshift-adp
  spec:
    hooks:
      resources:
        - name: <hook_name>
          includedNamespaces:
            - <namespace>
          excludedNamespaces:
            - <namespace>
          includedResources:
            - pods
  
  1 Add `excludedNamespaces` to the `resources` block.
  2 Add `includedResources` to the `resources` block.
  ```
Array of namespaces to which the hook applies. If this value is not specified, the hook applies to all namespaces.

Currently, pods are the only supported resource.

Optional: This hook only applies to objects matching the label selector.

Array of hooks to run before the backup.

Optional: If the container is not specified, the command runs in the first container in the pod.

Array of commands that the hook runs.

Allowed values for error handling are **Fail** and **Continue**. The default is **Fail**.

Optional: How long to wait for the commands to run. The default is **30s**.

This block defines an array of hooks to run after the backup, with the same parameters as the pre-backup hooks.

### 4.3.1.5. Scheduling backups

You schedule backups by creating a **Schedule** custom resource (CR) instead of a **Backup** CR.

**Prerequisites**

- You must install the OpenShift API for Data Protection (OADP) Operator.
- The **DataProtectionApplication** CR must be in a **Ready** state.

**Procedure**

1. Retrieve the **backupStorageLocations** CRs:

   ```
   $ oc get backupStorageLocations
   ```

   **Example output**
2. Create a **Schedule** CR, as in the following example:

```bash
$ cat << EOF | oc apply -f -
apиверсиия: velero.io/v1
вида: Schedule
metadata:
  имя: <дополнение>
  пространство имен: openshift-adp
spec:
schedule: 0 7 * * *  
template:
hooks: {} 
  включенные пространства имен:
- <дополнение> 
  месторасположение хранения: <velero-sample-1> 
  включить кластерные ресурсы: true 
  defaultVolumesToRestic: true  
  время жизни: 720h0m0s 
EOF
```

1. **cron** expression to schedule the backup, for example, **0 7 * * *** to perform a backup every day at 7:00.

2. Array of namespaces to back up.

3. Name of the **backupStorageLocations** CR.

4. Optional: Add the **defaultVolumesToRestic: true** key-value pair if you are backing up volumes with Restic.

3. Verify that the status of the **Schedule** CR is **Completed** after the scheduled backup runs:

```bash
$ oc get schedule -n openshift-adp <дополнение> -o jsonpath='{.status.phase}'
```

### 4.3.2. Restoring applications

You restore application backups by creating a **Restore** custom resources (CRs).

You can create **restore hooks** to run commands in init containers, before the application container starts, or in the application container itself.

#### 4.3.2.1. Creating a Restore CR

You restore a **Backup** custom resource (CR) by creating a **Restore** CR.

**Prerequisites**

- You must install the OpenShift API for Data Protection (OADP) Operator.
- The **DataProtectionApplication** CR must be in a **Ready** state.
You must have a Velero **Backup** CR.

**Procedure**

1. Create a **Restore** CR, as in the following example:

   ```yaml
   apiVersion: velero.io/v1
   kind: Restore
   metadata:
     name: <restore>
     namespace: openshift-adp
   spec:
     backupName: <backup>
     excludedResources:
       - nodes
       - events
       - events.events.k8s.io
       - backups.velero.io
       - restores.velero.io
       - resticrepositories.velero.io
     restorePVs: true
   ```

   1. Name of the **Backup** CR.

2. Verify that the status of the **Restore** CR is **Completed**:

   ```bash
   $ oc get restore -n openshift-adp <restore> -o jsonpath='{.status.phase}'
   ```

3. Verify that the backup resources have been restored:

   ```bash
   $ oc get all -n <namespace> 1
   ```

   1. Namespace that you backed up.

4.3.2.2. Creating restore hooks

You create restore hooks to run commands in a container in a pod while restoring your application by editing the **Restore** custom resource (CR).

You can create two types of restore hooks:

- An **init** hook adds an init container to a pod to perform setup tasks before the application container starts. If you restore a Restic backup, the `restic-wait` init container is added before the restore hook init container.

- An **exec** hook runs commands or scripts in a container of a restored pod.

**Procedure**

- Add a hook to the `spec.hooks` block of the **Restore** CR, as in the following example:
apiVersion: velero.io/v1
kind: Restore
metadata:
  name: <restore>
namespace: openshift-adp
spec:
hooks:
  resources:
    - name: <hook_name>
      includedNamespaces:
        - <namespace>  
      excludedNamespaces:
        - <namespace>
      includedResources:
        - pods  
      excludedResources: []
    labelSelector:  
      matchLabels:  
      app: velero  
      component: server
postHooks:
  - init:  
    initContainers:  
      - name: restore-hook-init  
        image: alpine:latest  
        volumeMounts:
          - mountPath: /restores/pvc1-vm  
            name: pvc1-vm  
            command:
              - /bin/ash  
              - -c  
            exec:  
              container: <container>  
              command:
                - /bin/bash  
                - -c  
                - "psql < /backup/backup.sql"  
    waitTimeout: 5m  
    execTimeout: 1m  
    onError: Continue  

1 Optional: Array of namespaces to which the hook applies. If this value is not specified, the hook applies to all namespaces.

2 Currently, pods are the only supported resource.

3 Optional: This hook only applies to objects matching the label selector.

4 Optional: If the container is not specified, the command runs in the first container in the pod.

5 Array of commands that the hook runs.

6 Optional: If the waitTimeout is not specified, the restore waits indefinitely. You can specify how long to wait for a container to start and for preceding hooks in the container to complete.
The wait timeout starts when the container is restored and might require time for the container to pull the image and mount the volumes.

7. Optional: How long to wait for the commands to run. The default is 30s.

8. Allowed values for error handling are **Fail** and **Continue**:
   - **Continue**: Only command failures are logged.
   - **Fail**: No more restore hooks run in any container in any pod. The status of the **Restore** CR will be **PartiallyFailed**.

### 4.4. TROUBLESHOOTING

You can debug Velero custom resources (CRs) by using the [OpenShift CLI tool](https://docs.openshift.com/container-platform/4.6/cli-reference/), or the [Velero CLI tool](https://velero.io/). The Velero CLI tool provides more detailed logs and information.

You can check **installation issues**, **backup and restore CR issues**, and **Restic issues**.

You can collect logs, CR information, and Prometheus metric data by using the [must-gather tool](https://github.com/vmware-tanzu/must-gather).

#### 4.4.1. Debugging Velero resources with the OpenShift CLI tool

You can debug a failed backup or restore by checking Velero custom resources (CRs) and the Velero pod log with the OpenShift CLI tool.

**Velero CRs**
Use the `oc describe` command to retrieve a summary of warnings and errors associated with a **Backup** or **Restore** CR:

```
$ oc describe <velero_cr> <cr_name>
```

**Velero pod logs**
Use the `oc logs` command to retrieve the Velero pod logs:

```
$ oc logs pod/<velero>
```

**Velero pod debug logs**
Use the `oc edit` command to set the Velero pod logs to debug level:

1. Edit the Velero deployment:

```
$ oc edit deployment/velero -n {namespace}
```

2. Add `--log-level` and `debug` to the `spec.template.speccontainers.velero.args` array:

```yaml
apiVersion: apps/v1
kind: Deployment
...  
spec:  
template:  
  spec:  
    containers:  
      - name: velero
```

4.4.2. Debugging Velero resources with the Velero CLI tool

You can debug **Backup** and **Restore** custom resources (CRs) and retrieve logs with the Velero CLI tool.

The Velero CLI tool provides more detailed information than the OpenShift CLI tool.

**Syntax**

Use the `oc exec` command to run a Velero CLI command:

```
$ oc exec $(oc get pods -n openshift-adp -o name | grep velero) \ 
  -- ./velero <backup_restore_cr> <command> <cr_name>
```

**Example**

```
$ oc exec $(oc get pods -n openshift-adp -o name | grep velero) \ 
  -- ./velero backup describe 0e44ae00-5dc3-11eb-9ca8-df7e5254778b-2d8ql
```

You can specify `velero-<pod> -n openshift-adp` in place of `$ (oc get pods -n openshift-adp -o name | grep velero)`.

**Example**

```
$ oc exec velero-<pod> -n openshift-adp -- ./velero backup describe 0e44ae00-5dc3-11eb-9ca8-df7e5254778b-2d8ql
```

**Help option**

Use the `velero --help` option to list all Velero CLI commands:

```
$ oc exec $(oc get pods -n openshift-adp -o name | grep velero) -- ./velero --help
```

**Describe command**

Use the `velero describe` command to retrieve a summary of warnings and errors associated with a **Backup** or **Restore** CR:

```
$ oc exec $(oc get pods -n openshift-adp -o name | grep velero) \ 
  -- ./velero <backup_restore_cr> describe <cr_name>
```

**Example**

```
$ oc exec $(oc get pods -n openshift-adp -o name | grep velero) \ 
  -- ./velero backup describe 0e44ae00-5dc3-11eb-9ca8-df7e5254778b-2d8ql
```

**Logs command**

```
...
Use the `velero logs` command to retrieve the logs of a Backup or Restore CR:

```
$ oc exec $(oc get pods -n openshift-adp -o name | grep velero) \
  -- ./velero <backup_restore_cr> logs <cr_name>
```

Example

```
$ oc exec $(oc get pods -n openshift-adp -o name | grep velero) \
  -- ./velero restore logs ccc7c2d0-6017-11eb-afab-85d0007f5a19-x4lbf
```

4.4.3. Installation issues

You might encounter issues caused by using invalid directories or incorrect credentials when you install the Data Protection Application.

4.4.3.1. Backup storage contains invalid directories

The Velero pod log displays the error message, **Backup storage contains invalid top-level directories.**

Cause

The object storage contains top-level directories that are not Velero directories.

Solution

If the object storage is not dedicated to Velero, you must specify a prefix for the bucket by setting the `spec.backupLocations.velero.objectStorage.prefix` parameter in the `DataProtectionApplication` manifest.

4.4.3.2. Incorrect AWS credentials

The `oadp-aws-registry` pod log displays the error message, **InvalidAccessKeyId: The AWS Access Key Id you provided does not exist in our records.**

The Velero pod log displays the error message, **NoCredentialProviders: no valid providers in chain.**

Cause

The `credentials-velero` file used to create the `Secret` object is incorrectly formatted.

Solution

Ensure that the `credentials-velero` file is correctly formatted, as in the following example:

**Example credentials-velero file**

```
[default]
aws_access_key_id=AIAOSFODNN7EXAMPLE
aws_secret_access_key=wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY
```

1. AWS default profile.
2. Do not enclose the values with quotation marks ("", ").
4.4.4. Backup and Restore CR issues

You might encounter these common issues with Backup and Restore custom resources (CRs).

4.4.4.1. Backup CR cannot retrieve volume

The Backup CR displays the error message, InvalidVolume.NotFound: The volume 'vol-xxxx' does not exist.

Cause

The persistent volume (PV) and the snapshot locations are in different regions.

Solution

1. Edit the value of the spec.snapshotLocations.velero.config.region key in the DataProtectionApplication manifest so that the snapshot location is in the same region as the PV.
2. Create a new Backup CR.

4.4.4.2. Backup CR status remains in progress

The status of a Backup CR remains in the InProgress phase and does not complete.

Cause

If a backup is interrupted, it cannot be resumed.

Solution

1. Retrieve the details of the Backup CR:

   $ oc exec $(oc get pods -n openshift-adp -o name | grep velero) \
   -- ./velero backup describe <backup>

2. Delete the Backup CR:

   $ oc delete backup <backup> -n openshift-adp

   You do not need to clean up the backup location because a Backup CR in progress has not uploaded files to object storage.
3. Create a new Backup CR.

4.4.5. Restic issues

You might encounter these issues when you back up applications with Restic.

4.4.5.1. Restic permission error for NFS data volumes with root_squash enabled

The Restic pod log displays the error message, controller=pod-volume-backup error="fork/exec/usr/bin/restic: permission denied".

Cause
If your NFS data volumes have root_squash enabled, Restic maps to nfsnobody and does not have permission to create backups.

Solution

You can resolve this issue by creating a supplemental group for Restic and adding the group ID to the DataProtectionApplication manifest:

1. Create a supplemental group for Restic on the NFS data volume.
2. Set the setgid bit on the NFS directories so that group ownership is inherited.
3. Add the spec.configuration.restic.supplementalGroups parameter and the group ID to the DataProtectionApplication manifest, as in the following example:

   ```yaml
   spec:
     configuration:
       restic:
         enable: true
         supplementalGroups:
         - <group_id>
   ```

   1 Specify the supplemental group ID.

4. Wait for the Restic pods to restart so that the changes are applied.

4.4.5.2. Restore CR of Restic backup is "PartiallyFailed", "Failed", or remains "InProgress"

The Restore CR of a Restic backup completes with a PartiallyFailed or Failed status or it remains InProgress and does not complete.

If the status is PartiallyFailed or Failed, the Velero pod log displays the error message, level=error msg="unable to successfully complete restic restores of pod’s volumes".

If the status is InProgress, the Restore CR logs are unavailable and no errors appear in the Restic pod logs.

Cause

The DeploymentConfig object redeloys the Restore pod, causing the Restore CR to fail.

Solution

1. Create a Restore CR that excludes the ReplicationController and DeploymentConfig resources:

   ```bash
   $ velero restore create --from-backup=<backup> -n openshift-adp
   --include-namespaces <namespace>  
   --exclude-resources replicationcontroller,deploymentconfig
   --restore-volumes=true
   ```

   1 Specify the name of the Backup CR.

   2 Specify the include-namespaces in the Backup CR.
2. Verify that the status of the Restore CR is Completed:

   ```
   $ oc get restore -n openshift-adp <restore> -o jsonpath='{.status.phase}'
   ```

3. Create a Restore CR that includes the ReplicationController and DeploymentConfig resources:

   ```
   $ velero restore create --from-backup=<backup> -n openshift-adp 
   --include-namespaces <namespace> 
   --include-resources replicationcontroller,deploymentconfig 
   --restore-volumes=true
   ```

4. Verify that the status of the Restore CR is Completed:

   ```
   $ oc get restore -n openshift-adp <restore> -o jsonpath='{.status.phase}'
   ```

5. Verify that the backup resources have been restored:

   ```
   $ oc get all -n <namespace>
   ```

4.4.5.3. Restic Backup CR cannot be recreated after bucket is emptied

If you create a Restic Backup CR for a namespace, empty the S3 bucket, and then recreate the Backup CR for the same namespace, the recreated Backup CR fails.

The velero pod log displays the error message, `msg="Error checking repository for stale locks"`.

**Cause**

Velero does not create the Restic repository from the ResticRepository manifest if the Restic directories are deleted on object storage. See ([Velero issue 4421](https://github.com/vmware/velero/issues/4421)) for details.

4.4.6. Using the must-gather tool

You can collect logs, metrics, and information about OADP custom resources by using the must-gather tool.

The must-gather data must be attached to all customer cases.

You can run the must-gather tool with the following data collection options:

- Full must-gather data collection collects Prometheus metrics, pod logs, and Velero CR information for all namespaces where the OADP Operator is installed.

- Essential must-gather data collection collects pod logs and Velero CR information for a specific duration of time, for example, one hour or 24 hours. Prometheus metrics and duplicate logs are not included.

- must-gather data collection with timeout. Data collection can take a long time if there are many failed Backup CRs. You can improve performance by setting a timeout value.

- Prometheus metrics data dump downloads an archive file containing the metrics data collected by Prometheus.
Prerequisites

- You must be logged in to the OpenShift Container Platform cluster as a user with the cluster-admin role.
- You must have the OpenShift CLI installed.

Procedure

1. Navigate to the directory where you want to store the must-gather data.

2. Run the `oc adm must-gather` command for one of the following data collection options:

   - **Full must-gather** data collection, including Prometheus metrics:
     ```
     $ oc adm must-gather --image=registry.redhat.io/oadp/oadp-mustgather-rhel8:v1.0
     ``
     The data is saved as `must-gather/must-gather.tar.gz`. You can upload this file to a support case on the [Red Hat Customer Portal](https://www.redhat.com/career/customer-portal-support).

   - **Essential must-gather** data collection, without Prometheus metrics, for a specific time duration:
     ```
     $ oc adm must-gather --image=registry.redhat.io/oadp/oadp-mustgather-rhel8:v1.0 \ 
     -- /usr/bin/gather_<time>_essential
     ```
     Specify the time in hours. Allowed values are `1h, 6h, 24h, 72h, or all`, for example, `gather_1h_essential` or `gather_all_essential`.

   - **must-gather** data collection with timeout:
     ```
     $ oc adm must-gather --image=registry.redhat.io/oadp/oadp-mustgather-rhel8:v1.0 \ 
     -- /usr/bin/gather_with_timeout <timeout>
     ```
     Specify a timeout value in seconds.

   - Prometheus metrics data dump:
     ```
     $ oc adm must-gather --image=registry.redhat.io/oadp/oadp-mustgather-rhel8:v1.0 \ 
     -- /usr/bin/gather_metrics_dump
     ```
     This operation can take a long time. The data is saved as `must-gather/metrics/prom_data.tar.gz`.

Viewing metrics data with the Prometheus console

You can view the metrics data with the Prometheus console.

Procedure

1. Decompress the `prom_data.tar.gz` file:
   ```
   $ tar -xvzf must-gather/metrics/prom_data.tar.gz
   ```
2. Create a local Prometheus instance:

$ make prometheus-run

The command outputs the Prometheus URL.

Output

Started Prometheus on http://localhost:9090

3. Launch a web browser and navigate to the URL to view the data by using the Prometheus web console.

4. After you have viewed the data, delete the Prometheus instance and data:

$ make prometheus-cleanup
CHAPTER 5. CONTROL PLANE BACKUP AND RESTORE

5.1. BACKING UP ETCD

etcd is the key-value store for OpenShift Container Platform, which persists the state of all resource objects.

Back up your cluster’s etcd data regularly and store in a secure location ideally outside the OpenShift Container Platform environment. Do not take an etcd backup before the first certificate rotation completes, which occurs 24 hours after installation, otherwise the backup will contain expired certificates. It is also recommended to take etcd backups during non-peak usage hours because the etcd snapshot has a high I/O cost.

Be sure to take an etcd backup after you upgrade your cluster. This is important because when you restore your cluster, you must use an etcd backup that was taken from the same z-stream release. For example, an OpenShift Container Platform 4.6.2 cluster must use an etcd backup that was taken from 4.6.2.

**IMPORTANT**

Back up your cluster’s etcd data by performing a single invocation of the backup script on a control plane host (also known as the master host). Do not take a backup for each control plane host.

After you have an etcd backup, you can [restore to a previous cluster state](#).

5.1.1. Backing up etcd data

Follow these steps to back up etcd data by creating an etcd snapshot and backing up the resources for the static pods. This backup can be saved and used at a later time if you need to restore etcd.

**IMPORTANT**

Only save a backup from a single control plane host (also known as the master host). Do not take a backup from each control plane host in the cluster.

**Prerequisites**

- You have access to the cluster as a user with the `cluster-admin` role.
- You have checked whether the cluster-wide proxy is enabled.

**TIP**

You can check whether the proxy is enabled by reviewing the output of `oc get proxy cluster -o yaml`. The proxy is enabled if the `httpProxy`, `httpsProxy`, and `noProxy` fields have values set.

**Procedure**

1. Start a debug session for a control plane node:

```
$ oc debug node/<node_name>
```
2. Change your root directory to the host:

```
sh-4.2# chroot /host
```

3. If the cluster-wide proxy is enabled, be sure that you have exported the `NO_PROXY`, `HTTP_PROXY`, and `HTTPS_PROXY` environment variables.

4. Run the `cluster-backup.sh` script and pass in the location to save the backup to.

**TIP**

The `cluster-backup.sh` script is maintained as a component of the etcd Cluster Operator and is a wrapper around the `etcdctl snapshot save` command.

```
sh-4.4# /usr/local/bin/cluster-backup.sh /home/core/assets/backup
```

**Example script output**

```bash
found latest kube-apiserver: /etc/kubernetes/static-pod-resources/kube-apiserver-pod-6
found latest kube-controller-manager: /etc/kubernetes/static-pod-resources/kube-controller-manager-pod-7
found latest kube-scheduler: /etc/kubernetes/static-pod-resources/kube-scheduler-pod-6
found latest etcd: /etc/kubernetes/static-pod-resources/etcd-pod-3
ede95fe688b87ba86a03c15e669fb4aa5bf0991c180d3c6895ce72eaade54a1
etcdctl version: 3.4.14
API version: 3.4

"["level":"info","ts":1624647639.0188997,"caller":"snapshot/v3_snapshot.go:119","msg":"created temporary db file","path":"/home/core/assets/backup/snapshot_2021-06-25_190035.db.part"]"
"["level":"info","ts":"2021-06-25T19:00:39.030Z","caller":"clientv3/maintenance.go:200","msg":"opened snapshot stream; downloading"
"
"["level":"info","ts":"1624647639.0301006","caller":"snapshot/v3_snapshot.go:127","msg":"fetching snapshot","endpoint":"https://10.0.0.5:2379"
"
"["level":"info","ts":"2021-06-25T19:00:40.215Z","caller":"clientv3/maintenance.go:208","msg":"completed snapshot read; closing"
"
"["level":"info","ts":"1624647640.6032252","caller":"snapshot/v3_snapshot.go:142","msg":"fetched snapshot","endpoint":"https://10.0.0.5:2379","size":"114 MB","took":1.584090459]
"
"["level":"info","ts":1624647640.6047094,"caller":"snapshot/v3_snapshot.go:152","msg":"saved","path":"/home/core/assets/backup/snapshot_2021-06-25_190035.db"
"
```

Snapshot saved at `/home/core/assets/backup/snapshot_2021-06-25_190035.db`

```
{"hash":3866667823,"revision":31407,"totalKey":12828,"totalSize":11446336}
```

In this example, two files are created in the `/home/core/assets/backup/` directory on the control plane host:

- **snapshot_<datetimestamp>.db**: This file is the etcd snapshot. The `cluster-backup.sh` script confirms its validity.
- **static_kuberessources_<datetimestamp>.tar.gz**: This file contains the resources for the static pods. If etcd encryption is enabled, it also contains the encryption keys for the etcd snapshot.
If etcd encryption is enabled, it is recommended to store this second file separately from the etcd snapshot for security reasons. However, this file is required in order to restore from the etcd snapshot.

Keep in mind that etcd encryption only encrypts values, not keys. This means that resource types, namespaces, and object names are unencrypted.

5.2. REPLACING AN UNHEALTHY ETCD MEMBER

This document describes the process to replace a single unhealthy etcd member.

This process depends on whether the etcd member is unhealthy because the machine is not running or the node is not ready, or whether it is unhealthy because the etcd pod is crashlooping.

NOTE

If you have lost the majority of your control plane hosts, leading to etcd quorum loss, then you must follow the disaster recovery procedure to restore to a previous cluster state instead of this procedure.

If the control plane certificates are not valid on the member being replaced, then you must follow the procedure to recover from expired control plane certificates instead of this procedure.

If a control plane node is lost and a new one is created, the etcd cluster Operator handles generating the new TLS certificates and adding the node as an etcd member.

5.2.1. Prerequisites

- Take an etcd backup prior to replacing an unhealthy etcd member.

5.2.2. Identifying an unhealthy etcd member

You can identify if your cluster has an unhealthy etcd member.

Prerequisites

- Access to the cluster as a user with the cluster-admin role.

Procedure

1. Check the status of the EtcdMembersAvailable status condition using the following command:

   $ oc get etcd -o=jsonpath='{range .items[0].status.conditions[? (@.type=="EtcdMembersAvailable")]}{.message}{"\n"}"

   2 of 3 members are available, ip-10-0-131-183.ec2.internal is unhealthy

   This example output shows that the ip-10-0-131-183.ec2.internal etcd member is unhealthy.
5.2.3. Determining the state of the unhealthy etcd member

The steps to replace an unhealthy etcd member depend on which of the following states your etcd member is in:

- The machine is not running or the node is not ready
- The etcd pod is crashlooping

This procedure determines which state your etcd member is in. This enables you to know which procedure to follow to replace the unhealthy etcd member.

**NOTE**

If you are aware that the machine is not running or the node is not ready, but you expect it to return to a healthy state soon, then you do not need to perform a procedure to replace the etcd member. The etcd cluster Operator will automatically sync when the machine or node returns to a healthy state.

**Prerequisites**

- You have access to the cluster as a user with the `cluster-admin` role.
- You have identified an unhealthy etcd member.

**Procedure**

1. Determine if the **machine is not running**.

   
   ```bash
   $ oc get machines -A -o jsonpath='{range .items[*]}{@.status.nodeRef.name}{"\t"}{@.status.providerStatus.instanceState}{\n} | grep -v running
   ```

   **Example output**

   ```
   ip-10-0-131-183.ec2.internal  stopped
   ```

   This output lists the node and the status of the node’s machine. If the status is anything other than **running**, then the **machine is not running**.

   If the **machine is not running** then follow the Replacing an unhealthy etcd member whose machine is not running or whose node is not ready procedure.

2. Determine if the **node is not ready**.

   If either of the following scenarios are true, then the **node is not ready**.

   - If the machine is running, then check whether the node is unreachable:

     ```bash
     $ oc get nodes -o jsonpath='{range .items[*]){\"\n\}\metadata.name}{\t}{range .spec.taints[*]){\"\}\.key}{\t} | grep unreachable
     ```

     **Example output**
If the node is listed with an unreachable taint, then the node is not ready.

- If the node is still reachable, then check whether the node is listed as NotReady:

  ```
  $ oc get nodes -l node-role.kubernetes.io/master | grep "NotReady"
  
  Example output
  
  ip-10-0-131-183.ec2.internal   NotReady   master   122m   v1.19.0
  
  If the node is listed as NotReady, then the node is not ready.
  ```

If the node is not ready, then follow the Replacing an unhealthy etcd member whose machine is not running or whose node is not ready procedure.

3. Determine if the etcd pod is crashlooping
   If the machine is running and the node is ready, then check whether the etcd pod is crashlooping.
   a. Verify that all control plane nodes (also known as the master nodes) are listed as Ready:

      ```
      $ oc get nodes -l node-role.kubernetes.io/master
      
      Example output
      
      NAME                           STATUS   ROLES    AGE     VERSION
      ip-10-0-131-183.ec2.internal   Ready    master   6h13m   v1.19.0
      ip-10-0-164-97.ec2.internal    Ready    master   6h13m   v1.19.0
      ip-10-0-154-204.ec2.internal   Ready    master   6h13m   v1.19.0
      
      $ oc get pods -n openshift-etcd | grep -v etcd-quorum-guard | grep etcd
      
      Example output
      
      etcd-ip-10-0-131-183.ec2.internal                2/3     Error       7          6h9m
      etcd-ip-10-0-164-97.ec2.internal                 3/3     Running     0          6h6m
      etcd-ip-10-0-154-204.ec2.internal                3/3     Running     0          6h6m
      
      Since this status of this pod is Error, then the etcd pod is crashlooping
      ```

   If the etcd pod is crashlooping then follow the Replacing an unhealthy etcd member whose etcd pod is crashlooping procedure.

5.2.4. Replacing the unhealthy etcd member
Depending on the state of your unhealthy etcd member, use one of the following procedures:

- Replacing an unhealthy etcd member whose machine is not running or whose node is not ready
- Replacing an unhealthy etcd member whose etcd pod is crashlooping

5.2.4.1. Replacing an unhealthy etcd member whose machine is not running or whose node is not ready

This procedure details the steps to replace an etcd member that is unhealthy either because the machine is not running or because the node is not ready.

Prerequisites

- You have identified the unhealthy etcd member.
- You have verified that either the machine is not running or the node is not ready.
- You have access to the cluster as a user with the `cluster-admin` role.
- You have taken an etcd backup.

**IMPORTANT**

It is important to take an etcd backup before performing this procedure so that your cluster can be restored if you encounter any issues.

Procedure

1. Remove the unhealthy member.
   a. Choose a pod that is not on the affected node:
      In a terminal that has access to the cluster as a `cluster-admin` user, run the following command:

      ```
      $ oc get pods -n openshift-etcd | grep -v etcd-quorum-guard | grep etcd
      ```

      **Example output**

      ```
      etcd-ip-10-0-131-183.ec2.internal                3/3     Running     0          123m
      etcd-ip-10-0-164-97.ec2.internal                 3/3     Running     0          123m
      etcd-ip-10-0-154-204.ec2.internal                3/3     Running     0          124m
      ```

   b. Connect to the running etcd container, passing in the name of a pod that is not on the affected node:
      In a terminal that has access to the cluster as a `cluster-admin` user, run the following command:

      ```
      $ oc rsh -n openshift-etcd etcd-ip-10-0-154-204.ec2.internal
      ```

   c. View the member list:

      ```
      sh-4.2# etcdctl member list -w table
      ```
Example output

<table>
<thead>
<tr>
<th>ID</th>
<th>STATUS</th>
<th>NAME</th>
<th>PEER ADDRS</th>
<th>CLIENT ADDRS</th>
</tr>
</thead>
<tbody>
<tr>
<td>ca8c2990a00a29d1</td>
<td>started</td>
<td>ip-10-0-154-204.ec2.internal</td>
<td><a href="https://10.0.154.204:2380">https://10.0.154.204:2380</a></td>
<td><a href="https://10.0.154.204:2379">https://10.0.154.204:2379</a></td>
</tr>
</tbody>
</table>

Take note of the ID and the name of the unhealthy etcd member, because these values are needed later in the procedure.

d. Remove the unhealthy etcd member by providing the ID to the `etcdctl member remove` command:

```
sh-4.2# etcdctl member remove 6fc1e7c9db35841d
```

Example output

Member 6fc1e7c9db35841d removed from cluster baa565c8919b060e

e. View the member list again and verify that the member was removed:

```
sh-4.2# etcdctl member list -w table
```

Example output

You can now exit the node shell.

2. Remove the old secrets for the unhealthy etcd member that was removed.

   a. List the secrets for the unhealthy etcd member that was removed.
Pass in the name of the unhealthy etcd member that you took note of earlier in this procedure.

There is a peer, serving, and metrics secret as shown in the following output:

**Example output**

```
<table>
<thead>
<tr>
<th>Secret Name</th>
<th>Type</th>
<th>Age</th>
</tr>
</thead>
<tbody>
<tr>
<td>etcd-peer-ip-10-0-131-183.ec2.internal</td>
<td>kubernetes.io/tls</td>
<td>47m</td>
</tr>
<tr>
<td>etcd-serving-ip-10-0-131-183.ec2.internal</td>
<td>kubernetes.io/tls</td>
<td>47m</td>
</tr>
<tr>
<td>etcd-serving-metrics-ip-10-0-131-183.ec2.internal</td>
<td>kubernetes.io/tls</td>
<td>47m</td>
</tr>
</tbody>
</table>
```

1. Delete the secrets for the unhealthy etcd member that was removed.
   i. Delete the peer secret:
      ```
      $ oc delete secret -n openshift-etcd etcd-peer-ip-10-0-131-183.ec2.internal
      ```
   ii. Delete the serving secret:
      ```
      $ oc delete secret -n openshift-etcd etcd-serving-ip-10-0-131-183.ec2.internal
      ```
   iii. Delete the metrics secret:
      ```
      $ oc delete secret -n openshift-etcd etcd-serving-metrics-ip-10-0-131-183.ec2.internal
      ```

3. Delete and recreate the control plane machine (also known as the master machine). After this machine is recreated, a new revision is forced and etcd scales up automatically. If you are running installer-provisioned infrastructure, or you used the Machine API to create your machines, follow these steps. Otherwise, you must create the new master using the same method that was used to originally create it.

   a. Obtain the machine for the unhealthy member.
      In a terminal that has access to the cluster as a `cluster-admin` user, run the following command:
      ```
      $ oc get machines -n openshift-machine-api -o wide
      ```
      **Example output**

      ```
      | Name                   | Phase      | Type      | Region     | Zone      | Age          |
      |------------------------|------------|-----------|------------|-----------|--------------|
      | clustername-8qw5l-master-0 | Running    | m4.xlarge | us-east-1  | us-east-1a| 3h37m        |
      |                        |            |           | ip-10-0-131-183.ec2.internal | aws:///us-east-1a/i-0ec2782f8287dfb7e | stopped |
      | clustername-8qw5l-master-1 | Running    | m4.xlarge | us-east-1  | us-east-1b| 3h37m        |
      |                        |            |           | ip-10-0-154-204.ec2.internal | aws:///us-east-1b/i-096c349b700a19631 | running |
      | clustername-8qw5l-master-2 | Running    | m4.xlarge | us-east-1  | us-east-1c| 3h37m        |
      |                        |            |           | ip-10-0-164-97.ec2.internal | aws:///us-east-1c/i-02626f1dba9ed5bba | running |
      ```
This is the control plane machine for the unhealthy node, ip-10-0-131-183.ec2.internal.

b. Save the machine configuration to a file on your file system:

```
$ oc get machine clustername-8qw5i-master-0 -n openshift-machine-api -o yaml > new-master-machine.yaml
```

Specify the name of the control plane machine for the unhealthy node.

c. Edit the **new-master-machine.yaml** file that was created in the previous step to assign a new name and remove unnecessary fields.

i. Remove the entire **status** section:

```
status:
  addresses:
  - address: 10.0.131.183
    type: InternalIP
  - address: ip-10-0-131-183.ec2.internal
    type: InternalDNS
  - address: ip-10-0-131-183.ec2.internal
    type: Hostname
  lastUpdated: "2020-04-20T17:44:29Z"
  nodeRef:
    kind: Node
    name: ip-10-0-131-183.ec2.internal
    uid: acca4411-af0d-4387-b73e-52b2484295ad
  phase: Running
  providerStatus:
    apiVersion: awsproviderconfig.openshift.io/v1beta1
    conditions:
      - lastProbeTime: "2020-04-20T16:53:50Z"
      lastTransitionTime: "2020-04-20T16:53:50Z"
      message: machine successfully created
      reason: MachineCreationSucceeded
      status: "True"
      type: MachineCreation
    instanceId: i-0f8db85790d76d0c3f
    instanceState: stopped
    kind: AWSMachineProviderStatus
```

ii. Change the **metadata.name** field to a new name.
It is recommended to keep the same base name as the old machine and change the ending number to the next available number. In this example, `clusternam-8qw5l-master-0` is changed to `clusternam-8qw5l-master-3`.

For example:

```yaml
apiVersion: machine.openshift.io/v1beta1
kind: Machine
metadata:
  ...  
  name: clusternam-8qw5l-master-3
  ...
```

iii. Update the `metadata.selfLink` field to use the new machine name from the previous step.

```yaml
apiVersion: machine.openshift.io/v1beta1
kind: Machine
metadata:
  ...  
  selfLink: /apis/machine.openshift.io/v1beta1/namespaces/openshift-machine-api/machines/clusternam-8qw5l-master-3
  ...
```

iv. Remove the `spec.providerID` field:

```yaml
providerID: aws:///us-east-1/a/i-0f85790d76d0c3f
```

v. Remove the `metadata.annotations` and `metadata.generation` fields:

```yaml
 annotations:
  machine.openshift.io/instance-state: running
  ...
  generation: 2
```

vi. Remove the `metadata.resourceVersion` and `metadata.uid` fields:

```yaml
resourceVersion: "13291"
uid: a282eb70-40a2-4e89-8009-d05dd420d31a
```

d. Delete the machine of the unhealthy member:

```
$ oc delete machine -n openshift-machine-api clusternam-8qw5l-master-0  
```

Specify the name of the control plane machine for the unhealthy node.

e. Verify that the machine was deleted:

```
$ oc get machines -n openshift-machine-api -o wide
```

**Example output**
f. Create the new machine using the `new-master-machine.yaml` file:

```bash
$ oc apply -f new-master-machine.yaml
```

g. Verify that the new machine has been created:

```bash
$ oc get machines -n openshift-machine-api -o wide
```

**Example output**

```
NAME                   PHASE           TYPE        REGION    ZONE     AGE
NODE                                PROVIDERID                            STATE
clusternamenew-master-1            Running         m4.xlarge   us-east-1   us-east-1b
3h37m   ip-10-0-154-204.ec2.internal   aws:///us-east-1b/i-096c349b700a19631   running
clusternamenew-master-2            Running         m4.xlarge   us-east-1   us-east-1c
3h37m   ip-10-0-164-97.ec2.internal   aws:///us-east-1c/i-02626f1dba9ed5bba   running
clusternamenew-worker-us-east-1a-wbtgd   Running       m4.large    us-east-1   us-east-1a
3h37m   ip-10-0-133-53.ec2.internal   aws:///us-east-1a/i-015b0888f17bc2c8   running
clusternamenew-worker-us-east-1b-lrdxb   Running       m4.large    us-east-1   us-east-1b
3h37m   ip-10-0-144-248.ec2.internal   aws:///us-east-1b/i-0cb45ac45a166173b   running
clusternamenew-worker-us-east-1c-pkg26   Running       m4.large    us-east-1   us-east-1c
3h37m   ip-10-0-170-181.ec2.internal   aws:///us-east-1c/i-06861c00007751b0a   running
```

The new machine, `clusternamenew-master-3` is being created and is ready once the phase changes from `Provisioning` to `Running`.

It might take a few minutes for the new machine to be created. The etcd cluster Operator will automatically sync when the machine or node returns to a healthy state.

**Verification**

1. Verify that all etcd pods are running properly.
In a terminal that has access to the cluster as a `cluster-admin` user, run the following command:

```
$ oc get pods -n openshift-etcd | grep -v etcd-quorum-guard | grep etcd
```

**Example output**

```
etcd-ip-10-0-133-53.ec2.internal     3/3     Running     0     7m49s
etcd-ip-10-0-164-97.ec2.internal     3/3     Running     0     123m
etcd-ip-10-0-154-204.ec2.internal    3/3     Running     0     124m
```

If the output from the previous command only lists two pods, you can manually force an etcd redeployment. In a terminal that has access to the cluster as a `cluster-admin` user, run the following command:

```
$ oc patch etcd cluster -p="{"spec": {"forceRedeploymentReason": "recovery-"$( date --rfc-3339=ns )"}}" --type=merge
```

1 The `forceRedeploymentReason` value must be unique, which is why a timestamp is appended.

2. Verify that there are exactly three etcd members.

   a. Connect to the running etcd container, passing in the name of a pod that was not on the affected node:

   In a terminal that has access to the cluster as a `cluster-admin` user, run the following command:

   ```
   $ oc rsh -n openshift-etcd etcd-ip-10-0-154-204.ec2.internal
   ```

   b. View the member list:

   ```
   sh-4.2# etcdctl member list -w table
   +------------------+---------+------------------------------+--------------------------+---------------------+
   |        ID        | STATUS  |             NAME             |        PEER ADDRS        |       CLIENT ADDR   |
   +------------------+---------+------------------------------+--------------------------+---------------------+
   | 5eb0d6b8ca24730c | started |  ip-10-0-133-53.ec2.internal |  https://10.0.133.53:2380 | https://10.0.133.53:2379 |
   | ca8c2990a0aa29d1 | started | ip-10-0-154-204.ec2.internal | https://10.0.154.204:2380 | https://10.0.154.204:2379 |
   +------------------+---------+------------------------------+--------------------------+---------------------+
   ```

   If the output from the previous command lists more than three etcd members, you must carefully remove the unwanted member.
5.2.4.2. Replacing an unhealthy etcd member whose etcd pod is crashlooping

This procedure details the steps to replace an etcd member that is unhealthy because the etcd pod is crashlooping.

Prerequisites

- You have identified the unhealthy etcd member.
- You have verified that the etcd pod is crashlooping.
- You have access to the cluster as a user with the `cluster-admin` role.
- You have taken an etcd backup.

**IMPORTANT**

It is important to take an etcd backup before performing this procedure so that your cluster can be restored if you encounter any issues.

Procedure

1. Stop the crashlooping etcd pod.
   
   a. Debug the node that is crashlooping.
      
      In a terminal that has access to the cluster as a `cluster-admin` user, run the following command:
      
      ```
      $ oc debug node/ip-10-0-131-183.ec2.internal
      
      Replace this with the name of the unhealthy node.
      ```

   b. Change your root directory to the host:
      
      ```
      sh-4.2# chroot /host
      ```

   c. Move the existing etcd pod file out of the kubelet manifest directory:
      
      ```
      sh-4.2# mkdir /var/lib/etcd-backup
      
      sh-4.2# mv /etc/kubernetes/manifests/etcd-pod.yaml /var/lib/etcd-backup/
      ```

   d. Move the etcd data directory to a different location:
You can now exit the node shell.

2. Remove the unhealthy member.
   
a. Choose a pod that is not on the affected node.
   
   In a terminal that has access to the cluster as a `cluster-admin` user, run the following command:

   ```bash
   $ oc get pods -n openshift-etcd | grep -v etcd-quorum-guard | grep etcd
   ``

   **Example output**

   ```
   etcd-ip-10-0-131-183.ec2.internal       2/3   Error    7   6h9m
   etcd-ip-10-0-164-97.ec2.internal        3/3   Running  0   6h6m
   etcd-ip-10-0-154-204.ec2.internal       3/3   Running  0   6h6m
   ```

   b. Connect to the running etcd container, passing in the name of a pod that is not on the affected node.
   
   In a terminal that has access to the cluster as a `cluster-admin` user, run the following command:

   ```bash
   $ oc rsh -n openshift-etcd etcd-ip-10-0-154-204.ec2.internal
   ``

   c. View the member list:

   ```bash
   sh-4.2# etcdctl member list -w table
   ``

   **Example output**

   ```
   +------------------+---------+------------------------------+---------------------------+----------------
   | ID               | STATUS  | NAME                         | PEER ADDRS                | CLIENT ADDRS |
   +------------------+---------+------------------------------+---------------------------+----------------
   | d022e10b498760d5 | started | ip-10-0-154-204.ec2.internal | https://10.0.154.204:2380 | https://10.0.154.204:2379 |
   +------------------+---------+------------------------------+---------------------------+----------------
   ```

   Take note of the ID and the name of the unhealthy etcd member, because these values are needed later in the procedure.

   d. Remove the unhealthy etcd member by providing the ID to the `etcdctl member remove` command:

   ```bash
   sh-4.2# etcdctl member remove 62bcf33650a7170a
   ```
Member 62bcf33650a7170a removed from cluster ead669ce1fbeb346

e. View the member list again and verify that the member was removed:

    sh-4.2# etcdctl member list -w table

You can now exit the node shell.

3. Remove the old secrets for the unhealthy etcd member that was removed.

a. List the secrets for the unhealthy etcd member that was removed.

    $ oc get secrets -n openshift-etcd | grep ip-10-0-131-183.ec2.internal

1 Pass in the name of the unhealthy etcd member that you took note of earlier in this procedure.

There is a peer, serving, and metrics secret as shown in the following output:

b. Delete the secrets for the unhealthy etcd member that was removed.

   i. Delete the peer secret:

       $ oc delete secret -n openshift-etcd etcd-peer-ip-10-0-131-183.ec2.internal

   ii. Delete the serving secret:

       $ oc delete secret -n openshift-etcd etcd-serving-ip-10-0-131-183.ec2.internal
iii. Delete the metrics secret:

```
$ oc delete secret -n openshift-etcd etcd-serving-metrics-ip-10-0-131-183.ec2.internal
```

4. Force etcd redeployment.
In a terminal that has access to the cluster as a `cluster-admin` user, run the following command:

```
$ oc patch etcd cluster -p="{"spec": {"forceRedeploymentReason": "single-master-recovery-
"$( date --rfc-3339=ns )""}}" --type=merge
```

The `forceRedeploymentReason` value must be unique, which is why a timestamp is appended.

When the etcd cluster Operator performs a redeployment, it ensures that all control plane
nodes (also known as the master nodes) have a functioning etcd pod.

**Verification**

- Verify that the new member is available and healthy.
  - a. Connect to the running etcd container again.
     In a terminal that has access to the cluster as a `cluster-admin` user, run the following command:
     
     ```
     $ oc rsh -n openshift-etcd etcd-ip-10-0-154-204.ec2.internal
     ```
  
  - b. Verify that all members are healthy:
    ```
    sh-4.2# etcdctl endpoint health --cluster
    ```

**Example output**

```
https://10.0.131.183:2379 is healthy: successfully committed proposal: took = 16.671434ms
https://10.0.154.204:2379 is healthy: successfully committed proposal: took = 16.698331ms
https://10.0.164.97:2379 is healthy: successfully committed proposal: took = 16.621645ms
```

### 5.3. DISASTER RECOVERY

#### 5.3.1. About disaster recovery

The disaster recovery documentation provides information for administrators on how to recover from several disaster situations that might occur with their OpenShift Container Platform cluster. As an administrator, you might need to follow one or more of the following procedures in order to return your cluster to a working state.
**IMPORTANT**

Disaster recovery requires you to have at least one healthy control plane host (also known as the master host).

**Restoring to a previous cluster state**

This solution handles situations where you want to restore your cluster to a previous state, for example, if an administrator deletes something critical. This also includes situations where you have lost the majority of your control plane hosts, leading to etcd quorum loss and the cluster going offline. As long as you have taken an etcd backup, you can follow this procedure to restore your cluster to a previous state.

If applicable, you might also need to recover from expired control plane certificates.

**WARNING**

Restoring to a previous cluster state is a destructive and destabilizing action to take on a running cluster. This procedure should only be used as a last resort.

Prior to performing a restore, see About restoring cluster state for more information on the impact to the cluster.

**NOTE**

If you have a majority of your masters still available and have an etcd quorum, then follow the procedure to replace a single unhealthy etcd member.

**Recovering from expired control plane certificates**

This solution handles situations where your control plane certificates have expired. For example, if you shut down your cluster before the first certificate rotation, which occurs 24 hours after installation, your certificates will not be rotated and will expire. You can follow this procedure to recover from expired control plane certificates.

**5.3.2. Restoring to a previous cluster state**

To restore the cluster to a previous state, you must have previously backed up etcd data by creating a snapshot. You will use this snapshot to restore the cluster state.

**5.3.2.1. About restoring cluster state**

You can use an etcd backup to restore your cluster to a previous state. This can be used to recover from the following situations:

- The cluster has lost the majority of control plane hosts (quorum loss).
- An administrator has deleted something critical and must restore to recover the cluster.
WARNING

Restoring to a previous cluster state is a destructive and destablizing action to take on a running cluster. This should only be used as a last resort.

If you are able to retrieve data using the Kubernetes API server, then etcd is available and you should not restore using an etcd backup.

Restoring etcd effectively takes a cluster back in time and all clients will experience a conflicting, parallel history. This can impact the behavior of watching components like kubelets, Kubernetes controller managers, SDN controllers, and persistent volume controllers.

It can cause Operator churn when the content in etcd does not match the actual content on disk, causing Operators for the Kubernetes API server, Kubernetes controller manager, Kubernetes scheduler, and etcd to get stuck when files on disk conflict with content in etcd. This can require manual actions to resolve the issues.

In extreme cases, the cluster can lose track of persistent volumes, delete critical workloads that no longer exist, reimage machines, and rewrite CA bundles with expired certificates.

5.3.2.2. Restoring to a previous cluster state

You can use a saved etcd backup to restore a previous cluster state or restore a cluster that has lost the majority of control plane hosts (also known as the master hosts).

IMPORTANT

When you restore your cluster, you must use an etcd backup that was taken from the same z-stream release. For example, an OpenShift Container Platform 4.6.2 cluster must use an etcd backup that was taken from 4.6.2.

Prerequisites

- Access to the cluster as a user with the `cluster-admin` role.
- A healthy control plane host to use as the recovery host.
- SSH access to control plane hosts.
- A backup directory containing both the etcd snapshot and the resources for the static pods, which were from the same backup. The file names in the directory must be in the following formats: `snapshot_<datetimestamp>.db` and `static_kuberesources_<datetimestamp>.tar.gz`.

IMPORTANT

For non-recovery control plane nodes, it is not required to establish SSH connectivity or to stop the static pods. You can delete and recreate other non-recovery, control plane machines, one by one.
Procedure

1. Select a control plane host to use as the recovery host. This is the host that you will run the restore operation on.

2. Establish SSH connectivity to each of the control plane nodes, including the recovery host. The Kubernetes API server becomes inaccessible after the restore process starts, so you cannot access the control plane nodes. For this reason, it is recommended to establish SSH connectivity to each control plane host in a separate terminal.

   **IMPORTANT**

   If you do not complete this step, you will not be able to access the control plane hosts to complete the restore procedure, and you will be unable to recover your cluster from this state.

3. Copy the etcd backup directory to the recovery control plane host. This procedure assumes that you copied the backup directory containing the etcd snapshot and the resources for the static pods to the `/home/core/` directory of your recovery control plane host.

4. Stop the static pods on any other control plane nodes.

   **NOTE**

   It is not required to manually stop the pods on the recovery host. The recovery script will stop the pods on the recovery host.

   a. Access a control plane host that is not the recovery host.

   b. Move the existing etcd pod file out of the kubelet manifest directory:

   ```
   $ sudo mv /etc/kubernetes/manifests/etcd-pod.yaml /tmp
   ```

   c. Verify that the etcd pods are stopped.

   ```
   $ sudo crictl ps | grep etcd | grep -v operator
   ```

   The output of this command should be empty. If it is not empty, wait a few minutes and check again.

   d. Move the existing Kubernetes API server pod file out of the kubelet manifest directory:

   ```
   $ sudo mv /etc/kubernetes/manifests/kube-apiserver-pod.yaml /tmp
   ```

   e. Verify that the Kubernetes API server pods are stopped.

   ```
   $ sudo crictl ps | grep kube-apiserver | grep -v operator
   ```

   The output of this command should be empty. If it is not empty, wait a few minutes and check again.

   f. Move the etcd data directory to a different location:

   ```
   ```
5. Access the recovery control plane host.

6. If the cluster-wide proxy is enabled, be sure that you have exported the `NO_PROXY`, `HTTP_PROXY`, and `HTTPS_PROXY` environment variables.

   **TIP**

   You can check whether the proxy is enabled by reviewing the output of `oc get proxy cluster -o yaml`. The proxy is enabled if the `httpProxy`, `httpsProxy`, and `noProxy` fields have values set.

7. Run the restore script on the recovery control plane host and pass in the path to the etcd backup directory:

   $ sudo -E /usr/local/bin/cluster-restore.sh /home/core/backup

   **Example script output**

   ...stopping kube-scheduler-pod.yaml
   ...stopping kube-controller-manager-pod.yaml
   ...stopping etcd-pod.yaml
   ...stopping kube-apiserver-pod.yaml
   Waiting for container etcd to stop
   .complete
   Waiting for container etcdctl to stop
   .........................complete
   Waiting for container etcd-metrics to stop
   complete
   Waiting for container kube-controller-manager to stop
   complete
   Waiting for container kube-apiserver to stop
   ..........................................................complete
   Waiting for container kube-scheduler to stop
   complete
   Moving etcd data-dir /var/lib/etcd/member to /var/lib/etcd-backup
   starting restore-etcd static pod
   starting kubectl-apiserver-pod.yaml
   static-pod-resources/kube-apiserver-pod-7/kube-apiserver-pod.yaml
   starting kubectl-controller-manager-pod.yaml
   static-pod-resources/kube-controller-manager-pod-7/kube-controller-manager-pod.yaml
   starting kubectl-scheduler-pod.yaml
   static-pod-resources/kube-scheduler-pod-8/kube-scheduler-pod.yaml

8. Restart the kubelet service on all control plane hosts.

   a. From the recovery host, run the following command:

   $ sudo systemctl restart kubelet.service

   b. Repeat this step on all other control plane hosts.
9. Approve the pending CSRs:
   a. Get the list of current CSRs:

   ```
   $ oc get csr
   
   Example output
   ```

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>SIGNERNAME</th>
<th>REQUESTOR</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-2s94x</td>
<td>8m3s</td>
<td>kubernetes.io/kubelet-serving</td>
<td>system:node:&lt;node_name&gt;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Pending 1</td>
<td></td>
</tr>
<tr>
<td>csr-4bd6t</td>
<td>8m3s</td>
<td>kubernetes.io/kubelet-serving</td>
<td>system:node:&lt;node_name&gt;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Pending 2</td>
<td></td>
</tr>
<tr>
<td>csr-4hl85</td>
<td>13m</td>
<td>kubernetes.io/kube-apiserver-client-kubelet</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
</tr>
<tr>
<td></td>
<td></td>
<td>3</td>
<td></td>
</tr>
<tr>
<td>csr-zhhhp</td>
<td>3m8s</td>
<td>kubernetes.io/kube-apiserver-client-kubelet</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
</tr>
<tr>
<td></td>
<td></td>
<td>4</td>
<td></td>
</tr>
</tbody>
</table>
   ...  

1 A pending kubernetes service CSR (for user-provisioned installations).
3 A pending node-bootstrapper CSR.

b. Review the details of a CSR to verify that it is valid:

   ```
   $ oc describe csr <csr_name> 1
   
   <csr_name> is the name of a CSR from the list of current CSRs.
   ```

c. Approve each valid node-bootstrapper CSR:

   ```
   $ oc adm certificate approve <csr_name>
   ```

d. For user-provisioned installations, approve each valid kubelet service CSR:

   ```
   $ oc adm certificate approve <csr_name>
   ```

10. Verify that the single member control plane has started successfully.
   a. From the recovery host, verify that the etcd container is running.

   ```
   $ sudo crictl ps | grep etcd | grep -v operator
   ```

   Example output

   ```
   3ad41b7908e32 36f86e2eaaaffe662df0d21041eb22b8198e0e58abeeae8c743c3e6e977e8009
   About a minute ago Running etcd 0
   ```
b. From the recovery host, verify that the etcd pod is running.

$$\text{oc get pods -n openshift-etcd | grep -v etcd-quorum-guard | grep etcd}$$

**NOTE**

If you attempt to run `oc login` prior to running this command and receive the following error, wait a few moments for the authentication controllers to start and try again.

Unable to connect to the server: EOF

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
<th>RESTARTS</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>etcd-ip-10-0-143-125.ec2.internal</td>
<td>1/1</td>
<td>Running</td>
<td>1</td>
<td>2m47s</td>
</tr>
</tbody>
</table>

If the status is **Pending**, or the output lists more than one running etcd pod, wait a few minutes and check again.

11. Force etcd redeployment.
   In a terminal that has access to the cluster as a `cluster-admin` user, run the following command:

$$\text{oc patch etcd cluster -p='\{"spec": \"forceRedeploymentReason\": \"recovery\"$( date --rfc-3339=ns )\\"\\"\'} --type=merge$$

The **forceRedeploymentReason** value must be unique, which is why a timestamp is appended.

When the etcd cluster Operator performs a redeployment, the existing nodes are started with new pods similar to the initial bootstrap scale up.

12. Verify all nodes are updated to the latest revision.
   In a terminal that has access to the cluster as a `cluster-admin` user, run the following command:

$$\text{oc get etcd -o=jsonpath=\"\{range .items[0].status.conditions[? (@.type==\"NodeInstallerProgressing\")][.reason[\"\"]][.message[\"\"]\}\\n\"\}$$

Review the **NodeInstallerProgressing** status condition for etcd to verify that all nodes are at the latest revision. The output shows **AllNodesAtLatestRevision** upon successful update:

<table>
<thead>
<tr>
<th>AllNodesAtLatestRevision</th>
</tr>
</thead>
<tbody>
<tr>
<td>3 nodes are at revision 7</td>
</tr>
</tbody>
</table>

In this example, the latest revision number is **7**.

If the output includes multiple revision numbers, such as **2 nodes are at revision 6; 1 nodes**
13. After etcd is redeployed, force new rollouts for the control plane. The Kubernetes API server will reinstall itself on the other nodes because the kubelet is connected to API servers using an internal load balancer. In a terminal that has access to the cluster as a `cluster-admin` user, run the following commands.

a. Force a new rollout for the Kubernetes API server:

   ```bash
   $ oc patch kubeapiserver cluster -p="{"forceRedeploymentReason": "recovery-"$( date --rfc-3339=ns )"}" --type=merge
   
   Verify all nodes are updated to the latest revision.
   ```

   ```bash
   $ oc get kubeapiserver -o=jsonpath='{range .items[0].status.conditions[?(@.type=="NodeInstallerProgressing")]}{.reason}{"\n"}{.message}{"\n"}'
   
   Review the `NodeInstallerProgressing` status condition to verify that all nodes are at the latest revision. The output shows `AllNodesAtLatestRevision` upon successful update:
   ```

   ```bash
   AllNodesAtLatestRevision
   3 nodes are at revision 7
   ```

   In this example, the latest revision number is 7.

   If the output includes multiple revision numbers, such as 2 nodes are at revision 6; 1 nodes are at revision 7, this means that the update is still in progress. Wait a few minutes and try again.

b. Force a new rollout for the Kubernetes controller manager:

   ```bash
   $ oc patch kubecontrollermanager cluster -p="{"forceRedeploymentReason": "recovery-"$( date --rfc-3339=ns )"}" --type=merge
   
   Verify all nodes are updated to the latest revision.
   ```

   ```bash
   $ oc get kubecontrollermanager -o=jsonpath='{range .items[0].status.conditions[?(@.type=="NodeInstallerProgressing")]}{.reason}{"\n"}{.message}{"\n"}'
   
   Review the `NodeInstallerProgressing` status condition to verify that all nodes are at the latest revision. The output shows `AllNodesAtLatestRevision` upon successful update:
   ```

   ```bash
   AllNodesAtLatestRevision
   3 nodes are at revision 7
   ```

   In this example, the latest revision number is 7.
If the output includes multiple revision numbers, such as 2 nodes are at revision 6; 1 nodes are at revision 7, this means that the update is still in progress. Wait a few minutes and try again.

c. Force a new rollout for the Kubernetes scheduler:

```
$ oc patch kubescheduler cluster -p=\"\""{\"forceRedeploymentReason\": \"recovery-"\"$( date --rfc-3339=ns )\"\"}\"\" --type=merge
```

Verify all nodes are updated to the latest revision.

```
$ oc get kubescheduler -o=jsonpath='{range .items[0].status.conditions[? (@.type==\"NodeInstallerProgressing\")]}{.reason}{\"\"}{.message}{\"\"}'
```

Review the `NodeInstallerProgressing` status condition to verify that all nodes are at the latest revision. The output shows `AllNodesAtLatestRevision` upon successful update:

```
AllNodesAtLatestRevision
3 nodes are at revision 7
```

In this example, the latest revision number is 7.

If the output includes multiple revision numbers, such as 2 nodes are at revision 6; 1 nodes are at revision 7, this means that the update is still in progress. Wait a few minutes and try again.

14. Verify that all control plane hosts have started and joined the cluster.

In a terminal that has access to the cluster as a `cluster-admin` user, run the following command:

```
$ oc get pods -n openshift-etcd | grep -v etcd-quorum-guard | grep etcd
```

**Example output**

```
etcd-ip-10-0-143-125.ec2.internal               2/2     Running     0          9h
etcd-ip-10-0-154-194.ec2.internal               2/2     Running     0          9h
etcd-ip-10-0-173-171.ec2.internal               2/2     Running     0          9h
```

To ensure that all workloads return to normal operation following a recovery procedure, restart each pod that stores Kubernetes API information. This includes OpenShift Container Platform components such as routers, Operators, and third-party components.

Note that it might take several minutes after completing this procedure for all services to be restored. For example, authentication by using `oc login` might not immediately work until the OAuth server pods are restarted.

### 5.3.2.3. Issues and workarounds for restoring a persistent storage state

If your OpenShift Container Platform cluster uses persistent storage of any form, a state of the cluster is typically stored outside etcd. It might be an Elasticsearch cluster running in a pod or a database running in a `StatefulSet` object. When you restore from an etcd backup, the status of the workloads in OpenShift Container Platform is also restored. However, if the etcd snapshot is old, the status might be invalid or outdated.
The contents of persistent volumes (PVs) are never part of the etcd snapshot. When you restore an OpenShift Container Platform cluster from an etcd snapshot, non-critical workloads might gain access to critical data, or vice-versa.

The following are some example scenarios that produce an out-of-date status:

- MySQL database is running in a pod backed up by a PV object. Restoring OpenShift Container Platform from an etcd snapshot does not bring back the volume on the storage provider, and does not produce a running MySQL pod, despite the pod repeatedly attempting to start. You must manually restore this pod by restoring the volume on the storage provider, and then editing the PV to point to the new volume.

- Pod P1 is using volume A, which is attached to node X. If the etcd snapshot is taken while another pod uses the same volume on node Y, then when the etcd restore is performed, pod P1 might not be able to start correctly due to the volume still being attached to node Y. OpenShift Container Platform is not aware of the attachment, and does not automatically detach it. When this occurs, the volume must be manually detached from node Y so that the volume can attach on node X, and then pod P1 can start.

- Cloud provider or storage provider credentials were updated after the etcd snapshot was taken. This causes any CSI drivers or Operators that depend on the those credentials to not work. You might have to manually update the credentials required by those drivers or Operators.

- A device is removed or renamed from OpenShift Container Platform nodes after the etcd snapshot is taken. The Local Storage Operator creates symlinks for each PV that it manages from `/dev/disk/by-id` or `/dev` directories. This situation might cause the local PVs to refer to devices that no longer exist. To fix this problem, an administrator must:
  1. Manually remove the PVs with invalid devices.
  2. Remove symlinks from respective nodes.
  3. Delete `LocalVolume` or `LocalVolumeSet` objects (see Storage → Configuring persistent storage → Persistent storage using local volumes → Deleting the Local Storage Operator Resources).

Additional resources

- See Accessing the hosts for how to create a bastion host to access OpenShift Container Platform instances and the control plane nodes with SSH.

5.3.3. Recovering from expired control plane certificates

5.3.3.1. Recovering from expired control plane certificates

The cluster can automatically recover from expired control plane certificates.

However, you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. For user-provisioned installations, you might also need to approve pending kubelet serving CSRs.

Use the following steps to approve the pending CSRs:
Procedure

1. Get the list of current CSRs:
   
   | $ oc get csr |

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>SIGNERNAME</th>
<th>REQUESTOR</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-2s94x</td>
<td>8m3s</td>
<td>kubernetes.io/kubelet-serving</td>
<td>system:node:&lt;node_name&gt;</td>
</tr>
<tr>
<td>Pending 1</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>csr-4bd6t</td>
<td>8m3s</td>
<td>kubernetes.io/kubelet-serving</td>
<td>system:node:&lt;node_name&gt;</td>
</tr>
<tr>
<td>Pending 2</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>csr-4hl85</td>
<td>13m</td>
<td>kubernetes.io/kube-apiserver-client-kubelet</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper Pending 3</td>
</tr>
<tr>
<td>csr-zhhhp</td>
<td>3m8s</td>
<td>kubernetes.io/kube-apiserver-client-kubelet</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper Pending 4</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

1 2 A pending kubelet service CSR (for user-provisioned installations).
3 4 A pending node-bootstrapper CSR.

2. Review the details of a CSR to verify that it is valid:

   | $ oc describe csr <csr_name> 1 |

   1 <csr_name> is the name of a CSR from the list of current CSRs.

3. Approve each valid node-bootstrapper CSR:

   | $ oc adm certificate approve <csr_name> |

4. For user-provisioned installations, approve each valid kubelet serving CSR:

   | $ oc adm certificate approve <csr_name> |
