OpenShift Container Platform 4.6

Installing

Installing and configuring OpenShift Container Platform clusters
Abstract

This document provides information about installing OpenShift Container Platform and details about some configuration processes.
# Table of Contents

## CHAPTER 1. MIRRORING IMAGES FOR A DISCONNECTED INSTALLATION

1.1. PREREQUISITES .................................................. 45
1.2. ABOUT THE MIRROR REGISTRY .................................. 45
1.3. PREPARING YOUR MIRROR HOST
   1.3.1. Installing the OpenShift CLI by downloading the binary
   1.3.1.1. Installing the OpenShift CLI on Linux ....................... 46
   1.3.1.2. Installing the OpenShift CLI on Windows .................. 47
   1.3.1.3. Installing the OpenShift CLI on macOS .................... 47
1.4. CONFIGURING CREDENTIALS THAT ALLOW IMAGES TO BE MIRRORED 48
1.5. MIRROR REGISTRY FOR RED HAT OPENSIGHT
   1.5.1. Mirror registry for Red Hat OpenShift introduction ........ 50
   1.5.2. Mirroring on a local host with mirror registry for Red Hat OpenShift 51
   1.5.3. Mirroring on a remote host with mirror registry for Red Hat OpenShift 53
1.6. UPGRADING THE MIRROR REGISTRY FOR RED HAT OPENSIGHT
   1.6.1. Uninstalling the mirror registry for Red Hat OpenShift .... 54
   1.6.2. Mirror registry for Red Hat OpenShift flags ............... 54
1.7. MIRRORING THE OPENSIGHT CONTAINER PLATFORM IMAGE REPOSITORY 56
1.8. THE CLUSTER SAMPLES OPERATOR IN A DISCONNECTED ENVIRONMENT 59
1.9. NEXT STEPS .................................................... 59
1.10. ADDITIONAL RESOURCES ...................................... 59

## CHAPTER 2. INSTALLING ON AWS

2.1. CONFIGURING AN AWS ACCOUNT ................................ 60
   2.1.1. Configuring Route 53 ........................................ 60
   2.1.1.1. Ingress Operator endpoint configuration for AWS Route 53 60
   2.1.2. AWS account limits ....................................... 61
   2.1.3. Required AWS permissions ................................ 63
   2.1.4. Creating an IAM user ..................................... 71
   2.1.5. Supported AWS regions ................................... 72
   2.1.6. Next steps ................................................. 73
2.2. MANUALLY CREATING IAM FOR AWS ......................... 73
   2.2.1. Alternatives to storing administrator-level secrets in the kube-system project 73
   2.2.2. Manually create IAM ..................................... 74
   2.2.3. Admin credentials root secret format ....................... 76
   2.2.4. Upgrading clusters with manually maintained credentials 76
   2.2.5. Mint mode ............................................... 77
   2.2.6. Mint Mode with removal or rotation of the admin credential 77
   2.2.7. Next steps ............................................... 78
2.3. INSTALLING A CLUSTER QUICKLY ON AWS ................. 78
   2.3.1. Prerequisites ............................................. 78
   2.3.2. Internet access for OpenShift Container Platform ........ 78
   2.3.3. Generating an SSH private key and adding it to the agent 79
   2.3.4. Obtaining the installation program ....................... 80
   2.3.5. Deploying the cluster ................................... 81
   2.3.6. Installing the OpenShift CLI by downloading the binary 83
   2.3.6.1. Installing the OpenShift CLI on Linux .................. 84
   2.3.6.2. Installing the OpenShift CLI on Windows .......... 84
   2.3.6.3. Installing the OpenShift CLI on macOS .......... 85
   2.3.7. Logging in to the cluster by using the CLI ............... 85
   2.3.8. Logging in to the cluster by using the web console ..... 86
   2.3.9. Telemetry access for OpenShift Container Platform ... 86
2.3.10. Next steps

2.4. INSTALLING A CLUSTER ON AWS WITH CUSTOMIZATIONS

2.4.1. Prerequisites

2.4.2. Internet access for OpenShift Container Platform

2.4.3. Generating an SSH private key and adding it to the agent

2.4.4. Obtaining the installation program

2.4.5. Creating the installation configuration file

2.4.5.1. Installation configuration parameters

2.4.5.1.1. Required configuration parameters

2.4.5.1.2. Network configuration parameters

2.4.5.1.3. Optional configuration parameters

2.4.5.1.4. Optional AWS configuration parameters

2.4.5.2. Sample customized install-config.yaml file for AWS

2.4.5.3. Configuring the cluster-wide proxy during installation

2.4.6. Deploying the cluster

2.4.7. Installing the OpenShift CLI by downloading the binary

2.4.7.1. Installing the OpenShift CLI on Linux

2.4.7.2. Installing the OpenShift CLI on Windows

2.4.7.3. Installing the OpenShift CLI on macOS

2.4.8. Logging in to the cluster by using the CLI

2.4.9. Logging in to the cluster by using the web console

2.4.10. Telemetry access for OpenShift Container Platform

2.4.11. Next steps

2.5. INSTALLING A CLUSTER ON AWS WITH NETWORK CUSTOMIZATIONS

2.5.1. Prerequisites

2.5.2. Internet access for OpenShift Container Platform

2.5.3. Generating an SSH private key and adding it to the agent

2.5.4. Obtaining the installation program

2.5.5. Network configuration phases

2.5.6. Creating the installation configuration file

2.5.6.1. Installation configuration parameters

2.5.6.1.1. Required configuration parameters

2.5.6.1.2. Network configuration parameters

2.5.6.1.3. Optional configuration parameters

2.5.6.1.4. Optional AWS configuration parameters

2.5.6.2. Sample customized install-config.yaml file for AWS

2.5.6.3. Configuring the cluster-wide proxy during installation

2.5.7. Cluster Network Operator configuration

2.5.7.1. Cluster Network Operator configuration object

defaultNetwork object configuration

Configuration for the OpenShift SDN CNI cluster network provider

Configuration for the OVN-Kubernetes CNI cluster network provider

kubeProxyConfig object configuration

2.5.8. Specifying advanced network configuration

2.5.9. Configuring an Ingress Controller Network Load Balancer on a new AWS cluster

2.5.10. Configuring hybrid networking with OVN-Kubernetes

2.5.11. Deploying the cluster

2.5.12. Installing the OpenShift CLI by downloading the binary

2.5.12.1. Installing the OpenShift CLI on Linux

2.5.12.2. Installing the OpenShift CLI on Windows

2.5.12.3. Installing the OpenShift CLI on macOS

2.5.13. Logging in to the cluster by using the CLI

2.5.14. Logging in to the cluster by using the web console
2.6. INSTALLING A CLUSTER ON AWS IN A RESTRICTED NETWORK

2.6.1. Prerequisites

2.6.2. About installations in restricted networks
   2.6.2.1. Additional limits

2.6.3. About using a custom VPC
   2.6.3.1. Requirements for using your VPC
   2.6.3.2. VPC validation
   2.6.3.3. Division of permissions
   2.6.3.4. Isolation between clusters

2.6.4. Internet access for OpenShift Container Platform

2.6.5. Generating an SSH private key and adding it to the agent

2.6.6. Creating the installation configuration file
   2.6.6.1. Installation configuration parameters
      2.6.6.1.1. Required configuration parameters
      2.6.6.1.2. Network configuration parameters
      2.6.6.1.3. Optional configuration parameters
      2.6.6.1.4. Optional AWS configuration parameters
   2.6.6.2. Sample customized install-config.yaml file for AWS
   2.6.6.3. Configuring the cluster-wide proxy during installation

2.6.7. Deploying the cluster

2.6.8. Installing the OpenShift CLI by downloading the binary
   2.6.8.1. Installing the OpenShift CLI on Linux
   2.6.8.2. Installing the OpenShift CLI on Windows
   2.6.8.3. Installing the OpenShift CLI on macOS

2.6.9. Logging in to the cluster by using the CLI

2.6.10. Disabling the default OperatorHub sources

2.6.11. Telemetry access for OpenShift Container Platform

2.6.12. Next steps

2.7. INSTALLING A CLUSTER ON AWS INTO AN EXISTING VPC

2.7.1. Prerequisites

2.7.2. About using a custom VPC
   2.7.2.1. Requirements for using your VPC
   2.7.2.2. VPC validation
   2.7.2.3. Division of permissions
   2.7.2.4. Isolation between clusters

2.7.3. Internet access for OpenShift Container Platform

2.7.4. Generating an SSH private key and adding it to the agent

2.7.5. Obtaining the installation program

2.7.6. Creating the installation configuration file
   2.7.6.1. Installation configuration parameters
      2.7.6.1.1. Required configuration parameters
      2.7.6.1.2. Network configuration parameters
      2.7.6.1.3. Optional configuration parameters
      2.7.6.1.4. Optional AWS configuration parameters
   2.7.6.2. Sample customized install-config.yaml file for AWS
   2.7.6.3. Configuring the cluster-wide proxy during installation

2.7.7. Deploying the cluster

2.7.8. Installing the OpenShift CLI by downloading the binary
   2.7.8.1. Installing the OpenShift CLI on Linux
   2.7.8.2. Installing the OpenShift CLI on Windows
   2.7.8.3. Installing the OpenShift CLI on macOS
2.7.9. Logging in to the cluster by using the CLI
2.7.10. Logging in to the cluster by using the web console
2.7.11. Telemetry access for OpenShift Container Platform
2.7.12. Next steps

2.8. INSTALLING A PRIVATE CLUSTER ON AWS
2.8.1. Prerequisites
2.8.2. Private clusters
  2.8.2.1. Private clusters in AWS
  2.8.2.1.1. Limitations
2.8.3. About using a custom VPC
  2.8.3.1. Requirements for using your VPC
  2.8.3.2. VPC validation
  2.8.3.3. Division of permissions
  2.8.3.4. Isolation between clusters
2.8.4. Internet access for OpenShift Container Platform
2.8.5. Generating an SSH private key and adding it to the agent
2.8.6. Obtaining the installation program
2.8.7. Manually creating the installation configuration file
  2.8.7.1. Installation configuration parameters
    2.8.7.1.1. Required configuration parameters
    2.8.7.1.2. Network configuration parameters
    2.8.7.1.3. Optional configuration parameters
    2.8.7.1.4. Optional AWS configuration parameters
  2.8.7.2. Sample customized install-config.yaml file for AWS
  2.8.7.3. Configuring the cluster-wide proxy during installation
2.8.8. Deploying the cluster
2.8.9. Installing the OpenShift CLI by downloading the binary
  2.8.9.1. Installing the OpenShift CLI on Linux
  2.8.9.2. Installing the OpenShift CLI on Windows
  2.8.9.3. Installing the OpenShift CLI on macOS
2.8.10. Logging in to the cluster by using the CLI
2.8.11. Logging in to the cluster by using the web console
2.8.12. Telemetry access for OpenShift Container Platform
2.8.13. Next steps

2.9. INSTALLING A CLUSTER ON AWS INTO A GOVERNMENT REGION
2.9.1. Prerequisites
2.9.2. AWS government regions
2.9.3. Private clusters
  2.9.3.1. Private clusters in AWS
  2.9.3.1.1. Limitations
2.9.4. About using a custom VPC
  2.9.4.1. Requirements for using your VPC
  2.9.4.2. VPC validation
  2.9.4.3. Division of permissions
  2.9.4.4. Isolation between clusters
2.9.5. Internet access for OpenShift Container Platform
2.9.6. Generating an SSH private key and adding it to the agent
2.9.7. Obtaining the installation program
2.9.8. Manually creating the installation configuration file
  2.9.8.1. Installation configuration parameters
    2.9.8.1.1. Required configuration parameters
    2.9.8.1.2. Network configuration parameters
    2.9.8.1.3. Optional configuration parameters

OpenShift Container Platform 4.6 Installing
2.9.8.1.4. Optional AWS configuration parameters
2.9.8.2. Sample customized install-config.yaml file for AWS
2.9.8.3. AWS regions without a published RHCOS AMI
2.9.8.4. Uploading a custom RHCOS AMI in AWS
2.9.8.5. Configuring the cluster-wide proxy during installation
2.9.9. Deploying the cluster
2.9.10. Installing the OpenShift CLI by downloading the binary
2.9.10.1. Installing the OpenShift CLI on Linux
2.9.10.2. Installing the OpenShift CLI on Windows
2.9.10.3. Installing the OpenShift CLI on macOS
2.9.11. Logging in to the cluster by using the CLI
2.9.12. Logging in to the cluster by using the web console
2.9.13. Telemetry access for OpenShift Container Platform
2.9.14. Next steps
2.10. INSTALLING A CLUSTER ON USER-PROVISIONED INFRASTRUCTURE IN AWS BY USING CLOUDFORMATION TEMPLATES
2.10.1. Prerequisites
2.10.2. Internet access for OpenShift Container Platform
2.10.3. Required AWS infrastructure components
2.10.3.1. Cluster machines
2.10.3.2. Other infrastructure components
2.10.3.3. Certificate signing requests management
2.10.3.4. Required AWS permissions
2.10.4. Obtaining the installation program
2.10.5. Generating an SSH private key and adding it to the agent
2.10.6. Creating the installation files for AWS
2.10.6.1. Optional: Creating a separate /var partition
2.10.6.2. Creating the installation configuration file
2.10.6.3. Configuring the cluster-wide proxy during installation
2.10.6.4. Creating the Kubernetes manifest and Ignition config files
2.10.7. Extracting the infrastructure name
2.10.8. Creating a VPC in AWS
2.10.8.1. CloudFormation template for the VPC
2.10.9. Creating networking and load balancing components in AWS
2.10.9.1. CloudFormation template for the network and load balancers
2.10.10. Creating security group and roles in AWS
2.10.10.1. CloudFormation template for security objects
2.10.11. RHCOS AMIs for the AWS infrastructure
2.10.11.1. AWS regions without a published RHCOS AMI
2.10.11.2. Uploading a custom RHCOS AMI in AWS
2.10.12. Creating the bootstrap node in AWS
2.10.12.1. CloudFormation template for the bootstrap machine
2.10.13. Creating the control plane machines in AWS
2.10.13.1. CloudFormation template for control plane machines
2.10.14. Creating the worker nodes in AWS
2.10.14.1. CloudFormation template for worker machines
2.10.15. Initializing the bootstrap sequence on AWS with user-provisioned infrastructure
2.10.16. Installing the OpenShift CLI by downloading the binary
2.10.16.1. Installing the OpenShift CLI on Linux
2.10.16.2. Installing the OpenShift CLI on Windows
2.10.16.3. Installing the OpenShift CLI on macOS
2.10.17. Logging in to the cluster by using the CLI
2.10.18. Approving the certificate signing requests for your machines
2.10.19. Initial Operator configuration
  2.10.19.1. Image registry storage configuration
    2.10.19.1.1. Configuring registry storage for AWS with user-provisioned infrastructure
    2.10.19.1.2. Configuring storage for the image registry in non-production clusters
  2.10.20. Deleting the bootstrap resources
  2.10.21. Creating the Ingress DNS Records
  2.10.22. Completing an AWS installation on user-provisioned infrastructure
  2.10.23. Logging in to the cluster by using the web console
  2.10.24. Telemetry access for OpenShift Container Platform
  2.10.25. Additional resources
  2.10.26. Next steps

2.11. INSTALLING A CLUSTER ON AWS IN A RESTRICTED NETWORK WITH USER-PROVISIONED INFRASTRUCTURE
  2.11.1. Prerequisites
  2.11.2. About installations in restricted networks
    2.11.2.1. Additional limits
  2.11.3. Internet access for OpenShift Container Platform
  2.11.4. Required AWS infrastructure components
    2.11.4.1. Cluster machines
    2.11.4.2. Other infrastructure components
    2.11.4.3. Certificate signing requests management
    2.11.4.4. Required AWS permissions
  2.11.5. Generating an SSH private key and adding it to the agent
  2.11.6. Creating the installation files for AWS
    2.11.6.1. Optional: Creating a separate /var partition
    2.11.6.2. Creating the installation configuration file
    2.11.6.3. Configuring the cluster-wide proxy during installation
    2.11.6.4. Creating the Kubernetes manifest and Ignition config files
  2.11.7. Extracting the infrastructure name
  2.11.8. Creating a VPC in AWS
    2.11.8.1. CloudFormation template for the VPC
  2.11.9. Creating networking and load balancing components in AWS
    2.11.9.1. CloudFormation template for the network and load balancers
  2.11.10. Creating security group and roles in AWS
    2.11.10.1. CloudFormation template for security objects
  2.11.11. RHCOS AMIs for the AWS infrastructure
  2.11.12. Creating the bootstrap node in AWS
    2.11.12.1. CloudFormation template for the bootstrap machine
  2.11.13. Creating the control plane machines in AWS
    2.11.13.1. CloudFormation template for control plane machines
  2.11.14. Creating the worker nodes in AWS
    2.11.14.1. CloudFormation template for worker machines
  2.11.15. Initializing the bootstrap sequence on AWS with user-provisioned infrastructure
  2.11.16. Logging in to the cluster by using the CLI
  2.11.17. Approving the certificate signing requests for your machines
  2.11.18. Initial Operator configuration
    2.11.18.1. Disabling the default OperatorHub sources
    2.11.18.2. Image registry storage configuration
      2.11.18.2.1. Configuring registry storage for AWS with user-provisioned infrastructure
      2.11.18.2.2. Configuring storage for the image registry in non-production clusters
  2.11.19. Deleting the bootstrap resources
  2.11.20. Creating the Ingress DNS Records
  2.11.21. Completing an AWS installation on user-provisioned infrastructure
2.11.22. Logging in to the cluster by using the web console
2.11.23. Telemetry access for OpenShift Container Platform
2.11.24. Additional resources
2.11.25. Next steps

2.12. UNINSTALLING A CLUSTER ON AWS
2.12.1. Removing a cluster that uses installer-provisioned infrastructure

CHAPTER 3. INSTALLING ON AZURE

3.1. CONFIGURING AN AZURE ACCOUNT
3.1.1. Azure account limits
3.1.2. Configuring a public DNS zone in Azure
3.1.3. Increasing Azure account limits
3.1.4. Required Azure roles
3.1.5. Creating a service principal
3.1.6. Supported Azure regions
   Supported Azure public regions
   Supported Azure Government regions
3.1.7. Next steps

3.2. MANUALLY CREATING IAM FOR AZURE
3.2.1. Alternatives to storing administrator-level secrets in the kube-system project
3.2.2. Manually create IAM
3.2.3. Admin credentials root secret format
3.2.4. Upgrading clusters with manually maintained credentials
3.2.5. Mint mode
3.2.6. Next steps

3.3. INSTALLING A CLUSTER QUICKLY ON AZURE
3.3.1. Prerequisites
3.3.2. Internet access for OpenShift Container Platform
3.3.3. Generating an SSH private key and adding it to the agent
3.3.4. Obtaining the installation program
3.3.5. Deploying the cluster
3.3.6. Installing the OpenShift CLI by downloading the binary
   3.3.6.1. Installing the OpenShift CLI on Linux
   3.3.6.2. Installing the OpenShift CLI on Windows
   3.3.6.3. Installing the OpenShift CLI on macOS
3.3.7. Logging in to the cluster by using the CLI
3.3.8. Telemetry access for OpenShift Container Platform
3.3.9. Next steps

3.4. INSTALLING A CLUSTER ON AZURE WITH CUSTOMIZATIONS
3.4.1. Prerequisites
3.4.2. Internet access for OpenShift Container Platform
3.4.3. Generating an SSH private key and adding it to the agent
3.4.4. Obtaining the installation program
3.4.5. Creating the installation configuration file
   3.4.5.1. Installation configuration parameters
      3.4.5.1.1. Required configuration parameters
      3.4.5.1.2. Network configuration parameters
      3.4.5.1.3. Optional configuration parameters
      3.4.5.1.4. Additional Azure configuration parameters
   3.4.5.2. Sample customized install-config.yaml file for Azure
   3.4.5.3. Configuring the cluster-wide proxy during installation
3.4.6. Deploying the cluster
3.4.7. Installing the OpenShift CLI by downloading the binary
3.4.7.1. Installing the OpenShift CLI on Linux
3.4.7.2. Installing the OpenShift CLI on Windows
3.4.7.3. Installing the OpenShift CLI on macOS
3.4.8. Logging in to the cluster by using the CLI
3.4.9. Telemetry access for OpenShift Container Platform
3.4.10. Next steps

3.5. INSTALLING A CLUSTER ON AZURE WITH NETWORK CUSTOMIZATIONS
3.5.1. Prerequisites
3.5.2. Internet access for OpenShift Container Platform
3.5.3. Generating an SSH private key and adding it to the agent
3.5.4. Obtaining the installation program
3.5.5. Creating the installation configuration file
  3.5.5.1. Installation configuration parameters
    3.5.5.1.1. Required configuration parameters
    3.5.5.1.2. Network configuration parameters
    3.5.5.1.3. Optional configuration parameters
    3.5.5.1.4. Additional Azure configuration parameters
  3.5.5.2. Sample customized install-config.yaml file for Azure
  3.5.5.3. Configuring the cluster-wide proxy during installation
3.5.6. Network configuration phases
3.5.7. Specifying advanced network configuration
3.5.8. Cluster Network Operator configuration
  3.5.8.1. Cluster Network Operator configuration object
    defaultNetwork object configuration
    Configuration for the OpenShift SDN CNI cluster network provider
    Configuration for the OVN-Kubernetes CNI cluster network provider
    kubeProxyConfig object configuration
3.5.9. Configuring hybrid networking with OVN-Kubernetes
3.5.10. Deploying the cluster
3.5.11. Installing the OpenShift CLI by downloading the binary
  3.5.11.1. Installing the OpenShift CLI on Linux
  3.5.11.2. Installing the OpenShift CLI on Windows
  3.5.11.3. Installing the OpenShift CLI on macOS
3.5.12. Logging in to the cluster by using the CLI
3.5.13. Telemetry access for OpenShift Container Platform
3.5.14. Next steps

3.6. INSTALLING A CLUSTER ON AZURE INTO AN EXISTING VNET
3.6.1. Prerequisites
3.6.2. About reusing a VNet for your OpenShift Container Platform cluster
  3.6.2.1. Requirements for using your VNet
    3.6.2.1.1. Network security group requirements
  3.6.2.2. Division of permissions
  3.6.2.3. Isolation between clusters
3.6.3. Internet access for OpenShift Container Platform
3.6.4. Generating an SSH private key and adding it to the agent
3.6.5. Obtaining the installation program
3.6.6. Creating the installation configuration file
  3.6.6.1. Installation configuration parameters
    3.6.6.1.1. Required configuration parameters
    3.6.6.1.2. Network configuration parameters
    3.6.6.1.3. Optional configuration parameters
    3.6.6.1.4. Additional Azure configuration parameters
  3.6.6.2. Sample customized install-config.yaml file for Azure
3.6.6.3. Configuring the cluster-wide proxy during installation
3.6.7. Deploying the cluster
3.6.8. Installing the OpenShift CLI by downloading the binary
  3.6.8.1. Installing the OpenShift CLI on Linux
  3.6.8.2. Installing the OpenShift CLI on Windows
  3.6.8.3. Installing the OpenShift CLI on macOS
3.6.9. Logging in to the cluster by using the CLI
3.6.10. Telemetry access for OpenShift Container Platform
3.6.11. Next steps

3.7. INSTALLING A PRIVATE CLUSTER ON AZURE
3.7.1. Prerequisites
3.7.2. Private clusters
  3.7.2.1. Private clusters in Azure
    3.7.2.1.1. Limitations
  3.7.2.2. User-defined outbound routing
    Private cluster with network address translation
    Private cluster with Azure Firewall
    Private cluster with a proxy configuration
    Private cluster with no Internet access
3.7.3. About reusing a VNet for your OpenShift Container Platform cluster
  3.7.3.1. Requirements for using your VNet
    3.7.3.1.1. Network security group requirements
  3.7.3.2. Division of permissions
  3.7.3.3. Isolation between clusters
3.7.4. Internet access for OpenShift Container Platform
3.7.5. Generating an SSH private key and adding it to the agent
3.7.6. Obtaining the installation program
3.7.7. Manually creating the installation configuration file
  3.7.7.1. Installation configuration parameters
    3.7.7.1.1. Required configuration parameters
    3.7.7.1.2. Network configuration parameters
    3.7.7.1.3. Optional configuration parameters
    3.7.7.1.4. Additional Azure configuration parameters
  3.7.7.2. Sample customized install-config.yaml file for Azure
  3.7.7.3. Configuring the cluster-wide proxy during installation
3.7.8. Deploying the cluster
3.7.9. Installing the OpenShift CLI by downloading the binary
  3.7.9.1. Installing the OpenShift CLI on Linux
  3.7.9.2. Installing the OpenShift CLI on Windows
  3.7.9.3. Installing the OpenShift CLI on macOS
3.7.10. Logging in to the cluster by using the CLI
3.7.11. Telemetry access for OpenShift Container Platform
3.7.12. Next steps

3.8. INSTALLING A CLUSTER ON AZURE INTO A GOVERNMENT REGION
3.8.1. Prerequisites
3.8.2. Azure government regions
3.8.3. Private clusters
  3.8.3.1. Private clusters in Azure
    3.8.3.1.1. Limitations
  3.8.3.2. User-defined outbound routing
    Private cluster with network address translation
    Private cluster with Azure Firewall
    Private cluster with a proxy configuration
Private cluster with no Internet access

3.8.4. About reusing a VNet for your OpenShift Container Platform cluster

3.8.4.1. Requirements for using your VNet

3.8.4.1.1. Network security group requirements

3.8.4.2. Division of permissions

3.8.4.3. Isolation between clusters

3.8.5. Internet access for OpenShift Container Platform

3.8.6. Generating an SSH private key and adding it to the agent

3.8.7. Obtaining the installation program

3.8.8. Manually creating the installation configuration file

3.8.8.1. Installation configuration parameters

3.8.8.1.1. Required configuration parameters

3.8.8.1.2. Network configuration parameters

3.8.8.1.3. Optional configuration parameters

3.8.8.1.4. Additional Azure configuration parameters

3.8.8.2. Sample customized install-config.yaml file for Azure

3.8.8.3. Configuring the cluster-wide proxy during installation

3.8.9. Deploying the cluster

3.8.10. Installing the OpenShift CLI by downloading the binary

3.8.10.1. Installing the OpenShift CLI on Linux

3.8.10.2. Installing the OpenShift CLI on Windows

3.8.10.3. Installing the OpenShift CLI on macOS

3.8.11. Logging in to the cluster by using the CLI

3.8.12. Telemetry access for OpenShift Container Platform

3.8.13. Next steps

3.9. INSTALLING A CLUSTER ON AZURE USING ARM TEMPLATES

3.9.1. Prerequisites

3.9.2. Internet access for OpenShift Container Platform

3.9.3. Configuring your Azure project

3.9.3.1. Azure account limits

3.9.3.2. Configuring a public DNS zone in Azure

3.9.3.3. Increasing Azure account limits

3.9.3.4. Certificate signing requests management

3.9.3.5. Required Azure roles

3.9.3.6. Creating a service principal

3.9.3.7. Supported Azure regions

3.9.3.8. Supported Azure public regions

3.9.4. Obtaining the installation program

3.9.5. Generating an SSH private key and adding it to the agent

3.9.6. Creating the installation files for Azure

3.9.6.1. Optional: Creating a separate /var partition

3.9.6.2. Creating the installation configuration file

3.9.6.3. Configuring the cluster-wide proxy during installation

3.9.6.4. Exporting common variables for ARM templates

3.9.6.5. Creating the Kubernetes manifest and Ignition config files

3.9.7. Creating the Azure resource group and identity

3.9.8. uploading the RHCOS cluster image and bootstrap Ignition config file

3.9.9. Example for creating DNS zones

3.9.10. Creating a VNet in Azure

3.9.10.1. ARM template for the VNet

3.9.11. Deploying the RHCOS cluster image for the Azure infrastructure

3.9.11.1. ARM template for image storage
3.9.12. Networking requirements for user-provisioned infrastructure
   Network topology requirements
   Load balancers
3.9.13. Creating networking and load balancing components in Azure
   3.9.13.1. ARM template for the network and load balancers
   3.9.14.1. ARM template for the bootstrap machine
3.9.15. Creating the control plane machines in Azure
   3.9.15.1. ARM template for control plane machines
3.9.16. Wait for bootstrap completion and remove bootstrap resources in Azure
3.9.17. Creating additional worker machines in Azure
   3.9.17.1. ARM template for worker machines
3.9.18. Installing the OpenShift CLI by downloading the binary
   3.9.18.1. Installing the OpenShift CLI on Linux
   3.9.18.2. Installing the OpenShift CLI on Windows
   3.9.18.3. Installing the OpenShift CLI on macOS
3.9.19. Logging in to the cluster by using the CLI
3.9.20. Approving the certificate signing requests for your machines
3.9.21. Adding the Ingress DNS records
3.9.22. Completing an Azure installation on user-provisioned infrastructure
3.9.23. Telemetry access for OpenShift Container Platform

3.10. UNINSTALLING A CLUSTER ON AZURE
3.10.1. Removing a cluster that uses installer-provisioned infrastructure

CHAPTER 4. INSTALLING ON GCP ................................................................. 687
4.1. CONFIGURING A GCP PROJECT ....................................................... 687
   4.1.1. Creating a GCP project
   4.1.2. Enabling API services in GCP
   4.1.3. Configuring DNS for GCP
   4.1.4. GCP account limits
   4.1.5. Creating a service account in GCP
      4.1.5.1. Required GCP permissions
   4.1.6. Supported GCP regions
   4.1.7. Next steps
4.2. MANUALLY CREATING IAM FOR GCP ........................................... 693
   4.2.1. Alternatives to storing administrator-level secrets in the kube-system project
   4.2.2. Manually create IAM
   4.2.3. Admin credentials root secret format
   4.2.4. Upgrading clusters with manually maintained credentials
   4.2.5. Mint mode
   4.2.6. Mint Mode with removal or rotation of the admin credential
   4.2.7. Next steps
4.3. INSTALLING A CLUSTER QUICKLY ON GCP ................................. 697
   4.3.1. Prerequisites
   4.3.2. Internet access for OpenShift Container Platform
   4.3.3. Generating an SSH private key and adding it to the agent
   4.3.4. Obtaining the installation program
   4.3.5. Deploying the cluster
   4.3.6. Installing the OpenShift CLI by downloading the binary
      4.3.6.1. Installing the OpenShift CLI on Linux
      4.3.6.2. Installing the OpenShift CLI on Windows
      4.3.6.3. Installing the OpenShift CLI on macOS
   4.3.7. Logging in to the cluster by using the CLI
4.3.8. Telemetry access for OpenShift Container Platform

4.3.9. Next steps

4.4. INSTALLING A CLUSTER ON GCP WITH CUSTOMIZATIONS

4.4.1. Prerequisites

4.4.2. Internet access for OpenShift Container Platform

4.4.3. Generating an SSH private key and adding it to the agent

4.4.4. Obtaining the installation program

4.4.5. Creating the installation configuration file

4.4.5.1. Installation configuration parameters

4.4.5.1.1. Required configuration parameters

4.4.5.1.2. Network configuration parameters

4.4.5.1.3. Optional configuration parameters

4.4.5.1.4. Additional Google Cloud Platform (GCP) configuration parameters

4.4.5.2. Sample customized install-config.yaml file for GCP

4.4.5.3. Configuring the cluster-wide proxy during installation

4.4.6. Deploying the cluster

4.4.7. Installing the OpenShift CLI by downloading the binary

4.4.7.1. Installing the OpenShift CLI on Linux

4.4.7.2. Installing the OpenShift CLI on Windows

4.4.7.3. Installing the OpenShift CLI on macOS

4.4.8. Logging in to the cluster by using the CLI

4.4.9. Telemetry access for OpenShift Container Platform

4.4.10. Next steps

4.5. INSTALLING A CLUSTER ON GCP WITH NETWORK CUSTOMIZATIONS

4.5.1. Prerequisites

4.5.2. Internet access for OpenShift Container Platform

4.5.3. Generating an SSH private key and adding it to the agent

4.5.4. Obtaining the installation program

4.5.5. Creating the installation configuration file

4.5.5.1. Installation configuration parameters

4.5.5.1.1. Required configuration parameters

4.5.5.1.2. Network configuration parameters

4.5.5.1.3. Optional configuration parameters

4.5.5.1.4. Additional Google Cloud Platform (GCP) configuration parameters

4.5.5.2. Sample customized install-config.yaml file for GCP

4.5.5.3. Configuring the cluster-wide proxy during installation

4.5.6. Network configuration phases

4.5.7. Specifying advanced network configuration

4.5.8. Cluster Network Operator configuration

4.5.8.1. Cluster Network Operator configuration object

4.5.8.1.1. defaultNetwork object configuration

4.5.8.1.2. Configuration for the OpenShift SDN CNI cluster network provider

4.5.8.1.3. Configuration for the OVN-Kubernetes CNI cluster network provider

4.5.8.1.4. kubeProxyConfig object configuration

4.5.9. Deploying the cluster

4.5.10. Installing the OpenShift CLI by downloading the binary

4.5.10.1. Installing the OpenShift CLI on Linux

4.5.10.2. Installing the OpenShift CLI on Windows

4.5.10.3. Installing the OpenShift CLI on macOS

4.5.11. Logging in to the cluster by using the CLI

4.5.12. Telemetry access for OpenShift Container Platform

4.5.13. Next steps

4.6. INSTALLING A CLUSTER ON GCP IN A RESTRICTED NETWORK

4.6.1. Prerequisites

4.6.2. Internet access for OpenShift Container Platform

4.6.3. Generating an SSH private key and adding it to the agent

4.6.4. Obtaining the installation program

4.6.5. Creating the installation configuration file

4.6.5.1. Installation configuration parameters

4.6.5.1.1. Required configuration parameters

4.6.5.1.2. Network configuration parameters

4.6.5.1.3. Optional configuration parameters

4.6.5.1.4. Additional Google Cloud Platform (GCP) configuration parameters

4.6.5.2. Sample customized install-config.yaml file for GCP

4.6.5.3. Configuring the cluster-wide proxy during installation

4.6.6. Specifying restricted network configuration

4.6.7. Cluster Network Operator configuration

4.6.7.1. defaultNetwork object configuration

4.6.7.2. Configuration for the OpenShift SDN CNI cluster network provider

4.6.7.3. Configuration for the OVN-Kubernetes CNI cluster network provider

4.6.7.4. kubeProxyConfig object configuration

4.6.8. Deploying the cluster

4.6.9. Installing the OpenShift CLI by downloading the binary

4.6.9.1. Installing the OpenShift CLI on Linux

4.6.9.2. Installing the OpenShift CLI on Windows

4.6.9.3. Installing the OpenShift CLI on macOS

4.6.10. Logging in to the cluster by using the CLI

4.6.11. Telemetry access for OpenShift Container Platform

4.6.12. Next steps
4.6.1. Prerequisites

4.6.2. About installations in restricted networks

4.6.2.1. Additional limits

4.6.3. Internet access for OpenShift Container Platform

4.6.4. Generating an SSH private key and adding it to the agent

4.6.5. Creating the installation configuration file

4.6.5.1. Installation configuration parameters

4.6.5.1.1. Required configuration parameters

4.6.5.1.2. Network configuration parameters

4.6.5.1.3. Optional configuration parameters

4.6.5.1.4. Additional Google Cloud Platform (GCP) configuration parameters

4.6.5.2. Sample customized install-config.yaml file for GCP

4.6.5.3. Configuring the cluster-wide proxy during installation

4.6.6. Deploying the cluster

4.6.7. Installing the OpenShift CLI by downloading the binary

4.6.7.1. Installing the OpenShift CLI on Linux

4.6.7.2. Installing the OpenShift CLI on Windows

4.6.7.3. Installing the OpenShift CLI on macOS

4.6.8. Logging in to the cluster by using the CLI

4.6.9. Disabling the default OperatorHub sources

4.6.10. Telemetry access for OpenShift Container Platform

4.6.11. Next steps

4.7. INSTALLING A CLUSTER ON GCP INTO AN EXISTING VPC

4.7.1. Prerequisites

4.7.2. Internet access for OpenShift Container Platform

4.7.3. Generating an SSH private key and adding it to the agent

4.7.4. Obtaining the installation program

4.7.5. Creating the installation configuration file

4.7.5.1. Installation configuration parameters

4.7.5.1.1. Required configuration parameters

4.7.5.1.2. Network configuration parameters

4.7.5.1.3. Optional configuration parameters

4.7.5.1.4. Additional Google Cloud Platform (GCP) configuration parameters

4.7.5.2. Sample customized install-config.yaml file for GCP

4.7.5.3. Configuring the cluster-wide proxy during installation

4.7.6. Deploying the cluster

4.7.7. Installing the OpenShift CLI by downloading the binary

4.7.7.1. Installing the OpenShift CLI on Linux

4.7.7.2. Installing the OpenShift CLI on Windows

4.7.7.3. Installing the OpenShift CLI on macOS

4.7.8. Logging in to the cluster by using the CLI

4.7.9. Telemetry access for OpenShift Container Platform

4.7.10. Next steps

4.8. INSTALLING A PRIVATE CLUSTER ON GCP

4.8.1. Prerequisites

4.8.2. Private clusters

4.8.2.1. Private clusters in GCP

4.8.2.1.1. Limitations

4.8.3. About using a custom VPC

4.8.3.1. Requirements for using your VPC

4.8.3.2. Division of permissions

4.8.3.3. Isolation between clusters

4.8.4. Internet access for OpenShift Container Platform
4.8.5. Generating an SSH private key and adding it to the agent

4.8.6. Obtaining the installation program

4.8.7. Manually creating the installation configuration file
   4.8.7.1. Installation configuration parameters
      4.8.7.1.1. Required configuration parameters
      4.8.7.1.2. Network configuration parameters
      4.8.7.1.3. Optional configuration parameters
      4.8.7.1.4. Additional Google Cloud Platform (GCP) configuration parameters
   4.8.7.2. Sample customized install-config.yaml file for GCP
   4.8.7.3. Configuring the cluster-wide proxy during installation

4.8.8. Deploying the cluster

4.8.9. Installing the OpenShift CLI by downloading the binary
   4.8.9.1. Installing the OpenShift CLI on Linux
   4.8.9.2. Installing the OpenShift CLI on Windows
   4.8.9.3. Installing the OpenShift CLI on macOS

4.8.10. Logging in to the cluster by using the CLI

4.8.11. Telemetry access for OpenShift Container Platform

4.8.12. Next steps

4.9. INSTALLING A CLUSTER ON USER-PROVISIONED INFRASTRUCTURE IN GCP BY USING DEPLOYMENT MANAGER TEMPLATES

4.9.1. Prerequisites

4.9.2. Certificate signing requests management

4.9.3. Internet access for OpenShift Container Platform

4.9.4. Configuring your GCP project
   4.9.4.1. Creating a GCP project
   4.9.4.2. Enabling API services in GCP
   4.9.4.3. Configuring DNS for GCP
   4.9.4.4. GCP account limits
   4.9.4.5. Creating a service account in GCP
      4.9.4.5.1. Required GCP permissions
   4.9.4.6. Supported GCP regions
   4.9.4.7. Installing and configuring CLI tools for GCP

4.9.5. Creating the installation files for GCP
   4.9.5.1. Optional: Creating a separate /var partition
   4.9.5.2. Creating the installation configuration file
   4.9.5.3. Configuring the cluster-wide proxy during installation
   4.9.5.4. Creating the Kubernetes manifest and Ignition config files

4.9.6. Exporting common variables
   4.9.6.1. Extracting the infrastructure name
   4.9.6.2. Exporting common variables for Deployment Manager templates

4.9.7. Creating a VPC in GCP
   4.9.7.1. Deployment Manager template for the VPC

4.9.8. Networking requirements for user-provisioned infrastructure
   Network topology requirements
   Load balancers

4.9.9. Creating load balancers in GCP
   4.9.9.1. Deployment Manager template for the external load balancer
   4.9.9.2. Deployment Manager template for the internal load balancer

4.9.10. Creating a private DNS zone in GCP
   4.9.10.1. Deployment Manager template for the private DNS

4.9.11. Creating firewall rules in GCP
   4.9.11.1. Deployment Manager template for firewall rules

4.9.12. Creating IAM roles in GCP
4.9.12.1. Deployment Manager template for IAM roles
4.9.13. Creating the RHCOs cluster image for the GCP infrastructure
4.9.14. Creating the bootstrap machine in GCP
  4.9.14.1. Deployment Manager template for the bootstrap machine
4.9.15. Creating the control plane machines in GCP
  4.9.15.1. Deployment Manager template for control plane machines
4.9.16. Wait for bootstrap completion and remove bootstrap resources in GCP
4.9.17. Creating additional worker machines in GCP
  4.9.17.1. Deployment Manager template for worker machines
4.9.18. Installing the OpenShift CLI by downloading the binary
  4.9.18.1. Installing the OpenShift CLI on Linux
  4.9.18.2. Installing the OpenShift CLI on Windows
  4.9.18.3. Installing the OpenShift CLI on macOS
4.9.19. Logging in to the cluster by using the CLI
4.9.20. Approving the certificate signing requests for your machines
4.9.21. Optional: Adding the ingress DNS records
4.9.22. Completing a GCP installation on user-provisioned infrastructure
4.9.23. Telemetry access for OpenShift Container Platform
4.9.24. Next steps

4.10. INSTALLING A CLUSTER INTO A SHARED VPC ON GCP USING DEPLOYMENT MANAGER TEMPLATES

4.10.1. Prerequisites
4.10.2. Certificate signing requests management
4.10.3. Internet access for OpenShift Container Platform
4.10.4. Configuring the GCP project that hosts your cluster
  4.10.4.1. Creating a GCP project
  4.10.4.2. Enabling API services in GCP
  4.10.4.3. GCP account limits
  4.10.4.4. Creating a service account in GCP
    4.10.4.4.1. Required GCP permissions
  4.10.4.5. Supported GCP regions
  4.10.4.6. Installing and configuring CLI tools for GCP
4.10.5. Configuring the GCP project that hosts your shared VPC network
  4.10.5.1. Configuring DNS for GCP
  4.10.5.2. Creating a VPC in GCP
    4.10.5.2.1. Deployment Manager template for the VPC
4.10.6. Creating the installation files for GCP
  4.10.6.1. Manually creating the installation configuration file
  4.10.6.2. Sample customized install-config.yaml file for GCP
  4.10.6.3. Configuring the cluster-wide proxy during installation
  4.10.6.4. Creating the Kubernetes manifest and Ignition config files
4.10.7. Exporting common variables
  4.10.7.1. Extracting the infrastructure name
  4.10.7.2. Exporting common variables for Deployment Manager templates
4.10.8. Networking requirements for user-provisioned infrastructure
  Network topology requirements
    Load balancers
  4.10.9. Creating load balancers in GCP
    4.10.9.1. Deployment Manager template for the external load balancer
    4.10.9.2. Deployment Manager template for the internal load balancer
4.10.10. Creating a private DNS zone in GCP
  4.10.10.1. Deployment Manager template for the private DNS
4.10.11. Creating firewall rules in GCP
4.10.11. Deployment Manager template for firewall rules

4.10.12. Creating IAM roles in GCP

4.10.12.1. Deployment Manager template for IAM roles

4.10.13. Creating the RHCOS cluster image for the GCP infrastructure

4.10.14. Creating the bootstrap machine in GCP

4.10.14.1. Deployment Manager template for the bootstrap machine

4.10.15. Creating the control plane machines in GCP

4.10.15.1. Deployment Manager template for control plane machines

4.10.16. Wait for bootstrap completion and remove bootstrap resources in GCP

4.10.17. Creating additional worker machines in GCP

4.10.17.1. Deployment Manager template for worker machines

4.10.18. Installing the OpenShift CLI by downloading the binary

4.10.18.1. Installing the OpenShift CLI on Linux

4.10.18.2. Installing the OpenShift CLI on Windows

4.10.18.3. Installing the OpenShift CLI on macOS

4.10.19. Logging in to the cluster by using the CLI

4.10.20. Approving the certificate signing requests for your machines

4.10.21. Adding the ingress DNS records

4.10.22. Adding ingress firewall rules

4.10.22.1. Creating cluster-wide firewall rules for a shared VPC in GCP

4.10.23. Completing a GCP installation on user-provisioned infrastructure

4.10.24. Telemetry access for OpenShift Container Platform

4.10.25. Next steps

4.11. INSTALLING A CLUSTER ON GCP IN A RESTRICTED NETWORK WITH USER-PROVISIONED INFRASTRUCTURE

4.11.1. Prerequisites

4.11.2. About installations in restricted networks

4.11.2.1. Additional limits

4.11.3. Internet access for OpenShift Container Platform

4.11.4. Configuring your GCP project

4.11.4.1. Creating a GCP project

4.11.4.2. Enabling API services in GCP

4.11.4.3. Configuring DNS for GCP

4.11.4.4. GCP account limits

4.11.4.5. Creating a service account in GCP

4.11.4.5.1. Required GCP permissions

4.11.4.6. Supported GCP regions

4.11.4.7. Installing and configuring CLI tools for GCP

4.11.5. Creating the installation files for GCP

4.11.5.1. Optional: Creating a separate /var partition

4.11.5.2. Creating the installation configuration file

4.11.5.3. Configuring the cluster-wide proxy during installation

4.11.5.4. Creating the Kubernetes manifest and Ignition config files

4.11.6. Exporting common variables

4.11.6.1. Extracting the infrastructure name

4.11.6.2. Exporting common variables for Deployment Manager templates

4.11.7. Creating a VPC in GCP

4.11.7.1. Deployment Manager template for the VPC

4.11.8. Networking requirements for user-provisioned infrastructure

Network topology requirements

Load balancers

4.11.9. Creating load balancers in GCP

4.11.9.1. Deployment Manager template for the external load balancer
4.11.9.2. Deployment Manager template for the internal load balancer
4.11.10. Creating a private DNS zone in GCP
  4.11.10.1. Deployment Manager template for the private DNS
4.11.11. Creating firewall rules in GCP
  4.11.11.1. Deployment Manager template for firewall rules
4.11.12. Creating IAM roles in GCP
  4.11.12.1. Deployment Manager template for IAM roles
4.11.13. Creating the RH COS cluster image for the GCP infrastructure
4.11.14. Creating the bootstrap machine in GCP
  4.11.14.1. Deployment Manager template for the bootstrap machine
4.11.15. Creating the control plane machines in GCP
  4.11.15.1. Deployment Manager template for control plane machines
4.11.16. Wait for bootstrap completion and remove bootstrap resources in GCP
4.11.17. Creating additional worker machines in GCP
  4.11.17.1. Deployment Manager template for worker machines
4.11.18. Logging in to the cluster by using the CLI
4.11.19. Disabling the default OperatorHub sources
4.11.20. Approving the certificate signing requests for your machines
4.11.21. Optional: Adding the ingress DNS records
4.11.22. Completing a GCP installation on user-provisioned infrastructure
4.11.23. Telemetry access for OpenShift Container Platform
4.11.24. Next steps

4.12. UNINSTALLING A CLUSTER ON GCP
  4.12.1. Removing a cluster that uses installer-provisioned infrastructure

CHAPTER 5. INSTALLING ON BARE METAL

5.1. INSTALLING A CLUSTER ON BARE METAL

  5.1.1. Prerequisites
  5.1.2. Internet access for OpenShift Container Platform
  5.1.3. Machine requirements for a cluster with user-provisioned infrastructure
    5.1.3.1. Required machines
    5.1.3.2. Network connectivity requirements
    5.1.3.3. Minimum resource requirements
    5.1.3.4. Certificate signing requests management
  5.1.4. Creating the user-provisioned infrastructure
    5.1.4.1. Networking requirements for user-provisioned infrastructure
      Network topology requirements
      Load balancers
      NTP configuration
    5.1.4.2. User-provisioned DNS requirements
  5.1.5. Generating an SSH private key and adding it to the agent
  5.1.6. Obtaining the installation program
  5.1.7. Installing the OpenShift CLI by downloading the binary
    5.1.7.1. Installing the OpenShift CLI on Linux
    5.1.7.2. Installing the OpenShift CLI on Windows
    5.1.7.3. Installing the OpenShift CLI on macOS
  5.1.8. Manually creating the installation configuration file
    5.1.8.1. Installation configuration parameters
      5.1.8.1.1. Required configuration parameters
      5.1.8.1.2. Network configuration parameters
      5.1.8.1.3. Optional configuration parameters
    5.1.8.2. Sample install-config.yaml file for bare metal
    5.1.8.3. Configuring the cluster-wide proxy during installation
5.1.11. Installing RHCOS and starting the OpenShift Container Platform bootstrap process
5.1.11.1. Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines using an ISO image
5.1.11.2. Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines by PXE or iPXE booting
5.1.11.3. Advanced Red Hat Enterprise Linux CoreOS (RHCOS) installation configuration
  5.1.11.3.1. Using advanced networking options for PXE and ISO installations
  5.1.11.3.2. Disk partitioning
    5.1.11.3.2.1. Creating a separate /var partition
    5.1.11.3.2.2. Retaining existing partitions
  5.1.11.3.3. Identifying Ignition configs
    5.1.11.3.3.1. Embedding an Ignition config in the RHCOS ISO
  5.1.11.3.4. Advanced RHCOS installation reference
    Routing and bonding options at RHCOS boot prompt
    coreos.inst boot options for ISO or PXE install
    coreos-installer options for ISO install
5.1.12. Creating the cluster
5.1.13. Logging in to the cluster by using the CLI
5.1.14. Approving the certificate signing requests for your machines
5.1.15. Initial Operator configuration
  5.1.15.1. Image registry removed during installation
  5.1.15.2. Image registry storage configuration
    5.1.15.2.1. Configuring registry storage for bare metal and other manual installations
    5.1.15.2.2. Configuring storage for the image registry in non-production clusters
    5.1.15.2.3. Configuring block registry storage
5.1.16. Completing installation on user-provisioned infrastructure
5.1.17. Telemetry access for OpenShift Container Platform
5.1.18. Next steps

5.2. INSTALLING A CLUSTER ON BARE METAL WITH NETWORK CUSTOMIZATIONS
5.2.1. Prerequisites
5.2.2. Internet access for OpenShift Container Platform
5.2.3. Machine requirements for a cluster with user-provisioned infrastructure
  5.2.3.1. Required machines
  5.2.3.2. Network connectivity requirements
  5.2.3.3. Minimum resource requirements
  5.2.3.4. Certificate signing requests management
5.2.4. Creating the user-provisioned infrastructure
  5.2.4.1. Networking requirements for user-provisioned infrastructure
    Network topology requirements
    Load balancers
    NTP configuration
  5.2.4.2. User-provisioned DNS requirements
5.2.5. Generating an SSH private key and adding it to the agent
5.2.6. Obtaining the installation program
5.2.7. Installing the OpenShift CLI by downloading the binary
  5.2.7.1. Installing the OpenShift CLI on Linux
  5.2.7.2. Installing the OpenShift CLI on Windows
  5.2.7.3. Installing the OpenShift CLI on macOS
5.2.8. Manually creating the installation configuration file
  5.2.8.1. Installation configuration parameters
    5.2.8.1.1. Required configuration parameters
    5.2.8.1.2. Network configuration parameters
    5.2.8.1.3. Optional configuration parameters
5.3.7.1.1. Required configuration parameters 1122
5.3.7.1.2. Network configuration parameters 1124
5.3.7.1.3. Optional configuration parameters 1125
5.3.7.2. Sample install-config.yaml file for bare metal 1130
5.3.7.3. Configuring the cluster-wide proxy during installation 1133
5.3.8. Configuring a three-node cluster 1134
5.3.9. Creating the Kubernetes manifest and Ignition config files 1134
5.3.10. Configuring chrony time service 1136
5.3.11. Installing RHCOS and starting the OpenShift Container Platform bootstrap process 1138
5.3.11.1. Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines using an ISO image 1139
5.3.11.2. Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines by PXE or iPXE booting 1140
5.3.11.3. Advanced Red Hat Enterprise Linux CoreOS (RHCOS) installation configuration 1144
5.3.11.3.1. Using advanced networking options for PXE and ISO installations 1144
5.3.11.3.2. Disk partitioning 1145
5.3.11.3.2.1. Creating a separate /var partition 1145
5.3.11.3.2.2. Retaining existing partitions 1147
5.3.11.3.3. Identifying Ignition configs 1148
5.3.11.3.3.1. Embedding an Ignition config in the RHCOS ISO 1149
5.3.11.3.4. Advanced RHCOS installation reference 1150
Routing and bonding options at RHCOS boot prompt 1150
coreos.inst boot options for ISO or PXE install 1153
coreos-installer options for ISO install 1155
5.3.12. Creating the cluster 1157
5.3.13. Logging in to the cluster by using the CLI 1158
5.3.14. Approving the certificate signing requests for your machines 1159
5.3.15. Initial Operator configuration 1161
5.3.15.1. Disabling the default OperatorHub sources 1162
5.3.15.2. Image registry storage configuration 1163
5.3.15.2.1. Changing the image registry’s management state 1163
5.3.15.2.2. Configuring registry storage for bare metal and other manual installations 1163
5.3.15.2.3. Configuring storage for the image registry in non-production clusters 1165
5.3.15.2.4. Configuring block registry storage 1165
5.3.16. Completing installation on user-provisioned infrastructure 1166
5.3.17. Telemetry access for OpenShift Container Platform 1168
5.3.18. Next steps 1168

CHAPTER 6. DEPLOYING INSTALLER-PROVISIONED CLUSTERS ON BARE METAL 1169

6.1. OVERVIEW 1169
6.2. PREREQUISITES 1169
6.2.1. Node requirements 1170
6.2.2. Network requirements 1170
6.2.3. Configuring nodes 1173
6.2.4. Out-of-band management 1174
6.2.5. Required data for installation 1174
6.2.6. Validation checklist for nodes 1174
6.3. SETTING UP THE ENVIRONMENT FOR AN OPENSФHT INSTALLATION 1175
6.3.1. Installing RHEL on the provisioner node 1175
6.3.2. Preparing the provisioner node for OpenShift Container Platform installation 1175
6.3.3. Retrieving the OpenShift Container Platform installer 1177
6.3.4. Extracting the OpenShift Container Platform installer 1178
6.3.5. Creating an RHCOS images cache (optional) 1178
6.3.6. Configuration files 1180
6.3.6.1. Configuring the install-config.yaml file 1180
6.3.6.2. Setting proxy settings within the install-config.yaml file (optional)
6.3.6.3. Modifying the install-config.yaml file for no provisioning network (optional)
6.3.6.4. Additional install-config parameters
6.3.6.5. BMC addressing
6.3.6.6. Root device hints
6.3.6.7. Creating the OpenShift Container Platform manifests
6.3.7. Creating a disconnected registry (optional)
   6.3.7.1. Preparing the registry node to host the mirrored registry (optional)
   6.3.7.2. Generating the self-signed certificate (optional)
   6.3.7.3. Creating the registry podman container (optional)
   6.3.7.4. Copy and update the pull-secret (optional)
   6.3.7.5. Mirroring the repository (optional)
   6.3.7.6. Modify the install-config.yaml file to use the disconnected registry (optional)
6.3.8. Deploying routers on worker nodes
6.3.9. Validation checklist for installation
6.3.10. Deploying the cluster via the OpenShift Container Platform installer
   6.3.11. Following the installation
6.4. EXPANDING THE CLUSTER
   6.4.1. Preparing the bare metal node
   6.4.2. Provisioning the bare metal node
6.5. TROUBLESHOOTING
   6.5.1. Troubleshooting the installer workflow
   6.5.2. Troubleshooting install-config.yaml
   6.5.3. Bootstrap VM issues
      6.5.3.1. Bootstrap VM cannot boot up the cluster nodes
      6.5.3.2. Inspecting logs
   6.5.4. Cluster nodes will not PXE boot
   6.5.5. The API is not accessible
   6.5.6. Cleaning up previous installations
   6.5.7. Issues with creating the registry
   6.5.8. Miscellaneous issues
      6.5.8.1. Addressing the runtime network not ready error
      6.5.8.2. Cluster nodes not getting the correct IPv6 address over DHCP
      6.5.8.3. Cluster nodes not getting the correct hostname over DHCP
      6.5.8.4. Routes do not reach endpoints
      6.5.8.5. Failed Ignition during Firstboot
      6.5.8.6. NTP out of sync
   6.5.9. Reviewing the installation
CHAPTER 7. INSTALLING ON IBM Z AND LINUXONE

7.1. INSTALLING A CLUSTER ON IBM Z AND LINUXONE
   7.1.1. Prerequisites
   7.1.2. Internet access for OpenShift Container Platform
   7.1.3. Machine requirements for a cluster with user-provisioned infrastructure
      7.1.3.1. Required machines
      7.1.3.2. Network connectivity requirements
      7.1.3.3. IBM Z network connectivity requirements
      7.1.3.4. Minimum resource requirements
      7.1.3.5. Minimum IBM Z system environment
         Hardware requirements
         Operating system requirements
         IBM Z network connectivity requirements
         Disk storage for the z/VM guest virtual machines
Storage / Main Memory
7.1.3.6. Preferred IBM Z system environment
   Hardware requirements
   Operating system requirements
   IBM Z network connectivity requirements
   Disk storage for the z/VM guest virtual machines
   Storage / Main Memory
7.1.3.7. Certificate signing requests management
7.1.4. Creating the user-provisioned infrastructure
   7.1.4.1. Networking requirements for user-provisioned infrastructure
      Network topology requirements
      Load balancers
      NTP configuration
   7.1.4.2. User-provisioned DNS requirements
7.1.5. Generating an SSH private key and adding it to the agent
7.1.6. Obtaining the installation program
7.1.7. Installing the OpenShift CLI by downloading the binary
   7.1.7.1. Installing the OpenShift CLI on Linux
   7.1.7.2. Installing the OpenShift CLI on Windows
   7.1.7.3. Installing the OpenShift CLI on macOS
7.1.8. Manually creating the installation configuration file
   7.1.8.1. Installation configuration parameters
      7.1.8.1.1. Required configuration parameters
      7.1.8.1.2. Network configuration parameters
      7.1.8.1.3. Optional configuration parameters
      7.1.8.2. Sample install-config.yaml file for IBM Z
7.1.9. Configuring the cluster-wide proxy during installation
7.1.10. Creating the Kubernetes manifest and Ignition config files
7.1.11. Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines
   7.1.11.1. Advanced RHCOS installation reference
      Routing and bonding options at RHCOS boot prompt
7.1.12. Creating the cluster
7.1.13. Logging in to the cluster by using the CLI
7.1.14. Approving the certificate signing requests for your machines
7.1.15. Initial Operator configuration
   7.1.15.1. Image registry storage configuration
      7.1.15.1.1. Configuring registry storage for IBM Z
      7.1.15.1.2. Configuring storage for the image registry in non-production clusters
7.1.16. Completing installation on user-provisioned infrastructure
7.1.17. Telemetry access for OpenShift Container Platform
7.1.18. Collecting debugging information
7.1.19. Next steps
7.2. INSTALLING A CLUSTER ON IBM Z AND LINUXONE IN A RESTRICTED NETWORK
    7.2.1. About installations in restricted networks
    7.2.1.1. Additional limits
    7.2.2. Internet access for OpenShift Container Platform
    7.2.3. Machine requirements for a cluster with user-provisioned infrastructure
       7.2.3.1. Required machines
       7.2.3.2. Network connectivity requirements
       7.2.3.3. IBM Z network connectivity requirements
       7.2.3.4. Minimum resource requirements
       7.2.3.5. Minimum IBM Z system environment
       Hardware requirements
7.2.4. Telemetry access for OpenShift Container Platform
Operating system requirements 1264
IBM Z network connectivity requirements 1264
Disk storage for the z/VM guest virtual machines 1264
Storage / Main Memory 1265
7.2.3.6. Preferred IBM Z system environment 1265
Hardware requirements 1265
Operating system requirements 1265
IBM Z network connectivity requirements 1265
Disk storage for the z/VM guest virtual machines 1265
Storage / Main Memory 1266
7.2.3.7. Certificate signing requests management 1266
7.2.4. Creating the user-provisioned infrastructure 1266
7.2.4.1. Networking requirements for user-provisioned infrastructure 1266
Network topology requirements 1268
Load balancers 1268
NTP configuration 1269
7.2.4.2. User-provisioned DNS requirements 1270
7.2.5. Generating an SSH private key and adding it to the agent 1272
7.2.6. Manually creating the installation configuration file 1274
7.2.6.1. Installation configuration parameters 1275
7.2.6.1.1. Required configuration parameters 1275
7.2.6.1.2. Network configuration parameters 1276
7.2.6.1.3. Optional configuration parameters 1278
7.2.6.2. Sample install-config.yaml file for IBM Z 1283
7.2.6.3. Configuring the cluster-wide proxy during installation 1286
7.2.7. Creating the Kubernetes manifest and Ignition config files 1287
7.2.8. Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines 1288
7.2.8.1. Advanced RHCOS installation reference 1290
Routing and bonding options at RHCOS boot prompt 1290
7.2.9. Creating the cluster 1293
7.2.10. Logging in to the cluster by using the CLI 1294
7.2.11. Approving the certificate signing requests for your machines 1295
7.2.12. Initial Operator configuration 1297
7.2.12.1. Disabling the default OperatorHub sources 1298
7.2.12.2. Image registry storage configuration 1299
7.2.12.2.1. Configuring registry storage for IBM Z 1299
7.2.12.2.2. Configuring storage for the image registry in non-production clusters 1300
7.2.13. Completing installation on user-provisioned infrastructure 1301
7.2.14. Telemetry access for OpenShift Container Platform 1303
7.2.15. Collecting debugging information 1303
7.2.16. Next steps 1304

CHAPTER 8. INSTALLING ON IBM POWER SYSTEMS .......................... 1305
8.1. INSTALLING A CLUSTER ON IBM POWER SYSTEMS 1305
8.1.1. Internet access for OpenShift Container Platform 1305
8.1.2. Machine requirements for a cluster with user-provisioned infrastructure 1306
8.1.2.1. Required machines 1306
8.1.2.2. Network connectivity requirements 1306
8.1.2.3. Minimum resource requirements 1306
8.1.2.4. Certificate signing requests management 1307
8.1.3. Creating the user-provisioned infrastructure 1307
8.1.3.1. Networking requirements for user-provisioned infrastructure 1307
Network topology requirements 1309
Load balancers
NTP configuration
8.1.3.2. User-provisioned DNS requirements
8.1.4. Generating an SSH private key and adding it to the agent
8.1.5. Obtaining the installation program
8.1.6. Installing the OpenShift CLI by downloading the binary
  8.1.6.1. Installing the OpenShift CLI on Linux
  8.1.6.2. Installing the OpenShift CLI on Windows
  8.1.6.3. Installing the OpenShift CLI on macOS
8.1.7. Manually creating the installation configuration file
  8.1.7.1. Sample install-config.yaml file for IBM Power Systems
  8.1.7.2. Configuring the cluster-wide proxy during installation
8.1.8. Creating the Kubernetes manifest and Ignition config files
8.1.9. Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines
  8.1.9.1. Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines using an ISO image
  8.1.9.1.1. Advanced RHCOS installation reference
  Routing and bonding options at RHCOS boot prompt
  8.1.9.2. Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines by PXE or iPXE booting
8.1.10. Creating the cluster
8.1.11. Logging in to the cluster by using the CLI
8.1.12. Approving the certificate signing requests for your machines
8.1.13. Initial Operator configuration
  8.1.13.1. Image registry storage configuration
    8.1.13.1.1. Configuring registry storage for IBM Power Systems
    8.1.13.1.2. Configuring storage for the image registry in non-production clusters
  8.1.14. Completing installation on user-provisioned infrastructure
8.1.15. Telemetry access for OpenShift Container Platform
8.1.16. Next steps
8.2. INSTALLING A CLUSTER ON IBM POWER SYSTEMS IN A RESTRICTED NETWORK
8.2.1. About installations in restricted networks
  8.2.1.1. Additional limits
8.2.2. Internet access for OpenShift Container Platform
8.2.3. Machine requirements for a cluster with user-provisioned infrastructure
  8.2.3.1. Required machines
  8.2.3.2. Network connectivity requirements
  8.2.3.3. Minimum resource requirements
  8.2.3.4. Certificate signing requests management
8.2.4. Creating the user-provisioned infrastructure
  8.2.4.1. Networking requirements for user-provisioned infrastructure
    Network topology requirements
    Load balancers
    NTP configuration
  8.2.4.2. User-provisioned DNS requirements
8.2.5. Generating an SSH private key and adding it to the agent
8.2.6. Manually creating the installation configuration file
  8.2.6.1. Sample install-config.yaml file for IBM Power Systems
  8.2.6.2. Configuring the cluster-wide proxy during installation
8.2.7. Creating the Kubernetes manifest and Ignition config files
8.2.8. Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines
  8.2.8.1. Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines using an ISO image
  8.2.8.1.1. Advanced RHCOS installation reference
  Routing and bonding options at RHCOS boot prompt
  8.2.8.2. Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines by PXE or iPXE booting
8.2.9. Creating the cluster
8.2.10. Logging in to the cluster by using the CLI
8.2.11. Approving the certificate signing requests for your machines
8.2.12. Initial Operator configuration
  8.2.12.1. Disabling the default OperatorHub sources
  8.2.12.2. Image registry storage configuration
    8.2.12.2.1. Changing the image registry’s management state
    8.2.12.2.2. Configuring registry storage for IBM Power Systems
    8.2.12.2.3. Configuring storage for the image registry in non-production clusters
  8.2.13. Completing installation on user-provisioned infrastructure
  8.2.14. Telemetry access for OpenShift Container Platform
8.2.15. Next steps

CHAPTER 9. INSTALLING ON OPENSTACK .................................................. 1377

9.1. INSTALLING A CLUSTER ON OPENSTACK WITH CUSTOMIZATIONS

9.1.1. Prerequisites
9.1.2. Resource guidelines for installing OpenShift Container Platform on RHOSP
  9.1.2.1. Control plane and compute machines
  9.1.2.2. Bootstrap machine
9.1.3. Internet access for OpenShift Container Platform
9.1.4. Enabling Swift on RHOSP
9.1.5. Verifying external network access
9.1.6. Defining parameters for the installation program
9.1.7. Obtaining the installation program
9.1.8. Creating the installation configuration file
  9.1.8.1. Configuring the cluster-wide proxy during installation
9.1.9. Installation configuration parameters
  9.1.9.1. Required configuration parameters
  9.1.9.2. Network configuration parameters
  9.1.9.3. Optional configuration parameters
  9.1.9.4. Additional Red Hat OpenStack Platform (RHOSP) configuration parameters
  9.1.9.5. Optional RHOSP configuration parameters
  9.1.9.6. Custom subnets in RHOSP deployments
  9.1.9.7. Sample customized install-config.yaml file for RHOSP
9.1.10. Setting compute machine affinity
9.1.11. Generating an SSH private key and adding it to the agent
9.1.12. Enabling access to the environment
  9.1.12.1. Enabling access with floating IP addresses
  9.1.12.2. Completing installation without floating IP addresses
9.1.13. Deploying the cluster
9.1.14. Verifying cluster status
9.1.15. Logging in to the cluster by using the CLI
9.1.16. Telemetry access for OpenShift Container Platform
9.1.17. Next steps

9.2. INSTALLING A CLUSTER ON OPENSTACK WITH KURYR

9.2.1. Prerequisites
9.2.2. About Kuryr SDN
9.2.3. Resource guidelines for installing OpenShift Container Platform on RHOSP with Kuryr
  9.2.3.1. Increasing quota
  9.2.3.2. Configuring Neutron
  9.2.3.3. Configuring Octavia
    9.2.3.3.1. The Octavia OVN Driver
  9.2.3.4. Known limitations of installing with Kuryr
RHOSP general limitations
RHOSP version limitations
RHOSP environment limitations
RHOSP upgrade limitations
9.2.3.5. Control plane and compute machines
9.2.3.6. Bootstrap machine
9.2.4. Internet access for OpenShift Container Platform
9.2.5. Enabling Swift on RHOSP
9.2.6. Verifying external network access
9.2.7. Defining parameters for the installation program
9.2.8. Obtaining the installation program
9.2.9. Creating the installation configuration file
9.2.9.1. Configuring the cluster-wide proxy during installation
9.2.10. Installation configuration parameters
9.2.10.1. Required configuration parameters
9.2.10.2. Network configuration parameters
9.2.10.3. Optional configuration parameters
9.2.10.4. Additional Red Hat OpenStack Platform (RHOSP) configuration parameters
9.2.10.5. Optional RHOSP configuration parameters
9.2.10.6. Custom subnets in RHOSP deployments
9.2.10.7. Sample customized install-config.yaml file for RHOSP with Kuryr
9.2.10.8. Kuryr ports pools
9.2.10.9. Adjusting Kuryr ports pools during installation
9.2.11. Setting compute machine affinity
9.2.12. Generating an SSH private key and adding it to the agent
9.2.13. Enabling access to the environment
9.2.13.1. Enabling access with floating IP addresses
9.2.13.2. Completing installation without floating IP addresses
9.2.14. Deploying the cluster
9.2.15. Verifying cluster status
9.2.16. Logging in to the cluster by using the CLI
9.2.17. Telemetry access for OpenShift Container Platform
9.2.18. Next steps

9.3. INSTALLING A CLUSTER ON OPENSTACK ON YOUR OWN INFRASTRUCTURE

9.3.1. Prerequisites
9.3.2. Internet access for OpenShift Container Platform
9.3.3. Resource guidelines for installing OpenShift Container Platform on RHOSP
9.3.3.1. Control plane and compute machines
9.3.3.2. Bootstrap machine
9.3.4. Downloading playbook dependencies
9.3.5. Downloading the installation playbooks
9.3.6. Obtaining the installation program
9.3.7. Generating an SSH private key and adding it to the agent
9.3.8. Creating the Red Hat Enterprise Linux CoreOS (RHCOS) image
9.3.9. Verifying external network access
9.3.10. Enabling access to the environment
9.3.10.1. Enabling access with floating IP addresses
9.3.10.2. Completing installation without floating IP addresses
9.3.11. Defining parameters for the installation program
9.3.12. Creating the installation configuration file
9.3.13. Installation configuration parameters
9.3.13.1. Required configuration parameters
9.3.13.2. Network configuration parameters
9.3.13.3. Optional configuration parameters
9.3.13.4. Additional Red Hat OpenStack Platform (RHOSP) configuration parameters
9.3.13.5. Optional RHOSP configuration parameters
9.3.13.6. Custom subnets in RHOSP deployments
9.3.13.7. Sample customized install-config.yaml file for RHOSP
9.3.13.8. Setting a custom subnet for machines
9.3.13.9. Emptying compute machine pools
9.3.14. Creating the Kubernetes manifest and Ignition config files
9.3.15. Preparing the bootstrap Ignition files
9.3.16. Creating control plane Ignition config files on RHOSP
9.3.17. Creating network resources on RHOSP
9.3.18. Creating the bootstrap machine on RHOSP
9.3.19. Creating the control plane machines on RHOSP
9.3.20. Logging in to the cluster by using the CLI
9.3.21. Deleting bootstrap resources from RHOSP
9.3.22. Creating compute machines on RHOSP
9.3.23. Approving the certificate signing requests for your machines
9.3.24. Verifying a successful installation
9.3.25. Telemetry access for OpenShift Container Platform
9.3.26. Next steps

9.4. INSTALLING A CLUSTER ON OPENSTACK WITH KURYR ON YOUR OWN INFRASTRUCTURE
9.4.1. Prerequisites
9.4.2. About Kuryr SDN
9.4.3. Resource guidelines for installing OpenShift Container Platform on RHOSP with Kuryr
  9.4.3.1. Increasing quota
  9.4.3.2. Configuring Neutron
  9.4.3.3. Configuring Octavia
    9.4.3.3.1. The Octavia OVN Driver
  9.4.3.4. Known limitations of installing with Kuryr
    RHOSP general limitations
    RHOSP version limitations
    RHOSP environment limitations
    RHOSP upgrade limitations
  9.4.3.5. Control plane and compute machines
  9.4.3.6. Bootstrap machine
9.4.4. Internet access for OpenShift Container Platform
9.4.5. Downloading playbook dependencies
9.4.6. Downloading the installation playbooks
9.4.7. Obtaining the installation program
9.4.8. Generating an SSH private key and adding it to the agent
9.4.9. Creating the Red Hat Enterprise Linux CoreOS (RHCOS) image
9.4.10. Verifying external network access
9.4.11. Enabling access to the environment
  9.4.11.1. Enabling access with floating IP addresses
  9.4.11.2. Completing installation without floating IP addresses
9.4.12. Defining parameters for the installation program
9.4.13. Creating the installation configuration file
  9.4.14.1. Required configuration parameters
  9.4.14.2. Network configuration parameters
  9.4.14.3. Optional configuration parameters
  9.4.14.4. Additional Red Hat OpenStack Platform (RHOSP) configuration parameters
  9.4.14.5. Optional RHOSP configuration parameters
9.4.14.6. Custom subnets in RHOSP deployments
9.4.14.7. Sample customized install-config.yaml file for RHOSP with Kuryr
9.4.14.9. Adjusting Kuryr ports pools during installation
9.4.14.10. Setting a custom subnet for machines
9.4.14.11. Emptying compute machine pools
9.4.14.12. Modifying the network type
9.4.15. Creating the Kubernetes manifest and Ignition config files
9.4.16. Preparing the bootstrap Ignition files
9.4.17. Creating control plane Ignition config files on RHOSP
9.4.18. Creating network resources on RHOSP
9.4.19. Creating the bootstrap machine on RHOSP
9.4.20. Creating the control plane machines on RHOSP
9.4.21. Logging in to the cluster by using the CLI
9.4.22. Deleting bootstrap resources from RHOSP
9.4.23. Creating compute machines on RHOSP
9.4.24. Approving the certificate signing requests for your machines
9.4.25. Verifying a successful installation
9.4.26. Telemetry access for OpenShift Container Platform
9.4.27. Next steps

9.5. INSTALLING A CLUSTER ON OPENSTACK IN A RESTRICTED NETWORK
9.5.1. About installations in restricted networks
9.5.1.1. Additional limits
9.5.2. Resource guidelines for installing OpenShift Container Platform on RHOSP
9.5.2.1. Control plane and compute machines
9.5.2.2. Bootstrap machine
9.5.3. Internet access for OpenShift Container Platform
9.5.4. Enabling Swift on RHOSP
9.5.5. Defining parameters for the installation program
9.5.6. Creating the RH COS image for restricted network installations
9.5.7. Creating the installation configuration file
9.5.7.1. Configuring the cluster-wide proxy during installation
9.5.7.2. Installation configuration parameters
9.5.7.2.1. Required configuration parameters
9.5.7.2.2. Network configuration parameters
9.5.7.2.3. Optional configuration parameters
9.5.7.2.4. Additional Red Hat OpenStack Platform (RHOSP) configuration parameters
9.5.7.2.5. Optional RHOSP configuration parameters
9.5.7.3. Sample customized install-config.yaml file for restricted OpenStack installations
9.5.8. Setting compute machine affinity
9.5.9. Generating an SSH private key and adding it to the agent
9.5.10. Enabling access to the environment
9.5.10.1. Enabling access with floating IP addresses
9.5.10.2. Completing installation without floating IP addresses
9.5.11. Deploying the cluster
9.5.12. Verifying cluster status
9.5.13. Logging in to the cluster by using the CLI
9.5.14. Disabling the default OperatorHub sources
9.5.15. Telemetry access for OpenShift Container Platform
9.5.16. Next steps

9.6. UNINSTALLING A CLUSTER ON OPENSTACK
9.6.1. Removing a cluster that uses installer-provisioned infrastructure

9.7. UNINSTALLING A CLUSTER ON RHOSP FROM YOUR OWN INFRASTRUCTURE
9.7.1. Downloading playbook dependencies 1573
9.7.2. Removing a cluster from RHOSP that uses your own infrastructure 1574

CHAPTER 10. INSTALLING ON RHV ................................................................. 1575

10.1. INSTALLING A CLUSTER QUICKLY ON RHV 1575
10.1.1. Prerequisites 1575
10.1.2. Internet access for OpenShift Container Platform 1576
10.1.3. Requirements for the RHV environment 1576
10.1.4. Verifying the requirements for the RHV environment 1577
10.1.5. Preparing the network environment on RHV 1579
10.1.6. Setting up the CA certificate for RHV 1580
10.1.7. Generating an SSH private key and adding it to the agent 1581
10.1.8. Obtaining the installation program 1582
10.1.9. Deploying the cluster 1583
10.1.10. Installing the OpenShift CLI by downloading the binary 1586
  10.1.10.1. Installing the OpenShift CLI on Linux 1586
  10.1.10.2. Installing the OpenShift CLI on Windows 1587
  10.1.10.3. Installing the OpenShift CLI on macOS 1587
10.1.11. Logging in to the cluster by using the CLI 1588
10.1.12. Verifying cluster status 1588
10.1.13. Accessing the OpenShift Container Platform web console on RHV 1589
10.1.14. Telemetry access for OpenShift Container Platform 1590
10.1.15. Troubleshooting common issues with installing on Red Hat Virtualization (RHV) 1590
  10.1.15.1. CPU load increases and nodes go into a Not Ready state 1590
  10.1.15.2. Trouble connecting the OpenShift Container Platform cluster API 1590
10.1.16. Post-installation tasks 1591

10.2. INSTALLING A CLUSTER ON RHV WITH CUSTOMIZATIONS 1591
10.2.1. Prerequisites 1592
10.2.2. Internet access for OpenShift Container Platform 1592
10.2.3. Requirements for the RHV environment 1592
10.2.4. Verifying the requirements for the RHV environment 1594
10.2.5. Preparing the network environment on RHV 1596
10.2.6. Setting up the CA certificate for RHV 1597
10.2.7. Generating an SSH private key and adding it to the agent 1597
10.2.8. Obtaining the installation program 1599
10.2.9. Creating the installation configuration file 1600
  10.2.9.1. Example install-config.yaml files for Red Hat Virtualization (RHV) 1602
  10.2.9.2. Installation configuration parameters 1604
    10.2.9.2.1. Required configuration parameters 1604
    10.2.9.2.2. Network configuration parameters 1606
    10.2.9.2.3. Optional configuration parameters 1607
    10.2.9.2.4. Additional Red Hat Virtualization (RHV) configuration parameters 1611
    10.2.9.2.5. Additional RHV parameters for machine pools 1612
10.2.10. Deploying the cluster 1613
10.2.11. Installing the OpenShift CLI by downloading the binary 1615
  10.2.11.1. Installing the OpenShift CLI on Linux 1615
  10.2.11.2. Installing the OpenShift CLI on Windows 1615
  10.2.11.3. Installing the OpenShift CLI on macOS 1616
10.2.12. Logging in to the cluster by using the CLI 1616
10.2.13. Verifying cluster status 1617
10.2.14. Accessing the OpenShift Container Platform web console on RHV 1618
10.2.15. Telemetry access for OpenShift Container Platform 1618
10.2.16. Troubleshooting common issues with installing on Red Hat Virtualization (RHV) 1618
10.2.16.1. CPU load increases and nodes go into a Not Ready state
10.2.16.2. Trouble connecting the OpenShift Container Platform cluster API
10.2.17. Post-installation tasks
10.2.18. Next steps

10.3. INSTALLING A CLUSTER ON RHV WITH USER-PROVISIONED INFRASTRUCTURE
10.3.1. Prerequisites
10.3.2. Internet access for OpenShift Container Platform
10.3.3. Requirements for the RHV environment
10.3.4. Verifying the requirements for the RHV environment
10.3.5. Networking requirements for user-provisioned infrastructure
   Network topology requirements
   Load balancers
   NTP configuration
10.3.6. Setting up the installation machine
10.3.7. Setting up the CA certificate for RHV
10.3.8. Generating an SSH private key and adding it to the agent
10.3.9. Obtaining the installation program
10.3.10. Downloading the Ansible playbooks
10.3.11. The inventory.yml file
10.3.12. Specifying the RHCOS image settings
10.3.13. Creating the install config file
10.3.14. Customizing install-config.yaml
10.3.15. Generate manifest files
10.3.16. Making control-plane nodes non-schedulable
10.3.17. Building the Ignition files
10.3.18. Creating templates and virtual machines
10.3.19. Creating the bootstrap machine
10.3.20. Creating the control plane nodes
10.3.21. Verifying cluster status
10.3.22. Removing the bootstrap machine
10.3.23. Creating the worker nodes and completing the installation
10.3.24. Telemetry access for OpenShift Container Platform

10.4. UNINSTALLING A CLUSTER ON RHV
10.4.1. Removing a cluster that uses installer-provisioned infrastructure
10.4.2. Removing a cluster that uses user-provisioned infrastructure

CHAPTER 11. INSTALLING ON VSPHERE
11.1. INSTALLING A CLUSTER ON VSPHERE
11.1.1. Prerequisites
11.1.2. Internet access for OpenShift Container Platform
11.1.3. VMware vSphere infrastructure requirements
11.1.4. vCenter requirements
   Required vCenter account privileges
   Using OpenShift Container Platform with vMotion
   Cluster resources
   Cluster limits
   Networking requirements
   Required IP Addresses
   DNS records
11.1.5. Generating an SSH private key and adding it to the agent
11.1.6. Obtaining the installation program
11.1.7. Adding vCenter root CA certificates to your system trust
11.1.8. Deploying the cluster
11.1.9. Installing the OpenShift CLI by downloading the binary
11.1.9.1. Installing the OpenShift CLI on Linux
11.1.9.2. Installing the OpenShift CLI on Windows
11.1.9.3. Installing the OpenShift CLI on macOS
11.1.10. Logging in to the cluster by using the CLI
11.1.11. Creating registry storage
11.1.11.1. Image registry removed during installation
11.1.11.2. Image registry storage configuration
   11.1.11.2.1. Configuring registry storage for VMware vSphere
   11.1.11.2.2. Configuring block registry storage for VMware vSphere
11.1.12. Backing up VMware vSphere volumes
11.1.13. Telemetry access for OpenShift Container Platform
11.1.14. Next steps

11.2. INSTALLING A CLUSTER ON VSPHERE WITH CUSTOMIZATIONS
11.2.1. Prerequisites
11.2.2. Internet access for OpenShift Container Platform
11.2.3. VMware vSphere infrastructure requirements
11.2.4. vCenter requirements
   Required vCenter account privileges
   Using OpenShift Container Platform with vMotion
   Cluster resources
   Cluster limits
   Networking requirements
   Required IP Addresses
   DNS records
11.2.5. Generating an SSH private key and adding it to the agent
11.2.6. Obtaining the installation program
11.2.7. Adding vCenter root CA certificates to your system trust
11.2.8. Creating the installation configuration file
   11.2.8.1. Installation configuration parameters
      11.2.8.1.1. Required configuration parameters
      11.2.8.1.2. Network configuration parameters
      11.2.8.1.3. Optional configuration parameters
      11.2.8.1.4. Additional VMware vSphere configuration parameters
      11.2.8.1.5. Optional VMware vSphere machine pool configuration parameters
   11.2.8.2. Sample install-config.yaml file for an installer-provisioned VMware vSphere cluster
   11.2.8.3. Configuring the cluster-wide proxy during installation
11.2.9. Deploying the cluster
11.2.10. Installing the OpenShift CLI by downloading the binary
   11.2.10.1. Installing the OpenShift CLI on Linux
   11.2.10.2. Installing the OpenShift CLI on Windows
   11.2.10.3. Installing the OpenShift CLI on macOS
11.2.11. Logging in to the cluster by using the CLI
11.2.12. Creating registry storage
   11.2.12.1. Image registry removed during installation
   11.2.12.2. Image registry storage configuration
      11.2.12.2.1. Configuring registry storage for VMware vSphere
      11.2.12.2.2. Configuring block registry storage for VMware vSphere
11.2.13. Backing up VMware vSphere volumes
11.2.14. Telemetry access for OpenShift Container Platform
11.2.15. Next steps

11.3. INSTALLING A CLUSTER ON VSPHERE WITH NETWORK CUSTOMIZATIONS
11.3.1. Prerequisites
11.3.2. Internet access for OpenShift Container Platform
11.3.3. VMware vSphere infrastructure requirements
11.3.4. vCenter requirements
  Required vCenter account privileges
  Using OpenShift Container Platform with vMotion
  Cluster resources
  Cluster limits
  Networking requirements
    Required IP Addresses
    DNS records
11.3.5. Generating an SSH private key and adding it to the agent
11.3.6. Obtaining the installation program
11.3.7. Adding vCenter root CA certificates to your system trust
11.3.8. Creating the installation configuration file
  11.3.8.1. Installation configuration parameters
    11.3.8.1.1. Required configuration parameters
    11.3.8.1.2. Network configuration parameters
    11.3.8.1.3. Optional configuration parameters
    11.3.8.1.4. Additional VMware vSphere configuration parameters
    11.3.8.1.5. Optional VMware vSphere machine pool configuration parameters
  11.3.8.2. Sample install-config.yaml file for an installer-provisioned VMware vSphere cluster
  11.3.8.3. Configuring the cluster-wide proxy during installation
11.3.9. Network configuration phases
11.3.10. Specifying advanced network configuration
11.3.11. Cluster Network Operator configuration
  11.3.11.1. Cluster Network Operator configuration object
    defaultNetwork object configuration
    Configuration for the OpenShift SDN CNI cluster network provider
    Configuration for the OVN-Kubernetes CNI cluster network provider
    kubeProxyConfig object configuration
11.3.12. Deploying the cluster
11.3.13. Installing the OpenShift CLI by downloading the binary
  11.3.13.1. Installing the OpenShift CLI on Linux
  11.3.13.2. Installing the OpenShift CLI on Windows
  11.3.13.3. Installing the OpenShift CLI on macOS
11.3.14. Logging in to the cluster by using the CLI
11.3.15. Creating registry storage
  11.3.15.1. Image registry removed during installation
  11.3.15.2. Image registry storage configuration
  11.3.15.2.1. Configuring registry storage for VMware vSphere
  11.3.15.2.2. Configuring block registry storage for VMware vSphere
11.3.16. Backing up VMware vSphere volumes
11.3.17. Telemetry access for OpenShift Container Platform
11.3.18. Next steps

11.4. INSTALLING A CLUSTER ON VSPHERE WITH USER-PROVISIONED INFRASTRUCTURE
11.4.1. Prerequisites
11.4.2. Internet access for OpenShift Container Platform
11.4.3. VMware vSphere infrastructure requirements
11.4.4. Machine requirements for a cluster with user-provisioned infrastructure
  11.4.4.1. Required machines
  11.4.4.2. Network connectivity requirements
  11.4.4.3. Minimum resource requirements
  11.4.4.4. Certificate signing requests management
11.4.5. Creating the user-provisioned infrastructure
11.4.5.1. Networking requirements for user-provisioned infrastructure
   Network topology requirements
   Load balancers
   Ethernet adaptor hardware address requirements
   NTP configuration
11.4.5.2. User-provisioned DNS requirements
11.4.6. Generating an SSH private key and adding it to the agent
11.4.7. Obtaining the installation program
11.4.8. Manually creating the installation configuration file
   11.4.8.1. Sample install-config.yaml file for VMware vSphere
   11.4.8.2. Configuring the cluster-wide proxy during installation
11.4.9. Creating the Kubernetes manifest and Ignition config files
11.4.10. Extracting the infrastructure name
11.4.11. Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines in vSphere
11.4.12. Creating more Red Hat Enterprise Linux CoreOS (RHCOS) machines in vSphere
11.4.13. Disk partitioning
   Creating a separate /var partition
11.4.14. Installing the OpenShift CLI by downloading the binary
   11.4.14.1. Installing the OpenShift CLI on Linux
   11.4.14.2. Installing the OpenShift CLI on Windows
   11.4.14.3. Installing the OpenShift CLI on macOS
11.4.15. Creating the cluster
11.4.16. Logging in to the cluster by using the CLI
11.4.17. Approving the certificate signing requests for your machines
11.4.18. Initial Operator configuration
   11.4.18.1. Image registry removed during installation
   11.4.18.2. Image registry storage configuration
   11.4.18.2.1. Configuring registry storage for VMware vSphere
   11.4.18.2.2. Configuring storage for the image registry in non-production clusters
   11.4.18.2.3. Configuring block registry storage for VMware vSphere
11.4.19. Completing installation on user-provisioned infrastructure
11.4.20. Backing up VMware vSphere volumes
11.4.21. Telemetry access for OpenShift Container Platform
11.4.22. Next steps

11.5. INSTALLING A CLUSTER ON VSPHERE WITH NETWORK CUSTOMIZATIONS
11.5.1. Prerequisites
11.5.2. Internet access for OpenShift Container Platform
11.5.3. VMware vSphere infrastructure requirements
11.5.4. Machine requirements for a cluster with user-provisioned infrastructure
   11.5.4.1. Required machines
   11.5.4.2. Network connectivity requirements
   11.5.4.3. Minimum resource requirements
   11.5.4.4. Certificate signing requests management
11.5.5. Creating the user-provisioned infrastructure
   11.5.5.1. Networking requirements for user-provisioned infrastructure
      Network topology requirements
      Load balancers
      Ethernet adaptor hardware address requirements
      NTP configuration
   11.5.5.2. User-provisioned DNS requirements
11.5.6. Generating an SSH private key and adding it to the agent
11.5.7. Obtaining the installation program
11.5.8. Manually creating the installation configuration file
  11.5.8.1. Sample install-config.yaml file for VMware vSphere
  11.5.8.2. Configuring the cluster-wide proxy during installation
11.5.9. Network configuration phases
11.5.10. Specifying advanced network configuration
11.5.11. Cluster Network Operator configuration
  11.5.11.1. Cluster Network Operator configuration object
    defaultNetwork object configuration
    Configuration for the OpenShift SDN CNI cluster network provider
    Configuration for the OVN-Kubernetes CNI cluster network provider
    kubeProxyConfig object configuration
11.5.12. Creating the Ignition config files
11.5.13. Extracting the infrastructure name
11.5.14. Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines in vSphere
11.5.15. Creating more Red Hat Enterprise Linux CoreOS (RHCOS) machines in vSphere
11.5.16. Disk partitioning
    Creating a separate /var partition
11.5.17. Creating the cluster
11.5.18. Logging in to the cluster by using the CLI
11.5.19. Approving the certificate signing requests for your machines
  11.5.19.1. Initial Operator configuration
  11.5.19.2. Image registry removed during installation
  11.5.19.3. Image registry storage configuration
    11.5.19.3.1. Configuring block registry storage for VMware vSphere
11.5.20. Completing installation on user-provisioned infrastructure
11.5.21. Backing up VMware vSphere volumes
11.5.22. Telemetry access for OpenShift Container Platform
11.5.23. Next steps

11.6. INSTALLING A CLUSTER ON VSPHERE IN A RESTRICTED NETWORK
11.6.1. Prerequisites
11.6.2. About installations in restricted networks
  11.6.2.1. Additional limits
11.6.3. Internet access for OpenShift Container Platform
11.6.4. VMware vSphere infrastructure requirements
11.6.5. vCenter requirements
    Required vCenter account privileges
    Using OpenShift Container Platform with vMotion
    Cluster resources
    Cluster limits
    Networking requirements
    Required IP Addresses
    DNS records
11.6.6. Generating an SSH private key and adding it to the agent
11.6.7. Adding vCenter root CA certificates to your system trust
11.6.8. Creating the RHCOS image for restricted network installations
11.6.9. Creating the installation configuration file
  11.6.9.1. Installation configuration parameters
    11.6.9.1.1. Required configuration parameters
    11.6.9.1.2. Network configuration parameters
    11.6.9.1.3. Optional configuration parameters
    11.6.9.1.4. Additional VMware vSphere configuration parameters
    11.6.9.1.5. Optional VMware vSphere machine pool configuration parameters
  11.6.9.2. Sample install-config.yaml file for an installer-provisioned VMware vSphere cluster
### 11.6.9.3. Configuring the cluster-wide proxy during installation

11.6.10. Deploying the cluster

11.6.11. Installing the OpenShift CLI by downloading the binary

11.6.11.1. Installing the OpenShift CLI on Linux

11.6.11.2. Installing the OpenShift CLI on Windows

11.6.11.3. Installing the OpenShift CLI on macOS

11.6.12. Logging in to the cluster by using the CLI

11.6.13. Disabling the default OperatorHub sources

11.6.14. Creating registry storage

11.6.14.1. Image registry removed during installation

11.6.14.2. Image registry storage configuration

11.6.14.2.1. Configuring registry storage for VMware vSphere

11.6.15. Telemetry access for OpenShift Container Platform

11.6.16. Next steps

### 11.7. INSTALLING A CLUSTER ON VSphere IN A RESTRICTED NETWORK WITH USER-PROVISIONED INFRASTRUCTURE

11.7.1. Prerequisites

11.7.2. About installations in restricted networks

11.7.2.1. Additional limits

11.7.3. Internet access for OpenShift Container Platform

11.7.4. VMware vSphere infrastructure requirements

11.7.5. Machine requirements for a cluster with user-provisioned infrastructure

11.7.5.1. Required machines

11.7.5.2. Network connectivity requirements

11.7.5.3. Minimum resource requirements

11.7.5.4. Certificate signing requests management

11.7.6. Creating the user-provisioned infrastructure

11.7.6.1. Networking requirements for user-provisioned infrastructure

   - Network topology requirements
   - Load balancers

   - Ethernet adaptor hardware address requirements
   - NTP configuration

11.7.6.2. User-provisioned DNS requirements

11.7.7. Generating an SSH private key and adding it to the agent

11.7.8. Manually creating the installation configuration file

11.7.8.1. Sample install-config.yaml file for VMware vSphere

11.7.8.2. Configuring the cluster-wide proxy during installation

11.7.9. Creating the Kubernetes manifest and Ignition config files

11.7.10. Configuring chrony time service

11.7.11. Extracting the infrastructure name

11.7.12. Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines in vSphere

11.7.13. Creating more Red Hat Enterprise Linux CoreOS (RHCOS) machines in vSphere

11.7.14. Disk partitioning

   - Creating a separate /var partition

11.7.15. Creating the cluster

11.7.16. Logging in to the cluster by using the CLI

11.7.17. Approving the certificate signing requests for your machines

11.7.18. Initial Operator configuration

11.7.18.1. Disabling the default OperatorHub sources

11.7.18.2. Image registry storage configuration

   - Configuring registry storage for VMware vSphere

   - Configuring storage for the image registry in non-production clusters

   - Configuring block registry storage for VMware vSphere
11.7.19. Completing installation on user-provisioned infrastructure
11.7.20. Backing up VMware vSphere volumes
11.7.21. Telemetry access for OpenShift Container Platform
11.7.22. Next steps

11.8. UNINSTALLING A CLUSTER ON VSPHERE THAT USES INSTALLER-PROVISIONED INFRASTRUCTURE

11.8.1. Removing a cluster that uses installer-provisioned infrastructure

CHAPTER 12. INSTALLING ON VMC

12.1. INSTALLING A CLUSTER ON VMC

12.1.1. Setting up VMC for vSphere
12.1.1.1. VMC Sizer tool
12.1.2. vSphere prerequisites
12.1.3. Internet access for OpenShift Container Platform
12.1.4. VMware vSphere infrastructure requirements
12.1.5. vCenter requirements
   Required vCenter account privileges
   Using OpenShift Container Platform with vMotion
   Cluster resources
   Cluster limits
   Networking requirements
   Required IP Addresses
   DNS records
12.1.6. Generating an SSH private key and adding it to the agent
12.1.7. Obtaining the installation program
12.1.8. Adding vCenter root CA certificates to your system trust
12.1.9. Deploying the cluster
12.1.10. Installing the OpenShift CLI by downloading the binary
   12.1.10.1. Installing the OpenShift CLI on Linux
   12.1.10.2. Installing the OpenShift CLI on Windows
   12.1.10.3. Installing the OpenShift CLI on macOS
12.1.11. Logging in to the cluster by using the CLI
12.1.12. Creating registry storage
   12.1.12.1. Image registry removed during installation
   12.1.12.2. Image registry storage configuration
   12.1.12.2.1. Configuring registry storage for VMware vSphere
   12.1.12.2.2. Configuring block registry storage for VMware vSphere
12.1.13. Backing up VMware vSphere volumes
12.1.14. Telemetry access for OpenShift Container Platform
12.1.15. Next steps

12.2. INSTALLING A CLUSTER ON VMC WITH CUSTOMIZATIONS

  17.2.2. Storage ............................................................................. 2241
  17.2.3. Runtimes ......................................................................... 2241
17.3. INSTALLING A CLUSTER IN FIPS MODE ......................................... 2241
CHAPTER 1. MIRRORING IMAGES FOR A DISCONNECTED INSTALLATION

You can use the procedures in this section to ensure your clusters only use container images that satisfy your organizational controls on external content. Before you install a cluster on infrastructure that you provision in a restricted network, you must mirror the required container images into that environment. To mirror container images, you must have a registry for mirroring.

**IMPORTANT**

You must have access to the internet to obtain the necessary container images. In this procedure, you place your mirror registry on a mirror host that has access to both your network and the Internet. If you do not have access to a mirror host, use the Mirroring an Operator catalog procedure to copy images to a device you can move across network boundaries with.

1.1. PREREQUISITES

- You must have a container image registry that supports Docker v2-2 in the location that will host the OpenShift Container Platform cluster, such as one of the following registries:
  - Red Hat Quay
  - JFrog Artifactory
  - Sonatype Nexus Repository
  - Harbor

  If you have an entitlement to Red Hat Quay, see the documentation on deploying Red Hat Quay for proof-of-concept purposes or by using the Quay Operator. If you need additional assistance selecting and installing a registry, contact your sales representative or Red Hat support.

- If you do not already have an existing solution for a container image registry, subscribers of OpenShift Container Platform are provided a mirror registry for Red Hat OpenShift. The mirror registry for Red Hat OpenShift is included with your subscription and is a small-scale container registry that can be used to mirror the required container images of OpenShift Container Platform in disconnected installations.

1.2. ABOUT THE MIRROR REGISTRY

You can mirror the images that are required for OpenShift Container Platform installation and subsequent product updates to a container mirror registry such as Red Hat Quay, JFrog Artifactory, Sonatype Nexus Repository, or Harbor. If you do not have access to a large-scale container registry, you can use the mirror registry for Red Hat OpenShift, a small-scale container registry included with OpenShift Container Platform subscriptions.

You can use any container registry that supports Docker v2-2, such as Red Hat Quay, the mirror registry for Red Hat OpenShift, Artifactory, Sonatype Nexus Repository, or Harbor. Regardless of your chosen registry, the procedure to mirror content from Red Hat hosted sites on the internet to an isolated image registry is the same. After you mirror the content, you configure each cluster to retrieve this content from your mirror registry.
IMPORTANT

The internal registry of the OpenShift Container Platform cluster cannot be used as the target registry because it does not support pushing without a tag, which is required during the mirroring process.

If choosing a container registry that is not the mirror registry for Red Hat OpenShift, it must be reachable by every machine in the clusters that you provision. If the registry is unreachable, installation, updating, or normal operations such as workload relocation might fail. For that reason, you must run mirror registries in a highly available way, and the mirror registries must at least match the production availability of your OpenShift Container Platform clusters.

When you populate your mirror registry with OpenShift Container Platform images, you can follow two scenarios. If you have a host that can access both the internet and your mirror registry, but not your cluster nodes, you can directly mirror the content from that machine. This process is referred to as connected mirroring. If you have no such host, you must mirror the images to a file system and then bring that host or removable media into your restricted environment. This process is referred to as disconnected mirroring.

For mirrored registries, to view the source of pulled images, you must review the Trying to access log entry in the CRI-O logs. Other methods to view the image pull source, such as using the crictl images command on a node, show the non-mirrored image name, even though the image is pulled from the mirrored location.

NOTE

Red Hat does not test third party registries with OpenShift Container Platform.

Additional information

For information on viewing the CRI-O logs to view the image source, see Viewing the image pull source.

1.3. PREPARING YOUR MIRROR HOST

Before you perform the mirror procedure, you must prepare the host to retrieve content and push it to the remote location.

1.3.1. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) in order to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

IMPORTANT

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.6. Download and install the new version of oc.

1.3.1.1. Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.6 Linux Client entry and save the file.

4. Unpack the archive:
   
   $ tar xzvf <file>

5. Place the oc binary in a directory that is on your PATH. To check your PATH, execute the following command:

   $ echo $PATH

After you install the OpenShift CLI, it is available using the oc command:

   $ oc <command>

### 1.3.1.2. Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.6 Windows Client entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the oc binary to a directory that is on your PATH. To check your PATH, execute the following command:

   C:\> path

After you install the OpenShift CLI, it is available using the oc command:

   C:\> oc <command>

### 1.3.1.3. Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.6 MacOSX Client entry and save the file.

4. Unpack and unzip the archive.

5. Move the oc binary to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:
   ```
   $ echo $PATH
   ```

After you install the OpenShift CLI, it is available using the oc command:

```
$ oc <command>
```

1.4. CONFIGURING CREDENTIALS THAT ALLOW IMAGES TO BE MIRRORED

Create a container image registry credentials file that allows mirroring images from Red Hat to your mirror.

**WARNING**

Do not use this image registry credentials file as the pull secret when you install a cluster. If you provide this file when you install cluster, all of the machines in the cluster will have write access to your mirror registry.

**WARNING**

This process requires that you have write access to a container image registry on the mirror registry and adds the credentials to a registry pull secret.

**Prerequisites**

- You configured a mirror registry to use in your restricted network.
- You identified an image repository location on your mirror registry to mirror images into.
- You provisioned a mirror registry account that allows images to be uploaded to that image repository.

**Procedure**

Complete the following steps on the installation host:
1. Download your `registry.redhat.io` pull secret from the Red Hat OpenShift Cluster Manager and save it to a `.json` file.

2. Generate the base64-encoded user name and password or token for your mirror registry:

   $ echo -n '<user_name>:<password>' | base64 -w0
   BGVtbYk3ZHAtqXs=

   For `<user_name>` and `<password>`, specify the user name and password that you configured for your registry.

3. Make a copy of your pull secret in JSON format:

   $ cat ./pull-secret.text | jq . > <path>/<pull_secret_file_in_json>

   Specify the path to the folder to store the pull secret in and a name for the JSON file that you create.

   The contents of the file resemble the following example:

   ```json
   {
     "auths": {
       "cloud.openshift.com": {
         "auth": "b3BlbnNo...",
         "email": "you@example.com"
       },
       "quay.io": {
         "auth": "b3BlbnNo...",
         "email": "you@example.com"
       },
       "registry.connect.redhat.com": {
         "auth": "NTE3Njg5Nj...",
         "email": "you@example.com"
       },
       "registry.redhat.io": {
         "auth": "NTE3Njg5Nj...",
         "email": "you@example.com"
       }
     }
   }
   
   4. Edit the new file and add a section that describes your registry to it:

   "auths": {
     "<mirror_registry>": {
       "auth": "<credentials>",
       "email": "you@example.com"
     },
   }

   For `<mirror_registry>`, specify the registry domain name, and optionally the port, that your mirror registry uses to serve content. For example, `registry.example.com` or `registry.example.com:5000`
2. For `<credentials>`, specify the base64-encoded user name and password for the mirror registry.

The file resembles the following example:

```json
{
  "auths": {
    "registry.example.com": {
      "auth": "BGVtbYk3ZHAtqXs=",
      "email": "you@example.com"
    },
    "cloud.openshift.com": {
      "auth": "b3BlbnNo...",
      "email": "you@example.com"
    },
    "quay.io": {
      "auth": "b3BlbnNo...",
      "email": "you@example.com"
    },
    "registry.connect.redhat.com": {
      "auth": "NTE3Njg5Nj...",
      "email": "you@example.com"
    },
    "registry.redhat.io": {
      "auth": "NTE3Njg5Nj...",
      "email": "you@example.com"
    }
  }
}
```

1.5. MIRROR REGISTRY FOR RED HAT OPENSSHIFT

The *mirror registry for Red Hat OpenShift* is a small and streamlined container registry that you can use as a target for mirroring the required container images of OpenShift Container Platform for disconnected installations.

If you already have a container image registry, such as Red Hat Quay, you can skip these steps and go straight to [Mirroring the OpenShift Container Platform image repository](#).

**Prerequisites**

- An OpenShift Container Platform subscription.
- Red Hat Enterprise Linux (RHEL) 8 with Podman 3.3 and OpenSSL installed.
- Fully qualified domain name for the Red Hat Quay service, which must resolve through a DNS server.
- Passwordless `sudo` access on the target host.
- Key-based SSH connectivity on the target host. SSH keys are automatically generated for local installs. For remote hosts, you must generate your own SSH keys.
- 2 or more vCPUs.
8 GB of RAM.

- About 6.8 GB for OpenShift Container Platform 4.6 Release images, or about 696 GB for OpenShift Container Platform 4.6 Release images and OpenShift Container Platform 4.6 Red Hat Operator images. Up to 1 TB per stream or more is suggested.

**IMPORTANT**

These requirements are based on local testing results with only Release images and Operator images tested. Storage requirements can vary based on your organization’s needs. Some users might require more space, for example, when they mirror multiple z-streams. You can use standard Red Hat Quay functionality to remove unnecessary images and free up space.

### 1.5.1. Mirror registry for Red Hat OpenShift introduction

For disconnected deployments of OpenShift Container Platform, a container registry is required to carry out the installation of the clusters. To run a production-grade registry service on such a cluster, you must create a separate registry deployment to install the first cluster. The mirror registry for Red Hat OpenShift addresses this need and is included in every OpenShift subscription. It is available for download on the OpenShift console Downloads page.

The mirror registry for Red Hat OpenShift allows users to install a small-scale version of Red Hat Quay and its required components using the mirror-registry command line interface (CLI) tool. The mirror registry for Red Hat OpenShift is deployed automatically with pre-configured local storage and a local database. It also includes auto-generated user credentials and access permissions with a single set of inputs and no additional configuration choices to get started.

The mirror registry for Red Hat OpenShift provides a pre-determined network configuration and reports deployed component credentials and access URLs upon success. A limited set of optional configuration inputs like fully qualified domain name (FQDN) services, superuser name and password, and custom TLS certificates are also provided. This provides users with a container registry so that they can easily create an offline mirror of all OpenShift Container Platform release content when running OpenShift Container Platform in restricted network environments.

The mirror registry for Red Hat OpenShift is limited to hosting images that are required to install a disconnected OpenShift Container Platform cluster, such as Release images or Red Hat Operator images. It uses local storage on your Red Hat Enterprise Linux (RHEL) machine, and storage supported by RHEL is supported by the mirror registry for Red Hat OpenShift. Content built by customers should not be hosted by the mirror registry for Red Hat OpenShift.

Unlike Red Hat Quay, the mirror registry for Red Hat OpenShift is not a highly-available registry and only local file system storage is supported. Using the mirror registry for Red Hat OpenShift with more than one cluster is discouraged, because multiple clusters can create a single point of failure when updating your cluster fleet. It is advised to leverage the mirror registry for Red Hat OpenShift to install a cluster that can host a production-grade, highly-available registry such as Red Hat Quay, which can serve OpenShift Container Platform content to other clusters.

Use of the mirror registry for Red Hat OpenShift is optional if another container registry is already available in the install environment.

### 1.5.2. Mirroring on a local host with mirror registry for Red Hat OpenShift
This procedure explains how to install the `mirror registry for Red Hat OpenShift` on a local host using the `mirror-registry` installer tool. By doing so, users can create a local host registry running on port 443 for the purpose of storing a mirror of OpenShift Container Platform images.

**NOTE**

Installing the `mirror registry for Red Hat OpenShift` using the `mirror-registry` CLI tool makes several changes to your machine. After installation, a `/etc/quay-install` directory is created, which has installation files, local storage, and the configuration bundle. Trusted SSH keys are generated in case the deployment target is the local host, and systemd files on the host machine are set up to ensure that container runtimes are persistent. Additionally, an initial user named `init` is created with an automatically generated password. All access credentials are printed at the end of the install routine.

**Procedure**

1. Download the `mirror-registry.tar.gz` package for the latest version of the `mirror registry for Red Hat OpenShift` found on the OpenShift console `Downloads` page.

2. Install the `mirror registry for Red Hat OpenShift` on your local host with your current user account by using the `mirror-registry` tool. For a full list of available flags, see "mirror registry for Red Hat OpenShift flags”.

   ```bash
   $ sudo ./mirror-registry install \
   --quayHostname <host_example_com> \
   --quayRoot <example_directory_name>
   ```

3. Use the user name and password generated during installation to log into the registry by running the following command:

   ```bash
   $ podman login --authfile pull-secret.txt \
   -u init \
   -p <password> \
   <host_example_com>:8443 \
   --tls-verify=false
   ```

   You can avoid running `--tls-verify=false` by configuring your system to trust the generated rootCA certificates. See "Using SSL to protect connections to Red Hat Quay” and "Configuring the system to trust the certificate authority” for more information.

**NOTE**

You can also log in by accessing the UI at `https://<host.example.com>:8443` after installation.

4. You can mirror OpenShift Container Platform images after logging in. Depending on your needs, see either the "Mirroring the OpenShift Container Platform image repository” or the “Mirroring an Operator catalog” sections of this document.
NOTE

If there are issues with images stored by the *mirror registry for Red Hat OpenShift* due to storage layer problems, you can remirror the OpenShift Container Platform images, or reinstall mirror registry on more stable storage.

1.5.3. Mirroring on a remote host with mirror registry for Red Hat OpenShift

This procedure explains how to install the *mirror registry for Red Hat OpenShift* on a remote host using the *mirror-registry* tool. By doing so, users can create a registry to hold a mirror of OpenShift Container Platform images.

**NOTE**

Installing the *mirror registry for Red Hat OpenShift* using the *mirror-registry* CLI tool makes several changes to your machine. After installation, a */etc/quay-install* directory is created, which has installation files, local storage, and the configuration bundle. Trusted SSH keys are generated in case the deployment target is the local host, and systemd files on the host machine are set up to ensure that container runtimes are persistent. Additionally, an initial user named *init* is created with an automatically generated password. All access credentials are printed at the end of the install routine.

**Procedure**

1. Download the *mirror-registry.tar.gz* package for the latest version of the *mirror registry for Red Hat OpenShift* found on the OpenShift console *Downloads* page.

2. Install the *mirror registry for Red Hat OpenShift* on your local host with your current user account by using the *mirror-registry* tool. For a full list of available flags, see "mirror registry for Red Hat OpenShift flags".

   ```
   $ sudo ./mirror-registry install -v
   --targetHostname <host_example_com>
   --targetUsername <example_user>
   -k ~/.ssh/my_ssh_key
   --quayHostname <host_example_com>
   --quayRoot <example_directory_name>
   ```

3. Use the user name and password generated during installation to log into the mirror registry by running the following command:

   ```
   $ podman login --authfile pull-secret.txt
   -u init
   -p <password>
   <host_example_com>:8443
   --tls-verify=false
   ```

   You can avoid running *--tls-verify=false* by configuring your system to trust the generated rootCA certificates. See "Using SSL to protect connections to Red Hat Quay" and "Configuring the system to trust the certificate authority" for more information.
NOTE

You can also log in by accessing the UI at https://<host.example.com>:8443 after installation.

4. You can mirror OpenShift Container Platform images after logging in. Depending on your needs, see either the “Mirroring the OpenShift Container Platform image repository” or the "Mirroring an Operator catalog" sections of this document.

NOTE

If there are issues with images stored by the mirror registry for Red Hat OpenShift due to storage layer problems, you can remirror the OpenShift Container Platform images, or reinstall mirror registry on more stable storage.

1.6. UPGRADING THE MIRROR REGISTRY FOR RED HAT OPENSHIFT

- You can upgrade the mirror registry for Red Hat OpenShift from your local host by running the following command:

```bash
$ sudo ./mirror-registry upgrade
```

NOTE

- Users who upgrade the mirror registry for Red Hat OpenShift with the ./mirror-registry upgrade flag must include the same credentials used when creating their mirror registry. For example, if you installed the mirror registry for Red Hat OpenShift with --quayHostname <host_example_com> and --quayRoot <example_directory_name>, you must include that string to properly upgrade the mirror registry.

1.6.1. Uninstalling the mirror registry for Red Hat OpenShift

- You can uninstall the mirror registry for Red Hat OpenShift from your local host by running the following command:

```bash
$ sudo ./mirror-registry uninstall -v \
--quayRoot <example_directory_name>
```

NOTE

- Deleting the mirror registry for Red Hat OpenShift will prompt the user before deletion. You can use --autoApprove to skip this prompt.

- Users who install the mirror registry for Red Hat OpenShift with the --quayRoot flag must include the --quayRoot flag when uninstalling. For example, if you installed the mirror registry for Red Hat OpenShift with --quayRoot example_directory_name, you must include that string to properly uninstall the mirror registry.

1.6.2. Mirror registry for Red Hat OpenShift flags

The following flags are available for the mirror registry for Red Hat OpenShift:

```bash
$ sudo ./mirror-registry uninstall -v \
--quayRoot <example_directory_name>
```
<table>
<thead>
<tr>
<th>Flags</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--autoApprove</td>
<td>A boolean value that disables interactive prompts. If set to true, the quayRoot directory is automatically deleted when uninstalling the mirror registry. Defaults to false if left unspecified.</td>
</tr>
<tr>
<td>--initPassword</td>
<td>The password of the init user created during Quay installation. Must be at least eight characters and contain no whitespace.</td>
</tr>
<tr>
<td>--initUser string</td>
<td>Shows the username of the initial user. Defaults to init if left unspecified.</td>
</tr>
<tr>
<td>--quayHostname</td>
<td>The fully-qualified domain name of the mirror registry that clients will use to contact the registry. Equivalent to SERVER_HOSTNAME in the Quay config.yaml. Must resolve by DNS. Defaults to &lt;targetHostname&gt;:8443 if left unspecified. [1]</td>
</tr>
<tr>
<td>--quayRoot, -r</td>
<td>The directory where container image layer and configuration data is saved, including rootCA.key, rootCA.pem, and rootCA.srl certificates. Requires about 6.8 GB for OpenShift Container Platform 4.6 Release images, or about 696 GB for OpenShift Container Platform 4.6 Release images and OpenShift Container Platform 4.6 Red Hat Operator images. Defaults to /etc/quay-install if left unspecified.</td>
</tr>
<tr>
<td>--ssh-key, -k</td>
<td>The path of your SSH identity key. Defaults to ~/.ssh/quay_installer if left unspecified.</td>
</tr>
<tr>
<td>--sslCert</td>
<td>The path to the SSL/TLS public key / certificate. Defaults to {quayRoot}/quay-config and is auto-generated if left unspecified.</td>
</tr>
<tr>
<td>--sslCheckSkip</td>
<td>Skips the check for the certificate hostname against the SERVER_HOSTNAME in the config.yaml file.</td>
</tr>
<tr>
<td>--sslKey</td>
<td>The path to the SSL/TLS private key used for HTTPS communication. Defaults to {quayRoot}/quay-config and is auto-generated if left unspecified.</td>
</tr>
<tr>
<td>--targetHostname, -H</td>
<td>The hostname of the target you want to install Quay to. Defaults to $HOST, for example, a local host, if left unspecified.</td>
</tr>
<tr>
<td>--targetUsername, -u</td>
<td>The user on the target host which will be used for SSH. Defaults to $USER, for example, the current user if left unspecified.</td>
</tr>
<tr>
<td>--verbose, -v</td>
<td>Shows debug logs and Ansible playbook outputs.</td>
</tr>
<tr>
<td>--version</td>
<td>Shows the version for the mirror registry for Red Hat OpenShift</td>
</tr>
</tbody>
</table>

1. --quayHostname must be modified if the public DNS name of your system is different from the local hostname.
2. `--sslCheckSkip` is used in cases when the mirror registry is set behind a proxy and the exposed hostname is different from the internal Quay hostname. It can also be used when users do not want the certificates to be validated against the provided Quay hostname during installation.

Additional resources

- Using SSL to protect connections to Red Hat Quay
- Configuring the system to trust the certificate authority
- Mirroring the OpenShift Container Platform image repository
- Mirroring an Operator catalog

1.7. MIRRORING THE OPENShift CONTAINER PLATFORM IMAGE REPOSITORY

Mirror the OpenShift Container Platform image repository to your registry to use during cluster installation or upgrade.

Prerequisites

- Your mirror host has access to the Internet.
- You configured a mirror registry to use in your restricted network and can access the certificate and credentials that you configured.
- You downloaded the pull secret from the Red Hat OpenShift Cluster Manager and modified it to include authentication to your mirror repository.
- If you use self-signed certificates that do not set a Subject Alternative Name, you must precede the `oc` commands in this procedure with `GODEBUG=x509ignoreCN=0`. If you do not set this variable, the `oc` commands will fail with the following error:

```
x509: certificate relies on legacy Common Name field, use SANs or temporarily enable Common Name matching with GODEBUG=x509ignoreCN=0
```

Procedure

Complete the following steps on the mirror host:

1. Review the OpenShift Container Platform downloads page to determine the version of OpenShift Container Platform that you want to install and determine the corresponding tag on the Repository Tags page.

2. Set the required environment variables:
   a. Export the release version:

```
$ OCP_RELEASE=<release_version>
```

   For `<release_version>`, specify the tag that corresponds to the version of OpenShift Container Platform to install, such as 4.5.4.

   b. Export the local registry name and host port:
For `<local_registry_host_name>`, specify the registry domain name for your mirror repository, and for `<local_registry_host_port>`, specify the port that it serves content on.

c. Export the local repository name:

```
$ LOCAL_REPOSITORY='"<local_repository_name>"'
```

For `<local_repository_name>`, specify the name of the repository to create in your registry, such as `ocp4/openshift4`.

d. Export the name of the repository to mirror:

```
$ PRODUCT_REPO='openshift-release-dev'
```

For a production release, you must specify `openshift-release-dev`.

e. Export the path to your registry pull secret:

```
$ LOCAL_SECRET_JSON='"<path_to_pull_secret>"'
```

For `<path_to_pull_secret>`, specify the absolute path to and file name of the pull secret for your mirror registry that you created.

f. Export the release mirror:

```
$ RELEASE_NAME="ocp-release"
```

For a production release, you must specify `ocp-release`.

g. Export the type of architecture for your server, such as `x86_64`:

```
$ ARCHITECTURE=<server_architecture>
```

h. Export the path to the directory to host the mirrored images:

```
$ REMOVABLE_MEDIA_PATH=<path>  
```

1. Specify the full path, including the initial forward slash (/) character.

3. Mirror the version images to the mirror registry:

- If your mirror host does not have internet access, take the following actions:
  
i. Connect the removable media to a system that is connected to the internet.
  
ii. Review the images and configuration manifests to mirror:

```
$ oc adm release mirror -a ${LOCAL_SECRET_JSON}  
--from=quay.io/${PRODUCT_REPO}/${RELEASE_NAME}:${OCP_RELEASE}-${ARCHITECTURE} 
--to=${LOCAL_REGISTRY}/${LOCAL_REPOSITORY} 
```
iii. Record the entire `imageContentSources` section from the output of the previous command. The information about your mirrors is unique to your mirrored repository, and you must add the `imageContentSources` section to the `install-config.yaml` file during installation.

iv. Mirror the images to a directory on the removable media:

```bash
$ oc adm release mirror -a ${LOCAL_SECRET_JSON} --to-dir=${REMOVABLE_MEDIA_PATH}/mirror
quay.io/${PRODUCT_REPO}/${RELEASE_NAME}:${OCP_RELEASE}-${ARCHITECTURE}
```

v. Take the media to the restricted network environment and upload the images to the local container registry.

```bash
$ oc image mirror -a ${LOCAL_SECRET_JSON} --from-dir=${REMOVABLE_MEDIA_PATH}/mirror
"file://openshift/release:${OCP_RELEASE}"
${LOCAL_REGISTRY}/${LOCAL_REPOSITORY}
```

For `REMOVABLE_MEDIA_PATH`, you must use the same path that you specified when you mirrored the images.

- If the local container registry is connected to the mirror host, take the following actions:
  i. Directly push the release images to the local registry by using following command:

```bash
$ oc adm release mirror -a ${LOCAL_SECRET_JSON} \\--from=quay.io/${PRODUCT_REPO}/${RELEASE_NAME}:${OCP_RELEASE}-${ARCHITECTURE} \\--to=${LOCAL_REGISTRY}/${LOCAL_REPOSITORY} \\--to-release-image=${LOCAL_REGISTRY}/${LOCAL_REPOSITORY}:${OCP_RELEASE}-${ARCHITECTURE}
```

This command pulls the release information as a digest, and its output includes the `imageContentSources` data that you require when you install your cluster.

ii. Record the entire `imageContentSources` section from the output of the previous command. The information about your mirrors is unique to your mirrored repository, and you must add the `imageContentSources` section to the `install-config.yaml` file during installation.

**NOTE**

The image name gets patched to Quay.io during the mirroring process, and the podman images will show Quay.io in the registry on the bootstrap virtual machine.
To create the installation program that is based on the content that you mirrored, extract it and pin it to the release:

- If your mirror host does not have Internet access, run the following command:

  ```
  $ oc adm release extract -a ${LOCAL_SECRET_JSON} --command=openshift-install "${{LOCAL_REGISTRY}/${LOCAL_REPOSITORY}:${OCP_RELEASE}}"
  ```

- If the local container registry is connected to the mirror host, run the following command:

  ```
  $ oc adm release extract -a ${LOCAL_SECRET_JSON} --command=openshift-install "${{LOCAL_REGISTRY}/${LOCAL_REPOSITORY}:${OCPRELEASE}-${ARCHITECTURE}}"
  ```

**IMPORTANT**

To ensure that you use the correct images for the version of OpenShift Container Platform that you selected, you must extract the installation program from the mirrored content.

You must perform this step on a machine with an active Internet connection.

If you are in a disconnected environment, use the `--image` flag as part of must-gather and point to the payload image.

### 1.8. THE CLUSTER SAMPLES OPERATOR IN A DISCONNECTED ENVIRONMENT

In a disconnected environment, you must take additional steps after you install a cluster to configure the Cluster Samples Operator.

### 1.9. NEXT STEPS

- **Mirror** the OperatorHub images for the Operators that you want to install in your cluster.

- **Install** a cluster on infrastructure that you provision in your restricted network, such as on [VMware vSphere](https://www.vmware.com/products/vsphere.html), bare metal, or [Amazon Web Services](https://aws.amazon.com/).

### 1.10. ADDITIONAL RESOURCES

- See [Gathering data about specific features](#) for more information about using must-gather.
CHAPTER 2. INSTALLING ON AWS

2.1. CONFIGURING AN AWS ACCOUNT

Before you can install OpenShift Container Platform, you must configure an Amazon Web Services (AWS) account.

2.1.1. Configuring Route 53

To install OpenShift Container Platform, the Amazon Web Services (AWS) account you use must have a dedicated public hosted zone in your Route 53 service. This zone must be authoritative for the domain. The Route 53 service provides cluster DNS resolution and name lookup for external connections to the cluster.

Procedure

1. Identify your domain, or subdomain, and registrar. You can transfer an existing domain and registrar or obtain a new one through AWS or another source.

   NOTE
   If you purchase a new domain through AWS, it takes time for the relevant DNS changes to propagate. For more information about purchasing domains through AWS, see Registering Domain Names Using Amazon Route 53 in the AWS documentation.

2. If you are using an existing domain and registrar, migrate its DNS to AWS. See Making Amazon Route 53 the DNS Service for an Existing Domain in the AWS documentation.

3. Create a public hosted zone for your domain or subdomain. See Creating a Public Hosted Zone in the AWS documentation.
   Use an appropriate root domain, such as openshiftcorp.com, or subdomain, such as clusters.openshiftcorp.com.

4. Extract the new authoritative name servers from the hosted zone records. See Getting the Name Servers for a Public Hosted Zone in the AWS documentation.

5. Update the registrar records for the AWS Route 53 name servers that your domain uses. For example, if you registered your domain to a Route 53 service in a different accounts, see the following topic in the AWS documentation: Adding or Changing Name Servers or Glue Records.

6. If you are using a subdomain, add its delegation records to the parent domain. This gives Amazon Route 53 responsibility for the subdomain. Follow the delegation procedure outlined by the DNS provider of the parent domain. See Creating a subdomain that uses Amazon Route 53 as the DNS service without migrating the parent domain in the AWS documentation for an example high level procedure.

2.1.1.1. Ingress Operator endpoint configuration for AWS Route 53

If you install in either Amazon Web Services (AWS) GovCloud (US) US-West or US-East region, the Ingress Operator uses us-gov-west-1 region for Route53 and tagging API clients.

The Ingress Operator uses https://tagging.us-gov-west-1.amazonaws.com as the tagging API endpoint if a tagging custom endpoint is configured that includes the string ‘us-gov-east-1’.
For more information on AWS GovCloud (US) endpoints, see the Service Endpoints in the AWS documentation about GovCloud (US).

**IMPORTANT**

Private, disconnected installations are not supported for AWS GovCloud when you install in the **us-gov-east-1** region.

Example Route 53 configuration

```
platform:
  aws:
    region: us-gov-west-1
    serviceEndpoints:
      - name: ec2
        url: https://ec2.us-gov-west-1.amazonaws.com
      - name: elasticloadbalancing
        url: https://elasticloadbalancing.us-gov-west-1.amazonaws.com
      - name: route53
        url: https://route53.us-gov.amazonaws.com
      - name: tagging
        url: https://tagging.us-gov-west-1.amazonaws.com
```

1. Route 53 defaults to **https://route53.us-gov.amazonaws.com** for both AWS GovCloud (US) regions.

2. Only the US-West region has endpoints for tagging. Omit this parameter if your cluster is in another region.

### 2.1.2. AWS account limits

The OpenShift Container Platform cluster uses a number of Amazon Web Services (AWS) components, and the default Service Limits affect your ability to install OpenShift Container Platform clusters. If you use certain cluster configurations, deploy your cluster in certain AWS regions, or run multiple clusters from your account, you might need to request additional resources for your AWS account.

The following table summarizes the AWS components whose limits can impact your ability to install and run OpenShift Container Platform clusters.
<table>
<thead>
<tr>
<th>Component</th>
<th>Number of clusters available by default</th>
<th>Default AWS limit</th>
<th>Description</th>
</tr>
</thead>
</table>
| Instance Limits | Varies | Varies | By default, each cluster creates the following instances:  
  - One bootstrap machine, which is removed after installation  
  - Three control plane nodes (also known as the master nodes)  
  - Three worker nodes  
  These instance type counts are within a new account’s default limit. To deploy more worker nodes, enable autoscaling, deploy large workloads, or use a different instance type, review your account limits to ensure that your cluster can deploy the machines that you need.  
  In most regions, the bootstrap and worker machines uses an m4.large machines and the control plane machines use m4.xlarge instances. In some regions, including all regions that do not support these instance types, m5.large and m5.xlarge instances are used instead. |
| Elastic IPs (EIPs) | 0 to 1 | 5 EIPs per account | To provision the cluster in a highly available configuration, the installation program creates a public and private subnet for each availability zone within a region. Each private subnet requires a NAT Gateway, and each NAT gateway requires a separate elastic IP. Review the AWS region map to determine how many availability zones are in each region. To take advantage of the default high availability, install the cluster in a region with at least three availability zones. To install a cluster in a region with more than five availability zones, you must increase the EIP limit.  
  **IMPORTANT**  
  To use the us-east-1 region, you must increase the EIP limit for your account. |
| Virtual Private Clouds (VPCs) | 5 | 5 VPCs per region | Each cluster creates its own VPC. |
### Component

<table>
<thead>
<tr>
<th>Component</th>
<th>Number of clusters available by default</th>
<th>Default AWS limit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Elastic Load Balancing (ELB/NLB)</td>
<td>3</td>
<td>20 per region</td>
<td>By default, each cluster creates internal and external network load balancers for the master API server and a single classic elastic load balancer for the router. Deploying more Kubernetes Service objects with type LoadBalancer will create additional load balancers.</td>
</tr>
<tr>
<td>NAT Gateways</td>
<td>5</td>
<td>5 per availability zone</td>
<td>The cluster deploys one NAT gateway in each availability zone.</td>
</tr>
<tr>
<td>Elastic Network Interfaces (ENIs)</td>
<td>At least 12</td>
<td>350 per region</td>
<td>The default installation creates 21 ENIs and an ENI for each availability zone in your region. For example, the us-east-1 region contains six availability zones, so a cluster that is deployed in that zone uses 27 ENIs. Review the AWS region map to determine how many availability zones are in each region. Additional ENIs are created for additional machines and elastic load balancers that are created by cluster usage and deployed workloads.</td>
</tr>
<tr>
<td>VPC Gateway</td>
<td>20</td>
<td>20 per account</td>
<td>Each cluster creates a single VPC Gateway for S3 access.</td>
</tr>
<tr>
<td>S3 buckets</td>
<td>99</td>
<td>100 buckets per account</td>
<td>Because the installation process creates a temporary bucket and the registry component in each cluster creates a bucket, you can create only 99 OpenShift Container Platform clusters per AWS account.</td>
</tr>
<tr>
<td>Security Groups</td>
<td>250</td>
<td>2,500 per account</td>
<td>Each cluster creates 10 distinct security groups.</td>
</tr>
</tbody>
</table>

### 2.1.3. Required AWS permissions

**NOTE**

Your IAM user must have the permission `tag:GetResources` in the region us-east-1 to delete the base cluster resources. As part of the AWS API requirement, the OpenShift Container Platform installation program performs various actions in this region.
When you attach the **AdministratorAccess** policy to the IAM user that you create in Amazon Web Services (AWS), you grant that user all of the required permissions. To deploy all components of an OpenShift Container Platform cluster, the IAM user requires the following permissions:

### Example 2.1. Required EC2 permissions for installation

- `tag:TagResources`
- `tag:UntagResources`
- `ec2:AllocateAddress`
- `ec2:AssociateAddress`
- `ec2:AuthorizeSecurityGroupEgress`
- `ec2:AuthorizeSecurityGroupIngress`
- `ec2:CopyImage`
- `ec2:CreateNetworkInterface`
- `ec2:AttachNetworkInterface`
- `ec2:CreateSecurityGroup`
- `ec2:CreateTags`
- `ec2:CreateVolume`
- `ec2:DeleteSecurityGroup`
- `ec2:DeleteSnapshot`
- `ec2:DeleteTags`
- `ec2:DeregisterImage`
- `ec2:DescribeAccountAttributes`
- `ec2:DescribeAddresses`
- `ec2:DescribeAvailabilityZones`
- `ec2:DescribeDhcpOptions`
- `ec2:DescribeImages`
- `ec2:DescribeInstanceAttribute`
- `ec2:DescribeInstanceCreditSpecifications`
- `ec2:DescribeInstances`
- `ec2:DescribeInternetGateways`
- `ec2:DescribeKeyPairs`
• `ec2:DescribeNatGateways`
• `ec2:DescribeNetworkAcls`
• `ec2:DescribeNetworkInterfaces`
• `ec2:DescribePrefixLists`
• `ec2:DescribeRegions`
• `ec2:DescribeRouteTables`
• `ec2:DescribeSecurityGroups`
• `ec2:DescribeSubnets`
• `ec2:DescribeTags`
• `ec2:DescribeVolumes`
• `ec2:DescribeVpcAttribute`
• `ec2:DescribeVpcClassicLink`
• `ec2:DescribeVpcClassicLinkDnsSupport`
• `ec2:DescribeVpcEndpoints`
• `ec2:DescribeVpcs`
• `ec2:GetEbsDefaultKmsKeyId`
• `ec2:ModifyInstanceAttribute`
• `ec2:ModifyNetworkInterfaceAttribute`
• `ec2:ReleaseAddress`
• `ec2:RevokeSecurityGroupEgress`
• `ec2:RevokeSecurityGroupIngress`
• `ec2:RunInstances`
• `ec2:TerminateInstances`

Example 2.2. Required permissions for creating network resources during installation

• `ec2:AssociateDhcpOptions`
• `ec2:AssociateRouteTable`
• `ec2:AttachInternetGateway`
• `ec2:CreateDhcpOptions`
• `ec2:CreateInternetGateway`
- ec2:CreateNatGateway
- ec2:CreateRoute
- ec2:CreateRouteTable
- ec2:CreateSubnet
- ec2:CreateVpc
- ec2:CreateVpcEndpoint
- ec2:ModifySubnetAttribute
- ec2:ModifyVpcAttribute

NOTE
If you use an existing VPC, your account does not require these permissions for creating network resources.

Example 2.3. Required Elastic Load Balancing permissions (ELB) for installation

- elasticloadbalancing:AddTags
- elasticloadbalancing:ApplySecurityGroupsToLoadBalancer
- elasticloadbalancing:AttachLoadBalancerToSubnets
- elasticloadbalancing:ConfigureHealthCheck
- elasticloadbalancing:CreateLoadBalancer
- elasticloadbalancing:CreateLoadBalancerListeners
- elasticloadbalancing:DeleteLoadBalancer
- elasticloadbalancing:DeregisterInstancesFromLoadBalancer
- elasticloadbalancing:DescribeInstanceHealth
- elasticloadbalancing:DescribeLoadBalancerAttributes
- elasticloadbalancing:DescribeLoadBalancers
- elasticloadbalancing:DescribeTags
- elasticloadbalancing:ModifyLoadBalancerAttributes
- elasticloadbalancing:RegisterInstancesWithLoadBalancer
- elasticloadbalancing:SetLoadBalancerPoliciesOfListener

Example 2.4. Required Elastic Load Balancing permissions (ELBv2) for installation
• elasticloadbalancing:AddTags
• elasticloadbalancing:CreateListener
• elasticloadbalancing:CreateLoadBalancer
• elasticloadbalancing:CreateTargetGroup
• elasticloadbalancing:DeleteLoadBalancer
• elasticloadbalancing:DeregisterTargets
• elasticloadbalancing:DescribeListeners
• elasticloadbalancing:DescribeLoadBalancerAttributes
• elasticloadbalancing:DescribeLoadBalancers
• elasticloadbalancing:DescribeTargetGroupAttributes
• elasticloadbalancing:DescribeTargetHealth
• elasticloadbalancing:ModifyLoadBalancerAttributes
• elasticloadbalancing:ModifyTargetGroup
• elasticloadbalancing:ModifyTargetGroupAttributes
• elasticloadbalancing:RegisterTargets

Example 2.5. Required IAM permissions for installation

• iam:AddRoleToInstanceProfile
• iam:CreateInstanceProfile
• iam:CreateRole
• iam:DeleteInstanceProfile
• iam:DeleteRole
• iam:DeleteRolePolicy
• iam:GetInstanceProfile
• iam:GetRole
• iam:GetRolePolicy
• iam:GetUser
• iam:ListInstanceProfilesForRole
• iam:ListRoles
• iam:ListUsers
• **iam:** PassRole
• **iam:** PutRolePolicy
• **iam:** RemoveRoleFromInstanceProfile
• **iam:** SimulatePrincipalPolicy
• **iam:** TagRole

**NOTE**
If you have not created an elastic load balancer (ELB) in your AWS account, the IAM user also requires the **iam:** CreateServiceLinkedRole permission.

Example 2.6. Required Route 53 permissions for installation
• **route53:** ChangeResourceRecordSets
• **route53:** ChangeTagsForResource
• **route53:** CreateHostedZone
• **route53:** DeleteHostedZone
• **route53:** GetChange
• **route53:** GetHostedZone
• **route53:** ListHostedZones
• **route53:** ListHostedZonesByName
• **route53:** ListResourceRecordSets
• **route53:** ListTagsForResource
• **route53:** UpdateHostedZoneComment

Example 2.7. Required S3 permissions for installation
• **s3:** CreateBucket
• **s3:** DeleteBucket
• **s3:** GetAccelerateConfiguration
• **s3:** GetBucketAcl
• **s3:** GetBucketCors
• **s3:** GetBucketLocation
• **s3:** GetBucketLogging
Example 2.8. S3 permissions that cluster Operators require

- s3:DeleteObject
- s3:GetObject
- s3:GetObjectAcl
- s3:GetObjectTagging
- s3:GetObjectVersion
- s3:PutObject
- s3:PutObjectAcl
- s3:PutObjectTagging

Example 2.9. Required permissions to delete base cluster resources

- autoscaling:DescribeAutoScalingGroups
- ec2:DeleteNetworkInterface
- ec2:DeleteVolume
- elasticloadbalancing:DeleteTargetGroup
- elasticloadbalancing:DescribeTargetGroups
**Example 2.10. Required permissions to delete network resources**

- ec2:DeleteDhcpOptions
- ec2:DeleteInternetGateway
- ec2:DeleteNatGateway
- ec2:DeleteRoute
- ec2:DeleteRouteTable
- ec2:DeleteSubnet
- ec2:DeleteVpc
- ec2:DeleteVpcEndpoints
- ec2:DetachInternetGateway
- ec2:DisassociateRouteTable
- ec2:ReplaceRouteTableAssociation

**NOTE**
If you use an existing VPC, your account does not require these permissions to delete network resources.

**Example 2.11. Additional IAM and S3 permissions that are required to create manifests**

- iam:DeleteAccessKey
- iam:DeleteUser
- iam:DeleteUserPolicy
- s3:DeleteObject
- s3:ListBucketVersions
- tag:GetResources
- `iam:GetUserPolicy`
- `iam:ListAccessKeys`
- `iam:PutUserPolicy`
- `iam:TagUser`
- `iam:GetUserPolicy`
- `iam:ListAccessKeys`
- `s3:PutBucketPublicAccessBlock`
- `s3:GetBucketPublicAccessBlock`
- `s3:PutLifecycleConfiguration`
- `s3:HeadBucket`
- `s3:ListBucketMultipartUploads`
- `s3:AbortMultipartUpload`

**NOTE**

If you are managing your cloud provider credentials with mint mode, the IAM user also requires the `iam:CreateAccessKey` and `iam:CreateUser` permissions.

---

**Example 2.12. Optional permission for quota checks for installation**

- `servicequotas:ListAWSDefaultServiceQuotas`

---

### 2.1.4. Creating an IAM user

Each Amazon Web Services (AWS) account contains a root user account that is based on the email address you used to create the account. This is a highly-privileged account, and it is recommended to use it for only initial account and billing configuration, creating an initial set of users, and securing the account.

Before you install OpenShift Container Platform, create a secondary IAM administrative user. As you complete the [Creating an IAM User in Your AWS Account](aws_documentation) procedure in the AWS documentation, set the following options:

**Procedure**

1. Specify the IAM user name and select **Programmatic access**.

2. Attach the **AdministratorAccess** policy to ensure that the account has sufficient permission to create the cluster. This policy provides the cluster with the ability to grant credentials to each OpenShift Container Platform component. The cluster grants the components only the credentials that they require.
NOTE

While it is possible to create a policy that grants the all of the required AWS permissions and attach it to the user, this is not the preferred option. The cluster will not have the ability to grant additional credentials to individual components, so the same credentials are used by all components.

3. Optional: Add metadata to the user by attaching tags.

4. Confirm that the user name that you specified is granted the AdministratorAccess policy.

5. Record the access key ID and secret access key values. You must use these values when you configure your local machine to run the installation program.

IMPORTANT

You cannot use a temporary session token that you generated while using a multi-factor authentication device to authenticate to AWS when you deploy a cluster. The cluster continues to use your current AWS credentials to create AWS resources for the entire life of the cluster, so you must use key-based, long-lived credentials.

Additional resources

- See Manually creating IAM for AWS for steps to set the Cloud Credential Operator (CCO) to manual mode prior to installation. Use this mode in environments where the cloud identity and access management (IAM) APIs are not reachable, or if you prefer not to store an administrator-level credential secret in the cluster kube-system project.

2.1.5. Supported AWS regions

You can deploy an OpenShift Container Platform cluster to the following public regions:

NOTE

Your IAM user must have the permission tag:GetResources in the region us-east-1 to delete the base cluster resources. As part of the AWS API requirement, the OpenShift Container Platform installation program performs various actions in this region.

- af-south-1 (Cape Town)
- ap-east-1 (Hong Kong)
- ap-northeast-1 (Tokyo)
- ap-northeast-2 (Seoul)
- ap-northeast-3 (Osaka)
- ap-south-1 (Mumbai)
- ap-southeast-1 (Singapore)
- ap-southeast-2 (Sydney)
- ca-central-1 (Central)
- eu-central-1 (Frankfurt)
- eu-north-1 (Stockholm)
- eu-south-1 (Milan)
- eu-west-1 (Ireland)
- eu-west-2 (London)
- eu-west-3 (Paris)
- me-south-1 (Bahrain)
- sa-east-1 (São Paulo)
- us-east-1 (N. Virginia)
- us-east-2 (Ohio)
- us-west-1 (N. California)
- us-west-2 (Oregon)

The following AWS GovCloud regions are supported:
- us-gov-west-1
- us-gov-east-1

### 2.1.6. Next steps
- Install an OpenShift Container Platform cluster:
  - [Quickly install a cluster](#) with default options on installer-provisioned infrastructure
  - [Install a cluster with cloud customizations](#) on installer-provisioned infrastructure
  - [Install a cluster with network customizations](#)
  - [Installing a cluster on user-provisioned](#) infrastructure in AWS by using CloudFormation templates

### 2.2. MANUALLY CREATING IAM FOR AWS

In environments where the cloud identity and access management (IAM) APIs are not reachable, or the administrator prefers not to store an administrator-level credential secret in the cluster `kube-system` namespace, you can put the Cloud Credential Operator (CCO) into manual mode before you install the cluster.

#### 2.2.1. Alternatives to storing administrator-level secrets in the `kube-system` project

The Cloud Credential Operator (CCO) manages cloud provider credentials as Kubernetes custom resource definitions (CRDs). You can configure the CCO to suit the security requirements of your
organization by setting different values for the `credentialsMode` parameter in the `install-config.yaml` file.

If you prefer not to store an administrator-level credential secret in the cluster `kube-system` project, you can choose one of the following options when installing OpenShift Container Platform:

- **Manage cloud credentials manually.**
  You can set the `credentialsMode` parameter for the CCO to `Manual` to manage cloud credentials manually. Using manual mode allows each cluster component to have only the permissions it requires, without storing an administrator-level credential in the cluster. You can also use this mode if your environment does not have connectivity to the cloud provider public IAM endpoint. However, you must manually reconcile permissions with new release images for every upgrade. You must also manually supply credentials for every component that requests them.

- **Remove the administrator-level credential secret after installing OpenShift Container Platform with mint mode:**
  If you are using the CCO with the `credentialsMode` parameter set to `Mint`, you can remove or rotate the administrator-level credential after installing OpenShift Container Platform. Mint mode is the default configuration for the CCO. This option requires the presence of the administrator-level credential during an installation. The administrator-level credential is used during the installation to mint other credentials with some permissions granted. The original credential secret is not stored in the cluster permanently.

  **NOTE**
  Prior to a non z-stream upgrade, you must reinstate the credential secret with the administrator-level credential. If the credential is not present, the upgrade might be blocked.

**Additional resources**

- To learn how to rotate or remove the administrator-level credential secret after installing OpenShift Container Platform, see Rotating or removing cloud provider credentials.

- For a detailed description of all available CCO credential modes and their supported platforms, see Cloud Credential Operator.

### 2.2.2. Manually create IAM

The Cloud Credential Operator (CCO) can be put into manual mode prior to installation in environments where the cloud identity and access management (IAM) APIs are not reachable, or the administrator prefers not to store an administrator-level credential secret in the cluster `kube-system` namespace.

**Procedure**

1. Change to the directory that contains the installation program and create the `install-config.yaml` file:

   ```
   $ openshift-install create install-config --dir <installation_directory>
   ```

2. Edit the `install-config.yaml` configuration file so that it contains the `credentialsMode` parameter set to `Manual`. 
Example install-config.yaml configuration file

```yaml
apiVersion: v1
baseDomain: cluster1.example.com
credentialsMode: Manual
compute:
  - architecture: amd64
    hyperthreading: Enabled
...
```

1. This line is added to set the `credentialsMode` parameter to *Manual*.

3. To generate the manifests, run the following command from the directory that contains the installation program:

   ```bash
   $ openshift-install create manifests --dir <installation_directory>
   ```

   1. For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

4. Remove the `admin` credential secret created using your local cloud credentials. This removal prevents your `admin` credential from being stored in the cluster:

   ```bash
   $ rm mycluster/openshift/99_cloud-creds-secret.yaml
   ```

5. From the directory that contains the installation program, obtain details of the OpenShift Container Platform release image that your `openshift-install` binary is built to use:

   ```bash
   $ openshift-install version
   release image quay.io/openshift-release-dev/ocp-release:4.y.z-x86_64
   ```

Example output

```bash
release image quay.io/openshift-release-dev/ocp-release:4.y.z-x86_64
```

6. Locate all `CredentialsRequest` objects in this release image that target the cloud you are deploying on:

   ```bash
   $ oc adm release extract quay.io/openshift-release-dev/ocp-release:4.y.z-x86_64 --credentials-requests --cloud=aws
   ```

   This displays the details for each request.

Sample `CredentialsRequest` object

```yaml
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
  name: cloud-credential-operator-iam-ro
  namespace: openshift-cloud-credential-operator
spec:
  secretRef:
```
7. Create YAML files for secrets in the `openshift-install` manifests directory that you generated previously. The secrets must be stored using the namespace and secret name defined in the `spec.secretRef` for each `credentialsRequest`. The format for the secret data varies for each cloud provider.

8. From the directory that contains the installation program, proceed with your cluster creation:

```bash
$ openshift-install create cluster --dir <installation_directory>
```

### IMPORTANT

Before upgrading a cluster that uses manually maintained credentials, you must ensure that the CCO is in an upgradeable state. For details, see the Upgrading clusters with manually maintained credentials section of the installation content for your cloud provider.

### 2.2.3. Admin credentials root secret format

Each cloud provider uses a credentials root secret in the `kube-system` namespace by convention, which is then used to satisfy all credentials requests and create their respective secrets. This is done either by minting new credentials, with `mint mode`, or by copying the credentials root secret, with `passthrough mode`.

The format for the secret varies by cloud, and is also used for each `CredentialsRequest` secret.

#### Amazon Web Services (AWS) secret format

```yaml
apiVersion: v1
deprecated:
  kubectlDeleteStrategy:
    apiVersion: v1
    kind: Pod
    metadata:
      namespace: kube-system
    name: aws-creds
    spec:
      containers:
      - name: aws-creds
        imagePullPolicy: Always
        image: "image"
        command:
          - "command"
        volumeMounts:
          - mountPath: "mountPath"
            name: "name"
        env:
          - name: "name"
            value: "value"
      volumes:
        - name: "name"
          emptyDir:
            medium: "medium"
        - name: "name"
          configMap:
            name: "name"
            resourceVersion: "resourceVersion"  
            optional: true  
            items:
              - key: "key"
                name: "name"
            defaultMode: "defaultMode"
          defaultMode: "defaultMode"
      initContainers:
        - name: "name"
          image: "image"
          command:
            - "command"
          volumeMounts:
            - mountPath: "mountPath"
              name: "name"
          env:
            - name: "name"
              value: "value"
```

### 2.2.4. Upgrading clusters with manually maintained credentials

If credentials are added in a future release, the Cloud Credential Operator (CCO) **upgradable** status for a cluster with manually maintained credentials changes to **false**. For minor release, for example, from 4.5 to 4.6, this status prevents you from upgrading until you have addressed any updated permissions.
For z-stream releases, for example, from 4.5.10 to 4.5.11, the upgrade is not blocked, but the credentials must still be updated for the new release.

Use the Administrator perspective of the web console to determine if the CCO is upgradeable.

1. Navigate to Administration → Cluster Settings.
2. To view the CCO status details, click cloud-credential in the Cluster Operators list.
3. If the Upgradeable status in the Conditions section is False, examine the credentialsRequests for the new release and update the manually maintained credentials on your cluster to match before upgrading.

In addition to creating new credentials for the release image that you are upgrading to, you must review the required permissions for existing credentials and accommodate any new permissions requirements for existing components in the new release. The CCO cannot detect these mismatches and will not set upgradable to false in this case.

The Manually creating IAM section of the installation content for your cloud provider explains how to obtain and use the credentials required for your cloud.

2.2.5. Mint mode

Mint mode is the default and recommended Cloud Credential Operator (CCO) credentials mode for OpenShift Container Platform. In this mode, the CCO uses the provided administrator-level cloud credential to run the cluster. Mint mode is supported for AWS, GCP, and Azure.

In mint mode, the admin credential is stored in the kube-system namespace and then used by the CCO to process the CredentialsRequest objects in the cluster and create users for each with specific permissions.

The benefits of mint mode include:

- Each cluster component has only the permissions it requires
- Automatic, on-going reconciliation for cloud credentials, including additional credentials or permissions that might be required for upgrades

One drawback is that mint mode requires admin credential storage in a cluster kube-system secret.

2.2.6. Mint Mode with removal or rotation of the admin credential

Currently, this mode is only supported on AWS.

In this mode, a user installs OpenShift Container Platform with an admin credential just like the normal mint mode. However, this mode removes the admin credential secret from the cluster post-installation.

The administrator can have the Cloud Credential Operator make its own request for a read-only credential that allows it to verify if all CredentialsRequest objects have their required permissions, thus the admin credential is not required unless something needs to be changed. After the associated credential is removed, it can be destroyed on the underlying cloud, if desired.

Prior to upgrade, the admin credential should be restored. In the future, upgrade might be blocked if the credential is not present.

The admin credential is not stored in the cluster permanently.
This mode still requires the **admin** credential in the cluster for brief periods of time. It also requires manually re-instating the secret with **admin** credentials for each upgrade.

### 2.2.7. Next steps

- Install an OpenShift Container Platform cluster:
  - Installing a cluster quickly on AWS with default options on installer-provisioned infrastructure
  - Install a cluster with cloud customizations on installer-provisioned infrastructure
  - Install a cluster with network customizations on installer-provisioned infrastructure
  - Installing a cluster on user-provisioned infrastructure in AWS by using CloudFormation templates

### 2.3. INSTALLING A CLUSTER QUICKLY ON AWS

In OpenShift Container Platform version 4.6, you can install a cluster on Amazon Web Services (AWS) that uses the default configuration options.

#### 2.3.1. Prerequisites

- Review details about the OpenShift Container Platform installation and update processes.
- Configure an AWS account to host the cluster.

**IMPORTANT**

If you have an AWS profile stored on your computer, it must not use a temporary session token that you generated while using a multi-factor authentication device. The cluster continues to use your current AWS credentials to create AWS resources for the entire life of the cluster, so you must use key-based, long-lived credentials. To generate appropriate keys, see Managing Access Keys for IAM Users in the AWS documentation. You can supply the keys when you run the installation program.

- If you use a firewall, you must configure it to allow the sites that your cluster requires access to.
- If you do not allow the system to manage identity and access management (IAM), then a cluster administrator can manually create and maintain IAM credentials. Manual mode can also be used in environments where the cloud IAM APIs are not reachable.

#### 2.3.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.6, you require access to the Internet to install your cluster.

You must have Internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
• Access Quay.io to obtain the packages that are required to install your cluster.

• Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

2.3.3. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your `ssh-agent` and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

**NOTE**

In a production environment, you require disaster recovery and debugging.

You can use this key to SSH into the master nodes as the user `core`. When you deploy the cluster, the key is added to the `core` user’s `~/.ssh/authorized_keys` list.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

**Procedure**

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>
   ```

   Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

   Running this command generates an SSH key that does not require a password in the location that you specified.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the `ed25519` algorithm. Instead, create a key that uses the `rsa` or `ecdsa` algorithm.
2. Start the `ssh-agent` process as a background task:

```
$ eval "$(ssh-agent -s)"
```

**Example output**

```
Agent pid 31874
```

**NOTE**

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the `ssh-agent`:

```
$ ssh-add <path>/<file_name>
```

**Example output**

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

**2.3.4. Obtaining the installation program**

Before you install OpenShift Container Platform, download the installation file on a local computer.

**Prerequisites**

- You have a computer that runs Linux or macOS, with 500 MB of local disk space

**Procedure**

1. Access the [Infrastructure Provider](#) page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.
IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```bash
$ tar xvf openshift-install-linux.tar.gz
```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 2.3.5. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

**Prerequisites**

- Configure an account with the cloud platform that hosts your cluster.
- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Change to the directory that contains the installation program and initialize the cluster deployment:

   ```bash
   $ ./openshift-install create cluster --dir <installation_directory> \
   --log-level=info
   ```

   1. For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

   2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`. 

Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

Provide values at the prompts:

a. Optional: Select an SSH key to use to access your cluster machines.

b. Select `aws` as the platform to target.

c. If you do not have an Amazon Web Services (AWS) profile stored on your computer, enter the AWS access key ID and secret access key for the user that you configured to run the installation program.

d. Select the AWS region to deploy the cluster to.

e. Select the base domain for the Route 53 service that you configured for your cluster.

f. Enter a descriptive name for your cluster.

g. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the `kubeadmin` user, display in your terminal.

Example output

...
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-Wi5AL"
INFO Time elapsed: 36m22s

NOTE
The cluster access and credential information also outputs to <installation_directory>/.openshift_install.log when an installation succeeds.

IMPORTANT
- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

IMPORTANT
You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

2. Optional: Remove or disable the AdministratorAccess policy from the IAM account that you used to install the cluster.

NOTE
The elevated permissions provided by the AdministratorAccess policy are required only during installation.

Additional resources
- See Configuration and credential file settings in the AWS documentation for more information about AWS profile and credential configuration.

2.3.6. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) in order to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.
2.3.6.1. Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.6 Linux Client entry and save the file.

4. Unpack the archive:

   $ tar xvzf <file>

5. Place the oc binary in a directory that is on your PATH. To check your PATH, execute the following command:

   $ echo $PATH

After you install the OpenShift CLI, it is available using the oc command:

   $ oc <command>

2.3.6.2. Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.6 Windows Client entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the oc binary to a directory that is on your PATH. To check your PATH, open the command prompt and execute the following command:

   C:\> path

After you install the OpenShift CLI, it is available using the oc command:
2.3.6.3. Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.6 MacOSX Client entry and save the file.

4. Unpack and unzip the archive.

5. Move the oc binary to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:

   $ echo $PATH

After you install the OpenShift CLI, it is available using the oc command:

$ oc <command>

2.3.7. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster kubeconfig file. The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the oc CLI.

Procedure

1. Export the kubeadmin credentials:

   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig

   For <installation_directory>, specify the path to the directory that you stored the installation files in.

2. Verify you can run oc commands successfully using the exported configuration:

   $ oc whoami
2.3.8. Logging in to the cluster by using the web console

The *kubeadmin* user exists by default after an OpenShift Container Platform installation. You can log in to your cluster as the *kubeadmin* user by using the OpenShift Container Platform web console.

**Prerequisites**

- You have access to the installation host.
- You completed a cluster installation and all cluster Operators are available.

**Procedure**

1. Obtain the password for the *kubeadmin* user from the *kubeadmin-password* file on the installation host:

   ```
   $ cat <installation_directory>/auth/kubeadmin-password
   ```

   **NOTE**

   Alternatively, you can obtain the *kubeadmin* password from the `<installation_directory>/openshift_install.log` log file on the installation host.

2. List the OpenShift Container Platform web console route:

   ```
   $ oc get routes -n openshift-conso1e | grep 'console-openshift'
   ```

   **NOTE**

   Alternatively, you can obtain the OpenShift Container Platform route from the `<installation_directory>/openshift_install.log` log file on the installation host.

   **Example output**

   ```
   console  console-openshift-console.apps.<cluster_name>.<base_domain>  console
   https  reencrypt/Redirect  None
   ```

3. Navigate to the route detailed in the output of the preceding command in a web browser and log in as the *kubeadmin* user.

**Additional resources**

- See [Accessing the web console](#) for more details about accessing and understanding the OpenShift Container Platform web console.

2.3.9. Telemetry access for OpenShift Container Platform
In OpenShift Container Platform 4.6, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service

2.3.10. Next steps

- Validating an installation.
- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- If necessary, you can remove cloud provider credentials.

2.4. INSTALLING A CLUSTER ON AWS WITH CUSTOMIZATIONS

In OpenShift Container Platform version 4.6, you can install a customized cluster on infrastructure that the installation program provisions on Amazon Web Services (AWS). To customize the installation, you modify parameters in the install-config.yaml file before you install the cluster.

2.4.1. Prerequisites

- Review details about the OpenShift Container Platform installation and update processes.
- Configure an AWS account to host the cluster.

**IMPORTANT**

If you have an AWS profile stored on your computer, it must not use a temporary session token that you generated while using a multi-factor authentication device. The cluster continues to use your current AWS credentials to create AWS resources for the entire life of the cluster, so you must use long-lived credentials. To generate appropriate keys, see Managing Access Keys for IAM Users in the AWS documentation. You can supply the keys when you run the installation program.

- If you use a firewall, you must configure it to allow the sites that your cluster requires access to.
- If you do not allow the system to manage identity and access management (IAM), then a cluster administrator can manually create and maintain IAM credentials. Manual mode can also be used in environments where the cloud IAM APIs are not reachable.

2.4.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.6, you require access to the Internet to install your cluster.
You must have Internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- Access Quay.io to obtain the packages that are required to install your cluster.

- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

2.4.3. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your `ssh-agent` and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

**NOTE**

In a production environment, you require disaster recovery and debugging.

You can use this key to SSH into the master nodes as the user `core`. When you deploy the cluster, the key is added to the `core` user’s `~/.ssh/authorized_keys` list.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

**Procedure**

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>  
   ```

   **Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.**

   Running this command generates an SSH key that does not require a password in the location that you specified.
NOTE
If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the ssh-agent process as a background task:

```
$ eval "$(ssh-agent -s)"
```

Example output

```
Agent pid 31874
```

NOTE
If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the ssh-agent:

```
$ ssh-add <path>/<file_name>
```

Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

Next steps
- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

2.4.4. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on a local computer.

Prerequisites
- You have a computer that runs Linux or macOS, with 500 MB of local disk space

Procedure
1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.
3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

**IMPORTANT**

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar xvf openshift-install-linux.tar.gz
```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 2.4.5. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Amazon Web Services (AWS).

**Prerequisites**

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Create the `install-config.yaml` file.
   
   a. Change to the directory that contains the installation program and run the following command:

   ```sh
   $ ./openshift-install create install-config --dir <installation_directory>  
   ```

   **Note:**
   
   For `<installation_directory>`, specify the directory name to store the files that the installation program creates.
b. At the prompts, provide the configuration details for your cloud:
   i. Optional: Select an SSH key to use to access your cluster machines.

   **NOTE**
   For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

   ii. Select AWS as the platform to target.

   iii. If you do not have an Amazon Web Services (AWS) profile stored on your computer, enter the AWS access key ID and secret access key for the user that you configured to run the installation program.

   iv. Select the AWS region to deploy the cluster to.

   v. Select the base domain for the Route 53 service that you configured for your cluster.

   vi. Enter a descriptive name for your cluster.

   vii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

2. Modify the `install-config.yaml` file. You can find more information about the available parameters in the Installation configuration parameters section.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

   **IMPORTANT**
   The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

### 2.4.5.1. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster’s platform. When you create the `install-config.yaml` installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the `install-config.yaml` file to provide more details about the platform.

   **NOTE**
   After installation, you cannot modify these parameters in the `install-config.yaml` file.
**IMPORTANT**

The `openshift-install` command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

### 2.4.5.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

**Table 2.1. Required parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is v1. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the <code>baseDomain</code> and <code>metadata.name</code> parameter values that uses the <code>&lt;metadata.name&gt;.&lt;baseDomain&gt;</code> format.</td>
<td>A fully-qualified domain or subdomain name, such as <code>example.com</code>.</td>
</tr>
<tr>
<td>metadata</td>
<td>Kubernetes resource <code>ObjectMeta</code>, from which only the <code>name</code> parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of <code>{{.metadata.name}}.{{.baseDomain}}</code>.</td>
<td>String of lowercase letters, hyphens (-), and periods (.), such as <code>dev</code>.</td>
</tr>
</tbody>
</table>
The configuration for the specific platform upon which to perform the installation: **aws, baremetal, azure, openstack, ovirt, vsphere.** For additional information about platform.<platform> parameters, consult the following table for your specific platform.

### Table 2.2. Network parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
</tbody>
</table>

**NOTE**

You cannot modify parameters specified by the **networking** object after installation.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking.network Type</td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN.</td>
</tr>
<tr>
<td>networking.clusterNetwork</td>
<td>The IP address blocks for pods. The default value is 10.128.0.0/14 with a host prefix of /23. If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td>An array of objects. For example: networking: clusterNetwork: - cidr: 10.128.0.0/14 hostPrefix: 23</td>
</tr>
<tr>
<td>networking.clusterNetwork.cidr</td>
<td>Required if you use networking.clusterNetwork. An IP address block. An IPv4 network.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td>networking.clusterNetwork.hostPrefix</td>
<td>The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given cidr. A hostPrefix value of 23 provides 510 (2^32 - 2^23 - 2) pod IP addresses.</td>
<td>A subnet prefix. The default value is 23.</td>
</tr>
<tr>
<td>networking.serviceNetwork</td>
<td>The IP address block for services. The default value is 172.30.0.0/16. The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.</td>
<td>An array with an IP address block in CIDR format. For example: networking: serviceNetwork: - 172.30.0.0/16</td>
</tr>
<tr>
<td>networking.machineNetwork</td>
<td>The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td>An array of objects. For example: networking: machineNetwork: - cidr: 10.0.0.0/16</td>
</tr>
</tbody>
</table>
### networking.machineNetwork.cidr

Required if you use `networking.machineNetwork`. An IP address block. The default value is `10.0.0.0/16` for all platforms other than libvirt. For libvirt, the default value is `192.168.126.0/24`.

An IP network block in CIDR notation. For example, `10.0.0.0/16`.

**NOTE**

Set the `networking.machineNetwork` to match the CIDR that the preferred NIC resides in.

### 2.4.5.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of machine-pool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>compute.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
</tbody>
</table>
Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.

**IMPORTANT**
If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>compute.hyperthreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>compute.name</td>
<td>Required if you use compute. The name of the machine pool.</td>
<td>worker</td>
</tr>
<tr>
<td>compute.platform</td>
<td>Required if you use compute. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the controlPlane.platform parameter value.</td>
<td>aws, azure, gcp, openstack, ovirt, vsphere, or{}</td>
</tr>
<tr>
<td>compute.replicas</td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td>controlPlane</td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of MachinePool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>controlPlane.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are amd64 (the default).</td>
<td>String</td>
</tr>
</tbody>
</table>
## Parameter Description

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlPlane.hypertreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>controlPlane.name</td>
<td>Required if you use controlPlane. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use controlPlane. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the compute.platform parameter value.</td>
<td>aws, azure, gcp, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (&quot;&quot;&quot;).</td>
</tr>
</tbody>
</table>

**NOTE**

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Red Hat Operators reference content.
**fips**

Enable or disable FIPS mode. The default is false (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>imageContentSources</strong></td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects. Includes a source and, optionally, mirrors, as described in the following rows of this table.</td>
</tr>
<tr>
<td><strong>imageContentSources.source</strong></td>
<td>Required if you use imageContentSources. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td><strong>imageContentSources.mirrors</strong></td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
<tr>
<td><strong>publish</strong></td>
<td>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</td>
<td>Internal or External. To deploy a private cluster, which cannot be accessed from the internet, set publish to Internal. The default value is External.</td>
</tr>
</tbody>
</table>
### sshKey

The SSH key or keys to authenticate access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

One or more keys. For example:

```
sshKey:
  <key1>
  <key2>
  <key3>
```

---

#### 2.4.5.1.4. Optional AWS configuration parameters

Optional AWS configuration parameters are described in the following table:

**Table 2.4. Optional AWS parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>compute.platform.aws.amiID</code></td>
<td>The AWS AMI used to boot compute machines for the cluster. This is required for regions that require a custom RHCOS AMI.</td>
<td>Any published or custom RHCOS AMI that belongs to the set AWS region.</td>
</tr>
<tr>
<td><code>compute.platform.aws.rootVolume.iops</code></td>
<td>The Input/Output Operations Per Second (IOPS) that is reserved for the root volume.</td>
<td>Integer, for example <strong>4000</strong>.</td>
</tr>
<tr>
<td><code>compute.platform.aws.rootVolume.size</code></td>
<td>The size in GiB of the root volume.</td>
<td>Integer, for example <strong>500</strong>.</td>
</tr>
<tr>
<td><code>compute.platform.aws.rootVolume.type</code></td>
<td>The type of the root volume.</td>
<td>Valid AWS EBS volume type, such as <strong>io1</strong>.</td>
</tr>
<tr>
<td><code>compute.platform.aws.type</code></td>
<td>The EC2 instance type for the compute machines.</td>
<td>Valid AWS instance type, such as <strong>c5.9xlarge</strong>.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>compute.platform.aws.zones</code></td>
<td>The availability zones where the installation program creates machines for the compute machine pool. If you provide your own VPC, you must provide a subnet in that availability zone.</td>
<td>A list of valid AWS availability zones, such as <strong>us-east-1c</strong>, in a <strong>YAML sequence</strong>.</td>
</tr>
<tr>
<td><code>compute.aws.region</code></td>
<td>The AWS region that the installation program creates compute resources in.</td>
<td>Any valid <strong>AWS region</strong>, such as <strong>us-east-1</strong>.</td>
</tr>
<tr>
<td><code>controlPlane.platform.aws.amiID</code></td>
<td>The AWS AMI used to boot control plane machines for the cluster. This is required for regions that require a custom RHCOS AMI.</td>
<td>Any published or custom RHCOS AMI that belongs to the set AWS region.</td>
</tr>
<tr>
<td><code>controlPlane.platform.aws.type</code></td>
<td>The EC2 instance type for the control plane machines.</td>
<td>Valid <strong>AWS instance type</strong>, such as <strong>c5.9xlarge</strong>.</td>
</tr>
<tr>
<td><code>controlPlane.platform.aws.zones</code></td>
<td>The availability zones where the installation program creates machines for the control plane machine pool.</td>
<td>A list of valid AWS availability zones, such as <strong>us-east-1c</strong>, in a <strong>YAML sequence</strong>.</td>
</tr>
<tr>
<td><code>controlPlane.aws.region</code></td>
<td>The AWS region that the installation program creates control plane resources in.</td>
<td>Valid <strong>AWS region</strong>, such as <strong>us-east-1</strong>.</td>
</tr>
<tr>
<td><code>platform.aws.amiID</code></td>
<td>The AWS AMI used to boot all machines for the cluster. If set, the AMI must belong to the same region as the cluster. This is required for regions that require a custom RHCOS AMI.</td>
<td>Any published or custom RHCOS AMI that belongs to the set AWS region.</td>
</tr>
<tr>
<td><code>platform.aws.serviceEndpoints.name</code></td>
<td>The AWS service endpoint name. Custom endpoints are only required for cases where alternative AWS endpoints, like FIPS, must be used. Custom API endpoints can be specified for EC2, S3, IAM, Elastic Load Balancing, Tagging, Route 53, and STS AWS services.</td>
<td>Valid <strong>AWS service endpoint name</strong>.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td>platform.aws.serviceEndpoints.url</td>
<td>The AWS service endpoint URL. The URL must use the https protocol and the host must trust the certificate.</td>
<td>Valid AWS service endpoint URL.</td>
</tr>
<tr>
<td>platform.aws.userTags</td>
<td>A map of keys and values that the installation program adds as tags to all resources that it creates.</td>
<td>Any valid YAML map, such as key value pairs in the <code>&lt;key&gt;: &lt;value&gt;</code> format. For more information about AWS tags, see Tagging Your Amazon EC2 Resources in the AWS documentation.</td>
</tr>
<tr>
<td>platform.aws.subnets</td>
<td>If you provide the VPC instead of allowing the installation program to create the VPC for you, specify the subnet for the cluster to use. The subnet must be part of the same <code>machineNetwork[].cidr</code> ranges that you specify. For a standard cluster, specify a public and a private subnet for each availability zone. For a private cluster, specify a private subnet for each availability zone.</td>
<td>Valid subnet IDs.</td>
</tr>
</tbody>
</table>

2.4.5.2. Sample customized `install-config.yaml` file for AWS

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

**IMPORTANT**

This sample YAML file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program and modify it.

```yaml
apiVersion: v1
baseDomain: example.com
credentialsMode: Mint
controlPlane: 3
hyperthreading: Enabled
name: master
platform:
  aws:
    zones:
    - us-west-2a
    - us-west-2b
    rootVolume:
      iops: 4000
      size: 500
```
Required. The installation program prompts you for this value.

Optional: Add this parameter to force the Cloud Credential Operator (CCO) to use the specified mode, instead of having the CCO dynamically try to determine the capabilities of the credentials. For details about CCO modes, see the Cloud Credential Operator entry in the Red Hat Operators reference content.

If you do not provide these parameters and values, the installation program provides the default value.

The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, -, and the first line of the controlPlane section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift
Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading, or hyperthreading. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to Disabled. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger instance types, such as m4.2xlarge or m5.2xlarge, for your machines if you disable simultaneous multithreading.

To configure faster storage for etcd, especially for larger clusters, set the storage type as io1 and set iops to 2000.

The ID of the AMI used to boot machines for the cluster. If set, the AMI must belong to the same region as the cluster.

The AWS service endpoints. Custom endpoints are required when installing to an unknown AWS region. The endpoint URL must use the https protocol and the host must trust the certificate.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

You can optionally provide the sshKey value that you use to access the machines in your cluster.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

2.4.5.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the install-config.yaml file.

**Prerequisites**

- You have an existing install-config.yaml file.
You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the Proxy object’s spec.noProxy field to bypass the proxy if necessary.

**NOTE**

The Proxy object status.noProxy field is populated with the values of the networking.machineNetwork[].cidr, networking.clusterNetwork[].cidr, and networking.serviceNetwork[] fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object status.noProxy field is also populated with the instance metadata endpoint (169.254.169.254).

If your cluster is on AWS, you added the ec2.<region>.amazonaws.com, elasticloadbalancing.<region>.amazonaws.com, and s3.<region>.amazonaws.com endpoints to your VPC endpoint. These endpoints are required to complete requests from the nodes to the AWS EC2 API. Because the proxy works on the container level, not the node level, you must route these requests to the AWS EC2 API through the AWS private network. Adding the public IP address of the EC2 API to your allowlist in your proxy server is not sufficient.

**Procedure**

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
     httpProxy: http://<username>:<pswd>@<ip>:<port>
     httpsProxy: https://<username>:<pswd>@<ip>:<port>
     noProxy: example.com
   additionalTrustBundle: |
     -----BEGIN CERTIFICATE-----
     <MY_TRUSTED_CA_CERT>
     -----END CERTIFICATE-----

   1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.
   2. A proxy URL to use for creating HTTPS connections outside the cluster.
   3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.
   4. If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace to hold the additional CA certificates. If you provide `additionalTrustBundle` and at least one proxy setting, the Proxy object is configured to reference the `user-ca-bundle` config map in the trustedCA field. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges the contents specified for the trustedCA parameter with the RH COS trust bundle. The
additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

NOTE

The installation program does not support the proxy readinessEndpoints field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

NOTE

Only the Proxy object named cluster is supported, and no additional proxies can be created.

2.4.6. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

IMPORTANT

You can run the create cluster command of the installation program only once, during initial installation.

Prerequisites

- Configure an account with the cloud platform that hosts your cluster.
- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Change to the directory that contains the installation program and initialize the cluster deployment:

   ```
   $ ./openshift-install create cluster --dir <installation_directory> \
   --log-level=info
   ```

   1 For <installation_directory>, specify the location of your customized ./install-config.yaml file.

   2 To view different installation details, specify warn, debug, or error instead of info.
NOTE

If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.

When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the **kubeadmin** user, display in your terminal.

**Example output**

```
... INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-Wi5AL"
INFO Time elapsed: 36m22s
```

NOTE

The cluster access and credential information also outputs to `<installation_directory>/openshift_install.log` when an installation succeeds.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

**IMPORTANT**

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

2. Optional: Remove or disable the **AdministratorAccess** policy from the IAM account that you used to install the cluster.
NOTE

The elevated permissions provided by the AdministratorAccess policy are required only during installation.

2.4.7. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) in order to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

IMPORTANT

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.6. Download and install the new version of oc.

2.4.7.1. Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.
3. Click Download Now next to the OpenShift v4.6 Linux Client entry and save the file.
4. Unpack the archive:

   $ tar xvzf <file>

5. Place the oc binary in a directory that is on your PATH.
   To check your PATH, execute the following command:

   $ echo $PATH

After you install the OpenShift CLI, it is available using the oc command:

   $ oc <command>

2.4.7.2. Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.
3. Click Download Now next to the OpenShift v4.6 Windows Client entry and save the file.
4. Unzip the archive with a ZIP program.

5. Move the `oc` binary to a directory that is on your **PATH**.
   To check your **PATH**, open the command prompt and execute the following command:

   ```
   C:\> path
   ```

   After you install the OpenShift CLI, it is available using the `oc` command:

   ```
   C:\> oc <command>
   ```

### 2.4.7.3. Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (`oc`) binary on macOS by using the following procedure.

#### Procedure

2. Select the appropriate version in the **Version** drop-down menu.

3. Click **Download Now** next to the **OpenShift v4.6 MacOSX Client** entry and save the file.

4. Unpack and unzip the archive.

5. Move the `oc` binary to a directory on your **PATH**.
   To check your **PATH**, open a terminal and execute the following command:

   ```
   $ echo $PATH
   ```

   After you install the OpenShift CLI, it is available using the `oc` command:

   ```
   $ oc <command>
   ```

### 2.4.8. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

#### Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

#### Procedure

1. Export the **kubeadmin** credentials:
1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   $ oc whoami

   **Example output**

   `system:admin`

---

### 2.4.9. Logging in to the cluster by using the web console

The `kubeadmin` user exists by default after an OpenShift Container Platform installation. You can log in to your cluster as the `kubeadmin` user by using the OpenShift Container Platform web console.

#### Prerequisites

- You have access to the installation host.
- You completed a cluster installation and all cluster Operators are available.

#### Procedure

1. Obtain the password for the `kubeadmin` user from the `kubeadmin-password` file on the installation host:

   $ cat `<installation_directory>/auth/kubeadmin-password`

   **NOTE**

   Alternatively, you can obtain the `kubeadmin` password from the `<installation_directory>/openshift_install.log` log file on the installation host.

2. List the OpenShift Container Platform web console route:

   $ oc get routes -n openshift-console | grep 'console-openshift'

   **NOTE**

   Alternatively, you can obtain the OpenShift Container Platform route from the `<installation_directory>/openshift_install.log` log file on the installation host.

   **Example output**

   ```
   console   console-openshift-console.apps.<cluster_name>.-<base_domain>   console
   https reencrypt/Redirect   None
   ```
3. Navigate to the route detailed in the output of the preceding command in a web browser and log in as the `kubeadmin` user.

Additional resources

- See Accessing the web console for more details about accessing and understanding the OpenShift Container Platform web console.

### 2.4.10. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.6, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use `subscription watch` to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service.

### 2.4.11. Next steps

- Validating an installation.
- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- If necessary, you can remove cloud provider credentials.

### 2.5. INSTALLING A CLUSTER ON AWS WITH NETWORK CUSTOMIZATIONS

In OpenShift Container Platform version 4.6, you can install a cluster on Amazon Web Services (AWS) with customized network configuration options. By customizing your network configuration, your cluster can coexist with existing IP address allocations in your environment and integrate with existing MTU and VXLAN configurations.

You must set most of the network configuration parameters during installation, and you can modify only `kubeProxy` configuration parameters in a running cluster.

### 2.5.1. Prerequisites

- Review details about the OpenShift Container Platform installation and update processes.
- Configure an AWS account to host the cluster.
IMPORTANT

If you have an AWS profile stored on your computer, it must not use a temporary session token that you generated while using a multi-factor authentication device. The cluster continues to use your current AWS credentials to create AWS resources for the entire life of the cluster, so you must use key-based, long-lived credentials. To generate appropriate keys, see Managing Access Keys for IAM Users in the AWS documentation. You can supply the keys when you run the installation program.

- If you use a firewall, you must configure it to allow the sites that your cluster requires access to.
- If you do not allow the system to manage identity and access management (IAM), then a cluster administrator can manually create and maintain IAM credentials. Manual mode can also be used in environments where the cloud IAM APIs are not reachable.

2.5.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.6, you require access to the Internet to install your cluster.

You must have Internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

IMPORTANT

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

2.5.3. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your ssh-agent and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

NOTE

In a production environment, you require disaster recovery and debugging.

You can use this key to SSH into the master nodes as the user core. When you deploy the cluster, the key is added to the core user’s ~/.ssh/authorized_keys list.
NOTE
You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

Procedure

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>
```

Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

Running this command generates an SSH key that does not require a password in the location that you specified.

NOTE
If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the `ssh-agent` process as a background task:

```
$ eval "$(ssh-agent -s)"
```

Example output

```
Agent pid 31874
```

NOTE
If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the `ssh-agent`:

```
$ ssh-add <path>/<file_name>
```

Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`
Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

2.5.4. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on a local computer.

Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space

Procedure

1. Access the **Infrastructure Provider** page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

   **IMPORTANT**
   
   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   **IMPORTANT**
   
   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ tar xvf openshift-install-linux.tar.gz
   ```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

2.5.5. Network configuration phases

When specifying a cluster configuration prior to installation, there are several phases in the installation procedures when you can modify the network configuration:

Phase 1
After entering the `openshift-install create install-config` command. In the `install-config.yaml` file, you can customize the following network-related fields:

- `networking.networkType`
- `networking.clusterNetwork`
- `networking.serviceNetwork`
- `networking.machineNetwork`

For more information on these fields, refer to "Installation configuration parameters".

**NOTE**

Set the `networking.machineNetwork` to match the CIDR that the preferred NIC resides in.

**Phase 2**

After entering the `openshift-install create manifests` command. If you must specify advanced network configuration, during this phase you can define a customized Cluster Network Operator manifest with only the fields you want to modify.

You cannot override the values specified in phase 1 in the `install-config.yaml` file during phase 2. However, you can further customize the cluster network provider during phase 2.

### 2.5.6. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Amazon Web Services (AWS).

**Prerequisites**

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Create the `install-config.yaml` file.
   
   a. Change to the directory that contains the installation program and run the following command:

   ```bash
   $ ./openshift-install create install-config --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the directory name to store the files that the installation program creates.
IMPORTANT

Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

b. At the prompts, provide the configuration details for your cloud:

i. Optional: Select an SSH key to use to access your cluster machines.

   NOTE

   For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

ii. Select AWS as the platform to target.

iii. If you do not have an Amazon Web Services (AWS) profile stored on your computer, enter the AWS access key ID and secret access key for the user that you configured to run the installation program.

iv. Select the AWS region to deploy the cluster to.

v. Select the base domain for the Route 53 service that you configured for your cluster.

vi. Enter a descriptive name for your cluster.

vii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

2. Modify the install-config.yaml file. You can find more information about the available parameters in the Installation configuration parameters section.

3. Back up the install-config.yaml file so that you can use it to install multiple clusters.

IMPORTANT

The install-config.yaml file is consumed during the installation process. If you want to reuse the file, you must back it up now.

2.5.6.1. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster’s platform. When you create the install-config.yaml installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the install-config.yaml file to provide more details about the platform.

NOTE

After installation, you cannot modify these parameters in the install-config.yaml file.
### IMPORTANT
The `openshift-install` command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

#### 2.5.6.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

Table 2.5. Required parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is v1. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the baseDomain and metadata.name parameter values that uses the <code>&lt;metadata.name&gt;</code>. <code>&lt;baseDomain&gt;</code> format.</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
</tr>
<tr>
<td>metadata</td>
<td>Kubernetes resource <code>ObjectMeta</code>, from which only the name parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of <code>{{.metadata.name}}</code>. <code>{{.baseDomain}}</code>.</td>
<td>String of lowercase letters, hyphens (-), and periods (.), such as dev.</td>
</tr>
</tbody>
</table>

CHAPTER 2. INSTALLING ON AWS
The configuration for the specific platform upon which to perform the installation: **aws, baremetal, azure, openstack, ovirt, vsphere.** For additional information about platform.<platform> parameters, consult the following table for your specific platform.

<table>

      "email":"you@example.com"  
    }  
  }  
}
```

### 2.5.6.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

**Table 2.6. Network parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
</tbody>
</table>

**NOTE**

You cannot modify parameters specified by the networking object after installation.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking.network Type</td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN.</td>
</tr>
</tbody>
</table>
| networking.clusterNetwork | The IP address blocks for pods. The default value is 10.128.0.0/14 with a host prefix of /23. If you specify multiple IP address blocks, the blocks must not overlap. | An array of objects. For example:  
  ```yaml  
networking:  
  clusterNetwork:  
    - cidr: 10.128.0.0/14  
      hostPrefix: 23  
  ``` |
| networking.clusterNetwork.hostPrefix | The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given cidr. A hostPrefix value of 23 provides 510 (2^32 - 2^23) - 2) pod IP addresses. | A subnet prefix. The default value is 23. |
| networking.serviceNetwork | The IP address block for services. The default value is 172.30.0.0/16. The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network. | An array with an IP address block in CIDR format. For example:  
  ```yaml  
networking:  
  serviceNetwork:  
    - 172.30.0.0/16  
  ``` |
| networking.machineNetwork | The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap. | An array of objects. For example:  
  ```yaml  
networking:  
  machineNetwork:  
    - cidr: 10.0.0.0/16  
  ``` |
### networking.machineNetwork.cidr

Required if you use `networking.machineNetwork`. An IP address block. The default value is `10.0.0.0/16` for all platforms other than libvirt. For libvirt, the default value is `192.168.126.0/24`.

**NOTE**

Set the `networking.machineNetwork` to match the CIDR that the preferred NIC resides in.

---

### 2.5.6.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

#### Table 2.7. Optional parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of machine-pool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>compute.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
</tbody>
</table>
Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.

**IMPORTANT**
If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>

<td>---------</td>
</tr>
<tr>
<td>fips</td>
<td>Enable or disable FIPS mode. The default is <strong>false</strong> (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</td>
<td><strong>false</strong> or <strong>true</strong></td>
</tr>
<tr>
<td><strong>IMPORTANT</strong></td>
<td>The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the <strong>x86_64</strong> architecture.</td>
<td></td>
</tr>
<tr>
<td><strong>NOTE</strong></td>
<td>If you are using Azure File storage, you cannot enable FIPS mode.</td>
<td></td>
</tr>
<tr>
<td>imageContentSources</td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects. Includes a <strong>source</strong> and, optionally, <strong>mirrors</strong>, as described in the following rows of this table.</td>
</tr>
<tr>
<td>imageContentSources.source</td>
<td>Required if you use <strong>imageContentSources</strong>. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td><strong>String</strong></td>
</tr>
<tr>
<td>imageContentSources.mirrors</td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td><strong>Array of strings</strong></td>
</tr>
<tr>
<td>publish</td>
<td>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</td>
<td><strong>Internal</strong> or <strong>External</strong>. To deploy a private cluster, which cannot be accessed from the internet, set <strong>publish</strong> to <strong>Internal</strong>. The default value is <strong>External</strong>.</td>
</tr>
</tbody>
</table>
The SSH key or keys to authenticate access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

One or more keys. For example:

```
sshKey:
  <key1>
  <key2>
  <key3>
```

### 2.5.6.1.4. Optional AWS configuration parameters

Optional AWS configuration parameters are described in the following table:

**Table 2.8. Optional AWS parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>compute.platform.amiID</code></td>
<td>The AWS AMI used to boot compute machines for the cluster. This is required for regions that require a custom RHCOS AMI.</td>
<td>Any published or custom RHCOS AMI that belongs to the set AWS region.</td>
</tr>
<tr>
<td><code>compute.platform.rootVolume.iops</code></td>
<td>The Input/Output Operations Per Second (IOPS) that is reserved for the root volume.</td>
<td>Integer, for example 4000.</td>
</tr>
<tr>
<td><code>compute.platform.rootVolume.size</code></td>
<td>The size in GiB of the root volume.</td>
<td>Integer, for example 500.</td>
</tr>
<tr>
<td><code>compute.platform.rootVolume.type</code></td>
<td>The type of the root volume.</td>
<td>Valid AWS EBS volume type, such as <code>io1</code>.</td>
</tr>
<tr>
<td><code>compute.platform.type</code></td>
<td>The EC2 instance type for the compute machines.</td>
<td>Valid AWS instance type, such as <code>c5.9xlarge</code>.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td><strong>compute.platform.aws.zones</strong></td>
<td>The availability zones where the installation program creates machines for the compute machine pool. If you provide your own VPC, you must provide a subnet in that availability zone.</td>
<td>A list of valid AWS availability zones, such as us-east-1c, in a YAML sequence.</td>
</tr>
<tr>
<td><strong>compute.aws.region</strong></td>
<td>The AWS region that the installation program creates compute resources in.</td>
<td>Any valid AWS region, such as us-east-1.</td>
</tr>
<tr>
<td><strong>controlPlaneplatform.aws.amiID</strong></td>
<td>The AWS AMI used to boot control plane machines for the cluster. This is required for regions that require a custom RHCOS AMI.</td>
<td>Any published or custom RHCOS AMI that belongs to the set AWS region.</td>
</tr>
<tr>
<td><strong>controlPlaneplatform.aws.type</strong></td>
<td>The EC2 instance type for the control plane machines.</td>
<td>Valid AWS instance type, such as c5.9xlarge.</td>
</tr>
<tr>
<td><strong>controlPlaneplatform.aws.zones</strong></td>
<td>The availability zones where the installation program creates machines for the control plane machine pool.</td>
<td>A list of valid AWS availability zones, such as us-east-1c, in a YAML sequence.</td>
</tr>
<tr>
<td><strong>controlPlane.aws.region</strong></td>
<td>The AWS region that the installation program creates control plane resources in.</td>
<td>Valid AWS region, such as us-east-1.</td>
</tr>
<tr>
<td><strong>platform.aws.amiID</strong></td>
<td>The AWS AMI used to boot all machines for the cluster. If set, the AMI must belong to the same region as the cluster. This is required for regions that require a custom RHCOS AMI.</td>
<td>Any published or custom RHCOS AMI that belongs to the set AWS region.</td>
</tr>
<tr>
<td><strong>platform.aws.serviceEndpoints.name</strong></td>
<td>The AWS service endpoint name. Custom endpoints are only required for cases where alternative AWS endpoints, like FIPS, must be used. Custom API endpoints can be specified for EC2, S3, IAM, Elastic Load Balancing, Tagging, Route 53, and STS AWS services.</td>
<td>Valid AWS service endpoint name.</td>
</tr>
</tbody>
</table>
### Parameter Description Values

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>platform.aws.serviceEndpoints.url</td>
<td>The AWS service endpoint URL. The URL must use the https protocol and the host must trust the certificate.</td>
<td>Valid AWS service endpoint URL.</td>
</tr>
<tr>
<td>platform.aws.userTags</td>
<td>A map of keys and values that the installation program adds as tags to all resources that it creates.</td>
<td>Any valid YAML map, such as key value pairs in the <code>&lt;key&gt;: &lt;value&gt;</code> format. For more information about AWS tags, see <a href="#">Tagging Your Amazon EC2 Resources</a> in the AWS documentation.</td>
</tr>
<tr>
<td>platform.aws.subnets</td>
<td>If you provide the VPC instead of allowing the installation program to create the VPC for you, specify the subnet for the cluster to use. The subnet must be part of the same machineNetwork[].cidr ranges that you specify. For a standard cluster, specify a public and a private subnet for each availability zone. For a private cluster, specify a private subnet for each availability zone.</td>
<td>Valid subnet IDs.</td>
</tr>
</tbody>
</table>

2.5.6.2. Sample customized install-config.yaml file for AWS

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

**IMPORTANT**

This sample YAML file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program and modify it.

```yaml
apiVersion: v1
baseDomain: example.com  
credentialsMode: Mint  
controlPlane:  
hyperthreading: Enabled  
name: master  
platform:  
aws:  
zones:  
  - us-west-2a  
  - us-west-2b  
rootVolume:  
iops: 4000  
size: 500
```
Required. The installation program prompts you for this value.

Optional: Add this parameter to force the Cloud Credential Operator (CCO) to use the specified mode, instead of having the CCO dynamically try to determine the capabilities of the credentials. For details about CCO modes, see the Cloud Credential Operator entry in the Red Hat Operators reference content.

If you do not provide these parameters and values, the installation program provides the default value.

The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, -, and the first line of the controlPlane section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift
Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading, or **hyperthreading**. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to **Disabled**. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger instance types, such as **m4.2xlarge** or **m5.2xlarge**, for your machines if you disable simultaneous multithreading.

To configure faster storage for etcd, especially for larger clusters, set the storage type as **io1** and set **iops** to **2000**.

The ID of the AMI used to boot machines for the cluster. If set, the AMI must belong to the same region as the cluster.

The AWS service endpoints. Custom endpoints are required when installing to an unknown AWS region. The endpoint URL must use the **https** protocol and the host must trust the certificate.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the **x86_64** architecture.

You can optionally provide the **sshKey** value that you use to access the machines in your cluster.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

### 2.5.6.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

**Prerequisites**

- You have an existing **install-config.yaml** file.
You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the Proxy object’s spec.noProxy field to bypass the proxy if necessary.

**NOTE**

The Proxy object status.noProxy field is populated with the values of the networking.machineNetwork[].cidr, networking.clusterNetwork[].cidr, and networking.serviceNetwork[] fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object status.noProxy field is also populated with the instance metadata endpoint (169.254.169.254).

If your cluster is on AWS, you added the ec2.<region>.amazonaws.com, elasticloadbalancing.<region>.amazonaws.com, and s3.<region>.amazonaws.com endpoints to your VPC endpoint. These endpoints are required to complete requests from the nodes to the AWS EC2 API. Because the proxy works on the container level, not the node level, you must route these requests to the AWS EC2 API through the AWS private network. Adding the public IP address of the EC2 API to your allowlist in your proxy server is not sufficient.

**Procedure**

1. Edit your install-config.yaml file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port> 1
  httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
  noProxy: example.com 3
additionalTrustBundle: |
  -----BEGIN CERTIFICATE-----
  <MY_TRUSTED_CA_CERT>
  -----END CERTIFICATE----- 4
```

1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.
2. A proxy URL to use for creating HTTPS connections outside the cluster.
3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.
4. If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace to hold the additional CA certificates. If you provide additionalTrustBundle and at least one proxy setting, the Proxy object is configured to reference the user-ca-bundle config map in the trustedCA field. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges the contents specified for the trustedCA parameter with the RHCOS trust bundle. The
additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

NOTE
The installation program does not support the proxy readinessEndpoints field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster–wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

NOTE
Only the Proxy object named cluster is supported, and no additional proxies can be created.

2.5.7. Cluster Network Operator configuration

The configuration for the cluster network is specified as part of the Cluster Network Operator (CNO) configuration and stored in a custom resource (CR) object that is named cluster. The CR specifies the fields for the Network API in the operator.openshift.io API group.

The CNO configuration inherits the following fields during cluster installation from the Network API in the Network.config.openshift.io API group and these fields cannot be changed:

- **clusterNetwork**
  - IP address pools from which pod IP addresses are allocated.
- **serviceNetwork**
  - IP address pool for services.
- **defaultNetwork.type**
  - Cluster network provider, such as OpenShift SDN or OVN-Kubernetes.

You can specify the cluster network provider configuration for your cluster by setting the fields for the defaultNetwork object in the CNO object named cluster.

2.5.7.1. Cluster Network Operator configuration object

The fields for the Cluster Network Operator (CNO) are described in the following table:

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>metadata.name</td>
<td>string</td>
<td>The name of the CNO object. This name is always cluster.</td>
</tr>
</tbody>
</table>
A list specifying the blocks of IP addresses from which pod IP addresses are allocated and the subnet prefix length assigned to each individual node in the cluster. For example:

```
spec:
  clusterNetwork:
    - cidr: 10.128.0.0/19
      hostPrefix: 23
    - cidr: 10.128.32.0/19
      hostPrefix: 23
```

This value is ready-only and specified in the `install-config.yaml` file.

A block of IP addresses for services. The OpenShift SDN and OVN-Kubernetes Container Network Interface (CNI) network providers support only a single IP address block for the service network. For example:

```
spec:
  serviceNetwork:
    - 172.30.0.0/14
```

This value is ready-only and specified in the `install-config.yaml` file.

Configures the Container Network Interface (CNI) cluster network provider for the cluster network.

The fields for this object specify the kube-proxy configuration. If you are using the OVN-Kubernetes cluster network provider, the kube-proxy configuration has no effect.

---

**defaultNetwork object configuration**

The values for the `defaultNetwork` object are defined in the following table:

### Table 2.10. defaultNetwork object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>spec</td>
<td>object</td>
<td>Configures the Container Network Interface (CNI) cluster network provider for the cluster network.</td>
</tr>
<tr>
<td>spec.kubeProxyConfig</td>
<td>object</td>
<td>The fields for this object specify the kube-proxy configuration. If you are using the OVN-Kubernetes cluster network provider, the kube-proxy configuration has no effect.</td>
</tr>
<tr>
<td>Field</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>---------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>type</td>
<td>string</td>
<td>Either OpenShiftSDN or OVNKubernetes. The cluster network provider is selected during installation. This value cannot be changed after cluster installation.</td>
</tr>
<tr>
<td>openShiftSDNConfig</td>
<td>object</td>
<td>This object is only valid for the OpenShift SDN cluster network provider.</td>
</tr>
<tr>
<td>ovnKubernetesConfig</td>
<td>object</td>
<td>This object is only valid for the OVN-Kubernetes cluster network provider.</td>
</tr>
</tbody>
</table>

**Configuration for the OpenShift SDN CNI cluster network provider**

The following table describes the configuration fields for the OpenShift SDN Container Network Interface (CNI) cluster network provider.

**Table 2.11. openShiftSDNConfig object**

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mode</td>
<td>string</td>
<td>Configures the network isolation mode for OpenShift SDN. The default value is NetworkPolicy. The values Multitenant and Subnet are available for backwards compatibility with OpenShift Container Platform 3.x but are not recommended. This value cannot be changed after cluster installation.</td>
</tr>
</tbody>
</table>
The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.

If the auto-detected value is not what you expected it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.

If your cluster requires different MTU values for different nodes, you must set this value to 50 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1450.

This value cannot be changed after cluster installation.

The port to use for all VXLAN packets. The default value is 4789. This value cannot be changed after cluster installation.

If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number.

On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port 9000 and port 9999.

Example OpenShift SDN configuration

```yaml
defaultNetwork:
  type: OpenShiftSDN
  openshiftSDNConfig:
    mode: NetworkPolicy
    mtu: 1450
    vxlanPort: 4789
```

Configuration for the OVN-Kubernetes CNI cluster network provider

The following table describes the configuration fields for the OVN-Kubernetes CNI cluster network provider.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mtu</td>
<td>integer</td>
<td>The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. <td>vxlanPort</td>
<td>integer</td>
<td>The port to use for all VXLAN packets. The default value is 4789. This value cannot be changed after cluster installation. If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number. On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port 9000 and port 9999.</td>
</tr>
</tbody>
</table>
The maximum transmission unit (MTU) for the Geneve (Generic Network Virtualization Encapsulation) overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.

If the auto-detected value is not what you expected it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.

If your cluster requires different MTU values for different nodes, you must set this value to 100 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1400.

This value cannot be changed after cluster installation.

genevePort: integer

The port to use for all Geneve packets. The default value is 6081. This value cannot be changed after cluster installation.

Example OVN-Kubernetes configuration

defaultNetwork:
    type: OVNKubernetes
    ovnKubernetesConfig:
        mtu: 1400
        genevePort: 6081

kubeProxyConfig object configuration

The values for the `kubeProxyConfig` object are defined in the following table:

Table 2.13. `kubeProxyConfig` object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>defaultNetwork:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>type: OVNKubernetes</td>
<td></td>
<td></td>
</tr>
<tr>
<td>ovnKubernetesConfig:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>mtu:</td>
<td>1400</td>
<td></td>
</tr>
<tr>
<td>genevePort:</td>
<td>6081</td>
<td></td>
</tr>
</tbody>
</table>
### Table of Fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>iptablesSyncPeriod</code></td>
<td>string</td>
<td>The refresh period for <code>iptables</code> rules. The default value is <strong>30s</strong>. Valid suffixes include <code>s</code>, <code>m</code>, and <code>h</code> and are described in the Go time package documentation.</td>
</tr>
<tr>
<td><code>proxyArguments.iptables-min-sync-period</code></td>
<td>array</td>
<td>The minimum duration before refreshing <code>iptables</code> rules. This field ensures that the refresh does not happen too frequently. Valid suffixes include <code>s</code>, <code>m</code>, and <code>h</code> and are described in the Go time package. The default value is: <code>0s</code></td>
</tr>
</tbody>
</table>

---

### 2.5.8. Specifying advanced network configuration

You can use advanced configuration customization to integrate your cluster into your existing network environment by specifying additional configuration for your cluster network provider. You can specify advanced network configuration only before you install the cluster.

**IMPORTANT**

Modifying the OpenShift Container Platform manifest files created by the installation program is not supported. Applying a manifest file that you create, as in the following procedure, is supported.

**Prerequisites**

- Create the `install-config.yaml` file and complete any modifications to it.

**Procedure**

1. Change to the directory that contains the installation program and create the manifests:

   ```bash
   $ ./openshift-install create manifests --dir <installation_directory>
   ```

   where:

   `<installation_directory>`
Specifies the name of the directory that contains the `install-config.yaml` file for your cluster.

2. Create a stub manifest file for the advanced network configuration that is named `cluster-network-03-config.yml` in the `<installation_directory>/manifests/` directory:

```bash
$ cat <<EOF > <installation_directory>/manifests/cluster-network-03-config.yml
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
  name: cluster
spec:
EOF
```

where:

```<installation_directory>```

Specifies the directory name that contains the `manifests/` directory for your cluster.

3. Open the `cluster-network-03-config.yml` file in an editor and specify the advanced network configuration for your cluster, such as in the following example:

Specify a different VXLAN port for the OpenShift SDN network provider

```yaml
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
  name: cluster
spec:
defaultNetwork:
  openshiftSDNConfig:
    vxlanPort: 4800
```

4. Save the `cluster-network-03-config.yml` file and quit the text editor.

5. Optional: Back up the `manifests/cluster-network-03-config.yml` file. The installation program deletes the `manifests/` directory when creating the cluster.

**NOTE**

For more information on using a Network Load Balancer (NLB) on AWS, see Configuring Ingress cluster traffic on AWS using a Network Load Balancer.

### 2.5.9. Configuring an Ingress Controller Network Load Balancer on a new AWS cluster

You can create an Ingress Controller backed by an AWS Network Load Balancer (NLB) on a new cluster.

**Prerequisites**

- Create the `install-config.yaml` file and complete any modifications to it.

**Procedure**

Create an Ingress Controller backed by an AWS NLB on a new cluster.
1. Change to the directory that contains the installation program and create the manifests:

```
$ ./openshift-install create manifests --dir <installation_directory>  
```

For `<installation_directory>`, specify the name of the directory that contains the `install-config.yaml` file for your cluster.

2. Create a file that is named `cluster-ingress-default-ingresscontroller.yaml` in the `<installation_directory>/manifests/` directory:

```
$ touch <installation_directory>/manifests/cluster-ingress-default-ingresscontroller.yaml  
```

For `<installation_directory>`, specify the directory name that contains the `manifests/` directory for your cluster.

After creating the file, several network configuration files are in the `manifests/` directory, as shown:

```
$ ls <installation_directory>/manifests/cluster-ingress-default-ingresscontroller.yaml
```

**Example output**

```
cluster-ingress-default-ingresscontroller.yaml
```

3. Open the `cluster-ingress-default-ingresscontroller.yaml` file in an editor and enter a CR that describes the Operator configuration you want:

```yaml
apiVersion: operator.openshift.io/v1
kind: IngressController
metadata:
  creationTimestamp: null
  name: default
  namespace: openshift-ingress-operator
spec:
  endpointPublishingStrategy:
    loadBalancer:
      scope: External
      providerParameters:
        type: AWS
        aws:
          type: NLB
        type: LoadBalancerService
```

4. Save the `cluster-ingress-default-ingresscontroller.yaml` file and quit the text editor.

5. Optional: Back up the `manifests/cluster-ingress-default-ingresscontroller.yaml` file. The installation program deletes the `manifests/` directory when creating the cluster.

**2.5.10. Configuring hybrid networking with OVN-Kubernetes**
You can configure your cluster to use hybrid networking with OVN-Kubernetes. This allows a hybrid cluster that supports different node networking configurations. For example, this is necessary to run both Linux and Windows nodes in a cluster.

**IMPORTANT**

You must configure hybrid networking with OVN-Kubernetes during the installation of your cluster. You cannot switch to hybrid networking after the installation process.

**Prerequisites**

- You defined OVNKubernetes for the networking.networkType parameter in the install-config.yaml file. See the installation documentation for configuring OpenShift Container Platform network customizations on your chosen cloud provider for more information.

**Procedure**

1. Change to the directory that contains the installation program and create the manifests:

   ```
   $ ./openshift-install create manifests --dir <installation_directory>
   ```

   where:

   `<installation_directory>`
   
   Specifies the name of the directory that contains the install-config.yaml file for your cluster.

2. Create a stub manifest file for the advanced network configuration that is named cluster-network-03-config.yml in the `<installation_directory>/manifests/` directory:

   ```
   $ cat <<EOF > <installation_directory>/manifests/cluster-network-03-config.yml
   apiVersion: operator.openshift.io/v1
   kind: Network
   metadata:
     name: cluster
   spec:
   EOF
   ```

   where:

   `<installation_directory>`
   
   Specifies the directory name that contains the manifests/ directory for your cluster.

3. Open the cluster-network-03-config.yml file in an editor and configure OVN-Kubernetes with hybrid networking, such as in the following example:

   **Specify a hybrid networking configuration**

   ```
   apiVersion: operator.openshift.io/v1
   kind: Network
   metadata:
     name: cluster
   spec:
     defaultNetwork:
   ```
Specify the CIDR configuration used for nodes on the additional overlay network. The `hybridClusterNetwork` CIDR cannot overlap with the `clusterNetwork` CIDR.

Specify a custom VXLAN port for the additional overlay network. This is required for running Windows nodes in a cluster installed on vSphere, and must not be configured for any other cloud provider. The custom port can be any open port excluding the default 4789 port. For more information on this requirement, see the Microsoft documentation on Pod-to-pod connectivity between hosts is broken.

4. Save the `cluster-network-03-config.yml` file and quit the text editor.

5. Optional: Back up the `manifests/cluster-network-03-config.yml` file. The installation program deletes the `manifests/` directory when creating the cluster.

**NOTE**

For more information on using Linux and Windows nodes in the same cluster, see Understanding Windows container workloads.

### 2.5.11. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

**Prerequisites**

- Configure an account with the cloud platform that hosts your cluster.
- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Change to the directory that contains the installation program and initialize the cluster deployment:

   ```bash
   ./openshift-install create cluster --dir <installation_directory> \
   --log-level=info
   ```

   For `<installation_directory>`, specify the location of your customized `./install-config.yaml` file.
To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

**NOTE**

If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.

When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the `kubeadm` user, display in your terminal.

**Example output**

```
INFO Install complete!
INFO To access the cluster as the system:admin user when using ‘oc’, run ‘export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig’
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: “kubeadm”, and password: “4vYBz-Ee6gm-ymBZj-Wi5AL”
INFO Time elapsed: 36m22s
```

**NOTE**

The cluster access and credential information also outputs to `<installation_directory>/openshift_install.log` when an installation succeeds.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

**IMPORTANT**

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

2. Optional: Remove or disable the `AdministratorAccess` policy from the IAM account that you used to install the cluster.
NOTE

The elevated permissions provided by the AdministratorAccess policy are required only during installation.

2.5.12. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) in order to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

IMPORTANT

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.6. Download and install the new version of oc.

2.5.12.1. Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.6 Linux Client entry and save the file.

4. Unpack the archive:

   $ tar xvf <file>

5. Place the oc binary in a directory that is on your PATH.
   To check your PATH, execute the following command:

   $ echo $PATH

After you install the OpenShift CLI, it is available using the oc command:

   $ oc <command>

2.5.12.2. Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.6 Windows Client entry and save the file.
4. Unzip the archive with a ZIP program.

5. Move the **oc** binary to a directory that is on your **PATH**.
   To check your **PATH**, open the command prompt and execute the following command:
   ```bash
   C:\> path
   ```

After you install the OpenShift CLI, it is available using the **oc** command:
   ```bash
   C:\> oc <command>
   ```

### 2.5.12.3. Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.
3. Click **Download Now** next to the **OpenShift v4.6 MacOSX Client** entry and save the file.
4. Unpack and unzip the archive.
5. Move the **oc** binary to a directory on your **PATH**.
   To check your **PATH**, open a terminal and execute the following command:
   ```bash
   $ echo $PATH
   ```

After you install the OpenShift CLI, it is available using the **oc** command:
   ```bash
   $ oc <command>
   ```

### 2.5.13. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

**Procedure**

1. Export the **kubeadmin** credentials:
2. Verify you can run `oc` commands successfully using the exported configuration:

```
$ oc whoami
```

**Example output**

```
system:admin
```

### 2.5.14. Logging in to the cluster by using the web console

The `kubeadmin` user exists by default after an OpenShift Container Platform installation. You can log in to your cluster as the `kubeadmin` user by using the OpenShift Container Platform web console.

**Prerequisites**

- You have access to the installation host.
- You completed a cluster installation and all cluster Operators are available.

**Procedure**

1. Obtain the password for the `kubeadmin` user from the `kubeadmin-password` file on the installation host:

```
$ cat <installation_directory>/auth/kubeadmin-password
```

**NOTE**

Alternatively, you can obtain the `kubeadmin` password from the `<installation_directory>/openshift_install.log` log file on the installation host.

2. List the OpenShift Container Platform web console route:

```
$ oc get routes -n openshift-console | grep 'console-openshift'
```

**Example output**

```
<table>
<thead>
<tr>
<th>Type</th>
<th>Name</th>
<th>Namespace</th>
<th>Port</th>
<th>Protocol</th>
<th>Scheme</th>
<th>Hostname</th>
<th>Path</th>
<th>Hosts</th>
</tr>
</thead>
<tbody>
<tr>
<td>console</td>
<td>console-openshift-console-apps.&lt;cluster_name&gt;.-&lt;base_domain&gt;</td>
<td>console</td>
<td></td>
<td></td>
<td>https</td>
<td>reencrypt/Redirect</td>
<td>None</td>
<td></td>
</tr>
</tbody>
</table>
```
3. Navigate to the route detailed in the output of the preceding command in a web browser and log in as the **kubeadmin** user.

Additional resources
- See [Accessing the web console](#) for more details about accessing and understanding the OpenShift Container Platform web console.

### 2.5.15. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.6, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to **OpenShift Cluster Manager**.

After you confirm that your **OpenShift Cluster Manager** inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use `subscription watch` to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources
- See [About remote health monitoring](#) for more information about the Telemetry service.

### 2.5.16. Next steps

- **Validating an installation**.
- **Customize your cluster**.
- If necessary, you can **opt out of remote health reporting**.
- If necessary, you can **remove cloud provider credentials**.

### 2.6. INSTALLING A CLUSTER ON AWS IN A RESTRICTED NETWORK

In OpenShift Container Platform version 4.6, you can install a cluster on Amazon Web Services (AWS) in a restricted network by creating an internal mirror of the installation release content on an existing Amazon Virtual Private Cloud (VPC).

#### 2.6.1. Prerequisites

- You **mirrored the images for a disconnected installation** to your registry and obtained the **imageContentSources** data for your version of OpenShift Container Platform.

  **IMPORTANT**

  Because the installation media is on the mirror host, you can use that computer to complete all installation steps.

- You have an existing VPC in AWS. When installing to a restricted network using installer-provisioned infrastructure, you cannot use the installer-provisioned VPC. You must use a user-provisioned VPC that satisfies one of the following requirements:
  - Contains the mirror registry.
Has firewall rules or a peering connection to access the mirror registry hosted elsewhere.

- You reviewed details about the OpenShift Container Platform installation and update processes.

- You configured an AWS account to host the cluster.

**IMPORTANT**

If you have an AWS profile stored on your computer, it must not use a temporary session token that you generated while using a multi-factor authentication device. The cluster continues to use your current AWS credentials to create AWS resources for the entire life of the cluster, so you must use key-based, long-lived credentials. To generate appropriate keys, see Managing Access Keys for IAM Users in the AWS documentation. You can supply the keys when you run the installation program.

- You downloaded the AWS CLI and installed it on your computer. See Install the AWS CLI Using the Bundled Installer (Linux, macOS, or Unix) in the AWS documentation.

- If you use a firewall and plan to use the Telemetry service, you configured the firewall to allow the sites that your cluster requires access to.

**NOTE**

If you are configuring a proxy, be sure to also review this site list.

- If you do not allow the system to manage identity and access management (IAM), then a cluster administrator can manually create and maintain IAM credentials. Manual mode can also be used in environments where the cloud IAM APIs are not reachable.

### 2.6.2. About installations in restricted networks

In OpenShift Container Platform 4.6, you can perform an installation that does not require an active connection to the Internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service's IAM service, require Internet access, so you might still require Internet access. Depending on your network, you might require less Internet access for an installation on bare metal hardware or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift Container Platform registry and contains the installation media. You can create this registry on a mirror host, which can access both the Internet and your closed network, or by using other methods that meet your restrictions.

#### 2.6.2.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The ClusterVersion status includes an Unable to retrieve available updates error.
• By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

2.6.3. About using a custom VPC

In OpenShift Container Platform 4.6, you can deploy a cluster into existing subnets in an existing Amazon Virtual Private Cloud (VPC) in Amazon Web Services (AWS). By deploying OpenShift Container Platform into an existing AWS VPC, you might be able to avoid limit constraints in new accounts or more easily abide by the operational constraints that your company’s guidelines set. If you cannot obtain the infrastructure creation permissions that are required to create the VPC yourself, use this installation option.

Because the installation program cannot know what other components are also in your existing subnets, it cannot choose subnet CIDRs and so forth on your behalf. You must configure networking for the subnets that you install your cluster to yourself.

2.6.3.1. Requirements for using your VPC

The installation program no longer creates the following components:

• Internet gateways
• NAT gateways
• Subnets
• Route tables
• VPCs
• VPC DHCP options
• VPC endpoints

If you use a custom VPC, you must correctly configure it and its subnets for the installation program and the cluster to use. See Amazon VPC console wizard configurations and Work with VPCs and subnets in the AWS documentation for more information on creating and managing an AWS VPC.

The installation program cannot:

• Subdivide network ranges for the cluster to use.
• Set route tables for the subnets.
• Set VPC options like DHCP.

You must complete these tasks before you install the cluster. See VPC networking components and Route tables for your VPC for more information on configuring networking in an AWS VPC.

Your VPC must meet the following characteristics:

• The VPC must not use the kubernetes.io/cluster/.*: owned tag.
  The installation program modifies your subnets to add the kubernetes.io/cluster/.*: shared tag, so your subnets must have at least one free tag slot available for it. See Tag Restrictions in the AWS documentation to confirm that the installation program can add a tag to each subnet that you specify.
You must enable the `enableDnsSupport` and `enableDnsHostnames` attributes in your VPC, so that the cluster can use the Route 53 zones that are attached to the VPC to resolve cluster’s internal DNS records. See DNS Support in Your VPC in the AWS documentation.

If you prefer to use your own Route 53 hosted private zone, you must associate the existing hosted zone with your VPC prior to installing a cluster. You can define your hosted zone using the `platform.aws.hostedZone` field in the `install-config.yaml` file.

If you use a cluster with public access, you must create a public and a private subnet for each availability zone that your cluster uses. Each availability zone can contain no more than one public and one private subnet.

If you are working in a disconnected environment, you are unable to reach the public IP addresses for EC2 and ELB endpoints. To resolve this, you must create a VPC endpoint and attach it to the subnet that the clusters are using. The endpoints should be named as follows:

- `ec2.<region>.amazonaws.com`
- `elasticloadbalancing.<region>.amazonaws.com`
- `s3.<region>.amazonaws.com`

**Required VPC components**

You must provide a suitable VPC and subnets that allow communication to your machines.

<table>
<thead>
<tr>
<th>Component</th>
<th>AWS type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>VPC</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>AWS::EC2::VPC</code></td>
<td>You must provide a public VPC for the cluster to use. The VPC uses an endpoint that references the route tables for each subnet to improve communication with the registry that is hosted in S3.</td>
</tr>
<tr>
<td></td>
<td><code>AWS::EC2::VPC Endpoint</code></td>
<td></td>
</tr>
<tr>
<td><strong>Public subnets</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>AWS::EC2::Subnet</code></td>
<td>Your VPC must have public subnets for between 1 and 3 availability zones and associate them with appropriate Ingress rules.</td>
</tr>
<tr>
<td></td>
<td><code>AWS::EC2::SubnetNetworkAclAssociation</code></td>
<td></td>
</tr>
<tr>
<td><strong>Internet gateway</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>AWS::EC2::InternetGateway</code></td>
<td>You must have a public Internet gateway, with public routes, attached to the VPC. In the provided templates, each public subnet has a NAT gateway with an EIP address. These NAT gateways allow cluster resources, like private subnet instances, to reach the Internet and are not required for some restricted network or proxy scenarios.</td>
</tr>
<tr>
<td></td>
<td><code>AWS::EC2::VPCGatewayAttachment</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>AWS::EC2::RouteTable</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>AWS::EC2::Route</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>AWS::EC2::SubnetRouteTableAssociation</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>AWS::EC2::NatGateway</code></td>
<td></td>
</tr>
<tr>
<td></td>
<td><code>AWS::EC2::EIP</code></td>
<td></td>
</tr>
</tbody>
</table>
You must allow the VPC to access the following ports:

<table>
<thead>
<tr>
<th>Port</th>
<th>Reason</th>
</tr>
</thead>
<tbody>
<tr>
<td>80</td>
<td>Inbound HTTP traffic</td>
</tr>
<tr>
<td>443</td>
<td>Inbound HTTPS traffic</td>
</tr>
<tr>
<td>22</td>
<td>Inbound SSH traffic</td>
</tr>
<tr>
<td>1024-65535</td>
<td>Inbound ephemeral traffic</td>
</tr>
<tr>
<td>0-65535</td>
<td>Outbound ephemeral traffic</td>
</tr>
</tbody>
</table>

Your VPC can have private subnets. The provided CloudFormation templates can create private subnets for between 1 and 3 availability zones. If you use private subnets, you must provide appropriate routes and tables for them.

### 2.6.3.2. VPC validation

To ensure that the subnets that you provide are suitable, the installation program confirms the following data:

- All the subnets that you specify exist.
- You provide private subnets.
- The subnet CIDRs belong to the machine CIDR that you specified.
- You provide subnets for each availability zone. Each availability zone contains no more than one public and one private subnet. If you use a private cluster, provide only a private subnet for each availability zone. Otherwise, provide exactly one public and private subnet for each availability zone.
- You provide a public subnet for each private subnet availability zone. Machines are not provisioned in availability zones that you do not provide private subnets for.
If you destroy a cluster that uses an existing VPC, the VPC is not deleted. When you remove the OpenShift Container Platform cluster from a VPC, the `kubernetes.io/cluster/.*: shared` tag is removed from the subnets that it used.

### 2.6.3.3. Division of permissions

Starting with OpenShift Container Platform 4.3, you do not need all of the permissions that are required for an installation program-provisioned infrastructure cluster to deploy a cluster. This change mimics the division of permissions that you might have at your company: some individuals can create different resource in your clouds than others. For example, you might be able to create application-specific items, like instances, buckets, and load balancers, but not networking-related components such as VPCs, subnets, or ingress rules.

The AWS credentials that you use when you create your cluster do not need the networking permissions that are required to make VPCs and core networking components within the VPC, such as subnets, routing tables, Internet gateways, NAT, and VPN. You still need permission to make the application resources that the machines within the cluster require, such as ELBs, security groups, S3 buckets, and nodes.

### 2.6.3.4. Isolation between clusters

If you deploy OpenShift Container Platform to an existing network, the isolation of cluster services is reduced in the following ways:

- You can install multiple OpenShift Container Platform clusters in the same VPC.
- ICMP ingress is allowed from the entire network.
- TCP 22 ingress (SSH) is allowed to the entire network.
- Control plane TCP 6443 ingress (Kubernetes API) is allowed to the entire network.
- Control plane TCP 22623 ingress (MCS) is allowed to the entire network.

### 2.6.4. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.6, you require access to the Internet to obtain the images that are necessary to install your cluster.

You must have Internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.
IMPORTANT

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

2.6.5. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your ssh-agent and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

NOTE

In a production environment, you require disaster recovery and debugging.

You can use this key to SSH into the master nodes as the user core. When you deploy the cluster, the key is added to the core user’s ~/.ssh/authorized_keys list.

NOTE

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

Procedure

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N " \n   -f <path>/<file_name> 1
   ```

   Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   Running this command generates an SSH key that does not require a password in the location that you specified.

   NOTE

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the ssh-agent process as a background task:
NOTE
If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the ssh-agent:

   $ ssh-add <path>/<file_name>

Example output

Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

2.6.6. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Amazon Web Services (AWS).

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster. For a restricted network installation, these files are on your mirror host.
- Have the imageContentSources values that were generated during mirror registry creation.
- Obtain the contents of the certificate for your mirror registry.

Procedure

1. Create the install-config.yaml file.
   a. Change to the directory that contains the installation program and run the following command:

      $ ./openshift-install create install-config --dir <installation_directory>

      For <installation_directory>, specify the directory name to store the files that the installation program creates.
IMPORTANT

Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

b. At the prompts, provide the configuration details for your cloud:

i. Optional: Select an SSH key to use to access your cluster machines.

NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

ii. Select AWS as the platform to target.

iii. If you do not have an Amazon Web Services (AWS) profile stored on your computer, enter the AWS access key ID and secret access key for the user that you configured to run the installation program.

iv. Select the AWS region to deploy the cluster to.

v. Select the base domain for the Route 53 service that you configured for your cluster.

vi. Enter a descriptive name for your cluster.

vii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

2. Edit the install-config.yaml file to provide the additional information that is required for an installation in a restricted network.

a. Update the pullSecret value to contain the authentication information for your registry:

```yaml
pullSecret: '{"auths":{"<mirror_host_name>:5000": {"auth": "<credentials>"} }}
```

For `<mirror_host_name>`, specify the registry domain name that you specified in the certificate for your mirror registry, and for `<credentials>`, specify the base64-encoded user name and password for your mirror registry.

b. Add the additionalTrustBundle parameter and value.

```yaml
additionalTrustBundle: |
-----BEGIN CERTIFICATE-----
ZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZ
-----END CERTIFICATE-----
```

```yaml
The value must be the contents of the certificate file that you used for your mirror registry.
```
The value must be the contents of the certificate file that you used for your mirror registry, which can be an existing, trusted certificate authority or the self-signed certificate that you generated for the mirror registry.

c. Define the subnets for the VPC to install the cluster in:

```
subnets:
- subnet-1
- subnet-2
- subnet-3
```

d. Add the image content resources, which look like this excerpt:

```
imageContentSources:
- mirrors:
  - <mirror_host_name>:5000/<repo_name>/release
    source: quay.example.com/openshift-release-dev/ocp-release
  - mirrors:
    - <mirror_host_name>:5000/<repo_name>/release
      source: registry.example.com/ocp/release
```

To complete these values, use the `imageContentSources` that you recorded during mirror registry creation.

3. Make any other modifications to the `install-config.yaml` file that you require. You can find more information about the available parameters in the Installation configuration parameters section.

4. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

**IMPORTANT**

The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

### 2.6.6.1. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster’s platform. When you create the `install-config.yaml` installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the `install-config.yaml` file to provide more details about the platform.

**NOTE**

After installation, you cannot modify these parameters in the `install-config.yaml` file.

**IMPORTANT**

The `openshift-install` command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

### 2.6.6.1.1. Required configuration parameters
Required installation configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the install-config.yaml content. The current version is v1. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the baseDomain and metadata.name parameter values that uses the &lt;metadata.name&gt;.&lt;baseDomain&gt; format.</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
</tr>
<tr>
<td>metadata</td>
<td>Kubernetes resource ObjectMeta, from which only the name parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of {{.metadata.name}}.{{.baseDomain}}.</td>
<td>String of lowercase letters, hyphens (-), and periods (.), such as dev.</td>
</tr>
<tr>
<td>platform</td>
<td>The configuration for the specific platform upon which to perform the installation: aws, baremetal, azure, openstack, ovirt, vsphere. For additional information about platform.&lt;platform&gt; parameters, consult the following table for your specific platform.</td>
<td>Object</td>
</tr>
</tbody>
</table>
### 2.6.6.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

**Table 2.15. Network parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>networking</strong></td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td><strong>networking.network</strong></td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either <strong>OpenShiftSDN</strong> or <strong>OVNKubernetes</strong>. The default value is <strong>OpenShiftSDN</strong>.</td>
</tr>
<tr>
<td><strong>networking.clusterNetwork</strong></td>
<td>The IP address blocks for pods.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td>The default value is <strong>10.128.0.0/14</strong> with a host prefix of <strong>/23</strong>.</td>
<td>available only if you specify multiple IP address blocks, the blocks must not overlap.</td>
</tr>
<tr>
<td></td>
<td>If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td><strong>networking:</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>clusterNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- cidr: <strong>10.128.0.0/14</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>hostPrefix: <strong>23</strong></td>
</tr>
</tbody>
</table>

**NOTE**

You cannot modify parameters specified by the `networking` object after installation.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>networking.clusterNetwork.cidr</code></td>
<td>Required if you use <code>networking.clusterNetwork</code>. An IP address block.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td></td>
<td>An IPv4 network.</td>
<td></td>
</tr>
<tr>
<td><code>networking.clusterNetwork.hostPrefix</code></td>
<td>The subnet prefix length to assign to each individual node. For example, if <code>hostPrefix</code> is set to <code>23</code> then each node is assigned a <code>/23</code> subnet out of the given <code>cidr</code>. A <code>hostPrefix</code> value of <code>23</code> provides 510 (2^(32 - 23) - 2) pod IP addresses.</td>
<td>A subnet prefix.</td>
</tr>
<tr>
<td><code>networking.serviceNetwork</code></td>
<td>The IP address block for services. The default value is <code>172.30.0.0/16</code>. The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.</td>
<td>An array with an IP address block in CIDR format. For example:</td>
</tr>
<tr>
<td><code>networking.machineNetwork</code></td>
<td>The IP address blocks for machines.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td>If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td></td>
</tr>
<tr>
<td><code>networking.machineNetwork.cidr</code></td>
<td>Required if you use <code>networking.machineNetwork</code>. An IP address block. The default value is <code>10.0.0.0/16</code> for all platforms other than <code>libvirt</code>. For <code>libvirt</code>, the default value is <code>192.168.126.0/24</code>.</td>
<td>An IP network block in CIDR notation.</td>
</tr>
<tr>
<td></td>
<td>For example, <code>10.0.0.0/16</code>.</td>
<td>NOTE</td>
</tr>
</tbody>
</table>

### Table 2.16. Optional parameters

**2.6.6.13. Optional configuration parameters**

Optional installation configuration parameters are described in the following table:
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes' trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of machine-pool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>compute.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td>compute.hyperthreading</td>
<td>Whether to enable or disable simultaneous multithreading, or <strong>hyperthreading</strong>, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td></td>
</tr>
<tr>
<td>compute.name</td>
<td>Required if you use <code>compute</code>. The name of the machine pool.</td>
<td>worker</td>
</tr>
<tr>
<td>compute.platform</td>
<td>Required if you use <code>compute</code>. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <code>controlPlane.platform</code> parameter value.</td>
<td><code>aws, azure, gcp, openstack, ovirt, vsphere, or {}</code></td>
</tr>
<tr>
<td>compute.replicas</td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>------------------------</td>
<td>------------------------------------------------------------------------------</td>
<td>---------------------------------------------</td>
</tr>
<tr>
<td>controlPlane</td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of <code>MachinePool</code> objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>controlPlane.architect</td>
<td>Determines the instruction set architecture of the machines in the pool.</td>
<td>String</td>
</tr>
<tr>
<td>controlPlane.hypertreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
</tbody>
</table>

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.

<table>
<thead>
<tr>
<th>controlPlane.name</th>
<th>Required if you use <code>controlPlane</code>. The name of the machine pool.</th>
<th>master</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use <code>controlPlane</code>. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the <code>compute.platform</code> parameter value.</td>
<td><code>aws</code>, <code>azure</code>, <code>gcp</code>, <code>openstack</code>, <code>ovirt</code>, <code>vsphere</code>, or <code>null</code></td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>----------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (&quot;&quot;&quot;).</td>
</tr>
</tbody>
</table>

**NOTE**

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Red Hat Operators reference content.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>fips</td>
<td>Enable or disable FIPS mode. The default is <strong>false</strong> (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</td>
<td><strong>false</strong> or <strong>true</strong></td>
</tr>
</tbody>
</table>

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the **x86_64** architecture.

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.

<table>
<thead>
<tr>
<th>imageContentSources</th>
<th>Sources and repositories for the release-image content.</th>
<th>Array of objects. Includes a <code>source</code> and, optionally, <code>mirrors</code>, as described in the following rows of this table.</th>
</tr>
</thead>
<tbody>
<tr>
<td>imageContentSources.source</td>
<td>Required if you use <code>imageContentSources</code>. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td>imageContentSources.mirrors</td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
<tr>
<td>publish</td>
<td>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</td>
<td><strong>Internal</strong> or <strong>External</strong>. To deploy a private cluster, which cannot be accessed from the internet, set <code>publish</code> to <strong>Internal</strong>. The default value is <strong>External</strong>.</td>
</tr>
</tbody>
</table>
The SSH key or keys to authenticate access your cluster machines.

**NOTE**
For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

One or more keys. For example:

sshKey:
<key1>
<key2>
<key3>

### 2.6.6.14. Optional AWS configuration parameters

Optional AWS configuration parameters are described in the following table:

**Table 2.17. Optional AWS parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>compute.platform.aws.amiID</code></td>
<td>The AWS AMI used to boot compute machines for the cluster. This is required for regions that require a custom RHCOS AMI.</td>
<td>Any published or custom RHCOS AMI that belongs to the set AWS region.</td>
</tr>
<tr>
<td><code>compute.platform.aws.rootVolume.iops</code></td>
<td>The Input/Output Operations Per Second (IOPS) that is reserved for the root volume.</td>
<td>Integer, for example 4000.</td>
</tr>
<tr>
<td><code>compute.platform.aws.rootVolume.size</code></td>
<td>The size in GiB of the root volume.</td>
<td>Integer, for example 500.</td>
</tr>
<tr>
<td><code>compute.platform.aws.rootVolume.type</code></td>
<td>The type of the root volume.</td>
<td>Valid AWS EBS volume type, such as io1.</td>
</tr>
<tr>
<td><code>compute.platform.aws.type</code></td>
<td>The EC2 instance type for the compute machines.</td>
<td>Valid AWS instance type, such as c5.9xlarge.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td>compute.platform.aws.zones</td>
<td>The availability zones where the installation program creates machines for the compute machine pool. If you provide your own VPC, you must provide a subnet in that availability zone.</td>
<td>A list of valid AWS availability zones, such as <strong>us-east-1c</strong>, in a YAML sequence.</td>
</tr>
<tr>
<td>compute.aws.region</td>
<td>The AWS region that the installation program creates compute resources in.</td>
<td>Any valid <strong>AWS region</strong>, such as <strong>us-east-1</strong>.</td>
</tr>
<tr>
<td>controlPlane.platform.aws.amiID</td>
<td>The AWS AMI used to boot control plane machines for the cluster. This is required for regions that require a custom RHCOS AMI.</td>
<td>Any published or custom RHCOS AMI that belongs to the set AWS region.</td>
</tr>
<tr>
<td>controlPlane.platform.aws.type</td>
<td>The EC2 instance type for the control plane machines.</td>
<td>Valid <strong>AWS instance type</strong>, such as <strong>c5.9xlarge</strong>.</td>
</tr>
<tr>
<td>controlPlane.platform.aws.zones</td>
<td>The availability zones where the installation program creates machines for the control plane machine pool.</td>
<td>A list of valid AWS availability zones, such as <strong>us-east-1c</strong>, in a YAML sequence.</td>
</tr>
<tr>
<td>controlPlane.aws.region</td>
<td>The AWS region that the installation program creates control plane resources in.</td>
<td>Valid <strong>AWS region</strong>, such as <strong>us-east-1</strong>.</td>
</tr>
<tr>
<td>platform.aws.amiID</td>
<td>The AWS AMI used to boot all machines for the cluster. If set, the AMI must belong to the same region as the cluster. This is required for regions that require a custom RHCOS AMI.</td>
<td>Any published or custom RHCOS AMI that belongs to the set AWS region.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td>platform.aws.serviceEndpoints.name</td>
<td>The AWS service endpoint name. Custom endpoints are only required for cases where alternative AWS endpoints, like FIPS, must be used. Custom API endpoints can be specified for EC2, S3, IAM, Elastic Load Balancing, Tagging, Route 53, and STS AWS services.</td>
<td>Valid AWS service endpoint name.</td>
</tr>
<tr>
<td>platform.aws.serviceEndpoints.url</td>
<td>The AWS service endpoint URL. The URL must use the https protocol and the host must trust the certificate.</td>
<td>Valid AWS service endpoint URL.</td>
</tr>
<tr>
<td>platform.aws.userTags</td>
<td>A map of keys and values that the installation program adds as tags to all resources that it creates.</td>
<td>Any valid YAML map, such as key value pairs in the &lt;key&gt;: &lt;value&gt; format. For more information about AWS tags, see Tagging Your Amazon EC2 Resources in the AWS documentation.</td>
</tr>
<tr>
<td>platform.aws.subnets</td>
<td>If you provide the VPC instead of allowing the installation program to create the VPC for you, specify the subnet for the cluster to use. The subnet must be part of the same machineNetwork[].cidr ranges that you specify. For a standard cluster, specify a public and a private subnet for each availability zone. For a private cluster, specify a private subnet for each availability zone.</td>
<td>Valid subnet IDs.</td>
</tr>
</tbody>
</table>

### 2.6.6.2. Sample customized install-config.yaml file for AWS

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

**IMPORTANT**

This sample YAML file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program and modify it.

```yaml
apiVersion: v1
baseDomain: example.com
```
credentialsMode: Mint

controlPlane:
- hyperthreading: Enabled
- name: master
- platform:
  - aws:
    - zones:
      - us-west-2a
      - us-west-2b
    rootVolume:
      - iops: 4000
      - size: 500
      - type: io1
    type: m5.xlarge
    replicas: 3
    compute:
    - hyperthreading: Enabled
    - name: worker
    - platform:
      - aws:
        - rootVolume:
          - iops: 2000
          - size: 500
          - type: io1
        - type: c5.4xlarge
        - zones:
          - us-west-2c
        replicas: 3
    metadata:
    - name: test-cluster
    networking:
    - clusterNetwork:
      - cidr: 10.128.0.0/14
      - hostPrefix: 23
      machineNetwork:
      - cidr: 10.0.0.0/16
      networkType: OpenShiftSDN
    serviceNetwork:
    - 172.30.0.0/16
    platform:
    - aws:
      - region: us-west-2
      userTags:
        - adminContact: jdoe
        - costCenter: 7536
    subnets:
    - subnet-1
    - subnet-2
    - subnet-3
    amiID: ami-96c6f8f7
    serviceEndpoints:
    - name: ec2
      url: https://vpce-id.ec2.us-west-2.vpce.amazonaws.com
    hostedZone: Z3URY6TWQ91KVV

CHAPTER 2. INSTALLING ON AWS
Required. The installation program prompts you for this value.

Optional: Add this parameter to force the Cloud Credential Operator (CCO) to use the specified mode, instead of having the CCO dynamically try to determine the capabilities of the credentials. For details about CCO modes, see the Cloud Credential Operator entry in the Red Hat Operators reference content.

If you do not provide these parameters and values, the installation program provides the default value.

The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, -, and the first line of the controlPlane section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading, or hyperthreading. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to Disabled. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

IMPORTANT

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger instance types, such as m4.2xlarge or m5.2xlarge, for your machines if you disable simultaneous multithreading.

To configure faster storage for etcd, especially for larger clusters, set the storage type as io1 and set iops to 2000.

If you provide your own VPC, specify subnets for each availability zone that your cluster uses.

The ID of the AMI used to boot machines for the cluster. If set, the AMI must belong to the same region as the cluster.

The AWS service endpoints. Custom endpoints are required when installing to an unknown AWS region. The endpoint URL must use the https protocol and the host must trust the certificate.
The ID of your existing Route 53 private hosted zone. Providing an existing hosted zone requires that you supply your own VPC and the hosted zone is already associated with the VPC prior to

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

You can optionally provide the `sshKey` value that you use to access the machines in your cluster.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

For `<local_registry>`, specify the registry domain name, and optionally the port, that your mirror registry uses to serve content. For example `registry.example.com` or `registry.example.com:5000`. For `<credentials>`, specify the base64-encoded user name and password for your mirror registry.

Provide the contents of the certificate file that you used for your mirror registry.

Provide the `imageContentSources` section from the output of the command to mirror the repository.

**2.6.6.3. Configuring the cluster-wide proxy during installation**

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**Prerequisites**

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.
NOTE

The Proxy object status.noProxy field is populated with the values of the networking.machineNetwork[].cidr, networking.clusterNetwork[].cidr, and networking.serviceNetwork[] fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object status.noProxy field is also populated with the instance metadata endpoint (169.254.169.254).

- If your cluster is on AWS, you added the ec2.<region>.amazonaws.com, elasticloadbalancing.<region>.amazonaws.com, and s3.<region>.amazonaws.com endpoints to your VPC endpoint. These endpoints are required to complete requests from the nodes to the AWS EC2 API. Because the proxy works on the container level, not the node level, you must route these requests to the AWS EC2 API through the AWS private network. Adding the public IP address of the EC2 API to your allowlist in your proxy server is not sufficient.

Procedure

1. Edit your install-config.yaml file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
     httpProxy: http://<username>:<pswd>@<ip>:<port> 1
     httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
     noProxy: example.com 3
   additionalTrustBundle: |
   -----BEGIN CERTIFICATE-----
   <MY_TRUSTED_CA_CERT>
   -----END CERTIFICATE-----
   ...
   
1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.

2 A proxy URL to use for creating HTTPS connections outside the cluster.

3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.

4 If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace to hold the additional CA certificates. If you provide additionalTrustBundle and at least one proxy setting, the Proxy object is configured to reference the user-ca-bundle config map in the trustedCA field. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges the contents specified for the trustedCA parameter with the RHCOS trust bundle. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.
The installation program does not support the proxy \texttt{readinessEndpoints} field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named \texttt{cluster} that uses the proxy settings in the provided \texttt{install-config.yaml} file. If no proxy settings are provided, a \texttt{cluster Proxy} object is still created, but it will have a nil \texttt{spec}.

\begin{itemize}
\item Only the \texttt{Proxy} object named \texttt{cluster} is supported, and no additional proxies can be created.
\end{itemize}

\subsection*{2.6.7. Deploying the cluster}

You can install OpenShift Container Platform on a compatible cloud platform.

\begin{itemize}
\item You can run the \texttt{create cluster} command of the installation program only once, during initial installation.
\end{itemize}

\textbf{Prerequisites}

\begin{itemize}
\item Configure an account with the cloud platform that hosts your cluster.
\item Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.
\end{itemize}

\textbf{Procedure}

1. Change to the directory that contains the installation program and initialize the cluster deployment:

   \begin{verbatim}
   $ ./openshift-install create cluster --dir <installation_directory> \ 1
   --log-level=info \ 2
   \end{verbatim}

   \begin{enumerate}
   \item For \texttt{<installation_directory>}, specify the location of your customized \texttt{./install-config.yaml} file.
   \item To view different installation details, specify \texttt{warn}, \texttt{debug}, or \texttt{error} instead of \texttt{info}.
   \end{enumerate}

\begin{itemize}
\item If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.
\end{itemize}

When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the \texttt{kubeadmin} user, display in your terminal.
Example output

```
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-WI5AL"
INFO Time elapsed: 36m22s
```

**NOTE**

The cluster access and credential information also outputs to `<installation_directory>/openshift_install.log` when an installation succeeds.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

**IMPORTANT**

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

2. Optional: Remove or disable the **AdministratorAccess** policy from the IAM account that you used to install the cluster.

**NOTE**

The elevated permissions provided by the **AdministratorAccess** policy are required only during installation.

### 2.6.8. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) in order to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.
IMPORTANT

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.6. Download and install the new version of oc.

2.6.8.1. Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.
3. Click Download Now next to the OpenShift v4.6 Linux Client entry and save the file.
4. Unpack the archive:
   
   ```sh
   $ tar xvzf <file>
   ```
5. Place the oc binary in a directory that is on your PATH. To check your PATH, execute the following command:
   
   ```sh
   $ echo $PATH
   ```

After you install the OpenShift CLI, it is available using the oc command:

```
$ oc <command>
```

2.6.8.2. Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.
3. Click Download Now next to the OpenShift v4.6 Windows Client entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the oc binary to a directory that is on your PATH. To check your PATH, open the command prompt and execute the following command:

   ```cmd
   C:\> path
   ```

After you install the OpenShift CLI, it is available using the oc command:
2.6.8.3. Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.
3. Click Download Now next to the OpenShift v4.6 MacOSX Client entry and save the file.
4. Unpack and unzip the archive.
5. Move the oc binary to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:

   ```
   $ echo $PATH
   ```

After you install the OpenShift CLI, it is available using the oc command:

```
$ oc <command>
```

2.6.9. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster kubeconfig file. The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the oc CLI.

Procedure

1. Export the kubeadmin credentials:

   ```
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   1 For <installation_directory>, specify the path to the directory that you stored the installation files in.

2. Verify you can run oc commands successfully using the exported configuration:

   ```
   $ oc whoami
   ```
2.6.10. Disabling the default OperatorHub sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

Procedure

- Disable the sources for the default catalogs by adding disableAllDefaultSources: true to the OperatorHub object:

  ```
  $ oc patch OperatorHub cluster --type json \n  -p '([^"\s]+, "value": true)]'
  ```

TIP

Alternatively, you can use the web console to manage catalog sources. From the Administration → Cluster Settings → Global Configuration → OperatorHub page, click the Sources tab, where you can create, delete, disable, and enable individual sources.

2.6.11. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.6, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service

2.6.12. Next steps

- Validate an installation.
- Customize your cluster.
- Configure image streams for the Cluster Samples Operator and the must-gather tool.
- Learn how to use Operator Lifecycle Manager (OLM) on restricted networks.
- If the mirror registry that you used to install your cluster has a trusted CA, add it to the cluster by configuring additional trust stores.
- If necessary, you can opt out of remote health reporting.
2.7. INSTALLING A CLUSTER ON AWS INTO AN EXISTING VPC

In OpenShift Container Platform version 4.6, you can install a cluster into an existing Amazon Virtual Private Cloud (VPC) on Amazon Web Services (AWS). The installation program provisions the rest of the required infrastructure, which you can further customize. To customize the installation, you modify parameters in the `install-config.yaml` file before you install the cluster.

2.7.1. Prerequisites

- Review details about the OpenShift Container Platform installation and update processes.
- Configure an AWS account to host the cluster.

**IMPORTANT**

If you have an AWS profile stored on your computer, it must not use a temporary session token that you generated while using a multi-factor authentication device. The cluster continues to use your current AWS credentials to create AWS resources for the entire life of the cluster, so you must use long-lived credentials. To generate appropriate keys, see Managing Access Keys for IAM Users in the AWS documentation. You can supply the keys when you run the installation program.

- If you use a firewall, you must configure it to allow the sites that your cluster requires access to.
- If you do not allow the system to manage identity and access management (IAM), then a cluster administrator can manually create and maintain IAM credentials. Manual mode can also be used in environments where the cloud IAM APIs are not reachable.

2.7.2. About using a custom VPC

In OpenShift Container Platform 4.6, you can deploy a cluster into existing subnets in an existing Amazon Virtual Private Cloud (VPC) in Amazon Web Services (AWS). By deploying OpenShift Container Platform into an existing AWS VPC, you might be able to avoid limit constraints in new accounts or more easily abide by the operational constraints that your company's guidelines set. If you cannot obtain the infrastructure creation permissions that are required to create the VPC yourself, use this installation option.

Because the installation program cannot know what other components are also in your existing subnets, it cannot choose subnet CIDRs and so forth on your behalf. You must configure networking for the subnets that you install your cluster to yourself.

2.7.2.1. Requirements for using your VPC

The installation program no longer creates the following components:

- Internet gateways
- NAT gateways
- Subnets
- Route tables
- VPCs
- VPC DHCP options
- VPC endpoints

If you use a custom VPC, you must correctly configure it and its subnets for the installation program and the cluster to use. See Amazon VPC console wizard configurations and Work with VPCs and subnets in the AWS documentation for more information on creating and managing an AWS VPC.

The installation program cannot:

- Subdivide network ranges for the cluster to use.
- Set route tables for the subnets.
- Set VPC options like DHCP.

You must complete these tasks before you install the cluster. See VPC networking components and Route tables for your VPC for more information on configuring networking in an AWS VPC.

Your VPC must meet the following characteristics:

- Create a public and private subnet for each availability zone that your cluster uses. Each availability zone can contain no more than one public and one private subnet. For an example of this type of configuration, see VPC with public and private subnets (NAT) in the AWS documentation.
  Record each subnet ID. Completing the installation requires that you enter these values in the platform section of the install-config.yaml file. See Finding a subnet ID in the AWS documentation.
- The VPC’s CIDR block must contain the Networking.MachineCIDR range, which is the IP address pool for cluster machines. The subnet CIDR blocks must belong to the machine CIDR that you specify.
- The VPC must have a public internet gateway attached to it. For each availability zone:
  - The public subnet requires a route to the internet gateway.
  - The public subnet requires a NAT gateway with an EIP address.
  - The private subnet requires a route to the NAT gateway in public subnet.
- The VPC must not use the kubernetes.io/cluster/.*: owned tag. The installation program modifies your subnets to add the kubernetes.io/cluster/.*: shared tag, so your subnets must have at least one free tag slot available for it. See Tag Restrictions in the AWS documentation to confirm that the installation program can add a tag to each subnet that you specify.
- You must enable the enableDnsSupport and enableDnsHostnames attributes in your VPC, so that the cluster can use the Route 53 zones that are attached to the VPC to resolve cluster’s internal DNS records. See DNS Support in Your VPC in the AWS documentation.
  If you prefer to use your own Route 53 hosted private zone, you must associate the existing hosted zone with your VPC prior to installing a cluster. You can define your hosted zone using the platform.aws.hostedZone field in the install-config.yaml file.

If you are working in a disconnected environment, you are unable to reach the public IP addresses for EC2 and ELB endpoints. To resolve this, you must create a VPC endpoint and attach it to the subnet that the clusters are using. The endpoints should be named as follows:
- ec2.<region>.amazonaws.com
- elasticloadbalancing.<region>.amazonaws.com
- s3.<region>.amazonaws.com

### Required VPC components

You must provide a suitable VPC and subnets that allow communication to your machines.

<table>
<thead>
<tr>
<th>Component</th>
<th>AWS type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VPC</td>
<td>• AWS::EC2::VPC</td>
<td>You must provide a public VPC for the cluster to use. The VPC uses an endpoint that references the route tables for each subnet to improve communication with the registry that is hosted in S3.</td>
</tr>
<tr>
<td></td>
<td>• AWS::EC2::VPCEndpoint</td>
<td></td>
</tr>
<tr>
<td>Public subnets</td>
<td>• AWS::EC2::Subnet</td>
<td>Your VPC must have public subnets for between 1 and 3 availability zones and associate them with appropriate Ingress rules.</td>
</tr>
<tr>
<td></td>
<td>• AWS::EC2::SubnetNetworkAclAssocia-</td>
<td></td>
</tr>
<tr>
<td>Internet gateway</td>
<td>• AWS::EC2::InternetGateway</td>
<td>You must have a public Internet gateway, with public routes, attached to the VPC. In the provided templates, each public subnet has a NAT gateway with an EIP address. These NAT gateways allow cluster resources, like private subnet instances, to reach the Internet and are not required for some restricted network or proxy scenarios.</td>
</tr>
<tr>
<td></td>
<td>• AWS::EC2::VPCGatewayAttachment</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• AWS::EC2::RouteTable</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• AWS::EC2::Route</td>
<td></td>
</tr>
<tr>

<tr>
<td>Network access</td>
<td>• AWS::EC2::NetworkAcl</td>
<td>You must allow the VPC to access the following ports:</td>
</tr>
<tr>
<td>control</td>
<td>• AWS::EC2::NetworkAclEntry</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Port</th>
<th>Reason</th>
</tr>
</thead>
<tbody>
<tr>
<td>80</td>
<td>Inbound HTTP traffic</td>
</tr>
<tr>
<td>443</td>
<td>Inbound HTTPS traffic</td>
</tr>
</tbody>
</table>
### 2.7.2.2. VPC validation

To ensure that the subnets that you provide are suitable, the installation program confirms the following data:

- All the subnets that you specify exist.
- You provide private subnets.
- The subnet CIDRs belong to the machine CIDR that you specified.
- You provide subnets for each availability zone. Each availability zone contains no more than one public and one private subnet. If you use a private cluster, provide only a private subnet for each availability zone. Otherwise, provide exactly one public and private subnet for each availability zone.
- You provide a public subnet for each private subnet availability zone. Machines are not provisioned in availability zones that you do not provide private subnets for.

If you destroy a cluster that uses an existing VPC, the VPC is not deleted. When you remove the OpenShift Container Platform cluster from a VPC, the `kubernetes.io/cluster/*`: shared tag is removed from the subnets that it used.

### 2.7.2.3. Division of permissions

Starting with OpenShift Container Platform 4.3, you do not need all of the permissions that are required for an installation program-provisioned infrastructure cluster to deploy a cluster. This change mimics the division of permissions that you might have at your company: some individuals can create different resource in your clouds than others. For example, you might be able to create application-specific items, like instances, buckets, and load balancers, but not networking-related components such as VPCs, subnets, or ingress rules.

The AWS credentials that you use when you create your cluster do not need the networking permissions that are required to make VPCs and core networking components within the VPC, such as subnets,
routing tables, Internet gateways, NAT, and VPN. You still need permission to make the application resources that the machines within the cluster require, such as ELBs, security groups, S3 buckets, and nodes.

2.7.2.4. Isolation between clusters

If you deploy OpenShift Container Platform to an existing network, the isolation of cluster services is reduced in the following ways:

- You can install multiple OpenShift Container Platform clusters in the same VPC.
- ICMP ingress is allowed from the entire network.
- TCP 22 ingress (SSH) is allowed to the entire network.
- Control plane TCP 6443 ingress (Kubernetes API) is allowed to the entire network.
- Control plane TCP 22623 ingress (MCS) is allowed to the entire network.

2.7.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.6, you require access to the Internet to install your cluster.

You must have Internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

2.7.4. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your `ssh-agent` and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

**NOTE**

In a production environment, you require disaster recovery and debugging.

You can use this key to SSH into the master nodes as the user `core`. When you deploy the cluster, the key is added to the `core` user’s `~/.ssh/authorized_keys` list.
NOTE
You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

Procedure

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N "\" \\
   -f <path>/<file_name> ①
   ```

   Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

   Running this command generates an SSH key that does not require a password in the location that you specified.

   NOTE
   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the `ssh-agent` process as a background task:

   ```bash
   $ eval "$(ssh-agent -s)"
   ```

   Example output

   ```
   Agent pid 31874
   ```

   NOTE
   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the `ssh-agent`:

   ```bash
   $ ssh-add <path>/<file_name> ①
   ```

   Example output

   ```
   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
   ```

   ① Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`
Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

2.7.5. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on a local computer.

Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

**IMPORTANT**

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar xvf openshift-install-linux.tar.gz
```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

2.7.6. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Amazon Web Services (AWS).
Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Create the `install-config.yaml` file.
   a. Change to the directory that contains the installation program and run the following command:

   ```
   $ ./openshift-install create install-config --dir <installation_directory>  
   ```

   For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

   IMPORTANT

   Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

   b. At the prompts, provide the configuration details for your cloud:
      i. Optional: Select an SSH key to use to access your cluster machines.

         NOTE

         For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

      ii. Select AWS as the platform to target.

      iii. If you do not have an Amazon Web Services (AWS) profile stored on your computer, enter the AWS access key ID and secret access key for the user that you configured to run the installation program.

      iv. Select the AWS region to deploy the cluster to.

      v. Select the base domain for the Route 53 service that you configured for your cluster.

      vi. Enter a descriptive name for your cluster.

      vii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

2. Modify the `install-config.yaml` file. You can find more information about the available parameters in the Installation configuration parameters section.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.
2.7.6.1. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster’s platform. When you create the `install-config.yaml` installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the `install-config.yaml` file to provide more details about the platform.

**NOTE**

After installation, you cannot modify these parameters in the `install-config.yaml` file.

**IMPORTANT**

The `openshift-install` command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

### 2.7.6.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is v1. The installer may also support older API versions.</td>
<td>String</td>
</tr>
</tbody>
</table>
| baseDomain   | The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the baseDomain and metadata.name parameter values that uses the `<metadata.name>..<baseDomain>` format. | A fully-qualified domain or subdomain name, such as `example.com`. }
### Parameter

**metadata**

Kubernetes resource ObjectMeta, from which only the name parameter is consumed.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>metadata</td>
<td>Kubernetes resource ObjectMeta, from which only the name parameter is consumed.</td>
<td>Object</td>
</tr>
</tbody>
</table>

**metadata.name**

The name of the cluster. DNS records for the cluster are all subdomains of {{.metadata.name}}.{{.baseDomain}}.

String of lowercase letters, hyphens (-), and periods (.), such as dev.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of {{.metadata.name}}.{{.baseDomain}}.</td>
<td>String of lowercase letters, hyphens (-), and periods (.), such as dev.</td>
</tr>
</tbody>
</table>

**platform**

The configuration for the specific platform upon which to perform the installation: aws, baremetal, azure, openstack, ovirt, vsphere.

For additional information about platform.<platform> parameters, consult the following table for your specific platform.

Object

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>platform</td>
<td>The configuration for the specific platform upon which to perform the installation: aws, baremetal, azure, openstack, ovirt, vsphere. For additional information about platform.&lt;platform&gt; parameters, consult the following table for your specific platform.</td>
<td>Object</td>
</tr>
</tbody>
</table>

**pullSecret**

Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.

```json
{
  "auths":{
    "cloud.openshift.com":{
      "auth":"b3Blb=",
      "email":"you@example.com"
    },
    "quay.io":{
      "auth":"b3Blb=",
      "email":"you@example.com"
    }
  }
}
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>pullSecret</td>
<td>Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.</td>
<td></td>
</tr>
</tbody>
</table>

#### 2.7.6.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

**Table 2.19. Network parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong></td>
<td>You cannot modify parameters specified by the <code>networking</code> object after installation.</td>
</tr>
<tr>
<td>networking.networkType</td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN.</td>
</tr>
<tr>
<td>networking.clusterNetwork</td>
<td>The IP address blocks for pods.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td>The default value is <strong>10.128.0.0/14</strong> with a host prefix of <strong>/23</strong>.</td>
<td>networking:</td>
</tr>
<tr>
<td></td>
<td>If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td>- clusterNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- cidr: <strong>10.128.0.0/14</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>- hostPrefix: <strong>23</strong></td>
</tr>
<tr>
<td>networking.clusterNetwork.cidr</td>
<td>Required if you use <code>networking.clusterNetwork</code>. An IP address block.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between <strong>0</strong> and <strong>32</strong>.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>An IPv4 network.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>An IPv4 network.</td>
</tr>
<tr>
<td>networking.clusterNetwork.hostPrefix</td>
<td>The subnet prefix length to assign to each individual node. For example, if <code>hostPrefix</code> is set to <strong>23</strong> then each node is assigned a <strong>/23</strong> subnet out of the given <code>cidr</code>. A <code>hostPrefix</code> value of <strong>23</strong> provides <strong>510</strong> (2^(32 - 23) - 2) pod IP addresses.</td>
<td>A subnet prefix.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The default value is <strong>23</strong>.</td>
</tr>
<tr>
<td>networking.serviceNetwork</td>
<td>The IP address block for services. The default value is <strong>172.30.0.0/16</strong>.</td>
<td>An array with an IP address block in CIDR format. For example:</td>

<tr>
<td></td>
<td></td>
<td>networking:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- serviceNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- <strong>172.30.0.0/16</strong></td>
</tr>
<tr>
<td>networking.machineNetwork</td>
<td>The IP address blocks for machines.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>networking:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- machineNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- cidr: <strong>10.0.0.0/16</strong></td>
</tr>
</tbody>
</table>
### Networking Machine Network cidr

Required if you use `networking.machineNetwork`. An IP address block. The default value is `10.0.0.0/16` for all platforms other than libvirt. For libvirt, the default value is `192.168.126.0/24`.

**NOTE**

Set the `networking.machineNetwork` to match the CIDR that the preferred NIC resides in.

#### 2.7.6.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>additionalTrustBundle</code></td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td><code>compute</code></td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of machine-pool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td><code>compute.architecture</code></td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
</tbody>
</table>
Whether to enable or disable simultaneous multithreading, or **hyperthreading**, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>compute.hypertreading</code></td>
<td>Whether to enable or disable simultaneous multithreading, or <strong>hyperthreading</strong>, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td><code>compute.name</code></td>
<td>Required if you use <code>compute</code>. The name of the machine pool.</td>
<td>worker</td>
</tr>
<tr>
<td><code>compute.platform</code></td>
<td>Required if you use <code>compute</code>. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <code>controlPlane.platform</code> parameter value.</td>
<td>aws, azure, gcp, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td><code>compute.replicas</code></td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td><code>controlPlane</code></td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of <code>MachinePool</code> objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td><code>controlPlane.architecture</code></td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>----------------------</td>
<td>------------------------------------------------------------------------------</td>
<td>-------------------------------</td>
</tr>
<tr>
<td>controlPlane.hypertreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>controlPlane.name</td>
<td>Required if you use controlPlane. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use controlPlane. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the compute.platform parameter value.</td>
<td>aws, azure, gcp, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (&quot;&quot;&quot;).</td>
</tr>
</tbody>
</table>

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.

**NOTE**

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Red Hat Operators reference content.
## fips

Enable or disable FIPS mode. The default is `false` (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the `x86_64` architecture.

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.

### imageContentSources

Sources and repositories for the release-image content.

- Array of objects. Includes a `source` and, optionally, `mirrors`, as described in the following rows of this table.

### imageContentSources.source

Required if you use `imageContentSources`. Specify the repository that users refer to, for example, in image pull specifications.

- String

### imageContentSources.mirrors

Specify one or more repositories that may also contain the same images.

- Array of strings

### publish

How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.

- `Internal` or `External`. To deploy a private cluster, which cannot be accessed from the internet, set `publish` to `Internal`. The default value is `External`. 
The SSH key or keys to authenticate access your cluster machines.

NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

One or more keys. For example:

```text
sshKey:
<key1>
<key2>
<key3>
```

2.7.6.1.4. Optional AWS configuration parameters

Optional AWS configuration parameters are described in the following table:

Table 2.21. Optional AWS parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>compute.platform.aws.amiID</code></td>
<td>The AWS AMI used to boot compute machines for the cluster. This is required for regions that require a custom RHCOS AMI.</td>
<td>Any published or custom RHCOS AMI that belongs to the set AWS region.</td>
</tr>
<tr>
<td><code>compute.platform.aws.rootVolume.iops</code></td>
<td>The Input/Output Operations Per Second (IOPS) that is reserved for the root volume.</td>
<td>Integer, for example <code>4000</code>.</td>
</tr>
<tr>
<td><code>compute.platform.aws.rootVolume.size</code></td>
<td>The size in GiB of the root volume.</td>
<td>Integer, for example <code>500</code>.</td>
</tr>
<tr>
<td><code>compute.platform.aws.rootVolume.type</code></td>
<td>The type of the root volume.</td>
<td>Valid AWS EBS volume type, such as <code>io1</code>.</td>
</tr>
<tr>
<td><code>compute.platform.aws.type</code></td>
<td>The EC2 instance type for the compute machines.</td>
<td>Valid AWS instance type, such as <code>c5.9xlarge</code>.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td><code>compute.platform.aws.zones</code></td>
<td>The availability zones where the installation program creates machines for the compute machine pool. If you provide your own VPC, you must provide a subnet in that availability zone.</td>
<td>A list of valid AWS availability zones, such as <code>us-east-1c</code>, in a YAML sequence.</td>
</tr>
<tr>
<td><code>compute.aws.region</code></td>
<td>The AWS region that the installation program creates compute resources in.</td>
<td>Any valid AWS region, such as <code>us-east-1</code>.</td>
</tr>
<tr>
<td><code>controlPlane.platform.aws.amiID</code></td>
<td>The AWS AMI used to boot control plane machines for the cluster. This is required for regions that require a custom RHCOS AMI.</td>
<td>Any published or custom RHCOS AMI that belongs to the set AWS region.</td>
</tr>
<tr>
<td><code>controlPlane.platform.aws.type</code></td>
<td>The EC2 instance type for the control plane machines.</td>
<td>Valid AWS instance type, such as <code>c5.9xlarge</code>.</td>
</tr>
<tr>
<td><code>controlPlane.platform.aws.zones</code></td>
<td>The availability zones where the installation program creates machines for the control plane machine pool.</td>
<td>A list of valid AWS availability zones, such as <code>us-east-1c</code>, in a YAML sequence.</td>
</tr>
<tr>
<td><code>controlPlane.aws.region</code></td>
<td>The AWS region that the installation program creates control plane resources in.</td>
<td>Valid AWS region, such as <code>us-east-1</code>.</td>
</tr>
<tr>
<td><code>platform.amiID</code></td>
<td>The AWS AMI used to boot all machines for the cluster. If set, the AMI must belong to the same region as the cluster. This is required for regions that require a custom RHCOS AMI.</td>
<td>Any published or custom RHCOS AMI that belongs to the set AWS region.</td>
</tr>
<tr>
<td><code>platform.serviceEndpoints.name</code></td>
<td>The AWS service endpoint name. Custom endpoints are only required for cases where alternative AWS endpoints, like FIPS, must be used. Custom API endpoints can be specified for EC2, S3, IAM, Elastic Load Balancing, Tagging, Route 53, and STS AWS services.</td>
<td>Valid AWS service endpoint name.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>------------------------------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>platform.aws.serviceEndpoints.url</code></td>
<td>The AWS service endpoint URL. The URL must use the <code>https</code> protocol and the host must trust the certificate.</td>
<td>Valid AWS service endpoint URL.</td>
</tr>
<tr>
<td><code>platform.aws.userTags</code></td>
<td>A map of keys and values that the installation program adds as tags to all resources that it creates.</td>
<td>Any valid YAML map, such as key value pairs in the <code>&lt;key&gt;: &lt;value&gt;</code> format. For more information about AWS tags, see Tagging Your Amazon EC2 Resources in the AWS documentation.</td>
</tr>
<tr>
<td><code>platform.aws.subnets</code></td>
<td>If you provide the VPC instead of allowing the installation program to create the VPC for you, specify the subnet for the cluster to use. The subnet must be part of the same <code>machineNetwork[].cidr</code> ranges that you specify. For a standard cluster, specify a public and a private subnet for each availability zone. For a private cluster, specify a private subnet for each availability zone.</td>
<td>Valid subnet IDs.</td>
</tr>
</tbody>
</table>

### 2.7.6.2. Sample customized `install-config.yaml` file for AWS

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

**IMPORTANT**

This sample YAML file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program and modify it.

```yaml
apiVersion: v1
baseDomain: example.com  # 1
credentialsMode: Mint  # 2
controlPlane:  # 3  # 4
hyperthreading: Enabled  # 5
name: master
platform:
  aws:
    zones:
    - us-west-2a
    - us-west-2b
  rootVolume:
    iops: 4000
    size: 500
```
Required. The installation program prompts you for this value.

Optional: Add this parameter to force the Cloud Credential Operator (CCO) to use the specified mode, instead of having the CCO dynamically try to determine the capabilities of the credentials. For details about CCO modes, see the Cloud Credential Operator entry in the Red Hat Operators reference content.

If you do not provide these parameters and values, the installation program provides the default
The `controlPlane` section is a single mapping, but the `compute` section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the `compute` section

Whether to enable or disable simultaneous multithreading, or **hyperthreading**. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to **Disabled**. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger instance types, such as **m4.2xlarge** or **m5.2xlarge**, for your machines if you disable simultaneous multithreading.

To configure faster storage for etcd, especially for larger clusters, set the storage type as **io1** and set `iops` to **2000**.

If you provide your own VPC, specify subnets for each availability zone that your cluster uses.

The ID of the AMI used to boot machines for the cluster. If set, the AMI must belong to the same region as the cluster.

The AWS service endpoints. Custom endpoints are required when installing to an unknown AWS region. The endpoint URL must use the **https** protocol and the host must trust the certificate.

The ID of your existing Route 53 private hosted zone. Providing an existing hosted zone requires that you supply your own VPC and the hosted zone is already associated with the VPC prior to installing your cluster. If undefined, the installation program creates a new hosted zone.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the **x86_64** architecture.

You can optionally provide the `sshKey` value that you use to access the machines in your cluster.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

### 2.7.6.3. Configuring the cluster-wide proxy during installation
Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**Prerequisites**

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

- If your cluster is on AWS, you added the `ec2.<region>.amazonaws.com`, `elasticloadbalancing.<region>.amazonaws.com`, and `s3.<region>.amazonaws.com` endpoints to your VPC endpoint. These endpoints are required to complete requests from the nodes to the AWS EC2 API. Because the proxy works on the container level, not the node level, you must route these requests to the AWS EC2 API through the AWS private network. Adding the public IP address of the EC2 API to your allowlist in your proxy server is not sufficient.

**Procedure**

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port> 1
  httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
  noProxy: example.com 3
additionalTrustBundle: |
  -----BEGIN CERTIFICATE-----
  <MY_TRUSTED_CA_CERT>
  -----END CERTIFICATE-----
...
```

1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.
2. A proxy URL to use for creating HTTPS connections outside the cluster.
3. A comma-separated list of destination domain names, IP addresses, or other network
A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For

4

If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace to hold the additional CA certificates. If you provide additionalTrustBundle and at least one proxy setting, the Proxy object is configured to reference the user-ca-bundle config map in the trustedCA field. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges the contents specified for the trustedCA parameter with the RHCOS trust bundle. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

NOTE

The installation program does not support the proxy readinessEndpoints field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

NOTE

Only the Proxy object named cluster is supported, and no additional proxies can be created.

2.7.7. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

IMPORTANT

You can run the create cluster command of the installation program only once, during initial installation.

Prerequisites

- Configure an account with the cloud platform that hosts your cluster.

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Change to the directory that contains the installation program and initialize the cluster deployment:

   $ ./openshift-install create cluster --dir <installation_directory> \ 
   --log-level=info

   For <installation_directory>, specify the location of your customized ./install-config.yaml file.
To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

**NOTE**

If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.

When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the **kubeadm** user, display in your terminal.

**Example output**

```
... INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadm", and password: "4vYBz-Ee6gm-ymBZj-Wi5AL"
INFO Time elapsed: 36m22s
```

**NOTE**

The cluster access and credential information also outputs to `<installation_directory>/openshift_install.log` when an installation succeeds.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending **node-bootstrapper** certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

**IMPORTANT**

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

2. Optional: Remove or disable the **AdministratorAccess** policy from the IAM account that you used to install the cluster.
NOTE
The elevated permissions provided by the AdministratorAccess policy are required only during installation.

2.7.8. Installing the OpenShift CLI by downloading the binary
You can install the OpenShift CLI (oc) in order to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

IMPORTANT
If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.6. Download and install the new version of oc.

2.7.8.1. Installing the OpenShift CLI on Linux
You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure
2. Select the appropriate version in the Version drop-down menu.
3. Click Download Now next to the OpenShift v4.6 Linux Client entry and save the file.
4. Unpack the archive:
   \[
   \text{
   $ \text{tar xzf } <\text{file>}
   \]
5. Place the oc binary in a directory that is on your PATH.
   To check your PATH, execute the following command:
   \[
   \text{
   $ \text{echo $PATH}
   \]
After you install the OpenShift CLI, it is available using the oc command:
\[
\text{
$ oc <command>
\]

2.7.8.2. Installing the OpenShift CLI on Windows
You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

Procedure
2. Select the appropriate version in the Version drop-down menu.
3. Click Download Now next to the OpenShift v4.6 Windows Client entry and save the file.
4. Unzip the archive with a ZIP program.

5. Move the `oc` binary to a directory that is on your **PATH**.
   To check your **PATH**, open the command prompt and execute the following command:

```
C:\> path
```

After you install the OpenShift CLI, it is available using the `oc` command:

```
C:\> oc <command>
```

---

### 2.7.8.3. Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (`oc`) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.
3. Click **Download Now** next to the **OpenShift v4.6 MacOSX Client** entry and save the file.
4. Unpack and unzip the archive.
5. Move the `oc` binary to a directory on your **PATH**.
   To check your **PATH**, open a terminal and execute the following command:

```
$ echo $PATH
```

After you install the OpenShift CLI, it is available using the `oc` command:

```
$ oc <command>
```

---

### 2.7.9. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadm` credentials:
For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   Example output
   system:admin
   ```

### 2.7.10. Logging in to the cluster by using the web console

The `kubeadmin` user exists by default after an OpenShift Container Platform installation. You can log in to your cluster as the `kubeadmin` user by using the OpenShift Container Platform web console.

**Prerequisites**

- You have access to the installation host.
- You completed a cluster installation and all cluster Operators are available.

**Procedure**

1. Obtain the password for the `kubeadmin` user from the `kubeadmin-password` file on the installation host:

   ```bash
   $ cat <installation_directory>/auth/kubeadmin-password
   ```

   **NOTE**
   
   Alternatively, you can obtain the `kubeadmin` password from the `<installation_directory>/openshift_install.log` log file on the installation host.

2. List the OpenShift Container Platform web console route:

   ```bash
   $ oc get routes -n openshift-console | grep 'console-openshift'
   ```

   **NOTE**
   
   Alternatively, you can obtain the OpenShift Container Platform route from the `<installation_directory>/openshift_install.log` log file on the installation host.

**Example output**

```
console  console-openshift-console.apps.<cluster_name>.-<base_domain>  console
https   reencrypt/Redirect   None
```
3. Navigate to the route detailed in the output of the preceding command in a web browser and log in as the `kubeadmin` user.

Additional resources
- See Accessing the web console for more details about accessing and understanding the OpenShift Container Platform web console.

2.7.11. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.6, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources
- See About remote health monitoring for more information about the Telemetry service.

2.7.12. Next steps

- Validating an installation.
- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- If necessary, you can remove cloud provider credentials.

2.8. INSTALLING A PRIVATE CLUSTER ON AWS

In OpenShift Container Platform version 4.6, you can install a private cluster into an existing VPC on Amazon Web Services (AWS). The installation program provisions the rest of the required infrastructure, which you can further customize. To customize the installation, you modify parameters in the `install-config.yaml` file before you install the cluster.

2.8.1. Prerequisites

- Review details about the OpenShift Container Platform installation and update processes.
- Configure an AWS account to host the cluster.

**IMPORTANT**

If you have an AWS profile stored on your computer, it must not use a temporary session token that you generated while using a multi-factor authentication device. The cluster continues to use your current AWS credentials to create AWS resources for the entire life of the cluster, so you must use long-lived credentials. To generate appropriate keys, see Managing Access Keys for IAM Users in the AWS documentation. You can supply the keys when you run the installation program.
• If you use a firewall, you must configure it to allow the sites that your cluster requires access to.

• If you do not allow the system to manage identity and access management (IAM), then a cluster administrator can manually create and maintain IAM credentials. Manual mode can also be used in environments where the cloud IAM APIs are not reachable.

2.8.2. Private clusters

You can deploy a private OpenShift Container Platform cluster that does not expose external endpoints. Private clusters are accessible from only an internal network and are not visible to the Internet.

By default, OpenShift Container Platform is provisioned to use publicly-accessible DNS and endpoints. A private cluster sets the DNS, Ingress Controller, and API server to private when you deploy your cluster. This means that the cluster resources are only accessible from your internal network and are not visible to the internet.

To deploy a private cluster, you must use existing networking that meets your requirements. Your cluster resources might be shared between other clusters on the network.

Additionally, you must deploy a private cluster from a machine that has access to the API services for the cloud you provision to, the hosts on the network that you provision, and to the internet to obtain installation media. You can use any machine that meets these access requirements and follows your company’s guidelines. For example, this machine can be a bastion host on your cloud network or a machine that has access to the network through a VPN.

2.8.2.1. Private clusters in AWS

To create a private cluster on Amazon Web Services (AWS), you must provide an existing private VPC and subnets to host the cluster. The installation program must also be able to resolve the DNS records that the cluster requires. The installation program configures the Ingress Operator and API server for access from only the private network.

The cluster still requires access to the Internet to access the AWS APIs.

The following items are not required or created when you install a private cluster:

• Public subnets

• Public load balancers, which support public ingress

• A public Route 53 zone that matches the baseDomain for the cluster

The installation program does use the baseDomain that you specify to create a private Route 53 zone and the required records for the cluster. The cluster is configured so that the Operators do not create public records for the cluster and all cluster machines are placed in the private subnets that you specify.

2.8.2.1.1. Limitations

The ability to add public functionality to a private cluster is limited.

• You cannot make the Kubernetes API endpoints public after installation without taking additional actions, including creating public subnets in the VPC for each availability zone in use, creating a public load balancer, and configuring the control plane security groups to allow traffic from Internet on 6443 (Kubernetes API port).
If you use a public Service type load balancer, you must tag a public subnet in each availability zone with `kubernetes.io/cluster/<cluster-infra-id>: shared` so that AWS can use them to create public load balancers.

2.8.3. About using a custom VPC

In OpenShift Container Platform 4.6, you can deploy a cluster into existing subnets in an existing Amazon Virtual Private Cloud (VPC) in Amazon Web Services (AWS). By deploying OpenShift Container Platform into an existing AWS VPC, you might be able to avoid limit constraints in new accounts or more easily abide by the operational constraints that your company’s guidelines set. If you cannot obtain the infrastructure creation permissions that are required to create the VPC yourself, use this installation option.

Because the installation program cannot know what other components are also in your existing subnets, it cannot choose subnet CIDRs and so forth on your behalf. You must configure networking for the subnets that you install your cluster to yourself.

2.8.3.1. Requirements for using your VPC

The installation program no longer creates the following components:

- Internet gateways
- NAT gateways
- Subnets
- Route tables
- VPCs
- VPC DHCP options
- VPC endpoints

If you use a custom VPC, you must correctly configure it and its subnets for the installation program and the cluster to use. See Amazon VPC console wizard configurations and Work with VPCs and subnets in the AWS documentation for more information on creating and managing an AWS VPC.

The installation program cannot:

- Subdivide network ranges for the cluster to use.
- Set route tables for the subnets.
- Set VPC options like DHCP.

You must complete these tasks before you install the cluster. See VPC networking components and Route tables for your VPC for more information on configuring networking in an AWS VPC.

Your VPC must meet the following characteristics:

- The VPC must not use the `kubernetes.io/cluster/.*: owned` tag.
  The installation program modifies your subnets to add the `kubernetes.io/cluster/.*: shared` tag, so your subnets must have at least one free tag slot available for it. See Tag Restrictions in the AWS documentation to confirm that the installation program can add a tag to each subnet that you specify.
- You must enable the `enableDnsSupport` and `enableDnsHostnames` attributes in your VPC, so that the cluster can use the Route 53 zones that are attached to the VPC to resolve cluster’s internal DNS records. See DNS Support in Your VPC in the AWS documentation. If you prefer to use your own Route 53 hosted private zone, you must associate the existing hosted zone with your VPC prior to installing a cluster. You can define your hosted zone using the `platform.aws.hostedZone` field in the `install-config.yaml` file.

- If you use a cluster with public access, you must create a public and a private subnet for each availability zone that your cluster uses. Each availability zone can contain no more than one public and one private subnet.

If you are working in a disconnected environment, you are unable to reach the public IP addresses for EC2 and ELB endpoints. To resolve this, you must create a VPC endpoint and attach it to the subnet that the clusters are using. The endpoints should be named as follows:

  - `ec2.<region>.amazonaws.com`
  - `elasticloadbalancing.<region>.amazonaws.com`
  - `s3.<region>.amazonaws.com`

**Required VPC components**

You must provide a suitable VPC and subnets that allow communication to your machines.

<table>
<thead>
<tr>
<th>Component</th>
<th>AWS type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VPC</td>
<td></td>
<td>You must provide a public VPC for the cluster to use. The VPC uses an endpoint that references the route tables for each subnet to improve communication with the registry that is hosted in S3.</td>
</tr>
<tr>
<td>Public subnets</td>
<td></td>
<td>Your VPC must have public subnets for between 1 and 3 availability zones and associate them with appropriate Ingress rules.</td>
</tr>
<tr>
<td>Internet gateway</td>
<td></td>
<td>You must have a public Internet gateway, with public routes, attached to the VPC. In the provided templates, each public subnet has a NAT gateway with an EIP address. These NAT gateways allow cluster resources, like private subnet instances, to reach the Internet and are not required for some restricted network or proxy scenarios.</td>
</tr>
</tbody>
</table>
### Network access control

- **AWS::EC2::NetworkAcl**
- **AWS::EC2::NetworkAclEntry**

You must allow the VPC to access the following ports:

<table>
<thead>
<tr>
<th>Port</th>
<th>Reason</th>
</tr>
</thead>
<tbody>
<tr>
<td>80</td>
<td>Inbound HTTP traffic</td>
</tr>
<tr>
<td>443</td>
<td>Inbound HTTPS traffic</td>
</tr>
<tr>
<td>22</td>
<td>Inbound SSH traffic</td>
</tr>
<tr>
<td>1024 - 65535</td>
<td>Inbound ephemeral traffic</td>
</tr>
<tr>
<td>0 - 65535</td>
<td>Outbound ephemeral traffic</td>
</tr>
</tbody>
</table>

### Private subnets

- **AWS::EC2::Subnet**
- **AWS::EC2::RouteTable**
- **AWS::EC2::SubnetRouteTableAssociation**

Your VPC can have private subnets. The provided CloudFormation templates can create private subnets for between 1 and 3 availability zones. If you use private subnets, you must provide appropriate routes and tables for them.

### 2.8.3.2. VPC validation

To ensure that the subnets that you provide are suitable, the installation program confirms the following data:

- All the subnets that you specify exist.
- You provide private subnets.
- The subnet CIDRs belong to the machine CIDR that you specified.
- You provide subnets for each availability zone. Each availability zone contains no more than one public and one private subnet. If you use a private cluster, provide only a private subnet for each availability zone. Otherwise, provide exactly one public and private subnet for each availability zone.
- You provide a public subnet for each private subnet availability zone. Machines are not provisioned in availability zones that you do not provide private subnets for.
If you destroy a cluster that uses an existing VPC, the VPC is not deleted. When you remove the OpenShift Container Platform cluster from a VPC, the `kubernetes.io/cluster/*.shared` tag is removed from the subnets that it used.

### 2.8.3.3. Division of permissions

Starting with OpenShift Container Platform 4.3, you do not need all of the permissions that are required for an installation program-provisioned infrastructure cluster to deploy a cluster. This change mimics the division of permissions that you might have at your company: some individuals can create different resource in your clouds than others. For example, you might be able to create application-specific items, like instances, buckets, and load balancers, but not networking-related components such as VPCs, subnets, or ingress rules.

The AWS credentials that you use when you create your cluster do not need the networking permissions that are required to make VPCs and core networking components within the VPC, such as subnets, routing tables, Internet gateways, NAT, and VPN. You still need permission to make the application resources that the machines within the cluster require, such as ELBs, security groups, S3 buckets, and nodes.

### 2.8.3.4. Isolation between clusters

If you deploy OpenShift Container Platform to an existing network, the isolation of cluster services is reduced in the following ways:

- You can install multiple OpenShift Container Platform clusters in the same VPC.
- ICMP ingress is allowed from the entire network.
- TCP 22 ingress (SSH) is allowed to the entire network.
- Control plane TCP 6443 ingress (Kubernetes API) is allowed to the entire network.
- Control plane TCP 22623 ingress (MCS) is allowed to the entire network.

### 2.8.4. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.6, you require access to the Internet to install your cluster.

You must have Internet access to:

- Access [OpenShift Cluster Manager](https://openshift.redhat.com) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](https://quay.io) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.
IMPORTANT

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

2.8.5. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your ssh-agent and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

NOTE

In a production environment, you require disaster recovery and debugging.

You can use this key to SSH into the master nodes as the user core. When you deploy the cluster, the key is added to the core user’s ~/.ssh/authorized_keys list.

NOTE

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

Procedure

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ ssh-keygen -t ed25519 -N "\n   -f <path>/<file_name> # 1
   ```

   1 Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   Running this command generates an SSH key that does not require a password in the location that you specified.

   NOTE

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the ssh-agent process as a background task:
NOTE
If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the `ssh-agent`:

```bash
$ ssh-add <path>/<file_name>
```

**Example output**

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

**2.8.6. Obtaining the installation program**

Before you install OpenShift Container Platform, download the installation file on a local computer.

**Prerequisites**

- You have a computer that runs Linux or macOS, with 500 MB of local disk space

**Procedure**

1. Access the **Infrastructure Provider** page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.
IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```bash
$ tar xvf openshift-install-linux.tar.gz
```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

2.8.7. Manually creating the installation configuration file

For installations of a private OpenShift Container Platform cluster that are only accessible from an internal network and are not visible to the Internet, you must manually generate your installation configuration file.

Prerequisites

- Obtain the OpenShift Container Platform installation program and the access token for your cluster.

Procedure

1. Create an installation directory to store your required installation assets in:

```bash
$ mkdir <installation_directory>
```

IMPORTANT

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the following `install-config.yaml` file template and save it in the `<installation_directory>`.

NOTE

You must name this configuration file `install-config.yaml`.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.
2.8.7.1. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster’s platform. When you create the **install-config.yaml** installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the **install-config.yaml** file to provide more details about the platform.

### NOTE

After installation, you cannot modify these parameters in the **install-config.yaml** file.

### IMPORTANT

The **openshift-install** command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

2.8.7.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the <strong>install-config.yaml</strong> content. The current version is <strong>v1</strong>. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the <strong>baseDomain</strong> and <strong>metadata.name</strong> parameter values that uses the <code>&lt;metadata.name&gt;.&lt;baseDomain&gt;</code> format.</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
</tr>
</tbody>
</table>
### Parameter ObjectMeta, from which only the name parameter is consumed.

**metadata**

The name of the cluster. DNS records for the cluster are all subdomains of 

\[
\text{\{.metadata.name\}. \text{\{.baseDomain\}.}}
\]

**metadata.name**

String of lowercase letters, hyphens (-), and periods (.), such as dev.

**platform**

The configuration for the specific platform upon which to perform the installation: aws, baremetal, azure, openstack, ovirt, vsphere. For additional information about platform.<platform> parameters, consult the following table for your specific platform.

**pullSecret**

Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.

```json
{
  "auths":{
    "cloud.openshift.com":{
      "auth":"b3Blb=",
      "email":"you@example.com"
    },
    "quay.io":{
      "auth":"b3Blb=",
      "email":"you@example.com"
    }
  }
}
```

2.8.7.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

### Table 2.23. Network parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>2.8.7.1.2. Network configuration parameters</td>
<td>You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.</td>
<td>Only IPv4 addresses are supported.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-------------------------------------</td>
</tr>
<tr>
<td>networking</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong>&lt;br&gt;You cannot modify parameters specified by the <code>networking</code> object after installation.</td>
<td></td>
</tr>
<tr>
<td>networking.network</td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN.</td>
</tr>
</tbody>
</table>
| networking.clusterNetwork | The IP address blocks for pods. The default value is `10.128.0.0/14` with a host prefix of `/23`. If you specify multiple IP address blocks, the blocks must not overlap. | An array of objects. For example:
|                        | `networking.clusterNetwork` An IP address block. An IPv4 network.          | `networking:
|                        | `clusterNetwork:` An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32. |
| networking.clusterNetwork.cidr | Required if you use `networking.clusterNetwork`. An IPv4 network.          | An IP address block in CIDR format. For example:
|                        | `networking:
|                        | `clusterNetwork:
|                        | `- cidr: 10.128.0.0/14`
|                        | `- hostPrefix: 23`                                                        |                                    |
| networking.clusterNetwork.hostPrefix | The subnet prefix length to assign to each individual node. For example, if `hostPrefix` is set to 23 then each node is assigned a /23 subnet out of the given `cidr`. A `hostPrefix` value of 23 provides 510 (2^(32 - 23) - 2) pod IP addresses. | A subnet prefix. The default value is 23. |
| networking.serviceNetwork | The IP address block for services. The default value is `172.30.0.0/16`. The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network. | An array with an IP address block in CIDR format. For example:
|                        | `networking:
|                        | `serviceNetwork:` An array with an IP address block in CIDR format. For example:
|                        | `- 172.30.0.0/16`                                                        |                                    |
| networking.machineNetwork | The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap. | An array of objects. For example:
|                        | `networking:
|                        | `machineNetwork:
|                        | `- cidr: 10.0.0.0/16`                                                    |                                    |
### networking.machineNetwork.cidr

Required if you use `networking.machineNetwork`. An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24. For example, 10.0.0.0/16.

**NOTE**

Set the `networking.machineNetwork` to match the CIDR that the preferred NIC resides in.

---

### 2.8.7.13. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

#### Table 2.24. Optional parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>additionalTrustBundle</strong></td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes' trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td><strong>compute</strong></td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of machine-pool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td><strong>compute.architecture</strong></td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <strong>amd64</strong> (the default).</td>
<td>String</td>
</tr>
</tbody>
</table>
Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.

**IMPORTANT**
If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>compute.hyperthreading</strong></td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td><strong>compute.name</strong></td>
<td>Required if you use <code>compute</code>. The name of the machine pool.</td>
<td>worker</td>
</tr>
<tr>
<td><strong>compute.platform</strong></td>
<td>Required if you use <code>compute</code>. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <code>controlPlane.platform</code> parameter value.</td>
<td>aws, azure, gcp, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td><strong>compute.replicas</strong></td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td><strong>controlPlane</strong></td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of <code>MachinePool</code> objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td><strong>controlPlane.architecture</strong></td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
</tbody>
</table>
Whether to enable or disable simultaneous multithreading, or **hyperthreading**, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlPlane.hypertreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>controlPlane.name</td>
<td>Required if you use controlPlane. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use controlPlane. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the compute.platform parameter value.</td>
<td>aws, azure, gcp, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision. The only supported value is 3, which is the default value.</td>
<td>3</td>
</tr>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (&quot;&quot;&quot;&quot;).</td>
</tr>
</tbody>
</table>

**NOTE**

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Red Hat Operators reference content.
Enable or disable FIPS mode. The default is `false` (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the `x86_64` architecture.

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>fips</td>
<td>Sources and repositories for the release-image content.</td>
<td>false or true</td>
</tr>
<tr>
<td>imageContentSources</td>
<td>Required if you use <code>imageContentSources</code>. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>Array of objects. Includes a <code>source</code> and, optionally, <code>mirrors</code>, as described in the following rows of this table.</td>
</tr>
<tr>
<td>imageContentSources.source</td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>String</td>
</tr>
<tr>
<td>imageContentSources.mirrors</td>
<td>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</td>
<td>Array of strings</td>
</tr>
<tr>
<td>publish</td>
<td>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</td>
<td>Internal or External</td>
</tr>
</tbody>
</table>
### Parameter Description Values

**sshKey**  
The SSH key or keys to authenticate access your cluster machines.  

**NOTE**  
For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.  

One or more keys. For example:

- `sshKey: <key1>`
- `<key2>`
- `<key3>`

---

**2.8.7.1.4. Optional AWS configuration parameters**

Optional AWS configuration parameters are described in the following table:

**Table 2.25. Optional AWS parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>compute.platform.amiID</code></td>
<td>The AWS AMI used to boot compute machines for the cluster. This is required for regions that require a custom RHCOS AMI.</td>
<td>Any published or custom RHCOS AMI that belongs to the set AWS region.</td>
</tr>
<tr>
<td><code>compute.platform.rootVolume.size</code></td>
<td>The size in GiB of the root volume.</td>
<td>Integer, for example <strong>500</strong>.</td>
</tr>
<tr>
<td><code>compute.platform.rootVolume.type</code></td>
<td>The type of the root volume.</td>
<td>Valid AWS EBS volume type, such as <strong>io1</strong>.</td>
</tr>
<tr>
<td><code>compute.platform.type</code></td>
<td>The EC2 instance type for the compute machines.</td>
<td>Valid AWS instance type, such as <strong>c5.9xlarge</strong>.</td>
</tr>
</tbody>
</table>

---
## CHAPTER 2. INSTALLING ON AWS

<table>
<thead>

<tr>
<td>platform.aws.userTags</td>
<td>A map of keys and values that the installation program adds as tags to all resources that it creates.</td>
<td>Any valid YAML map, such as key value pairs in the <code>&lt;key&gt;: &lt;value&gt;</code> format.</td>
</tr>
<tr>
<td>platform.aws.subnets</td>
<td>If you provide the VPC instead of allowing the installation program to create the VPC for you, specify the subnet for the cluster to use. The subnet must be part of the same <code>machineNetwork[].cidr</code> ranges that you specify. For a standard cluster, specify a public and a private subnet for each availability zone. For a private cluster, specify a private subnet for each availability zone.</td>
<td>Valid subnet IDs.</td>
</tr>
</tbody>
</table>

### 2.8.7.2. Sample customized install-config.yaml file for AWS

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

**IMPORTANT**

This sample YAML file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program and modify it.

```yaml
apiVersion: v1
baseDomain: example.com
credentialsMode: Mint
controlPlane: 
  hyperthreading: Enabled
name: master
platform:
  aws:
    zones:
    - us-west-2a
    - us-west-2b
    rootVolume:
      iops: 4000
      size: 500
```
Required. The installation program prompts you for this value.

Optional: Add this parameter to force the Cloud Credential Operator (CCO) to use the specified mode, instead of having the CCO dynamically try to determine the capabilities of the credentials. For details about CCO modes, see the Cloud Credential Operator entry in the Red Hat Operators reference content.
If you do not provide these parameters and values, the installation program provides the default value.

The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, -, and the first line of the controlPlane section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading, or hyperthreading. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to Disabled. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

IMPORTANT
If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger instance types, such as m4.2xlarge or m5.2xlarge, for your machines if you disable simultaneous multithreading.

To configure faster storage for etcd, especially for larger clusters, set the storage type as io1 and set iops to 2000.

If you provide your own VPC, specify subnets for each availability zone that your cluster uses.

The ID of the AMI used to boot machines for the cluster. If set, the AMI must belong to the same region as the cluster.

The AWS service endpoints. Custom endpoints are required when installing to an unknown AWS region. The endpoint URL must use the https protocol and the host must trust the certificate.

The ID of your existing Route 53 private hosted zone. Providing an existing hosted zone requires that you supply your own VPC and the hosted zone is already associated with the VPC prior to installing your cluster. If undefined, the installation program creates a new hosted zone.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

IMPORTANT
The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

You can optionally provide the sshKey value that you use to access the machines in your cluster.

NOTE
For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.
How to publish the user-facing endpoints of your cluster. Set `publish` to `Internal` to deploy a private cluster, which cannot be accessed from the Internet. The default value is `External`.

### 2.8.7.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**Prerequisites**

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

- If your cluster is on AWS, you added the `ec2.<region>.amazonaws.com`, `elasticloadbalancing.<region>.amazonaws.com`, and `s3.<region>.amazonaws.com` endpoints to your VPC endpoint. These endpoints are required to complete requests from the nodes to the AWS EC2 API. Because the proxy works on the container level, not the node level, you must route these requests to the AWS EC2 API through the AWS private network. Adding the public IP address of the EC2 API to your allowlist in your proxy server is not sufficient.

**Procedure**

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
     httpProxy: http://<username>:<pswd>@<ip>:<port>  # 1
     httpsProxy: https://<username>:<pswd>@<ip>:<port>  # 2
     noProxy: example.com  # 3
   additionalTrustBundle: |
     -----BEGIN CERTIFICATE-----
     <MY_TRUSTED_CA_CERT>
     -----END CERTIFICATE-----
   ```

   ...
A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.

A proxy URL to use for creating HTTPS connections outside the cluster.

A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.

If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace to hold the additional CA certificates. If you provide additionalTrustBundle and at least one proxy setting, the Proxy object is configured to reference the user-ca-bundle config map in the trustedCA field. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges the contents specified for the trustedCA parameter with the RHCOS trust bundle. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

NOTE
The installation program does not support the proxy readinessEndpoints field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

NOTE
Only the Proxy object named cluster is supported, and no additional proxies can be created.

2.8.8. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

IMPORTANT
You can run the create cluster command of the installation program only once, during initial installation.

Prerequisites

- Configure an account with the cloud platform that hosts your cluster.
- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure
1. Change to the directory that contains the installation program and initialize the cluster deployment:

```
$ ./openshift-install create cluster --dir <installation_directory> \
--log-level=info
```

1. For `<installation_directory>`, specify the <installation_directory>.

2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

**NOTE**

If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.

When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the `kubeadmin` user, display in your terminal.

**Example output**

```
... INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-Wt5AL"
INFO Time elapsed: 36m22s
```

**NOTE**

The cluster access and credential information also outputs to `<installation_directory>/openshift_install.log` when an installation succeeds.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.
IMPORTANT

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

2.8.9. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) in order to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

IMPORTANT

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.6. Download and install the new version of oc.

2.8.9.1. Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.6 Linux Client entry and save the file.

4. Unpack the archive:

   $ tar xvzf <file>

5. Place the oc binary in a directory that is on your PATH.

   To check your PATH, execute the following command:

   $ echo $PATH

After you install the OpenShift CLI, it is available using the oc command:

$ oc <command>

2.8.9.2. Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.6 Windows Client entry and save the file.
4. Unzip the archive with a ZIP program.

5. Move the `oc` binary to a directory that is on your **PATH**.
   To check your **PATH**, open the command prompt and execute the following command:

   ```
   C:\> path
   ```
   After you install the OpenShift CLI, it is available using the `oc` command:

   ```
   C:\> oc <command>
   ```

2.8.9.3. Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (`oc`) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.

3. Click **Download Now** next to the **OpenShift v4.6 MacOSX Client** entry and save the file.

4. Unpack and unzip the archive.

5. Move the `oc` binary to a directory on your **PATH**.
   To check your **PATH**, open a terminal and execute the following command:

   ```
   $ echo $PATH
   ```
   After you install the OpenShift CLI, it is available using the `oc` command:

   ```
   $ oc <command>
   ```

2.8.10. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:
For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

```bash
$ oc whoami
```

Example output

```
system:admin
```

### 2.8.11. Logging in to the cluster by using the web console

The `kubeadmin` user exists by default after an OpenShift Container Platform installation. You can log in to your cluster as the `kubeadmin` user by using the OpenShift Container Platform web console.

**Prerequisites**

- You have access to the installation host.
- You completed a cluster installation and all cluster Operators are available.

**Procedure**

1. Obtain the password for the `kubeadmin` user from the `kubeadmin-password` file on the installation host:

   ```bash
   $ cat <installation_directory>/auth/kubeadmin-password
   ```

   **NOTE**

   Alternatively, you can obtain the `kubeadmin` password from the `<installation_directory>/openshift_install.log` log file on the installation host.

2. List the OpenShift Container Platform web console route:

   ```bash
   $ oc get routes -n openshift-console | grep 'console-openshift'
   ```

   **NOTE**

   Alternatively, you can obtain the OpenShift Container Platform route from the `<installation_directory>/openshift_install.log` log file on the installation host.

**Example output**

```
console   console-openshift-console.apps.<cluster_name>.<base_domain>   console
https     reencrypt/Redirect   None
```
3. Navigate to the route detailed in the output of the preceding command in a web browser and log in as the kubeadmin user.

Additional resources

- See Accessing the web console for more details about accessing and understanding the OpenShift Container Platform web console.

2.8.12. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.6, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service.

2.8.13. Next steps

- Validating an installation.
- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- If necessary, you can remove cloud provider credentials.

2.9. INSTALLING A CLUSTER ON AWS INTO A GOVERNMENT REGION

In OpenShift Container Platform version 4.6, you can install a cluster on Amazon Web Services (AWS) into a government region. To configure the government region, modify parameters in the install-config.yaml file before you install the cluster.

2.9.1. Prerequisites

- Review details about the OpenShift Container Platform installation and update processes.
- Configure an AWS account to host the cluster.

IMPORTANT

If you have an AWS profile stored on your computer, it must not use a temporary session token that you generated while using a multi-factor authentication device. The cluster continues to use your current AWS credentials to create AWS resources for the entire life of the cluster, so you must use long-lived credentials. To generate appropriate keys, see Managing Access Keys for IAM Users in the AWS documentation. You can supply the keys when you run the installation program.
- If you use a firewall, you must **configure it to allow the sites** that your cluster requires access to.
- If you do not allow the system to manage identity and access management (IAM), then a cluster administrator can **manually create and maintain IAM credentials**. Manual mode can also be used in environments where the cloud IAM APIs are not reachable.

### 2.9.2. AWS government regions

OpenShift Container Platform supports deploying a cluster to **AWS GovCloud (US)** regions. AWS GovCloud is specifically designed for US government agencies at the federal, state, and local level, as well as contractors, educational institutions, and other US customers that must run sensitive workloads in the cloud.

These regions do not have published Red Hat Enterprise Linux CoreOS (RHCOS) Amazon Machine Images (AMI) to select, so you must upload a custom AMI that belongs to that region.

The following AWS GovCloud partitions are supported:

- **us-gov-west-1**
- **us-gov-east-1**

The AWS GovCloud region and custom AMI must be manually configured in the `install-config.yaml` file since RHCOS AMIs are not provided by Red Hat for those regions.

### 2.9.3. Private clusters

You can deploy a private OpenShift Container Platform cluster that does not expose external endpoints. Private clusters are accessible from only an internal network and are not visible to the Internet.

**NOTE**

Public zones are not supported in Route 53 in AWS GovCloud. Therefore, clusters must be private if they are deployed to an AWS government region.

By default, OpenShift Container Platform is provisioned to use publicly-accessible DNS and endpoints. A private cluster sets the DNS, Ingress Controller, and API server to private when you deploy your cluster. This means that the cluster resources are only accessible from your internal network and are not visible to the internet.

To deploy a private cluster, you must use existing networking that meets your requirements. Your cluster resources might be shared between other clusters on the network.

Additionally, you must deploy a private cluster from a machine that has access the API services for the cloud you provision to, the hosts on the network that you provision, and to the internet to obtain installation media. You can use any machine that meets these access requirements and follows your company’s guidelines. For example, this machine can be a bastion host on your cloud network or a machine that has access to the network through a VPN.

### 2.9.3.1. Private clusters in AWS

To create a private cluster on Amazon Web Services (AWS), you must provide an existing private VPC and subnets to host the cluster. The installation program must also be able to resolve the DNS records that the cluster requires. The installation program configures the Ingress Operator and API server for
access from only the private network.

The cluster still requires access to Internet to access the AWS APIs.

The following items are not required or created when you install a private cluster:

- Public subnets
- Public load balancers, which support public ingress
- A public Route 53 zone that matches the `baseDomain` for the cluster

The installation program does use the `baseDomain` that you specify to create a private Route 53 zone and the required records for the cluster. The cluster is configured so that the Operators do not create public records for the cluster and all cluster machines are placed in the private subnets that you specify.

### 2.9.3.1.1. Limitations

The ability to add public functionality to a private cluster is limited.

- You cannot make the Kubernetes API endpoints public after installation without taking additional actions, including creating public subnets in the VPC for each availability zone in use, creating a public load balancer, and configuring the control plane security groups to allow traffic from Internet on 6443 (Kubernetes API port).

- If you use a public Service type load balancer, you must tag a public subnet in each availability zone with `kubernetes.io/cluster/<cluster-infra-id>: shared` so that AWS can use them to create public load balancers.

### 2.9.4. About using a custom VPC

In OpenShift Container Platform 4.6, you can deploy a cluster into existing subnets in an existing Amazon Virtual Private Cloud (VPC) in Amazon Web Services (AWS). By deploying OpenShift Container Platform into an existing AWS VPC, you might be able to avoid limit constraints in new accounts or more easily abide by the operational constraints that your company’s guidelines set. If you cannot obtain the infrastructure creation permissions that are required to create the VPC yourself, use this installation option.

Because the installation program cannot know what other components are also in your existing subnets, it cannot choose subnet CIDRs and so forth on your behalf. You must configure networking for the subnets that you install your cluster to yourself.

### 2.9.4.1. Requirements for using your VPC

The installation program no longer creates the following components:

- Internet gateways
- NAT gateways
- Subnets
- Route tables
- VPCs
• VPC DHCP options

• VPC endpoints

If you use a custom VPC, you must correctly configure it and its subnets for the installation program and the cluster to use. See Amazon VPC console wizard configurations and Work with VPCs and subnets in the AWS documentation for more information on creating and managing an AWS VPC.

The installation program cannot:

• Subdivide network ranges for the cluster to use.

• Set route tables for the subnets.

• Set VPC options like DHCP.

You must complete these tasks before you install the cluster. See VPC networking components and Route tables for your VPC for more information on configuring networking in an AWS VPC.

Your VPC must meet the following characteristics:

• The VPC must not use the kubernetes.io/cluster/.*: owned tag. The installation program modifies your subnets to add the kubernetes.io/cluster/.*: shared tag, so your subnets must have at least one free tag slot available for it. See Tag Restrictions in the AWS documentation to confirm that the installation program can add a tag to each subnet that you specify.

• You must enable the enableDnsSupport and enableDnsHostnames attributes in your VPC, so that the cluster can use the Route 53 zones that are attached to the VPC to resolve cluster’s internal DNS records. See DNS Support in Your VPC in the AWS documentation.

If you prefer to use your own Route 53 hosted private zone, you must associate the existing hosted zone with your VPC prior to installing a cluster. You can define your hosted zone using the platform.aws.hostedZone field in the install-config.yaml file.

• If you use a cluster with public access, you must create a public and a private subnet for each availability zone that your cluster uses. Each availability zone can contain no more than one public and one private subnet.

If you are working in a disconnected environment, you are unable to reach the public IP addresses for EC2 and ELB endpoints. To resolve this, you must create a VPC endpoint and attach it to the subnet that the clusters are using. The endpoints should be named as follows:

• ec2.<region>.amazonaws.com

• elasticloadbalancing.<region>.amazonaws.com

• s3.<region>.amazonaws.com

Required VPC components

You must provide a suitable VPC and subnets that allow communication to your machines.

#### 2.9.4.2. VPC validation

To ensure that the subnets that you provide are suitable, the installation program confirms the following data:

- All the subnets that you specify exist.
- You provide private subnets.
- The subnet CIDRs belong to the machine CIDR that you specified.
- You provide subnets for each availability zone. Each availability zone contains no more than one public and one private subnet. If you use a private cluster, provide only a private subnet for each availability zone. Otherwise, provide exactly one public and private subnet for each availability zone.
- You provide a public subnet for each private subnet availability zone. Machines are not provisioned in availability zones that you do not provide private subnets for.

If you destroy a cluster that uses an existing VPC, the VPC is not deleted. When you remove the OpenShift Container Platform cluster from a VPC, the `kubernetes.io/cluster/.*: shared` tag is removed from the subnets that it used.

#### 2.9.4.3. Division of permissions

Starting with OpenShift Container Platform 4.3, you do not need all of the permissions that are required for an installation program-provisioned infrastructure cluster to deploy a cluster. This change mimics the division of permissions that you might have at your company: some individuals can create different resource in your clouds than others. For example, you might be able to create application-specific items, like instances, buckets, and load balancers, but not networking-related components such as VPCs, subnets, or ingress rules.

The AWS credentials that you use when you create your cluster do not need the networking permissions that are required to make VPCs and core networking components within the VPC, such as subnets, routing tables, Internet gateways, NAT, and VPN. You still need permission to make the application resources that the machines within the cluster require, such as ELBs, security groups, S3 buckets, and nodes.

#### 2.9.4.4. Isolation between clusters

If you deploy OpenShift Container Platform to an existing network, the isolation of cluster services is reduced in the following ways:
You can install multiple OpenShift Container Platform clusters in the same VPC.

- ICMP ingress is allowed from the entire network.
- TCP 22 ingress (SSH) is allowed to the entire network.
- Control plane TCP 6443 ingress (Kubernetes API) is allowed to the entire network.
- Control plane TCP 22623 ingress (MCS) is allowed to the entire network.

2.9.5. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.6, you require access to the Internet to install your cluster.

You must have Internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

2.9.6. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your `ssh-agent` and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

**NOTE**

In a production environment, you require disaster recovery and debugging.

You can use this key to SSH into the master nodes as the user `core`. When you deploy the cluster, the key is added to the `core` user’s `~/.ssh/authorized_keys` list.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

Procedure
1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N " \n   -f <path>/<file_name>  
   ```

   Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   Running this command generates an SSH key that does not require a password in the location that you specified.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the ssh-agent process as a background task:

   ```bash
   $ eval "$\{ssh-agent -s\}"
   ```

   **Example output**

   Agent pid 31874

   **NOTE**

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the ssh-agent:

   ```bash
   $ ssh-add <path>/<file_name>  
   ```

   **Example output**

   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

   Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

   **Next steps**

   - When you install OpenShift Container Platform, provide the SSH public key to the installation program.

   **2.9.7. Obtaining the installation program**
Before you install OpenShift Container Platform, download the installation file on a local computer.

**Prerequisites**

- You have a computer that runs Linux or macOS, with 500 MB of local disk space

**Procedure**

1. Access the **Infrastructure Provider** page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
2. Select your infrastructure provider.
3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

**IMPORTANT**

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ tar xvf openshift-install-linux.tar.gz
   ```

5. Download your installation **pull secret** from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

**2.9.8. Manually creating the installation configuration file**

When installing OpenShift Container Platform on Amazon Web Services (AWS) into a region requiring a custom Red Hat Enterprise Linux CoreOS (RHCOS) AMI, you must manually generate your installation configuration file.

**Prerequisites**

- Obtain the OpenShift Container Platform installation program and the access token for your cluster.

**Procedure**
1. Create an installation directory to store your required installation assets in:

```
$ mkdir <installation_directory>
```

**IMPORTANT**

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the following `install-config.yaml` file template and save it in the `<installation_directory>`.

**NOTE**

You must name this configuration file `install-config.yaml`.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

**IMPORTANT**

The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.

### 2.9.8.1. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster’s platform. When you create the `install-config.yaml` installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the `install-config.yaml` file to provide more details about the platform.

**NOTE**

After installation, you cannot modify these parameters in the `install-config.yaml` file.

**IMPORTANT**

The `openshift-install` command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

### 2.9.8.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

Table 2.26. Required parameters
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the install-config.yaml content. The current version is v1. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the baseDomain and metadata.name parameter values that uses the &lt;metadata.name&gt;.&lt;baseDomain&gt; format.</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
</tr>
<tr>
<td>metadata</td>
<td>Kubernetes resource ObjectMeta, from which only the name parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of {{.metadata.name}}.{{.baseDomain}}.</td>
<td>String of lowercase letters, hyphens (-), and periods (.), such as dev.</td>
</tr>
<tr>
<td>platform</td>
<td>The configuration for the specific platform upon which to perform the installation: aws, baremetal, azure, openstack, ovirt, vsphere. For additional information about platform.&lt;platform&gt; parameters, consult the following table for your specific platform.</td>
<td>Object</td>
</tr>
</tbody>
</table>
### pullSecret

Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.

```json
{
  "auths": {
    "cloud.openshift.com": {
      "auth": "b3Blb=",
      "email": "you@example.com"
    },
    "quay.io": {
      "auth": "b3Blb=",
      "email": "you@example.com"
    }
  }
}
```

---

#### 2.9.8.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

**Table 2.27. Network parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>networking</strong></td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td><strong>networking.network</strong></td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN.</td>
</tr>
</tbody>
</table>
| **networking.clusterNetwork** | The IP address blocks for pods. | An array of objects. For example:
  - networking:
    - clusterNetwork:
      - cidr: 10.128.0.0/14
      - hostPrefix: 23
      - hostPrefix: 23
```
### Table 2.28. Optional parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking.clusterNetwork.cidr</td>
<td>Required if you use <code>networking.clusterNetwork</code>. An IP address block.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td>networking.clusterNetwork.hostPrefix</td>
<td>The subnet prefix length to assign to each individual node. For example, if <code>hostPrefix</code> is set to 23 then each node is assigned a /23 subnet out of the given <code>cidr</code>. A <code>hostPrefix</code> value of 23 provides 510 (2^(32 - 23) - 2) pod IP addresses.</td>
<td>A subnet prefix. The default value is 23.</td>
</tr>
<tr>
<td>networking.serviceNetwork</td>
<td>The IP address block for services. The default value is 172.30.0.0/16.</td>
<td>An array with an IP address block in CIDR format. For example:</td>
</tr>
</tbody>
</table>
|                               | The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network. | networking:
|                               | serviceNetwork:                                                           | - 172.30.0.0/16                                                       |
| networking.machineNetwork     | The IP address blocks for machines.                                         | An array of objects. For example:                                      |
|                               | If you specify multiple IP address blocks, the blocks must not overlap.    | networking:
|                               |                                                                           | machineNetwork:                                                       |
|                               |                                                                           | - cidr: 10.0.0.0/16                                                   |
| networking.machineNetwork.cidr | Required if you use `networking.machineNetwork`. An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24. | An IP network block in CIDR notation.
|                               |                                                                           | For example, 10.0.0.0/16.                                             |

**NOTE**

Set the `networking.machineNetwork` to match the CIDR that the preferred NIC resides in.

### 2.9.8.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

**Table 2.28. Optional parameters**
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of machine-pool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>compute.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <strong>amd64</strong> (the default).</td>
<td>String</td>
</tr>
<tr>
<td>compute.hyperthreading</td>
<td>Whether to enable or disable simultaneous multithreading, or <strong>hyperthreading</strong>, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td></td>
</tr>
<tr>
<td>compute.name</td>
<td>Required if you use <strong>compute</strong>. The name of the machine pool.</td>
<td>worker</td>
</tr>
<tr>
<td>compute.platform</td>
<td>Required if you use <strong>compute</strong>. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <strong>controlPlane.platform</strong> parameter value.</td>
<td>aws, azure, gcp, openstack, ovirt, vsphere, or{}</td>
</tr>
<tr>
<td>compute.replicas</td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>----------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------</td>
</tr>
<tr>
<td>controlPlane</td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of MachinePool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>controlPlane.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool.</td>
<td>String</td>
</tr>
<tr>
<td></td>
<td>Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td></td>
</tr>
<tr>
<td>controlPlane.hypertreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td></td>
<td>IMPORTANT</td>
<td>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
</tr>
<tr>
<td>controlPlane.name</td>
<td>Required if you use controlPlane. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use controlPlane. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the compute.platform parameter value.</td>
<td>aws, azure, gcp, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>---------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------</td>
</tr>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (&quot;&quot;).</td>
</tr>
</tbody>
</table>

**NOTE**

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Red Hat Operators reference content.
Enable or disable FIPS mode. The default is `false` (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the **x86_64** architecture.

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>fips</strong></td>
<td>Enable or disable FIPS mode. The default is <code>false</code> (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</td>
<td><code>false</code> or <code>true</code></td>
</tr>
<tr>
<td><strong>imageContentSources</strong></td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects. Includes a <code>source</code> and, optionally, <code>mirrors</code>, as described in the following rows of this table.</td>
</tr>
<tr>
<td><strong>imageContentSources.source</strong></td>
<td>Required if you use <code>imageContentSources</code>. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td><strong>imageContentSources.mirrors</strong></td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
<tr>
<td><strong>publish</strong></td>
<td>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</td>
<td><code>Internal</code> or <code>External</code>. To deploy a private cluster, which cannot be accessed from the internet, set <code>publish</code> to <code>Internal</code>. The default value is <code>External</code>.</td>
</tr>
</tbody>
</table>
### Parameter Description Values

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>sshKey</strong></td>
<td>The SSH key or keys to authenticate access your cluster machines.</td>
<td>One or more keys. For example:</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>For production OpenShift Container Platform clusters on which you want to</td>
<td></td>
</tr>
<tr>
<td></td>
<td>perform installation debugging or disaster recovery, specify an SSH key</td>
<td></td>
</tr>
<tr>
<td></td>
<td>that your <strong>ssh-agent</strong> process uses.</td>
<td></td>
</tr>
</tbody>
</table>

#### 2.9.8.14. Optional AWS configuration parameters

Optional AWS configuration parameters are described in the following table:

**Table 2.29. Optional AWS parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>compute.platform.aws.amiID</code></td>
<td>The AWS AMI used to boot compute machines for the cluster. This is required</td>
<td>Any published or custom RHCOS AMI that belongs to the set AWS region.</td>
</tr>
<tr>
<td></td>
<td>for regions that require a custom RHCOS AMI.</td>
<td></td>
</tr>
<tr>
<td><code>compute.platform.aws.rootVolume.size</code></td>
<td>The size in GiB of the root volume.</td>
<td>Integer, for example 500.</td>
</tr>
<tr>
<td><code>compute.platform.aws.rootVolume.type</code></td>
<td>The type of the root volume.</td>
<td>Integer, for example 4000.</td>
</tr>
<tr>
<td></td>
<td><code>compute.platform.aws.type</code></td>
<td>Valid AWS EBS volume type, such as io1.</td>
</tr>
<tr>
<td></td>
<td>The EC2 instance type for the compute machines.</td>
<td>Valid AWS instance type, such as c5.9xlarge.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>compute.platform.aws.zones</code></td>
<td>The availability zones where the installation program creates machines for the compute machine pool. If you provide your own VPC, you must provide a subnet in that availability zone.</td>
<td>A list of valid AWS availability zones, such as <strong>us-east-1c</strong>, in a YAML sequence.</td>
</tr>
<tr>
<td><code>compute.aws.region</code></td>
<td>The AWS region that the installation program creates compute resources in.</td>
<td>Any valid <strong>AWS region</strong>, such as <strong>us-east-1</strong>.</td>
</tr>
<tr>
<td><code>controlPlane.platform.aws.amiID</code></td>
<td>The AWS AMI used to boot control plane machines for the cluster. This is required for regions that require a custom RHCOS AMI.</td>
<td>Any published or custom RHCOS AMI that belongs to the set AWS region.</td>
</tr>
<tr>
<td><code>controlPlane.platform.aws.type</code></td>
<td>The EC2 instance type for the control plane machines.</td>
<td>Valid <strong>AWS instance type</strong>, such as <strong>c5.9xlarge</strong>.</td>
</tr>
<tr>
<td><code>controlPlane.platform.aws.zones</code></td>
<td>The availability zones where the installation program creates machines for the control plane machine pool.</td>
<td>A list of valid AWS availability zones, such as <strong>us-east-1c</strong>, in a YAML sequence.</td>
</tr>
<tr>
<td><code>controlPlane.aws.region</code></td>
<td>The AWS region that the installation program creates control plane resources in.</td>
<td>Valid <strong>AWS region</strong>, such as <strong>us-east-1</strong>.</td>
</tr>
<tr>
<td><code>platform.aws.amiID</code></td>
<td>The AWS AMI used to boot all machines for the cluster. If set, the AMI must belong to the same region as the cluster. This is required for regions that require a custom RHCOS AMI.</td>
<td>Any published or custom RHCOS AMI that belongs to the set AWS region.</td>
</tr>
<tr>
<td><code>platform.aws.serviceEndpoints.name</code></td>
<td>The AWS service endpoint name. Custom endpoints are only required for cases where alternative AWS endpoints, like FIPS, must be used. Custom API endpoints can be specified for EC2, S3, IAM, Elastic Load Balancing, Tagging, Route 53, and STS AWS services.</td>
<td>Valid <strong>AWS service endpoint name</strong>.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>----------------------------------------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>platform.aws.serviceEndpoints.url</td>
<td>The AWS service endpoint URL. The URL must use the https protocol and the host must trust the certificate.</td>
<td>Valid AWS service endpoint URL.</td>
</tr>
<tr>
<td>platform.aws.userTags</td>
<td>A map of keys and values that the installation program adds as tags to all resources that it creates.</td>
<td>Any valid YAML map, such as key value pairs in the &lt;key&gt;: &lt;value&gt; format. For more information about AWS tags, see Tagging Your Amazon EC2 Resources in the AWS documentation.</td>
</tr>
<tr>
<td>platform.aws.subnets</td>
<td>If you provide the VPC instead of allowing the installation program to create the VPC for you, specify the subnet for the cluster to use. The subnet must be part of the same machineNetwork[].cidr ranges that you specify. For a standard cluster, specify a public and a private subnet for each availability zone. For a private cluster, specify a private subnet for each availability zone.</td>
<td>Valid subnet IDs.</td>
</tr>
</tbody>
</table>

2.9.8.2. Sample customized install-config.yaml file for AWS

You can customize the install-config.yaml file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

**IMPORTANT**

This sample YAML file is provided for reference only. You must obtain your install-config.yaml file by using the installation program and modify it.

```yaml
apiVersion: v1
baseDomain: example.com
credentialsMode: Mint
controlPlane: hyperthreading: Enabled
name: master
platform:
  aws:
    zones:
    - us-gov-west-1a
    - us-gov-west-1b
    rootVolume:
      iops: 4000
      size: 500
```
Required.

Optional: Add this parameter to force the Cloud Credential Operator (CCO) to use the specified
If you do not provide these parameters and values, the installation program provides the default value.

The `controlPlane` section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, `-`, and the first line of the controlPlane section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading, or hyperthreading. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores. You can disable it by setting the parameter value to Disabled. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

IMPORTANT

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger instance types, such as `m4.2xlarge` or `m5.2xlarge`, for your machines if you disable simultaneous multithreading.

To configure faster storage for etcd, especially for larger clusters, set the storage type as `io1` and set `iops` to `2000`.

If you provide your own VPC, specify subnets for each availability zone that your cluster uses.

The ID of the AMI used to boot machines for the cluster. If set, the AMI must belong to the same region as the cluster.

The AWS service endpoints. Custom endpoints are required when installing to an unknown AWS region. The endpoint URL must use the `https` protocol and the host must trust the certificate.

The ID of your existing Route 53 private hosted zone. Providing an existing hosted zone requires that you supply your own VPC and the hosted zone is already associated with the VPC prior to installing your cluster. If undefined, the installation program creates a new hosted zone.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

IMPORTANT

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the `x86_64` architecture.

You can optionally provide the `sshKey` value that you use to access the machines in your cluster.

NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.
How to publish the user-facing endpoints of your cluster. Set publish to Internal to deploy a private cluster, which cannot be accessed from the Internet. The default value is External.

The custom CA certificate. This is required when deploying to the AWS C2S Secret Region because the AWS API requires a custom CA trust bundle.

2.9.8.3. AWS regions without a published RHCOS AMI

You can deploy an OpenShift Container Platform cluster to Amazon Web Services (AWS) regions without native support for a Red Hat Enterprise Linux CoreOS (RHCOS) Amazon Machine Image (AMI) or the AWS software development kit (SDK). If a published AMI is not available for an AWS region, you can upload a custom AMI prior to installing the cluster. This is required if you are deploying your cluster to an AWS government region.

If you are deploying to a non-government region that does not have a published RHCOS AMI, and you do not specify a custom AMI, the installation program copies the us-east-1 AMI to the user account automatically. Then the installation program creates the control plane machines with encrypted EBS volumes using the default or user-specified Key Management Service (KMS) key. This allows the AMI to follow the same process workflow as published RHCOS AMIs.

A region without native support for an RHCOS AMI is not available to select from the terminal during cluster creation because it is not published. However, you can install to this region by configuring the custom AMI in the install-config.yaml file.

2.9.8.4. Uploading a custom RHCOS AMI in AWS

If you are deploying to a custom Amazon Web Services (AWS) region, you must upload a custom Red Hat Enterprise Linux CoreOS (RHCOS) Amazon Machine Image (AMI) that belongs to that region.

Prerequisites

- You configured an AWS account.
- You created an Amazon S3 bucket with the required IAM service role.
- You uploaded your RHCOS VMDK file to Amazon S3. The RHCOS VMDK file must be the highest version that is less than or equal to the OpenShift Container Platform version you are installing.
- You downloaded the AWS CLI and installed it on your computer. See Install the AWS CLI Using the Bundled Installer.

Procedure

1. Export your AWS profile as an environment variable:

   ```bash
   $ export AWS_PROFILE=<aws_profile> 1
   
   1 The AWS profile name that holds your AWS credentials, likegovcloud.
   ```

2. Export the region to associate with your custom AMI as an environment variable:

   ```bash
   $ export AWS_DEFAULT_REGION=<aws_region> 1
   ```
The AWS region, like us-gov-east-1.

3. Export the version of RHCOS you uploaded to Amazon S3 as an environment variable:

   $ export RHCOS_VERSION=<version>  

   The RHCOS VMDK version, like 4.6.0.

4. Export the Amazon S3 bucket name as an environment variable:

   $ export VMIMPORT_BUCKET_NAME=<s3_bucket_name>

5. Create the `containers.json` file and define your RHCOS VMDK file:

   $ cat <<EOF > containers.json
   {
     "Description": "rhcos-$\{RHCOS\_VERSION\}-x86\_64-aws.x86\_64",
     "Format": "vmdk",
     "UserBucket": {
       "S3Bucket": "$\{VMIMPORT\_BUCKET\_NAME\}"
     }
   }
   EOF

6. Import the RHCOS disk as an Amazon EBS snapshot:

   $ aws ec2 import-snapshot --region ${AWS\_DEFAULT\_REGION} \
     --description "<description>" \
     --disk-container "file://<file\_path>/containers.json"

   The description of your RHCOS disk being imported, like rhcos-$\{RHCOS\_VERSION\}-x86\_64-aws.x86\_64.

   The file path to the JSON file describing your RHCOS disk. The JSON file should contain your Amazon S3 bucket name and key.

7. Check the status of the image import:

   $ watch -n 5 aws ec2 describe-import-snapshot-tasks --region ${AWS\_DEFAULT\_REGION}

   Example output

   ```
   |
   | "ImportSnapshotTasks": [
   |   |
   |     "Description": "rhcos-4.6.0-x86_64-aws.x86_64",
   |     "ImportTaskId": "import-snap-fh6i8ui",
   |     "SnapshotTaskDetail": {
   |       "Description": "rhcos-4.6.0-x86_64-aws.x86_64",
   |       "DiskImageSize": 819056640.0,
   ```
Copy the **SnapshotId** to register the image.

8. Create a custom RHCOS AMI from the RHCOS snapshot:

```bash
$ aws ec2 register-image \
--region ${AWS_DEFAULT_REGION} \
--architecture x86_64 \
--description "rhcos-$(RHCOS_VERSION)-x86_64-aws.x86_64" \
--ena-support \
--name "rhcos-$(RHCOS_VERSION)-x86_64-aws.x86_64" \
--virtualization-type hvm \
--root-device-name '/dev/xvda' \
--block-device-mappings 'DeviceName=/dev/xvda,Ebs=\n{DeleteOnTermination=true,SnapshotId=<snapshot_ID>}'
```

1. The RHCOS VMDK architecture type, like `x86_64`, `s390x`, or `ppc64le`.
2. The **Description** from the imported snapshot.
3. The name of the RHCOS AMI.
4. The **SnapshotId** from the imported snapshot.

To learn more about these APIs, see the AWS documentation for [importing snapshots](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/import-snapshots.html) and [creating EBS-backed AMIs](https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/creating-ebs-backed-amis.html).

### 2.9.8.5. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**Prerequisites**

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object’s **spec.noProxy** field to bypass the proxy if necessary.
NOTE

The `Proxy` object's `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object's `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

- If your cluster is on AWS, you added the `ec2.<region>.amazonaws.com`, `elasticloadbalancing.<region>.amazonaws.com`, and `s3.<region>.amazonaws.com` endpoints to your VPC endpoint. These endpoints are required to complete requests from the nodes to the AWS EC2 API. Because the proxy works on the container level, not the node level, you must route these requests to the AWS EC2 API through the AWS private network. Adding the public IP address of the EC2 API to your allowlist in your proxy server is not sufficient.

Procedure

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
     httpProxy: http://<username>:<pswd>@<ip>:<port>  
     httpsProxy: https://<username>:<pswd>@<ip>:<port>  
     noProxy: example.com
   additionalTrustBundle: |
       -----BEGIN CERTIFICATE-----
       <MY_TRUSTED_CA_CERT>
       -----END CERTIFICATE-----
   ...
   ``

   - A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.
   - A proxy URL to use for creating HTTPS connections outside the cluster.
   - A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, `.y.com` matches `x.y.com`, but not `y.com`. Use `*` to bypass the proxy for all destinations.
   - If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace to hold the additional CA certificates. If you provide `additionalTrustBundle` and at least one proxy setting, the `Proxy` object is configured to reference the `user-ca-bundle` config map in the `trustedCA` field. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges the contents specified for the `trustedCA` parameter with the RHCOS trust bundle. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.
2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

**NOTE**

Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

### 2.9.9. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

**Prerequisites**

- Configure an account with the cloud platform that hosts your cluster.
- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Change to the directory that contains the installation program and initialize the cluster deployment:

```
$ ./openshift-install create cluster --dir <installation_directory> \
   --log-level=info
```

   1. For `<installation_directory>`, specify the location of your customized `/install-config.yaml` file.
   2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

**NOTE**

If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.

When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the `kubeadmin` user, display in your terminal.
Example output

```
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-Wi5AL"
INFO Time elapsed: 36m22s
```

### NOTE

The cluster access and credential information also outputs to `<installation_directory>/openshift_install.log` when an installation succeeds.

### IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

### IMPORTANT

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

2. Optional: Remove or disable the `AdministratorAccess` policy from the IAM account that you used to install the cluster.

### NOTE

The elevated permissions provided by the `AdministratorAccess` policy are required only during installation.

2.9.10. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (`oc`) in order to interact with OpenShift Container Platform from a command-line interface. You can install `oc` on Linux, Windows, or macOS.
IMPORTANT

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.6. Download and install the new version of oc.

2.9.10.1. Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.6 Linux Client entry and save the file.

4. Unpack the archive:

   $ tar xvzf <file>

5. Place the oc binary in a directory that is on your PATH.
   To check your PATH, execute the following command:

   $ echo $PATH

After you install the OpenShift CLI, it is available using the oc command:

$ oc <command>

2.9.10.2. Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.6 Windows Client entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the oc binary to a directory that is on your PATH.
   To check your PATH, open the command prompt and execute the following command:

   C:\> path

After you install the OpenShift CLI, it is available using the oc command:
2.9.10.3. Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (`oc`) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version in the Version drop-down menu.
3. Click Download Now next to the OpenShift v4.6 MacOSX Client entry and save the file.
4. Unpack and unzip the archive.
5. Move the `oc` binary to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:

   ```
   $ echo $PATH
   ```

   After you install the OpenShift CLI, it is available using the `oc` command:

   ```
   $ oc <command>
   ```

2.9.11. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

   ```
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```
   $ oc whoami
   ```
2.9.12. Logging in to the cluster by using the web console

The `kubeadmin` user exists by default after an OpenShift Container Platform installation. You can log in to your cluster as the `kubeadmin` user by using the OpenShift Container Platform web console.

Prerequisites

- You have access to the installation host.
- You completed a cluster installation and all cluster Operators are available.

Procedure

1. Obtain the password for the `kubeadmin` user from the `kubeadmin-password` file on the installation host:

   ```
   $ cat <installation_directory>/auth/kubeadmin-password
   ```

   **NOTE**

   Alternatively, you can obtain the `kubeadmin` password from the `<installation_directory>/openshift_install.log` log file on the installation host.

2. List the OpenShift Container Platform web console route:

   ```
   $ oc get routes -n openshift-console | grep 'console-openshift'
   ```

   **NOTE**

   Alternatively, you can obtain the OpenShift Container Platform route from the `<installation_directory>/openshift_install.log` log file on the installation host.

Example output

```
console     console-openshift-console.apps.<cluster_name>.<base_domain>            console
https   reencrypt/Redirect   None
```

3. Navigate to the route detailed in the output of the preceding command in a web browser and log in as the `kubeadmin` user.

Additional resources

- See [Accessing the web console](#) for more details about accessing and understanding the OpenShift Container Platform web console.

2.9.13. Telemetry access for OpenShift Container Platform
In OpenShift Container Platform 4.6, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service.

2.9.14. Next steps

- Validating an installation.
- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- If necessary, you can remove cloud provider credentials.

2.10. INSTALLING A CLUSTER ON USER-PROVISIONED INFRASTRUCTURE IN AWS BY USING CLOUDFORMATION TEMPLATES

In OpenShift Container Platform version 4.6, you can install a cluster on Amazon Web Services (AWS) that uses infrastructure that you provide.

One way to create this infrastructure is to use the provided CloudFormation templates. You can modify the templates to customize your infrastructure or use the information that they contain to create AWS objects according to your company’s policies.

**IMPORTANT**

The steps for performing a user-provisioned infrastructure installation are provided as an example only. Installing a cluster with infrastructure you provide requires knowledge of the cloud provider and the installation process of OpenShift Container Platform. Several CloudFormation templates are provided to assist in completing these steps or to help model your own. You are also free to create the required resources through other methods; the templates are just an example.

2.10.1. Prerequisites

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You configured an AWS account to host the cluster.
IMPORTANT

If you have an AWS profile stored on your computer, it must not use a temporary session token that you generated while using a multi-factor authentication device. The cluster continues to use your current AWS credentials to create AWS resources for the entire life of the cluster, so you must use key-based, long-lived credentials. To generate appropriate keys, see Managing Access Keys for IAM Users in the AWS documentation. You can supply the keys when you run the installation program.

- You downloaded the AWS CLI and installed it on your computer. See Install the AWS CLI Using the Bundled Installer (Linux, macOS, or Unix) in the AWS documentation.

- If you use a firewall, you configured it to allow the sites that your cluster requires access to.

NOTE

Be sure to also review this site list if you are configuring a proxy.

- If you do not allow the system to manage identity and access management (IAM), then a cluster administrator can manually create and maintain IAM credentials. Manual mode can also be used in environments where the cloud IAM APIs are not reachable.

2.10.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.6, you require access to the Internet to install your cluster.

You must have Internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- Access Quay.io to obtain the packages that are required to install your cluster.

- Obtain the packages that are required to perform cluster updates.

IMPORTANT

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

2.10.3. Required AWS infrastructure components

To install OpenShift Container Platform on user-provisioned infrastructure in Amazon Web Services (AWS), you must manually create both the machines and their supporting infrastructure.

For more information about the integration testing for different platforms, see the OpenShift Container Platform 4.x Tested Integrations page.
By using the provided CloudFormation templates, you can create stacks of AWS resources that represent the following components:

- An AWS Virtual Private Cloud (VPC)
- Networking and load balancing components
- Security groups and roles
- An OpenShift Container Platform bootstrap node
- OpenShift Container Platform control plane nodes
- An OpenShift Container Platform compute node

Alternatively, you can manually create the components or you can reuse existing infrastructure that meets the cluster requirements. Review the CloudFormation templates for more details about how the components interrelate.

### 2.10.3.1. Cluster machines

You need AWS::EC2::Instance objects for the following machines:

- A bootstrap machine. This machine is required during installation, but you can remove it after your cluster deploys.
- Three control plane machines. The control plane machines are not governed by a machine set.
- Compute machines. You must create at least two compute machines, which are also known as worker machines, during installation. These machines are not governed by a machine set.

You can use the following instance types for the cluster machines with the provided CloudFormation templates.

**IMPORTANT**

If m4 instance types are not available in your region, such as with eu-west-3, use m5 types instead.

<table>
<thead>
<tr>
<th>Instance type</th>
<th>Bootstrap</th>
<th>Control plane</th>
<th>Compute</th>
</tr>
</thead>
<tbody>
<tr>
<td>i3.large</td>
<td>x</td>
<td></td>
<td></td>
</tr>
<tr>
<td>m4.large</td>
<td></td>
<td></td>
<td>x</td>
</tr>
<tr>
<td>m4.xlarge</td>
<td></td>
<td>x</td>
<td></td>
</tr>
<tr>
<td>m4.2xlarge</td>
<td></td>
<td>x</td>
<td></td>
</tr>
<tr>
<td>m4.4xlarge</td>
<td></td>
<td>x</td>
<td></td>
</tr>
<tr>
<td>Instance type</td>
<td>Bootstrap</td>
<td>Control plane</td>
<td>Compute</td>
</tr>
<tr>
<td>----------------</td>
<td>-----------</td>
<td>---------------</td>
<td>---------</td>
</tr>
<tr>
<td>m4.8xlarge</td>
<td>x</td>
<td></td>
<td>x</td>
</tr>
<tr>
<td>m4.10xlarge</td>
<td></td>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>m4.16xlarge</td>
<td></td>
<td></td>
<td>x</td>
</tr>
<tr>
<td>m5.large</td>
<td></td>
<td></td>
<td>x</td>
</tr>
<tr>
<td>m5.xlarge</td>
<td></td>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>m5.2xlarge</td>
<td></td>
<td></td>
<td>x</td>
</tr>
<tr>
<td>m5.4xlarge</td>
<td></td>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>m5.8xlarge</td>
<td></td>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>m5.10xlarge</td>
<td></td>
<td></td>
<td>x</td>
</tr>
<tr>
<td>m5.16xlarge</td>
<td></td>
<td></td>
<td>x</td>
</tr>
<tr>
<td>m6i.xlarge</td>
<td></td>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>c4.2xlarge</td>
<td></td>
<td>x</td>
<td>x</td>
</tr>
<tr>
<td>c4.4xlarge</td>
<td></td>
<td></td>
<td>x</td>
</tr>
<tr>
<td>c4.8xlarge</td>
<td></td>
<td></td>
<td>x</td>
</tr>
<tr>
<td>r4.large</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>r4.xlarge</td>
<td></td>
<td></td>
<td>x</td>
</tr>
<tr>
<td>r4.2xlarge</td>
<td></td>
<td></td>
<td>x</td>
</tr>
<tr>
<td>r4.4xlarge</td>
<td></td>
<td></td>
<td>x</td>
</tr>
<tr>
<td>r4.8xlarge</td>
<td></td>
<td></td>
<td>x</td>
</tr>
<tr>
<td>r4.16xlarge</td>
<td></td>
<td></td>
<td>x</td>
</tr>
</tbody>
</table>

You might be able to use other instance types that meet the specifications of these instance types.

2.10.3.2. Other infrastructure components

- A VPC
• DNS entries
• Load balancers (classic or network) and listeners
• A public and a private Route 53 zone
• Security groups
• IAM roles
• S3 buckets

If you are working in a disconnected environment or use a proxy, you cannot reach the public IP addresses for EC2 and ELB endpoints. To reach these endpoints, you must create a VPC endpoint and attach it to the subnet that the clusters are using. Create the following endpoints:

• ec2.<region>.amazonaws.com
• elasticloadbalancing.<region>.amazonaws.com
• s3.<region>.amazonaws.com

**Required VPC components**

You must provide a suitable VPC and subnets that allow communication to your machines.

<table>
<thead>
<tr>
<th>Component</th>
<th>AWS type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VPC</td>
<td><img src="image1.png" alt="image" /></td>
<td>You must provide a public VPC for the cluster to use. The VPC uses an endpoint that references the route tables for each subnet to improve communication with the registry that is hosted in S3.</td>
</tr>
<tr>
<td>Public subnets</td>
<td><img src="image2.png" alt="image" /></td>
<td>Your VPC must have public subnets for between 1 and 3 availability zones and associate them with appropriate Ingress rules.</td>
</tr>
</tbody>
</table>
### Internet gateway

You must have a public Internet gateway, with public routes, attached to the VPC. In the provided templates, each public subnet has a NAT gateway with an EIP address. These NAT gateways allow cluster resources, like private subnet instances, to reach the Internet and are not required for some restricted network or proxy scenarios.

<table>
<thead>
<tr>
<th>Component</th>
<th>AWS type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Internet gateway</td>
<td>• AWS::EC2::InternetGateway</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• AWS::EC2::VPCGatewayAttachment</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• AWS::EC2::RouteTable</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• AWS::EC2::Route</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• AWS::EC2::SubnetRouteTableAssociation</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• AWS::EC2::NatGateway</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• AWS::EC2::EIP</td>
<td></td>
</tr>
</tbody>
</table>

### Network access control

You must allow the VPC to access the following ports:

<table>
<thead>
<tr>
<th>Port</th>
<th>Reason</th>
</tr>
</thead>
<tbody>
<tr>
<td>80</td>
<td>Inbound HTTP traffic</td>
</tr>
<tr>
<td>443</td>
<td>Inbound HTTPS traffic</td>
</tr>
<tr>
<td>22</td>
<td>Inbound SSH traffic</td>
</tr>
<tr>
<td>1024 - 65535</td>
<td>Inbound ephemeral traffic</td>
</tr>
<tr>
<td>0 - 65535</td>
<td>Outbound ephemeral traffic</td>
</tr>
</tbody>
</table>

### Private subnets

Your VPC can have private subnets. The provided CloudFormation templates can create private subnets for between 1 and 3 availability zones. If you use private subnets, you must provide appropriate routes and tables for them.

<table>
<thead>
<tr>
<th>Component</th>
<th>AWS type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Private subnets</td>
<td>• AWS::EC2::Subnet</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• AWS::EC2::RouteTable</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• AWS::EC2::SubnetRouteTableAssociation</td>
<td></td>
</tr>
</tbody>
</table>

### Required DNS and load balancing components

Your DNS and load balancer configuration needs to use a public hosted zone and can use a private hosted zone similar to the one that the installation program uses if it provisions the cluster’s infrastructure. You must create a DNS entry that resolves to your load balancer. An entry for api.
<cluster_name>.<domain> must point to the external load balancer, and an entry for api-int. <cluster_name>.<domain> must point to the internal load balancer.

The cluster also requires load balancers and listeners for port 6443, which are required for the Kubernetes API and its extensions, and port 22623, which are required for the Ignition config files for new machines. The targets will be the control plane nodes (also known as the master nodes). Port 6443 must be accessible to both clients external to the cluster and nodes within the cluster. Port 22623 must be accessible to nodes within the cluster.

<table>
<thead>
<tr>
<th>Component</th>
<th>AWS type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DNS</td>
<td>AWS::Route 53::HostedZone</td>
<td>The hosted zone for your internal DNS.</td>
</tr>
<tr>
<td>etcd record sets</td>
<td>AWS::Route 53::RecordSet</td>
<td>The registration records for etcd for your control plane machines.</td>
</tr>
<tr>
<td>Public load balancer</td>

### Security groups

The control plane and worker machines require access to the following ports:

<table>
<thead>
<tr>
<th>Group</th>
<th>Type</th>
<th>IP Protocol</th>
<th>Port range</th>
</tr>
</thead>
<tbody>
<tr>
<td>MasterSecurityGroup</td>
<td>AWS::EC2::SecurityGroup</td>
<td>icmp</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>tcp</td>
<td>22</td>
</tr>
<tr>
<td></td>
<td></td>
<td>tcp</td>
<td>6443</td>
</tr>
<tr>
<td></td>
<td></td>
<td>tcp</td>
<td>22623</td>
</tr>
<tr>
<td>WorkerSecurityGroup</td>
<td>AWS::EC2::SecurityGroup</td>
<td>icmp</td>
<td>0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>tcp</td>
<td>22</td>
</tr>
<tr>
<td>BootstrapSecurityGroup</td>
<td>AWS::EC2::SecurityGroup</td>
<td>tcp</td>
<td>22</td>
</tr>
<tr>
<td></td>
<td></td>
<td>tcp</td>
<td>19531</td>
</tr>
</tbody>
</table>

### Control plane Ingress

The control plane machines require the following Ingress groups. Each Ingress group is a AWS::EC2::SecurityGroupIngress resource.

<table>
<thead>
<tr>
<th>Ingress group</th>
<th>Description</th>
<th>IP protocol</th>
<th>Port range</th>
</tr>
</thead>
<tbody>
<tr>
<td>MasterIngress</td>
<td>etcd</td>
<td>tcp</td>
<td>2379-2380</td>

</tbody>
</table>
### Roles and instance profiles

You must grant the machines permissions in AWS. The provided CloudFormation templates grant the machines **Allow** permissions for the following **AWS::IAM::Role** objects and provide a **AWS::IAM::InstanceProfile** for each set of roles. If you do not use the templates, you can grant the machines the following broad permissions or the following individual permissions.

<table>
<thead>
<tr>
<th>Role</th>
<th>Effect</th>
<th>Action</th>
<th>Resource</th>
</tr>
</thead>
<tbody>
<tr>
<td>Master</td>
<td>Allow</td>
<td>ec2:*</td>
<td>*</td>
</tr>
<tr>

<td>ec2:AttachVolume</td>
<td>*</td>
</tr>
<tr>
<td></td>
<td>Allow</td>
<td>ec2:DetachVolume</td>
<td>*</td>
</tr>
</tbody>
</table>

### 2.10.3.3. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The **kube-controller-manager** only approves the kubelet client CSRs. The **machine-approver** cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

### 2.10.3.4. Required AWS permissions

**NOTE**

Your IAM user must have the permission **tag:GetResources** in the region **us-east-1** to delete the base cluster resources. As part of the AWS API requirement, the OpenShift Container Platform installation program performs various actions in this region.
When you attach the **AdministratorAccess** policy to the IAM user that you create in Amazon Web Services (AWS), you grant that user all of the required permissions. To deploy all components of an OpenShift Container Platform cluster, the IAM user requires the following permissions:

Example 2.13. Required EC2 permissions for installation

- `tag:TagResources`
- `tag:UntagResources`
- `ec2:AllocateAddress`
- `ec2:AssociateAddress`
- `ec2:AuthorizeSecurityGroupEgress`
- `ec2:AuthorizeSecurityGroupIngress`
- `ec2:CopyImage`
- `ec2:CreateNetworkInterface`
- `ec2:AttachNetworkInterface`
- `ec2:CreateSecurityGroup`
- `ec2:CreateTags`
- `ec2:CreateVolume`
- `ec2:DeleteSecurityGroup`
- `ec2:DeleteSnapshot`
- `ec2:DeleteTags`
- `ec2:DeregisterImage`
- `ec2:DescribeAccountAttributes`
- `ec2:DescribeAddresses`
- `ec2:DescribeAvailabilityZones`
- `ec2:DescribeDhcpOptions`
- `ec2:DescribeImages`
- `ec2:DescribeInstanceAttribute`
- `ec2:DescribeInstanceCreditSpecifications`
- `ec2:DescribeInstances`
- `ec2:DescribeInternetGateways`
- `ec2:DescribeKeyPairs`
Example 2.14. Required permissions for creating network resources during installation

- ec2:AssociateDhcpOptions
- ec2:AssociateRouteTable
- ec2:AttachInternetGateway
- ec2:CreateDhcpOptions
- ec2:CreateInternetGateway
- ec2:CreateNatGateway
- ec2:CreateRoute
- ec2:CreateRouteTable
- ec2:CreateSubnet
- ec2:CreateVpc
- ec2:CreateVpcEndpoint
- ec2:ModifySubnetAttribute
- ec2:ModifyVpcAttribute

**NOTE**
If you use an existing VPC, your account does not require these permissions for creating network resources.

Example 2.15. Required Elastic Load Balancing permissions (ELB) for installation

- elasticloadbalancing:AddTags
- elasticloadbalancing:ApplySecurityGroupsToLoadBalancer
- elasticloadbalancing:AttachLoadBalancerToSubnets
- elasticloadbalancing:ConfigureHealthCheck
- elasticloadbalancing:CreateLoadBalancer
- elasticloadbalancing:CreateLoadBalancerListeners
- elasticloadbalancing:DeleteLoadBalancer
- elasticloadbalancing:DeregisterInstancesFromLoadBalancer
- elasticloadbalancing:DescribeInstanceHealth
- elasticloadbalancing:DescribeLoadBalancerAttributes
- elasticloadbalancing:DescribeLoadBalancers
- elasticloadbalancing:DescribeTags
- elasticloadbalancing:ModifyLoadBalancerAttributes
- elasticloadbalancing:RegisterInstancesWithLoadBalancer
- elasticloadbalancing:SetLoadBalancerPoliciesOfListener

Example 2.16. Required Elastic Load Balancing permissions (ELBv2) for installation
- elasticloadbalancing:AddTags
- elasticloadbalancing:CreateListener
- elasticloadbalancing:CreateLoadBalancer
- elasticloadbalancing:CreateTargetGroup
- elasticloadbalancing:DeleteLoadBalancer
- elasticloadbalancing:DeregisterTargets
- elasticloadbalancing:DescribeListeners
- elasticloadbalancing:DescribeLoadBalancerAttributes
- elasticloadbalancing:DescribeLoadBalancers
- elasticloadbalancing:DescribeTargetGroupAttributes
- elasticloadbalancing:DescribeTargetHealth
- elasticloadbalancing:ModifyLoadBalancerAttributes
- elasticloadbalancing:ModifyTargetGroup
- elasticloadbalancing:ModifyTargetGroupAttributes
- elasticloadbalancing:RegisterTargets

Example 2.17. Required IAM permissions for installation

- iam:AddRoleToInstanceProfile
- iam:CreateInstanceProfile
- iam:CreateRole
- iam:DeleteInstanceProfile
- iam:DeleteRole
- iam:DeleteRolePolicy
- iam:GetInstanceProfile
- iam:GetRole
- iam:GetRolePolicy
- iam:GetUser
- iam:ListInstanceProfilesForRole
- iam:ListRoles
- iam:ListUsers
- iam:PassRole
- iam:PutRolePolicy
- iam:RemoveRoleFromInstanceProfile
- iam:SimulatePrincipalPolicy
- iam:TagRole

NOTE

If you have not created an elastic load balancer (ELB) in your AWS account, the IAM user also requires the **iam:CreateServiceLinkedRole** permission.

Example 2.18. Required Route 53 permissions for installation

- route53:ChangeResourceRecordSets
- route53:ChangeTagsForResource
- route53:CreateHostedZone
- route53:DeleteHostedZone
- route53:GetChange
- route53:GetHostedZone
- route53:ListHostedZones
- route53:ListHostedZonesByName
- route53:ListResourceRecordSets
- route53:ListTagsForResource
- route53:UpdateHostedZoneComment

Example 2.19. Required S3 permissions for installation

- s3:CreateBucket
- s3:DeleteBucket
- s3:GetAccelerateConfiguration
- s3:GetBucketAcl
- s3:GetBucketCors
- s3:GetBucketLocation
- s3:GetBucketLogging
Example 2.20. S3 permissions that cluster Operators require

- `s3:DeleteObject`
- `s3:GetObject`
- `s3:GetObjectAcl`
- `s3:GetObjectTagging`
- `s3:GetObjectVersion`
- `s3:PutObject`
- `s3:PutObjectAcl`
- `s3:PutObjectTagging`

Example 2.21. Required permissions to delete base cluster resources

- `autoscaling:DescribeAutoScalingGroups`
- `ec2:DeleteNetworkInterface`
- `ec2:DeleteVolume`
- `elasticloadbalancing:DeleteTargetGroup`
- `elasticloadbalancing:DescribeTargetGroups`
Example 2.22. Required permissions to delete network resources

- ec2:DeleteDhcpOptions
- ec2:DeleteInternetGateway
- ec2:DeleteNatGateway
- ec2:DeleteRoute
- ec2:DeleteRouteTable
- ec2:DeleteSubnet
- ec2:DeleteVpc
- ec2:DeleteVpcEndpoints
- ec2:DetachInternetGateway
- ec2:DisassociateRouteTable
- ec2:ReplaceRouteTableAssociation

**NOTE**
If you use an existing VPC, your account does not require these permissions to delete network resources.

Example 2.23. Additional IAM and S3 permissions that are required to create manifests

- iam:DeleteAccessKey
- iam:DeleteUser
- iam:DeleteUserPolicy
• iam:GetUserPolicy
• iam:ListAccessKeys
• iam:PutUserPolicy
• iam:TagUser
• iam:GetUserPolicy
• iam:ListAccessKeys
• s3:PutBucketPublicAccessBlock
• s3:GetBucketPublicAccessBlock
• s3:PutLifecycleConfiguration
• s3:HeadBucket
• s3:ListBucketMultipartUploads
• s3:AbortMultipartUpload

NOTE

If you are managing your cloud provider credentials with mint mode, the IAM user also requires the `iam:CreateAccessKey` and `iam:CreateUser` permissions.

Example 2.24. Optional permission for quota checks for installation

• `servicequotas:ListAWSDefaultServiceQuotas`

2.10.4. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on a local computer.

Prerequisites

• You have a computer that runs Linux or macOS, with 500 MB of local disk space

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.
The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ tar xvf openshift-install-linux.tar.gz
   ```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 2.10.5. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your ssh-agent and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

**NOTE**

In a production environment, you require disaster recovery and debugging.

You can use this key to SSH into the master nodes as the user core. When you deploy the cluster, the key is added to the core user’s ~/.ssh/authorized_keys list.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

**Procedure**

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N "" \\
   -f <path>/<file_name> 1
   ```

   1 Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.
Running this command generates an SSH key that does not require a password in the location that you specified.

NOTE
If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the ssh-agent process as a background task:

   $ eval "$(ssh-agent -s)"

   Example output
   Agent pid 31874

   NOTE
If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the ssh-agent:

   $ ssh-add <path>/<file_name> ①

   Example output
   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

   ① Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program. If you install a cluster on infrastructure that you provision, you must provide this key to your cluster’s machines.

2.10.6. Creating the installation files for AWS

To install OpenShift Container Platform on Amazon Web Services (AWS) using user-provisioned infrastructure, you must generate the files that the installation program needs to deploy your cluster and modify them so that the cluster creates only the machines that it will use. You generate and customize the install-config.yaml file, Kubernetes manifests, and Ignition config files. You also have the option to first set up a separate var partition during the preparation phases of installation.

2.10.6.1. Optional: Creating a separate /var partition
It is recommended that disk partitioning for OpenShift Container Platform be left to the installer. However, there are cases where you might want to create separate partitions in a part of the filesystem that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the /var partition or a subdirectory of /var. For example:

- /var/lib/containers: Holds container-related content that can grow as more images and containers are added to a system.
- /var/lib/etcd: Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.
- /var: Holds data that you might want to keep separate for purposes such as auditing.

Storing the contents of a /var directory separately makes it easier to grow storage for those areas as needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

Because /var must be in place before a fresh installation of Red Hat Enterprise Linux CoreOS (RHCOS), the following procedure sets up the separate /var partition by creating a machine config that is inserted during the openshift-install preparation phases of an OpenShift Container Platform installation.

**IMPORTANT**

If you follow the steps to create a separate /var partition in this procedure, it is not necessary to create the Kubernetes manifest and Ignition config files again as described later in this section.

**Procedure**

1. Create a directory to hold the OpenShift Container Platform installation files:

   ```
   $ mkdir $HOME/clusterconfig
   ```

2. Run openshift-install to create a set of files in the manifest and openshift subdirectories. Answer the system questions as you are prompted:

   ```
   $ openshift-install create manifests --dir $HOME/clusterconfig
   ```

**Example output**

? SSH Public Key ...
INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
INFO Consuming Install Config from target directory
INFO Manifests created in: $HOME/clusterconfig/manifests and $HOME/clusterconfig/openshift

3. Optional: Confirm that the installation program created manifests in the clusterconfig/openshift directory:

   ```
   $ ls $HOME/clusterconfig/openshift/
   ```
Example output

99_kubeadmin-password-secret.yaml
99_openshift-cluster-api_master-machines-0.yaml
99_openshift-cluster-api_master-machines-1.yaml
99_openshift-cluster-api_master-machines-2.yaml
...

4. Create a `MachineConfig` object and add it to a file in the `openshift` directory. For example, name the file `98-var-partition.yaml`, change the disk device name to the name of the storage device on the `worker` systems, and set the storage size as appropriate. This example places the `/var` directory on a separate partition:

```yaml
apiVersion: machineconfiguration.openshift.io/v1
kind: MachineConfig
metadata:
  labels:
    machineconfiguration.openshift.io/role: worker
  name: 98-var-partition
spec:
  config:
    ignition:
      version: 3.1.0
    storage:
      disks:
        - device: /dev/<device_name> ①
        partitions:
          - label: var
            startMiB: <partition_start_offset> ②
            sizeMiB: <partition_size> ③
      filesystems:
        - device: /dev/disk/by-partlabel/var
          path: /var
          format: xfs
    systemd:
      units:
        - name: var.mount ④
          enabled: true
          contents: |
            [Unit]
            Before=local-fs.target
            [Mount]
            What=/dev/disk/by-partlabel/var
            Where=/var
            Options=defaults,prjquota ⑤
            [Install]
            WantedBy=local-fs.target
```

① The storage device name of the disk that you want to partition.

② When adding a data partition to the boot disk, a minimum value of 25000 MiB (Mebibytes) is recommended. The root file system is automatically resized to fill all available space up to the specified offset. If no value is specified, or if the specified value is smaller than the recommended minimum, the resulting root file system will be too small, and future reinstalls of RHCOS might overwrite the beginning of the data partition.
The size of the data partition in mebibytes.

The name of the mount unit must match the directory specified in the `Where=` directive. For example, for a filesystem mounted on `/var/lib/containers`, the unit must be named `var-lib-containers.mount`.

The `prjquota` mount option must be enabled for filesystems used for container storage.

**NOTE**

When creating a separate `/var` partition, you cannot use different instance types for worker nodes, if the different instance types do not have the same device name.

5. Run `openshift-install` again to create Ignition configs from a set of files in the `manifest` and `openshift` subdirectories:

```bash
$ openshift-install create ignition-configs --dir $HOME/clusterconfig
$ ls $HOME/clusterconfig/
auth  bootstrap.ign  master.ign  metadata.json  worker.ign
```

Now you can use the Ignition config files as input to the installation procedures to install Red Hat Enterprise Linux CoreOS (RHCOS) systems.

### 2.10.6.2. Creating the installation configuration file

Generate and customize the installation configuration file that the installation program needs to deploy your cluster.

**Prerequisites**

- You obtained the OpenShift Container Platform installation program for user-provisioned infrastructure and the pull secret for your cluster.

- You checked that you are deploying your cluster to a region with an accompanying Red Hat Enterprise Linux CoreOS (RHCOS) AMI published by Red Hat. If you are deploying to a region that requires a custom AMI, such as an AWS GovCloud region, you must create the `install-config.yaml` file manually.

**Procedure**

1. Create the `install-config.yaml` file.

   a. Change to the directory that contains the installation program and run the following command:

   ```bash
   $ ./openshift-install create install-config --dir <installation_directory> ①
   ```

   ① For `<installation_directory>`, specify the directory name to store the files that the installation program creates.
IMPORTANT

Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

b. At the prompts, provide the configuration details for your cloud:

i. Optional: Select an SSH key to use to access your cluster machines.

NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

ii. Select aws as the platform to target.

iii. If you do not have an AWS profile stored on your computer, enter the AWS access key ID and secret access key for the user that you configured to run the installation program.

NOTE

The AWS access key ID and secret access key are stored in ~/.aws/credentials in the home directory of the current user on the installation host. You are prompted for the credentials by the installation program if the credentials for the exported profile are not present in the file. Any credentials that you provide to the installation program are stored in the file.

iv. Select the AWS region to deploy the cluster to.

v. Select the base domain for the Route 53 service that you configured for your cluster.

vi. Enter a descriptive name for your cluster.

vii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

2. Optional: Back up the install-config.yaml file.

IMPORTANT

The install-config.yaml file is consumed during the installation process. If you want to reuse the file, you must back it up now.

Additional resources

- See Configuration and credential file settings in the AWS documentation for more information about AWS profile and credential configuration.
2.10.6.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

Prerequisites

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the Proxy object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The Proxy object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

- If your cluster is on AWS, you added the `ec2.<region>.amazonaws.com`, `elasticloadbalancing.<region>.amazonaws.com`, and `s3.<region>.amazonaws.com` endpoints to your VPC endpoint. These endpoints are required to complete requests from the nodes to the AWS EC2 API. Because the proxy works on the container level, not the node level, you must route these requests to the AWS EC2 API through the AWS private network. Adding the public IP address of the EC2 API to your allowlist in your proxy server is not sufficient.

Procedure

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
     httpProxy: http://<username>:@<ip>:<port> ¹
     httpsProxy: https://<username>:@<ip>:<port> ²
     noProxy: example.com ³
   additionalTrustBundle: |
      -----BEGIN CERTIFICATE-----
      <MY_TRUSTED_CA_CERT>
      -----END CERTIFICATE-----
      ...
   
   ¹ A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.
   ² A proxy URL to use for creating HTTPS connections outside the cluster.
   ³ A comma-separated list of destination domain names, IP addresses, or other network hosts.
   ```
3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For

4 If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace to hold the additional CA certificates. If you provide `additionalTrustBundle` and at least one proxy setting, the `Proxy` object is configured to reference the `user-ca-bundle` config map in the `trustedCA` field. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges the contents specified for the `trustedCA` parameter with the RHCOS trust bundle. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

```
NOTE

The installation program does not support the proxy `readinessEndpoints` field.
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

```
NOTE

Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.
```

### 2.10.6.4. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to make its machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to create the cluster.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

**Prerequisites**

- You obtained the OpenShift Container Platform installation program.
You created the `install-config.yaml` installation configuration file.

**Procedure**

1. Change to the directory that contains the installation program and generate the Kubernetes manifests for the cluster:

   ```
   $ ./openshift-install create manifests --dir <installation_directory>
   ```

   **Example output**

   INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
   INFO Consuming Install Config from target directory
   INFO Manifests created in: install_dir/manifests and install_dir/openshift

   For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.

2. Remove the Kubernetes manifest files that define the control plane machines:

   ```
   $ rm -f <installation_directory>/openshift/99_openshift-cluster-api_master-machines*.yaml
   ```

   By removing these files, you prevent the cluster from automatically generating control plane machines.

3. Remove the Kubernetes manifest files that define the worker machines:

   ```
   $ rm -f <installation_directory>/openshift/99_openshift-cluster-api_worker-machineset*.yaml
   ```

   Because you create and manage the worker machines yourself, you do not need to initialize these machines.

4. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:

   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.
   
   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.
   
   c. Save and exit the file.

5. Optional: If you do not want the Ingress Operator to create DNS records on your behalf, remove the `privateZone` and `publicZone` sections from the `<installation_directory>/manifests/cluster-dns-02-config.yml` DNS configuration file:

   ```yml
   apiVersion: config.openshift.io/v1
   kind: DNS
   metadata:
     creationTimestamp: null
   name: cluster
   spec:
     baseDomain: example.openshift.com
   ```
6. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

```
$ ./openshift-install create ignition-configs --dir <installation_directory>
```

For `<installation_directory>`, specify the same installation directory.

The following files are generated in the directory:

```
├── auth
│   ├── kubeadmin-password
│   │   └── kubeconfig
│   └── bootstrap.ign
└── master.ign
    ├── metadata.json
    └── worker.ign
```

### 2.10.7. Extracting the infrastructure name

The Ignition config files contain a unique cluster identifier that you can use to uniquely identify your cluster in Amazon Web Services (AWS). The infrastructure name is also used to locate the appropriate AWS resources during an OpenShift Container Platform installation. The provided CloudFormation templates contain references to this infrastructure name, so you must extract it.

**Prerequisites**

- You obtained the OpenShift Container Platform installation program and the pull secret for your cluster.
- You generated the Ignition config files for your cluster.
- You installed the `jq` package.

**Procedure**

- To extract and view the infrastructure name from the Ignition config file metadata, run the following command:

```
$ jq -r .infraID <installation_directory>/metadata.json
```
For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

**Example output**

```
openshift-vw9j6
```

The output of this command is your cluster name and a random string.

### 2.10.8. Creating a VPC in AWS

You must create a Virtual Private Cloud (VPC) in Amazon Web Services (AWS) for your OpenShift Container Platform cluster to use. You can customize the VPC to meet your requirements, including VPN and route tables.

You can use the provided CloudFormation template and a custom parameter file to create a stack of AWS resources that represent the VPC.

**NOTE**

If you do not use the provided CloudFormation template to create your AWS infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

**Prerequisites**

- You configured an AWS account.
- You added your AWS keys and region to your local AWS profile by running `aws configure`.
- You generated the Ignition config files for your cluster.

**Procedure**

1. Create a JSON file that contains the parameter values that the template requires:

```
[
  {
    "ParameterKey": "VpcCidr", 1
    "ParameterValue": "10.0.0.0/16" 2
  },
  {
    "ParameterKey": "AvailabilityZoneCount", 3
    "ParameterValue": "1" 4
  },
  {
    "ParameterKey": "SubnetBits", 5
    "ParameterValue": "12" 6
  }
]
```
1. The CIDR block for the VPC.

2. Specify a CIDR block in the format \texttt{x.x.x.x/16-24}.

3. The number of availability zones to deploy the VPC in.

4. Specify an integer between 1 and 3.

5. The size of each subnet in each availability zone.

6. Specify an integer between 5 and 13, where 5 is /27 and 13 is /19.

2. Copy the template from the \textbf{CloudFormation template for the VPC} section of this topic and save it as a YAML file on your computer. This template describes the VPC that your cluster requires.

3. Launch the CloudFormation template to create a stack of AWS resources that represent the VPC:

   \begin{center}
   \textbf{IMPORTANT}
   
   You must enter the command on a single line.
   \end{center}

   \begin{verbatim}
   $ aws cloudformation create-stack --stack-name <name>  
   --template-body file://<template>.yaml  
   --parameters file://<parameters>.json
   \end{verbatim}

   \begin{itemize}
   \item \texttt{<name>} is the name for the CloudFormation stack, such as \texttt{cluster-vpc}. You need the name of this stack if you remove the cluster.
   \item \texttt{<template>} is the relative path to and name of the CloudFormation template YAML file that you saved.
   \item \texttt{<parameters>} is the relative path to and name of the CloudFormation parameters JSON file.
   \end{itemize}

4. Confirm that the template components exist:

   \begin{verbatim}
   $ aws cloudformation describe-stacks --stack-name <name>
   \end{verbatim}

   After the \texttt{StackStatus} displays \texttt{CREATE_COMPLETE}, the output displays values for the following parameters. You must provide these parameter values to the other CloudFormation templates that you run to create your cluster:

   \begin{table}[h]
   \centering
   \begin{tabular}{|c|p{8cm}|}
   \hline
   \textbf{VpcId} & The ID of your VPC. \\
   \hline
   \end{tabular}
   \end{table}
PublicSubnetIds
The IDs of the new public subnets.

PrivateSubnetIds
The IDs of the new private subnets.

2.10.8.1. CloudFormation template for the VPC

You can use the following CloudFormation template to deploy the VPC that you need for your OpenShift Container Platform cluster.

Example 2.25. CloudFormation template for the VPC

AWSTemplateFormatVersion: 2010-09-09
Description: Template for Best Practice VPC with 1-3 AZs

Parameters:
  VpcCidr:
    AllowedPattern: ^((\[0-9]\[1-9]\[0-9]\[1-9]\[0-9]\[2][0-4]\[0-9]\[2][0-5]\])\./3){1-3}((\[0-9]\[1-9]\[0-9]\[0-9]\[2][0-4]\[0-9]\[2][0-5]\])\./24){1-3}((\[0-9]\[1-9]\[0-9]\[0-9]\[2][0-4]\[0-9]\[2][0-5]\])\./[1-9]\[6-9]\[2][0-4]\))$
    ConstraintDescription: CIDR block parameter must be in the form x.x.x.x/16-24.
    Default: 10.0.0.0/16
    Description: CIDR block for VPC.
    Type: String
  AvailabilityZoneCount:
    ConstraintDescription: "The number of availability zones. (Min: 1, Max: 3)"
    MinValue: 1
    MaxValue: 3
    Default: 1
    Description: "How many AZs to create VPC subnets for. (Min: 1, Max: 3)"
    Type: Number
  SubnetBits:
    ConstraintDescription: CIDR block parameter must be in the form x.x.x.x/19-27.
    MinValue: 5
    MaxValue: 13
    Default: 12
    Description: "Size of each subnet to create within the availability zones. (Min: 5 = /27, Max: 13 = /19)"
    Type: Number

Metadata:
AWS::CloudFormation::Interface:
  ParameterGroups:
  - Label:
    - default: "Network Configuration"
      Parameters:
      - VpcCidr
      - SubnetBits
      - Label:
        - default: "Availability Zones"
          Parameters:
          - AvailabilityZoneCount

You can view details about the CloudFormation stacks that you create by navigating to the AWS CloudFormation console.

### 2.10.9. Creating networking and load balancing components in AWS

You must configure networking and classic or network load balancing in Amazon Web Services (AWS) that your OpenShift Container Platform cluster can use.

You can use the provided CloudFormation template and a custom parameter file to create a stack of AWS resources. The stack represents the networking and load balancing components that your OpenShift Container Platform cluster requires. The template also creates a hosted zone and subnet tags.

You can run the template multiple times within a single Virtual Private Cloud (VPC).

**NOTE**

If you do not use the provided CloudFormation template to create your AWS infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.
Prerequisites

- You configured an AWS account.
- You added your AWS keys and region to your local AWS profile by running `aws configure`.
- You generated the Ignition config files for your cluster.
- You created and configured a VPC and associated subnets in AWS.

Procedure

1. Obtain the hosted zone ID for the Route 53 base domain that you specified in the `install-config.yaml` file for your cluster. You can obtain details about your hosted zone by running the following command:

   ```bash
   $ aws route53 list-hosted-zones-by-name --dns-name <route53_domain>
   ```

   For the `<route53_domain>`, specify the Route 53 base domain that you used when you generated the `install-config.yaml` file for the cluster.

Example output

   ```
   mycluster.example.com. False 100
   HOSTEDZONES 65F8F38E-2268-B835-E15C-AB55336FCBFA
   /hostedzone/Z21IXYZABCZ2A4 mycluster.example.com. 10
   ```

   In the example output, the hosted zone ID is `Z21IXYZABCZ2A4`.

2. Create a JSON file that contains the parameter values that the template requires:

   ```json
   [
   {
     "ParameterKey": "ClusterName", 1
     "ParameterValue": "mycluster" 2
   },
   {
     "ParameterKey": "InfrastructureName", 3
     "ParameterValue": "mycluster-<random_string>" 4
   },
   {
     "ParameterKey": "HostedZoneld", 5
     "ParameterValue": "<random_string>" 6
   },
   {
     "ParameterKey": "HostedZoneName", 7
     "ParameterValue": "example.com" 8
   },
   {
     "ParameterKey": "PublicSubnets", 9
     "ParameterValue": "subnet-<random_string>" 10
   }]
   ```
A short, representative cluster name to use for hostnames, etc.

Specify the cluster name that you used when you generated the `install-config.yaml` file for the cluster.

The name for your cluster infrastructure that is encoded in your Ignition config files for the cluster.

Specify the infrastructure name that you extracted from the Ignition config file metadata, which has the format `<cluster-name>-<random-string>`.

The Route 53 public zone ID to register the targets with.

Specify the Route 53 public zone ID, which as a format similar to `Z21IXYZABCZ2A4`. You can obtain this value from the AWS console.

The Route 53 base domain that you used when you generated the `install-config.yaml` file for the cluster. Do not include the trailing period (.) that is displayed in the AWS console.

The public subnets that you created for your VPC.

Specify the `PublicSubnetIds` value from the output of the CloudFormation template for the VPC.

The private subnets that you created for your VPC.

Specify the `PrivateSubnetIds` value from the output of the CloudFormation template for the VPC.

The VPC that you created for the cluster.

Specify the `VpcId` value from the output of the CloudFormation template for the VPC.

3. Copy the template from the CloudFormation template for the network and load balancers section of this topic and save it as a YAML file on your computer. This template describes the networking and load balancing objects that your cluster requires.

**IMPORTANT**

If you are deploying your cluster to an AWS government region, you must update the `InternalApiServerRecord` in the CloudFormation template to use **CNAME** records. Records of type **ALIAS** are not supported for AWS government regions.
4. Launch the CloudFormation template to create a stack of AWS resources that provide the networking and load balancing components:

**IMPORTANT**

You must enter the command on a single line.

```
$ aws cloudformation create-stack --stack-name <name>  
  --template-body file://<template>.yaml  
  --parameters file://<parameters>.json  
  --capabilities CAPABILITY_NAMED_IAM
```

1. `<name>` is the name for the CloudFormation stack, such as `cluster-dns`. You need the name of this stack if you remove the cluster.

2. `<template>` is the relative path to and name of the CloudFormation template YAML file that you saved.

3. `<parameters>` is the relative path to and name of the CloudFormation parameters JSON file.

4. You must explicitly declare the `CAPABILITY_NAMED_IAM` capability because the provided template creates some `AWS::IAM::Role` resources.

**Example output**

```
arn:aws:cloudformation:us-east-1:269333783861:stack/cluster-dns/cd3e5de0-2fd4-11eb-5cf0-12be5c33a183
```

5. Confirm that the template components exist:

```
$ aws cloudformation describe-stacks --stack-name <name>
```

After the `StackStatus` displays `CREATE_COMPLETE`, the output displays values for the following parameters. You must provide these parameter values to the other CloudFormation templates that you run to create your cluster:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>

### Table

| **ApiServer** | Full hostname of the API server. |
| **DnsName** | |
| **RegisterN** | Lambda ARN useful to help register/deregister IP targets for these load balancers. |
| **lbIpTarget** | |
| **sLambda** | |
| **ExternalA** | ARN of external API target group. |
| **piTargetG** | |
| **roupArn** | |
| **InternalAp** | ARN of internal API target group. |
| **iTargetGr** | |
| **oupArn** | |
| **InternalSe** | ARN of internal service target group. |
| **rviceTarg** | |
| **etGroupA** | |
| **rn** | |

#### 2.10.9.1. CloudFormation template for the network and load balancers

You can use the following CloudFormation template to deploy the networking objects and load balancers that you need for your OpenShift Container Platform cluster.

**Example 2.26. CloudFormation template for the network and load balancers**

```yaml
AWSTemplateFormatVersion: 2010-09-09
Description: Template for OpenShift Cluster Network Elements (Route53 & LBs)

Parameters:
ClusterName:
  AllowedPattern: ^([a-zA-Z][a-zA-Z0-9-]{0,26})$
  MaxLength: 27
  MinLength: 1
  ConstraintDescription: Cluster name must be alphanumeric, start with a letter, and have a maximum of 27 characters.
  Description: A short, representative cluster name to use for host names and other identifying names.
  Type: String
InfrastructureName:
  AllowedPattern: ^([a-zA-Z][a-zA-Z0-9-]{0,26})$
  MaxLength: 27
  MinLength: 1
  ConstraintDescription: Infrastructure name must be alphanumeric, start with a letter, and have a maximum of 27 characters.
  Description: A short, unique cluster ID used to tag cloud resources and identify items owned or used by the cluster.
  Type: String
HostedZoneId:
  Description: The Route53 public zone ID to register the targets with, such as
```
Z21IXYZABCZ2A4.

Type: String
HostedZoneName:
  Description: The Route53 zone to register the targets with, such as example.com. Omit the trailing period.
  Type: String
  Default: "example.com"

PublicSubnets:
  Description: The internet-facing subnets.
  Type: List<AWS::EC2::Subnet::Id>

PrivateSubnets:
  Description: The internal subnets.
  Type: List<AWS::EC2::Subnet::Id>

VpcId:
  Description: The VPC-scoped resources will belong to this VPC.
  Type: AWS::EC2::VPC::Id

Metadata:
AWS::CloudFormation::Interface:
  ParameterGroups:
    - Label: default: "Cluster Information"
      Parameters:
        - ClusterName
        - InfrastructureName
    - Label: default: "Network Configuration"
      Parameters:
        - VpcId
        - PublicSubnets
        - PrivateSubnets
    - Label: default: "DNS"
      Parameters:
        - HostedZoneName
        - HostedZoneId

ParameterLabels:
  ClusterName:
    default: "Cluster Name"
  InfrastructureName:
    default: "Infrastructure Name"
  VpcId:
    default: "VPC ID"
  PublicSubnets:
    default: "Public Subnets"
  PrivateSubnets:
    default: "Private Subnets"
  HostedZoneName:
    default: "Public Hosted Zone Name"
  HostedZoneId:
    default: "Public Hosted Zone ID"

Resources:
ExtApiElb:
  Type: AWS::ElasticLoadBalancingV2::LoadBalancer
  Properties:
Name: \texttt{!Join ["-", [\texttt{!Ref InfrastructureName}, "ext"]]}

    Runtime: "python3.7"
    Timeout: 120

RegisterPublicSubnetTags:
    Type: Custom::SubnetRegister
    Properties:
        ServiceToken: !GetAtt RegisterSubnetTags.Arn
        InfrastructureName: !Ref InfrastructureName
        Subnets: !Ref PublicSubnets

RegisterPrivateSubnetTags:
    Type: Custom::SubnetRegister
    Properties:
        ServiceToken: !GetAtt RegisterSubnetTags.Arn
        InfrastructureName: !Ref InfrastructureName
        Subnets: !Ref PrivateSubnets

Outputs:
PrivateHostedZoneld:
    Description: Hosted zone ID for the private DNS, which is required for private records.
    Value: !Ref IntDns
ExternalApiLoadBalancerName:
    Description: Full name of the external API load balancer.
    Value: !GetAtt ExtApiElb.LoadBalancerFullName
InternalApiLoadBalancerName:
    Description: Full name of the internal API load balancer.
    Value: !GetAtt IntApiElb.LoadBalancerFullName
ApiServerDnsName:
    Description: Full hostname of the API server, which is required for the Ignition config files.
    Value: !Join [".", ["api-int", !Ref ClusterName, !Ref HostedZoneName]]
RegisterNlbIpTargetsLambda:
    Description: Lambda ARN useful to help register or deregister IP targets for these load
    balancers.
    Value: !GetAtt RegisterNlbIpTargets.Arn
ExternalApiTargetGroupArn:
    Description: ARN of the external API target group.
    Value: !Ref ExternalApiTargetGroup
InternalApiTargetGroupArn:
    Description: ARN of the internal API target group.
    Value: !Ref InternalApiTargetGroup
InternalServiceTargetGroupArn:
    Description: ARN of the internal service target group.
    Value: !Ref InternalServiceTargetGroup
IMPORTANT

If you are deploying your cluster to an AWS government region, you must update the `InternalApiServerRecord` to use `CNAME` records. Records of type `ALIAS` are not supported for AWS government regions. For example:

```
Type: CNAME
TTL: 10
ResourceRecords:
  - !GetAtt IntApiElb.DNSName
```

Additional resources

- You can view details about the CloudFormation stacks that you create by navigating to the AWS CloudFormation console.
- You can view details about your hosted zones by navigating to the AWS Route 53 console.
- See Listing public hosted zones in the AWS documentation for more information about listing public hosted zones.

2.10.10. Creating security group and roles in AWS

You must create security groups and roles in Amazon Web Services (AWS) for your OpenShift Container Platform cluster to use.

You can use the provided CloudFormation template and a custom parameter file to create a stack of AWS resources. The stack represents the security groups and roles that your OpenShift Container Platform cluster requires.

NOTE

If you do not use the provided CloudFormation template to create your AWS infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

Prerequisites

- You configured an AWS account.
- You added your AWS keys and region to your local AWS profile by running `aws configure`.
- You generated the Ignition config files for your cluster.
- You created and configured a VPC and associated subnets in AWS.

Procedure

1. Create a JSON file that contains the parameter values that the template requires:

```json
[
  {
    "ParameterKey": "InfrastructureName"
  }
]
The name for your cluster infrastructure that is encoded in your Ignition config files for the cluster.

Specify the infrastructure name that you extracted from the Ignition config file metadata, which has the format `<cluster-name>-<random-string>`.

The CIDR block for the VPC.

Specify the CIDR block parameter that you used for the VPC that you defined in the form `x.x.x.x/16-24`.

The private subnets that you created for your VPC.

Specify the `PrivateSubnetIds` value from the output of the CloudFormation template for the VPC.

The VPC that you created for the cluster.

Specify the `VpcId` value from the output of the CloudFormation template for the VPC.

2. Copy the template from the CloudFormation template for security objects section of this topic and save it as a YAML file on your computer. This template describes the security groups and roles that your cluster requires.

3. Launch the CloudFormation template to create a stack of AWS resources that represent the security groups and roles:

```
$ aws cloudformation create-stack --stack-name <name>  
    --template-body file://<template>.yaml  
    --parameters file://<parameters>.json  
    --capabilities CAPABILITY_NAMED_IAM
```

You must enter the command on a single line.
<name> is the name for the CloudFormation stack, such as cluster-sec. You need the name of this stack if you remove the cluster.

<template> is the relative path to and name of the CloudFormation template YAML file that you saved.

<parameters> is the relative path to and name of the CloudFormation parameters JSON file.

You must explicitly declare the CAPABILITY_NAMED_IAM capability because the provided template creates some AWS::IAM::Role and AWS::IAM::InstanceProfile resources.

Example output

```
arn:aws:cloudformation:us-east-1:269333783861:stack/cluster-sec/03bd4210-2ed7-11eb-6d7a-13fc0b61e9db
```

4. Confirm that the template components exist:

```
$ aws cloudformation describe-stacks --stack-name <name>
```

After the StackStatus displays CREATE_COMPLETE, the output displays values for the following parameters. You must provide these parameter values to the other CloudFormation templates that you run to create your cluster:

<table>
<thead>
<tr>
<th>MasterSecurityGroupId</th>
<th>Master Security Group ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>WorkerSecurityGroupId</td>
<td>Worker Security Group ID</td>
</tr>
<tr>
<td>MasterInstanceProfile</td>
<td>Master IAM Instance Profile</td>
</tr>
<tr>
<td>WorkerInstanceProfile</td>
<td>Worker IAM Instance Profile</td>
</tr>
</tbody>
</table>

2.10.10.1. CloudFormation template for security objects

You can use the following CloudFormation template to deploy the security objects that you need for your OpenShift Container Platform cluster.

Example 2.27. CloudFormation template for security objects

```
AWSTemplateFormatVersion: 2010-09-09
Description: Template for OpenShift Cluster Security Elements (Security Groups & IAM)
```
Parameters:
InfrastructureName:
  AllowedPattern: ^([a-zA-Z][a-zA-Z0-9-]0,26)$
  MaxLength: 27
  MinLength: 1
  ConstraintDescription: Infrastructure name must be alphanumeric, start with a letter, and have a maximum of 27 characters.
  Description: A short, unique cluster ID used to tag cloud resources and identify items owned or used by the cluster.
  Type: String
VpcCidr:
  ConstraintDescription: CIDR block parameter must be in the form x.x.x.x/16-24.
  Default: 10.0.0.0/16
  Description: CIDR block for VPC.
  Type: String
VpcId:
  Description: The VPC-scoped resources will belong to this VPC.
  Type: AWS::EC2::VPC::Id
PrivateSubnets:
  Description: The internal subnets.
  Type: List<AWS::EC2::Subnet::Id>

Metadata:
AWS::CloudFormation::Interface:
  ParameterGroups:
  - Label: "Cluster Information"
    Parameters:
    - InfrastructureName
      - Label: "Network Configuration"
        Parameters:
        - VpcId
        - VpcCidr
        - PrivateSubnets
  ParameterLabels:
    InfrastructureName: "Infrastructure Name"
    VpcId: "VPC ID"
    VpcCidr: "VPC CIDR"
    PrivateSubnets: "Private Subnets"

Resources:
MasterSecurityGroup:
  Type: AWS::EC2::SecurityGroup

2.10.11. RHCOS AMIs for the AWS infrastructure

Red Hat provides Red Hat Enterprise Linux CoreOS (RHCOS) AMIs valid for the various Amazon Web Services (AWS) zones you can specify for your OpenShift Container Platform nodes.

NOTE

You can also install to regions that do not have a RHCOS AMI published by importing your own AMI.
### Table 2.31. RHCOS AMIs

</table>

2.10.11.1. AWS regions without a published RHCOS AMI

You can deploy an OpenShift Container Platform cluster to Amazon Web Services (AWS) regions without native support for a Red Hat Enterprise Linux CoreOS (RHCOS) Amazon Machine Image (AMI)
or the AWS software development kit (SDK). If a published AMI is not available for an AWS region, you can upload a custom AMI prior to installing the cluster. This is required if you are deploying your cluster to an AWS government region.

If you are deploying to a non-government region that does not have a published RHCOS AMI, and you do not specify a custom AMI, the installation program copies the us-east-1 AMI to the user account automatically. Then the installation program creates the control plane machines with encrypted EBS volumes using the default or user-specified Key Management Service (KMS) key. This allows the AMI to follow the same process workflow as published RHCOS AMIs.

A region without native support for an RHCOS AMI is not available to select from the terminal during cluster creation because it is not published. However, you can install to this region by configuring the custom AMI in the install-config.yaml file.

### 2.10.11.2. Uploading a custom RHCOS AMI in AWS

If you are deploying to a custom Amazon Web Services (AWS) region, you must upload a custom Red Hat Enterprise Linux CoreOS (RHCOS) Amazon Machine Image (AMI) that belongs to that region.

**Prerequisites**

- You configured an AWS account.
- You created an Amazon S3 bucket with the required IAM service role.
- You uploaded your RHCOS VMDK file to Amazon S3. The RHCOS VMDK file must be the highest version that is less than or equal to the OpenShift Container Platform version you are installing.
- You downloaded the AWS CLI and installed it on your computer. See Install the AWS CLI Using the Bundled Installer.

**Procedure**

1. Export your AWS profile as an environment variable:

   ```bash
   $ export AWS_PROFILE=<aws_profile> 1
   1 The AWS profile name that holds your AWS credentials, like govcloud.
   ```

2. Export the region to associate with your custom AMI as an environment variable:

   ```bash
   $ export AWS_DEFAULT_REGION=<aws_region> 1
   1 The AWS region, like us-gov-east-1.
   ```

3. Export the version of RHCOS you uploaded to Amazon S3 as an environment variable:

   ```bash
   $ export RHCOS_VERSION=<version> 1
   1 The RHCOS VMDK version, like 4.6.0.
   ```
4. Export the Amazon S3 bucket name as an environment variable:

```bash
$ export VMIMPORT_BUCKET_NAME=<s3_bucket_name>
```

5. Create the `containers.json` file and define your RHCOS VMDK file:

```bash
$ cat <<EOF > containers.json
{
   "Description": "rhcos-$(RHCOS_VERSION)-x86_64-aws.x86_64",
   "Format": "vmdk",
   "UserBucket": {
      "S3Bucket": "${VMIMPORT_BUCKET_NAME}",
      "S3Key": "rhcos-$(RHCOS_VERSION)-x86_64-aws.x86_64.vmdk"
   }
}
EOF
```

6. Import the RHCOS disk as an Amazon EBS snapshot:

```bash
$ aws ec2 import-snapshot --region ${AWS_DEFAULT_REGION} \
   --description "<description>" \
   --disk-container "file://<file_path>/containers.json"
```

1. The description of your RHCOS disk being imported, like `rhcos-$(RHCOS_VERSION)-x86_64-aws.x86_64`.

2. The file path to the JSON file describing your RHCOS disk. The JSON file should contain your Amazon S3 bucket name and key.

7. Check the status of the image import:

```bash
$ watch -n 5 aws ec2 describe-import-snapshot-tasks --region ${AWS_DEFAULT_REGION}
```

Example output

```json
{
   "ImportSnapshotTasks": [
      {
         "Description": "rhcos-4.6.0-x86_64-aws.x86_64",
         "ImportTaskId": "import-snap-fh6i8uil",
         "SnapshotTaskDetail": {
            "Description": "rhcos-4.6.0-x86_64-aws.x86_64",
            "DiskImageSize": 819056640.0,
            "Format": "VMDK",
            "SnapshotId": "snap-06331325870076318",
            "Status": "completed",
            "UserBucket": {
               "S3Bucket": "external-images",
               "S3Key": "rhcos-4.6.0-x86_64-aws.x86_64.vmdk"
            }
         }
      }
   ]
}
```
Copy the SnapshotId to register the image.

8. Create a custom RHCOS AMI from the RHCOS snapshot:

```
$ aws ec2 register-image \
  --region ${AWS_DEFAULT_REGION} \
  --architecture x86_64 \
  --description "rhcos-${RHCOS_VERSION}-x86_64-aws.x86_64" \
  --ena-support \
  --name "rhcos-${RHCOS_VERSION}-x86_64-aws.x86_64" \
  --virtualization-type hvm \
  --root-device-name '/dev/xvda' \
  --block-device-mappings 'DeviceName=/dev/xvda,Ebs=\n  {DeleteOnTermination=true,SnapshotId=<snapshot_ID>}'
```

1. The RHCOS VMDK architecture type, like x86_64, s390x, or ppc64le.
2. The Description from the imported snapshot.
3. The name of the RHCOS AMI.
4. The SnapshotId from the imported snapshot.

To learn more about these APIs, see the AWS documentation for importing snapshots and creating EBS-backed AMIs.

### 2.10.12. Creating the bootstrap node in AWS

You must create the bootstrap node in Amazon Web Services (AWS) to use during OpenShift Container Platform cluster initialization.

You can use the provided CloudFormation template and a custom parameter file to create a stack of AWS resources. The stack represents the bootstrap node that your OpenShift Container Platform installation requires.

**NOTE**

If you do not use the provided CloudFormation template to create your bootstrap node, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

**Prerequisites**

- You configured an AWS account.
- You added your AWS keys and region to your local AWS profile by running `aws configure`.
- You generated the Ignition config files for your cluster.
You created and configured a VPC and associated subnets in AWS.

You created and configured DNS, load balancers, and listeners in AWS.

You created the security groups and roles required for your cluster in AWS.

Procedure

1. Provide a location to serve the `bootstrap.ign` Ignition config file to your cluster. This file is located in your installation directory. One way to do this is to create an S3 bucket in your cluster’s region and upload the Ignition config file to it.

   **IMPORTANT**

   The provided CloudFormation Template assumes that the Ignition config files for your cluster are served from an S3 bucket. If you choose to serve the files from another location, you must modify the templates.

   **IMPORTANT**

   If you are deploying to a region that has endpoints that differ from the AWS SDK, or you are providing your own custom endpoints, you must use a presigned URL for your S3 bucket instead of the `s3://` schema.

   **NOTE**

   The bootstrap Ignition config file does contain secrets, like X.509 keys. The following steps provide basic security for the S3 bucket. To provide additional security, you can enable an S3 bucket policy to allow only certain users, such as the OpenShift IAM user, to access objects that the bucket contains. You can avoid S3 entirely and serve your bootstrap Ignition config file from any address that the bootstrap machine can reach.

   a. Create the bucket:

   ```
   $ aws s3 mb s3://<cluster-name>-infra
   ```

   `<cluster-name>-infra` is the bucket name. When creating the `install-config.yaml` file, replace `<cluster-name>` with the name specified for the cluster.

   b. Upload the `bootstrap.ign` Ignition config file to the bucket:

   ```
   $ aws s3 cp <installation_directory>/bootstrap.ign s3://<cluster-name>-infra
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   c. Verify that the file uploaded:

   ```
   $ aws s3 ls s3://<cluster-name>-infra/
   ```
Example output

```
2019-04-03 16:15:16    314878 bootstrap.ign
```

2. Create a JSON file that contains the parameter values that the template requires:

```
[
    {
        "ParameterKey": "InfrastructureName",  
        "ParameterValue": "mycluster-<random_string>"
    },
    {
        "ParameterKey": "RhcosAmi",
        "ParameterValue": "ami-<random_string>"
    },
    {
        "ParameterKey": "AllowedBootstrapSshCidr",
        "ParameterValue": "0.0.0.0/0"
    },
    {
        "ParameterKey": "PublicSubnet",
        "ParameterValue": "subnet-<random_string>"
    },
    {
        "ParameterKey": "MasterSecurityGroupId",
        "ParameterValue": "sg-<random_string>"
    },
    {
        "ParameterKey": "VpcId",
        "ParameterValue": "vpc-<random_string>"
    },
    {
        "ParameterKey": "BootstrapIgnitionLocation",
        "ParameterValue": "s3://<bucket_name>/bootstrap.ign"
    },
    {
        "ParameterKey": "AutoRegisterELB",
        "ParameterValue": "yes"
    },
    {
        "ParameterKey": "RegisterNlbIpTargetsLambdaArn",
        "ParameterValue": "arn:aws:lambda:<region>:<account_number>:function:<dns_stack_name>-RegisterNlbIpTargets-<random_string>"
    },
    {
        "ParameterKey": "ExternalApiTargetGroupArn",
        "ParameterValue": "arn:aws:elasticloadbalancing:<region>:<account_number>:targetgroup/<dns_stack_name>-Exter-<random_string>"
    },
    {
        "ParameterKey": "InternalApiTargetGroupArn",
        "ParameterValue": "arn:aws:elasticloadbalancing:<region>:
```
The name for your cluster infrastructure that is encoded in your Ignition config files for the cluster.

Specify the infrastructure name that you extracted from the Ignition config file metadata, which has the format `<cluster-name>-<random-string>`.

Current Red Hat Enterprise Linux CoreOS (RHCOS) AMI to use for the bootstrap node.

Specify a valid `AWS::EC2::Image::Id` value.

CIDR block to allow SSH access to the bootstrap node.

Specify a CIDR block in the format `x.x.x.x/16-24`.

The public subnet that is associated with your VPC to launch the bootstrap node into.

Specify the `PublicSubnetIds` value from the output of the CloudFormation template for the VPC.

The master security group ID (for registering temporary rules)

Specify the `MasterSecurityGroupId` value from the output of the CloudFormation template for the security group and roles.

The VPC created resources will belong to.

Specify the `VpcId` value from the output of the CloudFormation template for the VPC.

Location to fetch bootstrap Ignition config file from.

Specify the S3 bucket and file name in the form `s3://<bucket_name>/bootstrap.ign`.

Whether or not to register a network load balancer (NLB).

Specify `yes` or `no`. If you specify `yes`, you must provide a Lambda Amazon Resource Name (ARN) value.

The ARN for NLB IP target registration lambda group.

Specify the `RegisterNlbIpTargetsLambda` value from the output of the CloudFormation template for DNS and load balancing. Use `arn:aws:us-gov` if deploying the cluster to an AWS GovCloud region.

The ARN for external API load balancer target group.

Specify the `ExternalApiTargetGroupArn` value from the output of the CloudFormation template for DNS and load balancing. Use `arn:aws:us-gov` if deploying the cluster to an AWS GovCloud region.
The ARN for internal API load balancer target group.

Specify the InternalApiTargetGroupArn value from the output of the CloudFormation template for DNS and load balancing. Use arn:aws-us-gov if deploying the cluster to an AWS GovCloud region.

The ARN for internal service load balancer target group.

Specify the InternalServiceTargetGroupArn value from the output of the CloudFormation template for DNS and load balancing. Use arn:aws-us-gov if deploying the cluster to an AWS GovCloud region.

3. Copy the template from the CloudFormation template for the bootstrap machine section of this topic and save it as a YAML file on your computer. This template describes the bootstrap machine that your cluster requires.

4. Launch the CloudFormation template to create a stack of AWS resources that represent the bootstrap node:

   **IMPORTANT**
   You must enter the command on a single line.

   ```bash
   $ aws cloudformation create-stack --stack-name <name>  
       --template-body file://<template>.yaml  
       --parameters file://<parameters>.json  
       --capabilities CAPABILITY_NAMED_IAM
   
   <name> is the name for the CloudFormation stack, such as cluster-bootstrap. You need the name of this stack if you remove the cluster.

   <template> is the relative path to and name of the CloudFormation template YAML file that you saved.

   <parameters> is the relative path to and name of the CloudFormation parameters JSON file.

   You must explicitly declare the CAPABILITY_NAMED_IAM capability because the provided template creates some AWS::IAM::Role and AWS::IAM::InstanceProfile resources.

   Example output

   arn:aws:cloudformation:us-east-1:269333783861:stack/cluster-bootstrap/12944486-2add-11eb-9dee-12dace8e3a83

5. Confirm that the template components exist:

   ```bash
   $ aws cloudformation describe-stacks --stack-name <name>
   ```
After the StackStatus displays \texttt{CREATE\_COMPLETE}, the output displays values for the following parameters. You must provide these parameter values to the other CloudFormation templates that you run to create your cluster:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap InstanceId</td>
<td>The bootstrap Instance ID.</td>
</tr>
<tr>
<td>Bootstrap PublicIp</td>
<td>The bootstrap node public IP address.</td>
</tr>
<tr>
<td>Bootstrap PrivateIp</td>
<td>The bootstrap node private IP address.</td>
</tr>
</tbody>
</table>

### 2.10.12.1. CloudFormation template for the bootstrap machine

You can use the following CloudFormation template to deploy the bootstrap machine that you need for your OpenShift Container Platform cluster.

#### Example 2.28. CloudFormation template for the bootstrap machine

```yaml
AWSTemplateFormatVersion: 2010-09-09
Description: Template for OpenShift Cluster Bootstrap (EC2 Instance, Security Groups and IAM)

Parameters:
  InfrastructureName:
    AllowedPattern: ^([a-zA-Z][a-zA-Z0-9-]{0,26})$
    MaxLength: 27
    MinLength: 1
    ConstraintDescription: Infrastructure name must be alphanumeric, start with a letter, and have a maximum of 27 characters.
    Type: String
  RhcosAmi:
    Description: Current Red Hat Enterprise Linux CoreOS AMI to use for bootstrap.
    Type: AWS::EC2::Image::Id
  AllowedBootstrapSshCidr:
    AllowedPattern: ^((\[0-9]\[1-9]\[0-9][2][0-4]\[0-9][0-5]\(\[3][0-9]\[1-9][0-9][0-9][2][0-4]\[0-9][0-5]\(\[3][0-9]\[1-9][0-9][0-9][2][0-4]\[0-9][0-5]\%\[0-32].$\)
    ConstraintDescription: CIDR block parameter must be in the form x.x.x.x/0-32.
    Default: 0.0.0.0/0
    Description: CIDR block to allow SSH access to the bootstrap node.
    Type: String
  PublicSubnet:
    Description: The public subnet to launch the bootstrap node into.
    Type: AWS::EC2::Subnet::Id
  MasterSecurityGroupId:
    Description: The master security group ID for registering temporary rules.
    Type: AWS::EC2::SecurityGroup::Id
  VpcId:
    Description: The VPC-scoped resources will belong to this VPC.
    Type: AWS::EC2::VPC::Id
  BootstrapIgnitionLocation:
    Default: s3://my-s3-bucket/bootstrap.ign
```
Description: Ignition config file location.
Type: String
AutoRegisterELB:
  Default: "yes"
  AllowedValues:
  - "yes"
  - "no"
Description: Do you want to invoke NLB registration, which requires a Lambda ARN parameter?
Type: String
RegisterNlbIpTargetsLambdaArn:
  Description: ARN for NLB IP target registration lambda.
  Type: String
ExternalApiTargetGroupArn:
  Description: ARN for external API load balancer target group.
  Type: String
InternalApiTargetGroupArn:
  Description: ARN for internal API load balancer target group.
  Type: String

You can view details about the CloudFormation stacks that you create by navigating to the AWS CloudFormation console.

See RHCOS AMIs for the AWS infrastructure for details about the Red Hat Enterprise Linux CoreOS (RHCOS) AMIs for the AWS zones.

2.10.13. Creating the control plane machines in AWS

You must create the control plane machines in Amazon Web Services (AWS) that your cluster will use.

You can use the provided CloudFormation template and a custom parameter file to create a stack of AWS resources that represent the control plane nodes.

IMPORTANT

The CloudFormation template creates a stack that represents three control plane nodes.

NOTE

If you do not use the provided CloudFormation template to create your control plane nodes, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

Prerequisites

- You configured an AWS account.
- You added your AWS keys and region to your local AWS profile by running `aws configure`.
- You generated the Ignition config files for your cluster.
- You created and configured a VPC and associated subnets in AWS.
- You created and configured DNS, load balancers, and listeners in AWS.
- You created the security groups and roles required for your cluster in AWS.
- You created the bootstrap machine.
Procedure

1. Create a JSON file that contains the parameter values that the template requires:

```json
[
  {
    "ParameterKey": "InfrastructureName", 1
    "ParameterValue": "mycluster-<random_string>" 2
  },
  {
    "ParameterKey": "RhcosAmi", 3
    "ParameterValue": "ami-<random_string>" 4
  },
  {
    "ParameterKey": "AutoRegisterDNS", 5
    "ParameterValue": "yes" 6
  },
  {
    "ParameterKey": "PrivateHostedZoneId", 7
    "ParameterValue": "<random_string>" 8
  },
  {
    "ParameterKey": "PrivateHostedZoneName", 9
    "ParameterValue": "mycluster.example.com" 10
  },
  {
    "ParameterKey": "Master0Subnet", 11
    "ParameterValue": "subnet-<random_string>" 12
  },
  {
    "ParameterKey": "Master1Subnet", 13
    "ParameterValue": "subnet-<random_string>" 14
  },
  {
    "ParameterKey": "Master2Subnet", 15
    "ParameterValue": "subnet-<random_string>" 16
  },
  {
    "ParameterKey": "MasterSecurityGroupId", 17
    "ParameterValue": "sg-<random_string>" 18
  },
  {
    "ParameterKey": "IgnitionLocation", 19
    "ParameterValue": "https://api-int.<cluster_name>.<domain_name>:22623/config/master" 20
  },
  {
    "ParameterKey": "CertificateAuthorities", 21
    "ParameterValue": "data:text/plain;charset=utf-8;base64,ABC...xYz=" 22
  },
  {
    "ParameterKey": "MasterInstanceProfileName", 23
    "ParameterValue": "<roles_stack>-MasterInstanceProfile-<random_string>" 24
  }
]```
The name for your cluster infrastructure that is encoded in your Ignition config files for the cluster.

Specify the infrastructure name that you extracted from the Ignition config file metadata, which has the format `<cluster-name>-<random-string>.

Current Red Hat Enterprise Linux CoreOS (RHCOS) AMI to use for the control plane machines.

Specify an AWS::EC2::Image::Id value.

Whether or not to perform DNS etcd registration.

Specify yes or no. If you specify yes, you must provide hosted zone information.

The Route 53 private zone ID to register the etcd targets with.

Specify the PrivateHostedZoneId value from the output of the CloudFormation template for DNS and load balancing.

The Route 53 zone to register the targets with.

Specify `<cluster_name>.<domain_name>` where `<domain_name>` is the Route 53 base domain that you used when you generated `install-config.yaml` file for the cluster. Do not include the trailing period (.) that is displayed in the AWS console.
A subnet, preferably private, to launch the control plane machines on.

Specify a subnet from the **PrivateSubnets** value from the output of the CloudFormation template for DNS and load balancing.

The master security group ID to associate with control plane nodes (also known as the master nodes).

Specify the **MasterSecurityGroupId** value from the output of the CloudFormation template for the security group and roles.

The location to fetch control plane Ignition config file from.

Specify the generated Ignition config file location, https://api-int.<cluster_name>.<domain_name>:22623/config/master.

The base64 encoded certificate authority string to use.

Specify the value from the **master.ign** file that is in the installation directory. This value is the long string with the format `data:text/plain;charset=utf-8;base64,ABC...xYz==`.

The IAM profile to associate with control plane nodes.

Specify the **MasterInstanceProfile** parameter value from the output of the CloudFormation template for the security group and roles.

The type of AWS instance to use for the control plane machines.

Allowed values:

- m4.xlarge
- m4.2xlarge
- m4.4xlarge
- m4.8xlarge
- m4.10xlarge
- m4.16xlarge
- m5.xlarge
- m5.2xlarge
- m5.4xlarge
- m5.8xlarge
- m5.10xlarge
- m5.16xlarge
- m6i.xlarge
- c4.2xlarge
- c4.4xlarge
- c4.8xlarge
- r4.xlarge
- r4.2xlarge
- r4.4xlarge
- r4.8xlarge
- r4.16xlarge

**IMPORTANT**

If m4 instance types are not available in your region, such as with eu-west-3, specify an m5 type, such as m5.xlarge, instead.

2. Whether or not to register a network load balancer (NLB).
3. Specify **yes** or **no**. If you specify **yes**, you must provide a Lambda Amazon Resource Name (ARN) value.
4. The ARN for NLB IP target registration lambda group.
5. Specify the **RegisterNlbIpTargetsLambda** value from the output of the CloudFormation template for DNS and load balancing. Use **arn:aws-us-gov** if deploying the cluster to an AWS GovCloud region.
6. The ARN for external API load balancer target group.
7. Specify the **ExternalApiTargetGroupArn** value from the output of the CloudFormation template for DNS and load balancing. Use **arn:aws-us-gov** if deploying the cluster to an AWS GovCloud region.
8. The ARN for internal API load balancer target group.
9. Specify the **InternalApiTargetGroupArn** value from the output of the CloudFormation template for DNS and load balancing. Use **arn:aws-us-gov** if deploying the cluster to an AWS GovCloud region.
10. The ARN for internal service load balancer target group.
11. Specify the **InternalServiceTargetGroupArn** value from the output of the CloudFormation template for DNS and load balancing. Use **arn:aws-us-gov** if deploying the cluster to an AWS GovCloud region.

2. Copy the template from the CloudFormation template for control plane machines section of this topic and save it as a YAML file on your computer. This template describes the control plane machines that your cluster requires.
3. If you specified an m5 instance type as the value for **MasterInstanceType**, add that instance type to the **MasterInstanceType ALLOWED VALUES** parameter in the CloudFormation template.
4. Launch the CloudFormation template to create a stack of AWS resources that represent the control plane nodes:

**IMPORTANT**

You must enter the command on a single line.

```bash
$ aws cloudformation create-stack --stack-name <name>  
   --template-body file://<template>.yaml  
   --parameters file://<parameters>.json
```

1. `<name>` is the name for the CloudFormation stack, such as `cluster-control-plane`. You need the name of this stack if you remove the cluster.

2. `<template>` is the relative path to and name of the CloudFormation template YAML file that you saved.

3. `<parameters>` is the relative path to and name of the CloudFormation parameters JSON file.

**Example output**

```bash
arn:aws:cloudformation:us-east-1:269333783861:stack/cluster-control-plane/21c7e2b0-2ee2-11eb-c6f6-0aa34627df4b
```

**NOTE**

The CloudFormation template creates a stack that represents three control plane nodes.

5. Confirm that the template components exist:

```bash
$ aws cloudformation describe-stacks --stack-name <name>
```

### 2.10.13.1. CloudFormation template for control plane machines

You can use the following CloudFormation template to deploy the control plane machines that you need for your OpenShift Container Platform cluster.

**Example 2.29. CloudFormation template for control plane machines**

```yaml
AWSTemplateFormatVersion: 2010-09-09
Description: Template for OpenShift Cluster Node Launch (EC2 master instances)

Parameters:
  InfrastructureName:
    AllowedPattern: ^([a-zA-Z][a-zA-Z0-9-]{0,26})$
    MaxLength: 27
    MinLength: 1
    ConstraintDescription: Infrastructure name must be alphanumeric, start with a letter, and have a maximum of 27 characters.
```
Description: A short, unique cluster ID used to tag nodes for the kubelet cloud provider.
Type: String
RhcosAmi:
Description: Current Red Hat Enterprise Linux CoreOS AMI to use for bootstrap.
Type: AWS::EC2::Image::Id
AutoRegisterDNS:
Default: "yes"
AllowedValues:
- "yes"
- "no"
Description: Do you want to invoke DNS etcd registration, which requires Hosted Zone information?
Type: String
PrivateHostedZoneId:
Description: The Route53 private zone ID to register the etcd targets with, such as Z21IXYZABCZ2A4.
Type: String
PrivateHostedZoneName:
Description: The Route53 zone to register the targets with, such as cluster.example.com. Omit the trailing period.
Type: String
Master0Subnet:
Description: The subnets, recommend private, to launch the master nodes into.
Type: AWS::EC2::Subnet::Id
Master1Subnet:
Description: The subnets, recommend private, to launch the master nodes into.
Type: AWS::EC2::Subnet::Id
Master2Subnet:
Description: The subnets, recommend private, to launch the master nodes into.
Type: AWS::EC2::Subnet::Id
MasterSecurityGroupId:
Description: The master security group ID to associate with master nodes.
Type: AWS::EC2::SecurityGroup::Id
IgnitionLocation:
Default: https://api-int.$CLUSTER_NAME.$DOMAIN:22623/config/master
Description: Ignition config file location.
Type: String
CertificateAuthorities:
Default: data:text/plain;charset=utf-8;base64,ABC...xYz==
Description: Base64 encoded certificate authority string to use.
Type: String
MasterInstanceProfileName:
Description: IAM profile to associate with master nodes.
Type: String
MasterInstanceType:
Default: m5.xlarge
Type: String
AllowedValues:
- "m4.xlarge"
- "m4.2xlarge"
- "m4.4xlarge"
- "m4.10xlarge"
- "m4.16xlarge"
- "m5.xlarge"
- "m5.2xlarge"
- "m5.4xlarge"
AutoRegisterELB:
  Default: "yes"
  AllowedValues:
  - "yes"
  - "no"
  Description: Do you want to invoke NLB registration, which requires a Lambda ARN parameter?
  Type: String

RegisterNlbIpTargetsLambdaArn:
  Description: ARN for NLB IP target registration lambda. Supply the value from the cluster infrastructure or select "no" for AutoRegisterELB.
  Type: String

ExternalApiTargetGroupArn:
Description: ARN for external API load balancer target group. Supply the value from the cluster infrastructure or select "no" for AutoRegisterELB.

Type: String

InternalApiTargetGroupArn:
Description: ARN for internal API load balancer target group. Supply the value from the cluster infrastructure or select "no" for AutoRegisterELB.

Type: String

InternalServiceTargetGroupArn:
Description: ARN for internal service load balancer target group. Supply the value from the cluster infrastructure or select "no" for AutoRegisterELB.

Type: String

Etcd1Record:

You can create worker nodes in Amazon Web Services (AWS) for your cluster to use.

You can use the provided CloudFormation template and a custom parameter file to create a stack of AWS resources that represent a worker node.

**IMPORTANT**

The CloudFormation template creates a stack that represents one worker node. You must create a stack for each worker node.

**NOTE**

If you do not use the provided CloudFormation template to create your worker nodes, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

Additional resources

- You can view details about the CloudFormation stacks that you create by navigating to the AWS CloudFormation console.

2.10.14. Creating the worker nodes in AWS

You can view details about the CloudFormation stacks that you create by navigating to the AWS CloudFormation console.

Additional resources

- You can view details about the CloudFormation stacks that you create by navigating to the AWS CloudFormation console.

**Note**

If you do not use the provided CloudFormation template to create your worker nodes, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.
Prerequisites

- You configured an AWS account.
- You added your AWS keys and region to your local AWS profile by running `aws configure`.
- You generated the Ignition config files for your cluster.
- You created and configured a VPC and associated subnets in AWS.
- You created and configured DNS, load balancers, and listeners in AWS.
- You created the security groups and roles required for your cluster in AWS.
- You created the bootstrap machine.
- You created the control plane machines.

Procedure

1. Create a JSON file that contains the parameter values that the CloudFormation template requires:

   ```json
   [
   {
   "ParameterKey": "InfrastructureName", 1
   "ParameterValue": "mycluster-<random_string>" 2
   },
   {
   "ParameterKey": "RhcosAmi", 3
   "ParameterValue": "ami-<random_string>" 4
   },
   {
   "ParameterKey": "Subnet", 5
   "ParameterValue": "subnet-<random_string>" 6
   },
   {
   "ParameterKey": "WorkerSecurityGroupId", 7
   "ParameterValue": "sg-<random_string>" 8
   },
   {
   "ParameterKey": "IgnitionLocation", 9
   "ParameterValue": "https://api-int.<cluster_name>.<domain_name>:22623/config/worker" 10
   },
   {
   "ParameterKey": "CertificateAuthorities", 11
   "ParameterValue": "" 12
   },
   {
   "ParameterKey": "WorkerInstanceProfileName", 13
   "ParameterValue": "" 14
   },
   {  
   ```
The name for your cluster infrastructure that is encoded in your Ignition config files for the cluster.

Specify the infrastructure name that you extracted from the Ignition config file metadata, which has the format `<cluster-name>-<random-string>`.

Current Red Hat Enterprise Linux CoreOS (RHCOS) AMI to use for the worker nodes.

Specify an `AWS::EC2::Image::Id` value.

A subnet, preferably private, to launch the worker nodes on.

Specify a subnet from the `PrivateSubnets` value from the output of the CloudFormation template for DNS and load balancing.

The worker security group ID to associate with worker nodes.

Specify the `WorkerSecurityGroupId` value from the output of the CloudFormation template for the security group and roles.

The location to fetch bootstrap Ignition config file from.

Specify the generated Ignition config location, `https://api-int.<cluster_name>.<domain_name>:22623/config/worker`.

Base64 encoded certificate authority string to use.

Specify the value from the `worker.ign` file that is in the installation directory. This value is the long string with the format `data:text/plain;charset=utf-8;base64,ABC...xYz==`.

The IAM profile to associate with worker nodes.

Specify the `WorkerInstanceProfile` parameter value from the output of the CloudFormation template for the security group and roles.

The type of AWS instance to use for the control plane machines.

Allowed values:

- `m4.large`
- `m4.xlarge`
- `m4.2xlarge`
- `m4.4xlarge`
- `m4.8xlarge`
- `m4.10xlarge`
- `m4.16xlarge`
• m5.large
• m5.xlarge
• m5.2xlarge
• m5.4xlarge
• m5.8xlarge
• m5.10xlarge
• m5.16xlarge
• m6i.xlarge
• c4.2xlarge
• c4.4xlarge
• c4.8xlarge
• r4.large
• r4.xlarge
• r4.2xlarge
• r4.4xlarge
• r4.8xlarge
• r4.16xlarge

**IMPORTANT**

If m4 instance types are not available in your region, such as with eu-west-3, use m5 types instead.

2. Copy the template from the CloudFormation template for worker machines section of this topic and save it as a YAML file on your computer. This template describes the networking objects and load balancers that your cluster requires.

3. If you specified an m5 instance type as the value for WorkerInstanceType, add that instance type to the WorkerInstanceType.AllowedValues parameter in the CloudFormation template.

4. Launch the CloudFormation template to create a stack of AWS resources that represent a worker node:

**IMPORTANT**

You must enter the command on a single line.
$ aws cloudformation create-stack --stack-name <name>  
   --template-body file://<template>.yaml  
   --parameters file://<parameters>.json

1 <name> is the name for the CloudFormation stack, such as cluster-worker-1. You need the name of this stack if you remove the cluster.

2 <template> is the relative path to and name of the CloudFormation template YAML file that you saved.

3 <parameters> is the relative path to and name of the CloudFormation parameters JSON file.

Example output

NOTE

The CloudFormation template creates a stack that represents one worker node.

5. Confirm that the template components exist:

   $ aws cloudformation describe-stacks --stack-name <name>

6. Continue to create worker stacks until you have created enough worker machines for your cluster. You can create additional worker stacks by referencing the same template and parameter files and specifying a different stack name.

IMPORTANT

You must create at least two worker machines, so you must create at least two stacks that use this CloudFormation template.

2.10.14.1. CloudFormation template for worker machines

You can use the following CloudFormation template to deploy the worker machines that you need for your OpenShift Container Platform cluster.

Example 2.30. CloudFormation template for worker machines

AWSTemplateFormatVersion: 2010-09-09
Description: Template for OpenShift Cluster Node Launch (EC2 worker instance)

Parameters:
InfrastructureName:
   AllowedPattern: ^([a-zA-Z][a-zA-Z0-9-]{0,26})$
   MaxLength: 27
   MinLength: 1
   ConstraintDescription: Infrastructure name must be alphanumeric, start with a letter, and have a maximum of 27 characters.
**Cluster ID**

Description: A short, unique cluster ID used to tag nodes for the kubelet cloud provider.
Type: String

**RhcosAmi:**

Description: Current Red Hat Enterprise Linux CoreOS AMI to use for bootstrap.
Type: AWS::EC2::Image::Id

**Subnet:**

Description: The subnets, recommend private, to launch the master nodes into.
Type: AWS::EC2::Subnet::Id

**WorkerSecurityGroupId:**

Description: The master security group ID to associate with master nodes.
Type: AWS::EC2::SecurityGroup::Id

**IgnitionLocation:**

Default: https://api-int.$CLUSTER_NAME.$DOMAIN:22623/config/worker
Description: Ignition config file location.
Type: String

**CertificateAuthorities:**

Default: data:text/plain;charset=utf-8;base64,ABC...xYz==
Description: Base64 encoded certificate authority string to use.
Type: String

**WorkerInstanceProfileName:**

Description: IAM profile to associate with master nodes.
Type: String

**WorkerInstanceType:**

Default: m5.large
Type: String

AllowedValues:
- "m4.large"
- "m4.xlarge"
- "m4.2xlarge"
- "m4.4xlarge"
- "m4.10xlarge"
- "m4.16xlarge"
- "m5.large"
- "m5.xlarge"
- "m5.2xlarge"
- "m5.4xlarge"
- "m5.8xlarge"
- "m5.12xlarge"
- "m5.16xlarge"
- "m5a.large"
- "m5a.xlarge"
- "m5a.2xlarge"
- "m5a.4xlarge"
- "m5a.8xlarge"
- "m5a.10xlarge"
- "m5a.16xlarge"
- "c4.large"
- "c4.xlarge"
- "c4.2xlarge"
- "c4.4xlarge"
- "c4.8xlarge"
- "c5.large"
- "c5.xlarge"
- "c5.2xlarge"
- "c5.4xlarge"
- "c5.9xlarge"
Metadata:
AWS::CloudFormation::Interface:
ParameterGroups:
- Label:
  default: "Cluster Information"
Parameters:

Outputs:
PrivateIP:
  Description: The compute node private IP address.
  Value: !GetAtt Worker0.PrivateIp
Additional resources

- You can view details about the CloudFormation stacks that you create by navigating to the AWS CloudFormation console.

2.10.15. Initializing the bootstrap sequence on AWS with user-provisioned infrastructure

After you create all of the required infrastructure in Amazon Web Services (AWS), you can start the bootstrap sequence that initializes the OpenShift Container Platform control plane.

Prerequisites

- You configured an AWS account.
- You added your AWS keys and region to your local AWS profile by running `aws configure`.
- You generated the Ignition config files for your cluster.
- You created and configured a VPC and associated subnets in AWS.
- You created and configured DNS, load balancers, and listeners in AWS.
- You created the security groups and roles required for your cluster in AWS.
- You created the bootstrap machine.
- You created the control plane machines.
- You created the worker nodes.

Procedure

1. Change to the directory that contains the installation program and start the bootstrap process that initializes the OpenShift Container Platform control plane:

   ```bash
   $ ./openshift-install wait-for bootstrap-complete --dir <installation_directory> \  
   --log-level=info
   ```

   1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.
   2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

Example output

```
INFO Waiting up to 20m0s for the Kubernetes API at https://api.mycluster.example.com:6443...
INFO API v1.19.0+9f84db3 up
INFO Waiting up to 30m0s for bootstrapping to complete...
INFO It is now safe to remove the bootstrap resources
INFO Time elapsed: 1s
```
If the command exits without a **FATAL** warning, your OpenShift Container Platform control plane has initialized.

**NOTE**

After the control plane initializes, it sets up the compute nodes and installs additional services in the form of Operators.

Additional resources

- See [Monitoring installation progress](#) for details about monitoring the installation, bootstrap, and control plane logs as an OpenShift Container Platform installation progresses.

- See [Gathering bootstrap node diagnostic data](#) for information about troubleshooting issues related to the bootstrap process.

- You can view details about the running instances that are created by using the [AWS EC2 console](#).

### 2.10.16. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) in order to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of **oc**, you cannot use it to complete all of the commands in OpenShift Container Platform 4.6. Download and install the new version of **oc**.

#### 2.10.16.1. Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (**oc**) binary on Linux by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.

3. Click **Download Now** next to the **OpenShift v4.6 Linux Client** entry and save the file.

4. Unpack the archive:

   ```
   $ tar xzvf <file>
   ```

5. Place the **oc** binary in a directory that is on your **PATH**.
   
   To check your **PATH**, execute the following command:

   ```
   $ echo $PATH
   ```

After you install the OpenShift CLI, it is available using the **oc** command:
2.10.16.2. Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version in the Version drop-down menu.
3. Click Download Now next to the OpenShift v4.6 Windows Client entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the oc binary to a directory that is on your PATH.
   To check your PATH, open the command prompt and execute the following command:

   ```
   C:\> path
   ```

After you install the OpenShift CLI, it is available using the oc command:

```
C:\> oc <command>
```

2.10.16.3. Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version in the Version drop-down menu.
3. Click Download Now next to the OpenShift v4.6 MacOSX Client entry and save the file.
4. Unpack and unzip the archive.
5. Move the oc binary to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:

   ```
   $ echo $PATH
   ```

After you install the OpenShift CLI, it is available using the oc command:

```
$ oc <command>
```

2.10.17. Logging in to the cluster by using the CLI
You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

   ```
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   **Note**: For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```
   $ oc whoami
   ```

   **Example output**
   
   `system:admin`

**2.10.18. Approving the certificate signing requests for your machines**

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

**Prerequisites**

- You added machines to your cluster.

**Procedure**

1. Confirm that the cluster recognizes the machines:

   ```
   $ oc get nodes
   ```

   **Example output**

   ```
   NAME      STATUS    ROLES   AGE  VERSION
   master-0  Ready     master  63m  v1.19.0
   master-1  Ready     master  63m  v1.19.0
   master-2  Ready     master  64m  v1.19.0
   ```

   The output lists all of the machines that you created.
NOTE
The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

   $ oc get csr

**Example output**

```
NAME        AGE     REQUESTOR                                                                   CONDITION
csr-8b2br   15m     system:serviceaccount:openshift-machine-config-operator:node-bootstrapper   Pending
csr-8vnps   15m     system:serviceaccount:openshift-machine-config-operator:node-bootstrapper   Pending
...
```

In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

   **NOTE**

   Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. Once the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the `machine approver` if the Kubelet requests a new certificate with identical parameters.

   **NOTE**

   For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the `oc exec`, `oc rsh`, and `oc logs` commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the `node-bootstrapper` service account in the `system:node` or `system:admin` groups, and confirm the identity of the node.

   - To approve them individually, run the following command for each valid CSR:

     $ oc adm certificate approve <csr_name>
<csr_name> is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs --no-run-if-empty oc adm certificate approve
```

**NOTE**

Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-c57lv</td>
<td>5m26s</td>
<td>system:node:ip-10-0-95-157.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name>
```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.20.0</td>
</tr>
</tbody>
</table>
It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

**Additional information**

- For more information on CSRs, see [Certificate Signing Requests](#).

### 2.10.19. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

**Prerequisites**

- Your control plane has initialized.

**Procedure**

1. Watch the cluster components come online:

   ```
   $ watch -n5 oc get clusteroperators
   ```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>

</table>
2. Configure the Operators that are not available.

2.10.19.1. Image registry storage configuration

Amazon Web Services provides default storage, which means the Image Registry Operator is available after installation. However, if the Registry Operator cannot create an S3 bucket and automatically configure storage, you must manually configure registry storage.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the `Recreate` rollout strategy during upgrades.

You can configure registry storage for user-provisioned infrastructure in AWS to deploy OpenShift Container Platform to hidden regions. See Configuring the registry for AWS user-provisioned infrastructure for more information.

2.10.19.1.1. Configuring registry storage for AWS with user-provisioned infrastructure

During installation, your cloud credentials are sufficient to create an Amazon S3 bucket and the Registry Operator will automatically configure storage.

If the Registry Operator cannot create an S3 bucket and automatically configure storage, you can create an S3 bucket and configure storage with the following procedure.

**Prerequisites**

- You have a cluster on AWS with user-provisioned infrastructure.
- For Amazon S3 storage, the secret is expected to contain two keys:
  - `REGISTRY_STORAGE_S3_ACCESSKEY`
  - `REGISTRY_STORAGE_S3_SECRETKEY`

**Procedure**

Use the following procedure if the Registry Operator cannot create an S3 bucket and automatically configure storage.

1. Set up a Bucket Lifecycle Policy to abort incomplete multipart uploads that are one day old.

2. Fill in the storage configuration in `configs.imageregistry.operator.openshift.io/cluster`:

   ```bash
   $ oc edit configs.imageregistry.operator.openshift.io/cluster
   ```
Example configuration

```yaml
storage:
s3:
  bucket: <bucket-name>
  region: <region-name>
```

**WARNING**
To secure your registry images in AWS, block public access to the S3 bucket.

2.10.19.1.2. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

**Procedure**

- To set the image registry storage to an empty directory:

  ```bash
  $ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec": {"storage": {"emptyDir": {}}}}'
  ```

**WARNING**
Configure this option for only non-production clusters.

If you run this command before the Image Registry Operator initializes its components, the `oc patch` command fails with the following error:

```
Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
```

Wait a few minutes and run the command again.

2.10.20. Deleting the bootstrap resources

After you complete the initial Operator configuration for the cluster, remove the bootstrap resources from Amazon Web Services (AWS).

**Prerequisites**

- You completed the initial Operator configuration for your cluster.

**Procedure**
Procedure

1. Delete the bootstrap resources. If you used the CloudFormation template, delete its stack:

   - Delete the stack by using the AWS CLI:

     ```sh
     $ aws cloudformation delete-stack --stack-name <name>  # 1
     ```

     `<name>` is the name of your bootstrap stack.

   - Delete the stack by using the AWS CloudFormation console.

2.10.21. Creating the Ingress DNS Records

If you removed the DNS Zone configuration, manually create DNS records that point to the Ingress load balancer. You can create either a wildcard record or specific records. While the following procedure uses A records, you can use other record types that you require, such as CNAME or alias.

Prerequisites

- You deployed an OpenShift Container Platform cluster on Amazon Web Services (AWS) that uses infrastructure that you provisioned.

- You installed the OpenShift CLI (`oc`).

- You installed the `jq` package.

- You downloaded the AWS CLI and installed it on your computer. See Install the AWS CLI Using the Bundled Installer (Linux, macOS, or Unix).

Procedure

1. Determine the routes to create.

   - To create a wildcard record, use `*.apps.<cluster_name>.<domain_name>`, where `<cluster_name>` is your cluster name, and `<domain_name>` is the Route 53 base domain for your OpenShift Container Platform cluster.

   - To create specific records, you must create a record for each route that your cluster uses, as shown in the output of the following command:

     ```sh
     $ oc get --all-namespaces -o jsonpath='{range .items[*]}{range .status.ingress[*]}{.host}
     \n     \"\"\n     \}end}end\' routes
     ```

Example output

```
oauth-openshift.apps.<cluster_name>.<domain_name>
console-openshift-console.apps.<cluster_name>.<domain_name>
downloads-openshift-console.apps.<cluster_name>.<domain_name>
alertmanager-main-openshift-monitoring.apps.<cluster_name>.<domain_name>
grafana-openshift-monitoring.apps.<cluster_name>.<domain_name>
prometheus-k8s-openshift-monitoring.apps.<cluster_name>.<domain_name>
```
2. Retrieve the Ingress Operator load balancer status and note the value of the external IP address that it uses, which is shown in the **EXTERNAL-IP** column:

```
$ oc -n openshift-ingress get service router-default
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>CLUSTER-IP</th>
<th>EXTERNAL-IP</th>
<th>PORT(S)</th>
</tr>
</thead>
<tbody>
<tr>
<td>router-default</td>
<td>LoadBalancer</td>
<td>172.30.62.215</td>
<td>ab3...28.us-east-2.elb.amazonaws.com</td>
<td>80:31499/TCP,443:30693/TCP 5m</td>
</tr>
</tbody>
</table>

3. Locate the hosted zone ID for the load balancer:

```
$ aws elb describe-load-balancers | jq -r '.LoadBalancerDescriptions[] | select(.DNSName == "<external_ip>").CanonicalHostedZoneNameID'
```

1. For `<external_ip>`, specify the value of the external IP address of the Ingress Operator load balancer that you obtained.

**Example output**

Z3AADJGX6KTTL2

The output of this command is the load balancer hosted zone ID.

4. Obtain the public hosted zone ID for your cluster’s domain:

```
$ aws route53 list-hosted-zones-by-name \
   --dns-name "<domain_name>" \ 1
   --query 'HostedZones[? Config.PrivateZone != `true` && Name == `<domain_name>`.].Id' 2
   --output text
```

1 2. For `<domain_name>`, specify the Route 53 base domain for your OpenShift Container Platform cluster.

**Example output**

/hostedzone/Z3URY6TWQ91KVV

The public hosted zone ID for your domain is shown in the command output. In this example, it is Z3URY6TWQ91KVV.

5. Add the alias records to your private zone:

```
$ aws route53 change-resource-record-sets --hosted-zone-id "<private_hosted_zone_id>" --change-batch '{
  "Changes": [
    {
      "Action": "CREATE",
      "Name": "<domain_name>.",
      "Type": "A",
      "Value": ["<external_ip>"]
    }
  ]}'
```

--change-batch '{
  "Changes": [
    {
      "Action": "CREATE",
      "Name": "<domain_name>.",
      "Type": "A",
      "Value": ["<external_ip>"]
    }
  ]}'
For `<private_hosted_zone_id>`, specify the value from the output of the CloudFormation template for DNS and load balancing.

For `<cluster_domain>`, specify the domain or subdomain that you use with your OpenShift Container Platform cluster.

For `<hosted_zone_id>`, specify the public hosted zone ID for the load balancer that you obtained.

For `<external_ip>`, specify the value of the external IP address of the Ingress Operator load balancer. Ensure that you include the trailing period (`.`) in this parameter value.

6. Add the records to your public zone:

```
$ aws route53 change-resource-record-sets --hosted-zone-id "<public_hosted_zone_id>" --change-batch '{
    "Changes": [
        {
            "Action": "CREATE",
            "ResourceRecordSet": {
                "Name": "\052.apps.<cluster_domain>",
                "Type": "A",
                "AliasTarget": {
                    "HostedZoneId": "<hosted_zone_id>",
                    "DNSName": "<external_ip>",
                    "EvaluateTargetHealth": false
                }
            }
        }
    ]
}
```

1. For `<public_hosted_zone_id>`, specify the public hosted zone for your domain.

2. For `<cluster_domain>`, specify the domain or subdomain that you use with your OpenShift Container Platform cluster.

3. For `<hosted_zone_id>`, specify the public hosted zone ID for the load balancer that you obtained.

4. For `<external_ip>`, specify the value of the external IP address of the Ingress Operator load balancer. Ensure that you include the trailing period (`.`) in this parameter value.
2.10.22. Completing an AWS installation on user-provisioned infrastructure

After you start the OpenShift Container Platform installation on Amazon Web Service (AWS) user-provisioned infrastructure, monitor the deployment to completion.

Prerequisites

- You removed the bootstrap node for an OpenShift Container Platform cluster on user-provisioned AWS infrastructure.
- You installed the oc CLI.

Procedure

- From the directory that contains the installation program, complete the cluster installation:

  $ ./openshift-install --dir <installation_directory> wait-for install-complete

  For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

Example output

```
INFO Waiting up to 40m0s for the cluster at https://api.mycluster.example.com:6443 to initialize...
INFO Waiting up to 10m0s for the openshift-console route to be created...
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Fe5en-ymBEc-Wt6NL"
INFO Time elapsed: 1s
```

IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.
2.10.23. Logging in to the cluster by using the web console

The **kubeadmin** user exists by default after an OpenShift Container Platform installation. You can log in to your cluster as the **kubeadmin** user by using the OpenShift Container Platform web console.

**Prerequisites**

- You have access to the installation host.
- You completed a cluster installation and all cluster Operators are available.

**Procedure**

1. Obtain the password for the **kubeadmin** user from the **kubeadmin-password** file on the installation host:

   ```
   $ cat <installation_directory>/auth/kubeadmin-password
   ```

   **NOTE**
   
   Alternatively, you can obtain the **kubeadmin** password from the `<installation_directory>/openshift_install.log` log file on the installation host.

2. List the OpenShift Container Platform web console route:

   ```
   $ oc get routes -n openshift-console | grep 'console-openshift'
   ```

   **NOTE**
   
   Alternatively, you can obtain the OpenShift Container Platform route from the `<installation_directory>/openshift_install.log` log file on the installation host.

   **Example output**

   ```
   console     console-openshift-console.apps.<cluster_name>.<base_domain>            console
   https   reencrypt/Redirect   None
   ```

3. Navigate to the route detailed in the output of the preceding command in a web browser and log in as the **kubeadmin** user.

**Additional resources**

- See [Accessing the web console](#) for more details about accessing and understanding the OpenShift Container Platform web console.

2.10.24. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.6, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to **OpenShift Cluster Manager**.
After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service.

2.10.25. Additional resources

- See Working with stacks in the AWS documentation for more information about AWS CloudFormation stacks.

2.10.26. Next steps

- Validating an installation.
- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- If necessary, you can remove cloud provider credentials.

2.11. INSTALLING A CLUSTER ON AWS IN A RESTRICTED NETWORK WITH USER-PROVISIONED INFRASTRUCTURE

In OpenShift Container Platform version 4.6, you can install a cluster on Amazon Web Services (AWS) using infrastructure that you provide and an internal mirror of the installation release content.

IMPORTANT

While you can install an OpenShift Container Platform cluster by using mirrored installation release content, your cluster still requires Internet access to use the AWS APIs.

One way to create this infrastructure is to use the provided CloudFormation templates. You can modify the templates to customize your infrastructure or use the information that they contain to create AWS objects according to your company’s policies.

IMPORTANT

The steps for performing a user-provisioned infrastructure installation are provided as an example only. Installing a cluster with infrastructure you provide requires knowledge of the cloud provider and the installation process of OpenShift Container Platform. Several CloudFormation templates are provided to assist in completing these steps or to help model your own. You are also free to create the required resources through other methods; the templates are just an example.

2.11.1. Prerequisites

- You created a mirror registry on your mirror host and obtained the imageContentSources data for your version of OpenShift Container Platform.
IMPORTANT

Because the installation media is on the mirror host, you can use that computer to complete all installation steps.

- You reviewed details about the OpenShift Container Platform installation and update processes.
- You configured an AWS account to host the cluster.

IMPORTANT

If you have an AWS profile stored on your computer, it must not use a temporary session token that you generated while using a multi-factor authentication device. The cluster continues to use your current AWS credentials to create AWS resources for the entire life of the cluster, so you must use key-based, long-lived credentials. To generate appropriate keys, see Managing Access Keys for IAM Users in the AWS documentation. You can supply the keys when you run the installation program.

- You downloaded the AWS CLI and installed it on your computer. See Install the AWS CLI Using the Bundled Installer (Linux, macOS, or Unix) in the AWS documentation.
- If you use a firewall and plan to use the Telemetry service, you configured the firewall to allow the sites that your cluster requires access to.

NOTE

Be sure to also review this site list if you are configuring a proxy.

- If you do not allow the system to manage identity and access management (IAM), then a cluster administrator can manually create and maintain IAM credentials. Manual mode can also be used in environments where the cloud IAM APIs are not reachable.

2.11.2. About installations in restricted networks

In OpenShift Container Platform 4.6, you can perform an installation that does not require an active connection to the Internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service’s IAM service, require Internet access, so you might still require Internet access. Depending on your network, you might require less Internet access for an installation on bare metal hardware or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift Container Platform registry and contains the installation media. You can create this registry on a mirror host, which can access both the Internet and your closed network, or by using other methods that meet your restrictions.
Because of the complexity of the configuration for user-provisioned installations, consider completing a standard user-provisioned infrastructure installation before you attempt a restricted network installation using user-provisioned infrastructure. Completing this test installation might make it easier to isolate and troubleshoot any issues that might arise during your installation in a restricted network.

2.11.2.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The `ClusterVersion` status includes an *Unable to retrieve available updates* error.
- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

2.11.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.6, you require access to the Internet to obtain the images that are necessary to install your cluster.

You must have Internet access to:

- Access [OpenShift Cluster Manager](https://openshift.com) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](https://quay.io) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

2.11.4. Required AWS infrastructure components

To install OpenShift Container Platform on user-provisioned infrastructure in Amazon Web Services (AWS), you must manually create both the machines and their supporting infrastructure.

For more information about the integration testing for different platforms, see the [OpenShift Container Platform 4.x Tested Integrations](https://openshift.com) page.

By using the provided CloudFormation templates, you can create stacks of AWS resources that represent the following components:

- An AWS Virtual Private Cloud (VPC)
- Networking and load balancing components
• Security groups and roles
• An OpenShift Container Platform bootstrap node
• OpenShift Container Platform control plane nodes
• An OpenShift Container Platform compute node

Alternatively, you can manually create the components or you can reuse existing infrastructure that meets the cluster requirements. Review the CloudFormation templates for more details about how the components interrelate.

2.11.4.1. Cluster machines

You need AWS::EC2::Instance objects for the following machines:

• A bootstrap machine. This machine is required during installation, but you can remove it after your cluster deploys.

• Three control plane machines. The control plane machines are not governed by a machine set.

• Compute machines. You must create at least two compute machines, which are also known as worker machines, during installation. These machines are not governed by a machine set.

You can use the following instance types for the cluster machines with the provided CloudFormation templates.

IMPORTANT

If m4 instance types are not available in your region, such as with eu-west-3, use m5 types instead.

Table 2.32. Instance types for machines

<table>
<thead>
<tr>
<th>Instance type</th>

<tr>
<td>r4.8xlarge</td>
<td>x</td>
<td></td>
<td></td>
</tr>
<tr>
<td>r4.16xlarge</td>
<td>x</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

You might be able to use other instance types that meet the specifications of these instance types.

2.11.4.2. Other infrastructure components

- A VPC
- DNS entries
- Load balancers (classic or network) and listeners
- A public and a private Route 53 zone
Security groups
IAM roles
S3 buckets

If you are working in a disconnected environment or use a proxy, you cannot reach the public IP addresses for EC2 and ELB endpoints. To reach these endpoints, you must create a VPC endpoint and attach it to the subnet that the clusters are using. Create the following endpoints:

- `ec2.<region>.amazonaws.com`
- `elasticloadbalancing.<region>.amazonaws.com`
- `s3.<region>.amazonaws.com`

**Required VPC components**

You must provide a suitable VPC and subnets that allow communication to your machines.

<table>
<thead>
<tr>
<th>Component</th>
<th>AWS type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>VPC</strong></td>
<td><strong>AWS::EC2::VPC</strong></td>
<td>You must provide a public VPC for the cluster to use. The VPC uses an endpoint that references the route tables for each subnet to improve communication with the registry that is hosted in S3.</td>
</tr>
<tr>
<td></td>
<td><strong>AWS::EC2::VPCEndpoint</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Public subnets</strong></td>
<td><strong>AWS::EC2::Subnet</strong></td>
<td>Your VPC must have public subnets for between 1 and 3 availability zones and associate them with appropriate Ingress rules.</td>
</tr>
<tr>
<td></td>
<td><strong>AWS::EC2::SubnetNetworkAclAssociation</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Internet gateway</strong></td>
<td><strong>AWS::EC2::InternetGateway</strong></td>
<td>You must have a public Internet gateway, with public routes, attached to the VPC. In the provided templates, each public subnet has a NAT gateway with an EIP address. These NAT gateways allow cluster resources, like private subnet instances, to reach the Internet and are not required for some restricted network or proxy scenarios.</td>
</tr>
<tr>
<td></td>
<td><strong>AWS::EC2::VPCEndpoint</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>AWS::EC2::VPCRouteTable</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>AWS::EC2::Route</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>AWS::EC2::SubnetRouteTableAssociation</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>AWS::EC2::NatGateway</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td><strong>AWS::EC2::EIP</strong></td>
<td></td>
</tr>
</tbody>
</table>
Network access control

- AWS::EC2::NetworkAcl
- AWS::EC2::NetworkAclEntry

You must allow the VPC to access the following ports:

<table>
<thead>
<tr>
<th>Port</th>
<th>Reason</th>
</tr>
</thead>
<tbody>
<tr>
<td>80</td>
<td>Inbound HTTP traffic</td>
</tr>
<tr>
<td>443</td>
<td>Inbound HTTPS traffic</td>
</tr>
<tr>
<td>22</td>
<td>Inbound SSH traffic</td>
</tr>
<tr>
<td>1024 - 65535</td>
<td>Inbound ephemeral traffic</td>
</tr>
<tr>
<td>0 - 65535</td>
<td>Outbound ephemeral traffic</td>
</tr>
</tbody>
</table>

Private subnets

- AWS::EC2::Subnet
- AWS::EC2::RouteTable
- AWS::EC2::SubnetRouteTableAssociation

Your VPC can have private subnets. The provided CloudFormation templates can create private subnets for between 1 and 3 availability zones. If you use private subnets, you must provide appropriate routes and tables for them.

Required DNS and load balancing components

Your DNS and load balancer configuration needs to use a public hosted zone and can use a private hosted zone similar to the one that the installation program uses if it provisions the cluster’s infrastructure. You must create a DNS entry that resolves to your load balancer. An entry for `api.<cluster_name>.<domain>` must point to the external load balancer, and an entry for `api-int.<cluster_name>.<domain>` must point to the internal load balancer.

The cluster also requires load balancers and listeners for port 6443, which are required for the Kubernetes API and its extensions, and port 22623, which are required for the Ignition config files for new machines. The targets will be the control plane nodes (also known as the master nodes). Port 6443 must be accessible to both clients external to the cluster and nodes within the cluster. Port 22623 must be accessible to nodes within the cluster.

<table>
<thead>
<tr>
<th>Component</th>
<th>AWS type</th>
<th>Description</th>
</tr>

</tr>
<tr>
<td>Internal listener</td>
<td>AWS::Elastic LoadBalancingV2::Listener</td>
<td>A listener on port 6443 for the internal load balancer.</td>
</tr>
</tbody>
</table>
Security groups

The control plane and worker machines require access to the following ports:

<table>
<thead>
<tr>
<th>Group</th>
<th>Type</th>
<th>IP Protocol</th>
<th>Port range</th>
</tr>
</thead>
<tbody>
<tr>
<td>MasterSecurityGroup</td>
<td>AWS::EC2::SecurityGroup</td>
<td>icmp</td>
<td>0</td>
</tr>
<tr>

</tr>
</tbody>
</table>

### Worker Ingress

The worker machines require the following Ingress groups. Each Ingress group is a AWS::EC2::SecurityGroupIngress resource.

<table>
<thead>
<tr>
<th>Ingress group</th>
<th>Description</th>
<th>IP protocol</th>
<th>Port range</th>
</tr>
</thead>
<tbody>

**Roles and instance profiles**

You must grant the machines permissions in AWS. The provided CloudFormation templates grant the machines **Allow** permissions for the following **AWS::IAM::Role** objects and provide a **AWS::IAM::InstanceProfile** for each set of roles. If you do not use the templates, you can grant the machines the following broad permissions or the following individual permissions.
<table>

2.11.4.3. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The `kube-controller-manager` only approves the kubelet client CSRs. The `machine Approver` cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

2.11.4.4. Required AWS permissions

**NOTE**

Your IAM user must have the permission `tag:GetResources` in the region `us-east-1` to delete the base cluster resources. As part of the AWS API requirement, the OpenShift Container Platform installation program performs various actions in this region.

When you attach the `AdministratorAccess` policy to the IAM user that you create in Amazon Web Services (AWS), you grant that user all of the required permissions. To deploy all components of an OpenShift Container Platform cluster, the IAM user requires the following permissions:

Example 2.31. Required EC2 permissions for installation

- `tag:TagResources`
- `tag:UntagResources`
- `ec2:AllocateAddress`
- `ec2:AssociateAddress`
- ec2:AuthorizeSecurityGroupEgress
- ec2:AuthorizeSecurityGroupIngress
- ec2:CopyImage
- ec2:CreateNetworkInterface
- ec2:AttachNetworkInterface
- ec2:CreateSecurityGroup
- ec2:CreateTags
- ec2:CreateVolume
- ec2:DeleteSecurityGroup
- ec2:DeleteSnapshot
- ec2:DeleteTags
- ec2:DeregisterImage
- ec2:DescribeAccountAttributes
- ec2:DescribeAddresses
- ec2:DescribeAvailabilityZones
- ec2:DescribeDhcpOptions
- ec2:DescribeImages
- ec2:DescribeInstanceAttribute
- ec2:DescribeInstanceCreditSpecifications
- ec2:DescribeInstances
- ec2:DescribeInternetGateways
- ec2:DescribeKeyPairs
- ec2:DescribeNatGateways
- ec2:DescribeNetworkAcls
- ec2:DescribeNetworkInterfaces
- ec2:DescribePrefixLists
- ec2:DescribeRegions
- ec2:DescribeRouteTables
- ec2:DescribeSecurityGroups
Example 2.32. Required permissions for creating network resources during installation

- ec2:AssociateDhcpOptions
- ec2:AssociateRouteTable
- ec2:AttachInternetGateway
- ec2:CreateDhcpOptions
- ec2:CreateInternetGateway
- ec2:CreateNatGateway
- ec2:CreateRoute
- ec2:CreateRouteTable
- ec2:CreateSubnet
- ec2:CreateVpc
- ec2:CreateVpcEndpoint
- ec2:ModifySubnetAttribute
• ec2:ModifyVpcAttribute

NOTE

If you use an existing VPC, your account does not require these permissions for creating network resources.

Example 2.33. Required Elastic Load Balancing permissions (ELB) for installation

• elasticloadbalancing:AddTags
• elasticloadbalancing:ApplySecurityGroupsToLoadBalancer
• elasticloadbalancing:AttachLoadBalancerToSubnets
• elasticloadbalancing:ConfigureHealthCheck
• elasticloadbalancing:CreateLoadBalancer
• elasticloadbalancing:CreateLoadBalancerListeners
• elasticloadbalancing:DeleteLoadBalancer
• elasticloadbalancing:DeregisterInstancesFromLoadBalancer
• elasticloadbalancing:DescribeInstanceHealth
• elasticloadbalancing:DescribeLoadBalancerAttributes
• elasticloadbalancing:DescribeLoadBalancers
• elasticloadbalancing:DescribeTags
• elasticloadbalancing:ModifyLoadBalancerAttributes
• elasticloadbalancing:RegisterInstancesWithLoadBalancer
• elasticloadbalancing:SetLoadBalancerPoliciesOfListener

Example 2.34. Required Elastic Load Balancing permissions (ELBv2) for installation

• elasticloadbalancing:AddTags
• elasticloadbalancing:CreateListener
• elasticloadbalancing:CreateLoadBalancer
• elasticloadbalancing:CreateTargetGroup
• elasticloadbalancing:DeleteLoadBalancer
• elasticloadbalancing:DeregisterTargets
• elasticloadbalancing:DescribeListeners
- elasticloadbalancing:DescribeLoadBalancerAttributes
- elasticloadbalancing:DescribeLoadBalancers
- elasticloadbalancing:DescribeTargetGroupAttributes
- elasticloadbalancing:DescribeTargetHealth
- elasticloadbalancing:ModifyLoadBalancerAttributes
- elasticloadbalancing:ModifyTargetGroup
- elasticloadbalancing:ModifyTargetGroupAttributes
- elasticloadbalancing:RegisterTargets

Example 2.35. Required IAM permissions for installation

- iam:AddRoleToInstanceProfile
- iam:CreateInstanceProfile
- iam:CreateRole
- iam:DeleteInstanceProfile
- iam:DeleteRole
- iam:DeleteRolePolicy
- iam:GetInstanceProfile
- iam:GetRole
- iam:GetRolePolicy
- iam:GetUser
- iam:ListInstanceProfilesForRole
- iam:ListRoles
- iam:ListUsers
- iam:PassRole
- iam:PutRolePolicy
- iam:RemoveRoleFromInstanceProfile
- iam:SimulatePrincipalPolicy
- iam:TagRole
NOTE

If you have not created an elastic load balancer (ELB) in your AWS account, the IAM user also requires the `iam:CreateServiceLinkedRole` permission.

Example 2.36. Required Route 53 permissions for installation

- `route53:ChangeResourceRecordSets`
- `route53:ChangeTagsForResource`
- `route53:CreateHostedZone`
- `route53:DeleteHostedZone`
- `route53:GetChange`
- `route53:GetHostedZone`
- `route53:ListHostedZones`
- `route53:ListHostedZonesByName`
- `route53:ListResourceRecordSets`
- `route53:ListTagsForResource`
- `route53:UpdateHostedZoneComment`

Example 2.37. Required S3 permissions for installation

- `s3:CreateBucket`
- `s3:DeleteBucket`
- `s3:GetAccelerateConfiguration`
- `s3:GetBucketAcl`
- `s3:GetBucketCors`
- `s3:GetBucketLocation`
- `s3:GetBucketLogging`
- `s3:GetBucketObjectLockConfiguration`
- `s3:GetBucketReplication`
- `s3:GetBucketRequestPayment`
- `s3:GetBucketTagging`
- `s3:GetBucketVersioning`
• s3:GetBucketWebsite
• s3:GetEncryptionConfiguration
• s3:GetLifecycleConfiguration
• s3:GetReplicationConfiguration
• s3:ListBucket
• s3:PutBucketAcl
• s3:PutBucketTagging
• s3:PutEncryptionConfiguration

Example 2.38. S3 permissions that cluster Operators require
• s3:DeleteObject
• s3:GetObject
• s3:GetObjectAcl
• s3:GetObjectTagging
• s3:GetObjectVersion
• s3:PutObject
• s3:PutObjectAcl
• s3:PutObjectTagging

Example 2.39. Required permissions to delete base cluster resources
• autoscaling:DescribeAutoScalingGroups
• ec2:DeleteNetworkInterface
• ec2:DeleteVolume
• elasticloadbalancing:DeleteTargetGroup
• elasticloadbalancing:DescribeTargetGroups
• iam:DeleteAccessKey
• iam:DeleteUser
• iam:ListAttachedRolePolicies
• iam:ListInstanceProfiles
• iam:ListRolePolicies
Example 2.40. Required permissions to delete network resources

- ec2:DeleteDhcpOptions
- ec2:DeleteInternetGateway
- ec2:DeleteNatGateway
- ec2:DeleteRoute
- ec2:DeleteRouteTable
- ec2:DeleteSubnet
- ec2:DeleteVpc
- ec2:DeleteVpcEndpoints
- ec2:DetachInternetGateway
- ec2:DisassociateRouteTable
- ec2:ReplaceRouteTableAssociation

NOTE
If you use an existing VPC, your account does not require these permissions to delete network resources.

Example 2.41. Additional IAM and S3 permissions that are required to create manifests

- iam:DeleteAccessKey
- iam:DeleteUser
- iam:DeleteUserPolicy
- iam:GetUserPolicy
- iam:ListAccessKeys
- iam:PutUserPolicy
- iam:TagUser
- iam:GetUserPolicy
• iam:ListAccessKeys
• s3:PutBucketPublicAccessBlock
• s3:GetBucketPublicAccessBlock
• s3:PutLifecycleConfiguration
• s3:HeadBucket
• s3:ListBucketMultipartUploads
• s3:AbortMultipartUpload

NOTE
If you are managing your cloud provider credentials with mint mode, the IAM user also requires the iam:CreateAccessKey and iam:CreateUser permissions.

Example 2.42. Optional permission for quota checks for installation

• servicequotas:ListAWSDefaultServiceQuotas

2.11.5. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your ssh-agent and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

NOTE
In a production environment, you require disaster recovery and debugging.

You can use this key to SSH into the master nodes as the user core. When you deploy the cluster, the key is added to the core user’s ~/.ssh/authorized_keys list.

NOTE
You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

Procedure

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name> 

   1

386
Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

Running this command generates an SSH key that does not require a password in the location that you specified.

**NOTE**

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the `ssh-agent` process as a background task:

```
$ eval "$(ssh-agent -s)"
```

**Example output**

```
Agent pid 31874
```

**NOTE**

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the `ssh-agent`:

```
$ ssh-add <path>/<file_name>
```

**Example output**

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program. If you install a cluster on infrastructure that you provision, you must provide this key to your cluster’s machines.

**2.11.6. Creating the installation files for AWS**

To install OpenShift Container Platform on Amazon Web Services (AWS) using user-provisioned infrastructure, you must generate the files that the installation program needs to deploy your cluster and modify them so that the cluster creates only the machines that it will use. You generate and customize the `install-config.yaml` file, Kubernetes manifests, and Ignition config files. You also have the option to first set up a separate `var` partition during the preparation phases of installation.
2.11.6.1. Optional: Creating a separate /var partition

It is recommended that disk partitioning for OpenShift Container Platform be left to the installer. However, there are cases where you might want to create separate partitions in a part of the filesystem that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the /var partition or a subdirectory of /var. For example:

- /var/lib/containers: Holds container-related content that can grow as more images and containers are added to a system.
- /var/lib/etcd: Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.
- /var: Holds data that you might want to keep separate for purposes such as auditing.

Storing the contents of a /var directory separately makes it easier to grow storage for those areas as needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

Because /var must be in place before a fresh installation of Red Hat Enterprise Linux CoreOS (RHCOS), the following procedure sets up the separate /var partition by creating a machine config that is inserted during the openshift-install preparation phases of an OpenShift Container Platform installation.

**IMPORTANT**

If you follow the steps to create a separate /var partition in this procedure, it is not necessary to create the Kubernetes manifest and Ignition config files again as described later in this section.

**Procedure**

1. Create a directory to hold the OpenShift Container Platform installation files:

   ```bash
   $ mkdir $HOME/clusterconfig
   ```

2. Run openshift-install to create a set of files in the manifest and openshift subdirectories. Answer the system questions as you are prompted:

   ```bash
   $ openshift-install create manifests --dir $HOME/clusterconfig
   ```

**Example output**

```
? SSH Public Key ...
INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
INFO Consuming Install Config from target directory
INFO Manifests created in: $HOME/clusterconfig/manifests and $HOME/clusterconfig/openshift
```

3. Optional: Confirm that the installation program created manifests in the clusterconfig/openshift directory:
Example output

```
99_kubeadmin-password-secret.yaml
99_openshift-cluster-api_master-machines-0.yaml
99_openshift-cluster-api_master-machines-1.yaml
99_openshift-cluster-api_master-machines-2.yaml
...
```

4. Create a MachineConfig object and add it to a file in the openshift directory. For example, name the file `98-var-partition.yaml`, change the disk device name to the name of the storage device on the worker systems, and set the storage size as appropriate. This example places the /var directory on a separate partition:

```yaml
apiVersion: machineconfiguration.openshift.io/v1
kind: MachineConfig
metadata:
  labels:
    machineconfiguration.openshift.io/role: worker
  name: 98-var-partition
spec:
  config:
    ignition:
      version: 3.1.0
    storage:
      disks:
        - device: /dev/<device_name>
          partitions:
            - label: var
              startMiB: <partition_start_offset>
              sizeMiB: <partition_size>
      filesystems:
        - device: /dev/disk/by-partlabel/var
          path: /var
          format: xfs
      systemd:
        units:
          - name: var.mount
            enabled: true
            contents: |
              [Unit]
              Before=local-fs.target
              [Mount]
              What=/dev/disk/by-partlabel/var
              Where=/var
              Options=defaults,prjquota
              [Install]
              WantedBy=local-fs.target
```

1 The storage device name of the disk that you want to partition.

2
When adding a data partition to the boot disk, a minimum value of 25000 MiB (Mebibytes) is recommended. The root file system is automatically resized to fill all available space up

3. The size of the data partition in mebibytes.

4. The name of the mount unit must match the directory specified in the `Where=` directive. For example, for a filesystem mounted on `/var/lib/containers`, the unit must be named `var-lib-containers.mount`.

5. The `prjquota` mount option must be enabled for filesystems used for container storage.

NOTE

When creating a separate `/var` partition, you cannot use different instance types for worker nodes, if the different instance types do not have the same device name.

5. Run `openshift-install` again to create Ignition configs from a set of files in the `manifest` and `openshift` subdirectories:

```
$ openshift-install create ignition-configs --dir $HOME/clusterconfig
$ ls $HOME/clusterconfig/
auth bootstrap.ign master.ign metadata.json worker.ign
```

Now you can use the Ignition config files as input to the installation procedures to install Red Hat Enterprise Linux CoreOS (RHCOS) systems.

2.11.6.2. Creating the installation configuration file

Generate and customize the installation configuration file that the installation program needs to deploy your cluster.

Prerequisites

- You obtained the OpenShift Container Platform installation program for user-provisioned infrastructure and the pull secret for your cluster. For a restricted network installation, these files are on your mirror host.

- You checked that you are deploying your cluster to a region with an accompanying Red Hat Enterprise Linux CoreOS (RHCOS) AMI published by Red Hat. If you are deploying to a region that requires a custom AMI, such as an AWS GovCloud region, you must create the `install-config.yaml` file manually.

Procedure

1. Create the `install-config.yaml` file.

   a. Change to the directory that contains the installation program and run the following command:

   ```
   $ ./openshift-install create install-config --dir <installation_directory>
   ```
For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

**IMPORTANT**

Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

b. At the prompts, provide the configuration details for your cloud:

i. Optional: Select an SSH key to use to access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

ii. Select `aws` as the platform to target.

iii. If you do not have an AWS profile stored on your computer, enter the AWS access key ID and secret access key for the user that you configured to run the installation program.

**NOTE**

The AWS access key ID and secret access key are stored in `~/.aws/credentials` in the home directory of the current user on the installation host. You are prompted for the credentials by the installation program if the credentials for the exported profile are not present in the file. Any credentials that you provide to the installation program are stored in the file.

iv. Select the AWS region to deploy the cluster to.

v. Select the base domain for the Route 53 service that you configured for your cluster.

vi. Enter a descriptive name for your cluster.

vii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

2. Edit the `install-config.yaml` file to provide the additional information that is required for an installation in a restricted network.

a. Update the `pullSecret` value to contain the authentication information for your registry:

```
pullSecret: '{"auths": {"<local_registry>": {"auth": "<credentials>","email": "you@example.com"}}}'}
```
For `<local_registry>`, specify the registry domain name, and optionally the port, that your mirror registry uses to serve content. For example `registry.example.com` or `registry.example.com:5000`. For `<credentials>`, specify the base64-encoded user name and password for your mirror registry.

b. Add the `additionalTrustBundle` parameter and value. The value must be the contents of the certificate file that you used for your mirror registry, which can be an existing, trusted certificate authority or the self-signed certificate that you generated for the mirror registry.

```yaml
additionalTrustBundle: |
-----BEGIN CERTIFICATE-----
ZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZ
-----END CERTIFICATE-----
```

c. Add the image content resources:

```yaml
imageContentSources:
  - mirrors:
    - `<local_registry>/<local_repository_name>/release`
      source: `quay.io/openshift-release-dev/ocp-release`
    - mirrors:
      - `<local_registry>/<local_repository_name>/release`
        source: `quay.io/openshift-release-dev/ocp-v4.0-art-dev`
```

Use the `imageContentSources` section from the output of the command to mirror the repository or the values that you used when you mirrored the content from the media that you brought into your restricted network.

d. Optional: Set the publishing strategy to `Internal`:

```yaml
publish: Internal
```

By setting this option, you create an internal Ingress Controller and a private load balancer.

3. Optional: Back up the `install-config.yaml` file.

**IMPORTANT**

The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

**Additional resources**

- See [Configuration and credential file settings](#) in the AWS documentation for more information about AWS profile and credential configuration.

**2.11.6.3. Configuring the cluster-wide proxy during installation**

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**Prerequisites**
You have an existing `install-config.yaml` file.

You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

### NOTE

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (`169.254.169.254`).

If your cluster is on AWS, you added the `ec2.<region>.amazonaws.com`, `elasticloadbalancing.<region>.amazonaws.com`, and `s3.<region>.amazonaws.com` endpoints to your VPC endpoint. These endpoints are required to complete requests from the nodes to the AWS EC2 API. Because the proxy works on the container level, not the node level, you must route these requests to the AWS EC2 API through the AWS private network. Adding the public IP address of the EC2 API to your allowlist in your proxy server is not sufficient.

### Procedure

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
     httpProxy: http://<username>:<pswd>@<ip>:<port> ①
     httpsProxy: https://<username>:<pswd>@<ip>:<port> ②
     noProxy: example.com ③
   additionalTrustBundle:
     -----BEGIN CERTIFICATE-----
     <MY_TRUSTED_CA_CERT>
     -----END CERTIFICATE-----
   ...
   ...
   ```

   ① A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.

   ② A proxy URL to use for creating HTTPS connections outside the cluster.

   ③ A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with `.` to match subdomains only. For

   ④ If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace to hold the additional CA certificates. If you provide `additionalTrustBundle` and at least one proxy setting, the `Proxy` object is configured to reference the `user-ca-bundle` config map in the `trustedCA` field. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges the contents specified for the `trustedCA` parameter with the RHCOS trust bundle. The
additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

NOTE

The installation program does not support the proxy readinessEndpoints field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

NOTE

Only the Proxy object named cluster is supported, and no additional proxies can be created.

2.11.6.4. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to make its machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to create the cluster.

IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

Prerequisites

- You obtained the OpenShift Container Platform installation program. For a restricted network installation, these files are on your mirror host.

- You created the install-config.yaml installation configuration file.

Procedure

1. Change to the directory that contains the installation program and generate the Kubernetes manifests for the cluster:
1. For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.

2. Remove the Kubernetes manifest files that define the control plane machines:

   ```
   $ rm -f <installation_directory>/openshift/99_openshift-cluster-api_master-machines-*.yaml
   ```

   By removing these files, you prevent the cluster from automatically generating control plane machines.

3. Remove the Kubernetes manifest files that define the worker machines:

   ```
   $ rm -f <installation_directory>/openshift/99_openshift-cluster-api_worker-machineset-*.yaml
   ```

   Because you create and manage the worker machines yourself, you do not need to initialize these machines.

4. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:

   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.

   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.

   c. Save and exit the file.

5. Optional: If you do not want the Ingress Operator to create DNS records on your behalf, remove the `privateZone` and `publicZone` sections from the `<installation_directory>/manifests/cluster-dns-02-config.yml` DNS configuration file:
Remove this section completely.

If you do so, you must add ingress DNS records manually in a later step.

6. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

$ ./openshift-install create ignition-configs --dir <installation_directory>

For `<installation_directory>`, specify the same installation directory.

The following files are generated in the directory:

```
├── auth
│   ├── kubeadmin-password
│   └── kubeconfig
├── bootstrap.ign
├── master.ign
├── metadata.json
└── worker.ign
```

### 2.11.7. Extracting the infrastructure name

The Ignition config files contain a unique cluster identifier that you can use to uniquely identify your cluster in Amazon Web Services (AWS). The infrastructure name is also used to locate the appropriate AWS resources during an OpenShift Container Platform installation. The provided CloudFormation templates contain references to this infrastructure name, so you must extract it.

**Prerequisites**

- You obtained the OpenShift Container Platform installation program and the pull secret for your cluster.
- You generated the Ignition config files for your cluster.
- You installed the `jq` package.

**Procedure**

- To extract and view the infrastructure name from the Ignition config file metadata, run the following command:

  $ jq -r .infraID <installation_directory>/metadata.json

  For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

**Example output**

```
openshift-vw9j6
```
The output of this command is your cluster name and a random string.

2.11.8. Creating a VPC in AWS

You must create a Virtual Private Cloud (VPC) in Amazon Web Services (AWS) for your OpenShift Container Platform cluster to use. You can customize the VPC to meet your requirements, including VPN and route tables.

You can use the provided CloudFormation template and a custom parameter file to create a stack of AWS resources that represent the VPC.

**NOTE**

If you do not use the provided CloudFormation template to create your AWS infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

**Prerequisites**

- You configured an AWS account.
- You added your AWS keys and region to your local AWS profile by running `aws configure`.
- You generated the Ignition config files for your cluster.

**Procedure**

1. Create a JSON file that contains the parameter values that the template requires:

```json
[
  {
    "ParameterKey": "VpcCidr",
    "ParameterValue": "10.0.0.0/16"
  },
  {
    "ParameterKey": "AvailabilityZoneCount",
    "ParameterValue": "1"
  },
  {
    "ParameterKey": "SubnetBits",
    "ParameterValue": "12"
  }
]
```

1. The CIDR block for the VPC.
2. Specify a CIDR block in the format `x.x.x.x/16-24`.
3. The number of availability zones to deploy the VPC in.
4. Specify an integer between 1 and 3.
5. The size of each subnet in each availability zone.

6. Specify an integer between 5 and 13, where 5 is \(\frac{27}{19}\) and 13 is \(\frac{19}{19}\).

2. Copy the template from the **CloudFormation template for the VPC** section of this topic and save it as a YAML file on your computer. This template describes the VPC that your cluster requires.

3. Launch the CloudFormation template to create a stack of AWS resources that represent the VPC:

   **IMPORTANT**

   You must enter the command on a single line.

   ```
   $ aws cloudformation create-stack --stack-name <name>  
   --template-body file://<template>.yaml  
   --parameters file://<parameters>.json
   ```

   - `<name>` is the name for the CloudFormation stack, such as `cluster-vpc`. You need the name of this stack if you remove the cluster.
   - `<template>` is the relative path to and name of the CloudFormation template YAML file that you saved.
   - `<parameters>` is the relative path to and name of the CloudFormation parameters JSON file.

   **Example output**

   ```
   arn:aws:cloudformation:us-east-1:269333783861:stack/cluster-vpc/dbedae40-2fd3-11eb-820e-12a48460849f
   ```

4. Confirm that the template components exist:

   ```
   $ aws cloudformation describe-stacks --stack-name <name>
   ```

   After the **StackStatus** displays **CREATE_COMPLETE**, the output displays values for the following parameters. You must provide these parameter values to the other CloudFormation templates that you run to create your cluster:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VpcId</td>
<td>The ID of your VPC.</td>
</tr>
<tr>
<td>PublicSubnetIds</td>
<td>The IDs of the new public subnets.</td>
</tr>
<tr>
<td>PrivateSubnetIds</td>
<td>The IDs of the new private subnets.</td>
</tr>
</tbody>
</table>
2.11.8.1. CloudFormation template for the VPC

You can use the following CloudFormation template to deploy the VPC that you need for your OpenShift Container Platform cluster.

Example 2.43. CloudFormation template for the VPC

AWSTemplateFormatVersion: 2010-09-09
Description: Template for Best Practice VPC with 1-3 AZs

Parameters:
VpcCidr:
  ConstraintDescription: CIDR block parameter must be in the form x.x.x.x/16-24.  
  Default: 10.0.0.0/16  
  Description: CIDR block for VPC.  
  Type: String
AvailabilityZoneCount:
  ConstraintDescription: "The number of availability zones. (Min: 1, Max: 3)"  
  MinValue: 1  
  MaxValue: 3  
  Default: 1  
  Description: "How many AZs to create VPC subnets for. (Min: 1, Max: 3)"  
  Type: Number
SubnetBits:
  ConstraintDescription: CIDR block parameter must be in the form x.x.x.x/19-27.  
  MinValue: 5  
  MaxValue: 13  
  Default: 12  
  Description: "Size of each subnet to create within the availability zones. (Min: 5 = /27, Max: 13 = /19)"  
  Type: Number

Metadata:
AWS::CloudFormation::Interface:
  ParameterGroups:
    - Label: "Network Configuration"
      Parameters:
        - VpcCidr
        - SubnetBits
    - Label: "Availability Zones"
      Parameters:
        - AvailabilityZoneCount
  ParameterLabels:
    AvailabilityZoneCount:
      default: "Availability Zone Count"
    VpcCidr:
      default: "VPC CIDR"
    SubnetBits:
      default: "Bits Per Subnet"

Conditions:

Outputs:
2.11.9. Creating networking and load balancing components in AWS

You must configure networking and classic or network load balancing in Amazon Web Services (AWS) that your OpenShift Container Platform cluster can use.

You can use the provided CloudFormation template and a custom parameter file to create a stack of AWS resources. The stack represents the networking and load balancing components that your OpenShift Container Platform cluster requires. The template also creates a hosted zone and subnet tags.

You can run the template multiple times within a single Virtual Private Cloud (VPC).

NOTE

If you do not use the provided CloudFormation template to create your AWS infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

Prerequisites

- You configured an AWS account.
- You added your AWS keys and region to your local AWS profile by running `aws configure`.
- You generated the Ignition config files for your cluster.
- You created and configured a VPC and associated subnets in AWS.

Procedure

1. Obtain the hosted zone ID for the Route 53 base domain that you specified in the `install-config.yaml` file for your cluster. You can obtain details about your hosted zone by running the following command:
$ aws route53 list-hosted-zones-by-name --dns-name <route53_domain> ①

For the `<route53_domain>`, specify the Route 53 base domain that you used when you generated the `install-config.yaml` file for the cluster.

Example output

```
mycluster.example.com. False 100
HOSTEDZONES 65F8F38E-2268-B835-E15C-AB55336FCBFA /hostedzone/Z21IXYZABCZ2A4 mycluster.example.com. 10
```

In the example output, the hosted zone ID is **Z21IXYZABCZ2A4**.

2. Create a JSON file that contains the parameter values that the template requires:

```json
[
  {
    "ParameterKey": "ClusterName", ①
    "ParameterValue": "mycluster" ②
  },
  {
    "ParameterKey": "InfrastructureName", ③
    "ParameterValue": "mycluster-<random_string>" ④
  },
  {
    "ParameterKey": "HostedZoneId", ⑤
    "ParameterValue": "<random_string>" ⑥
  },
  {
    "ParameterKey": "HostedZoneName", ⑦
    "ParameterValue": "example.com" ⑧
  },
  {
    "ParameterKey": "PublicSubnets", ⑨
    "ParameterValue": "subnet-<random_string>" ⑩
  },
  {
    "ParameterKey": "PrivateSubnets", ⑪
    "ParameterValue": "subnet-<random_string>" ⑫
  },
  {
    "ParameterKey": "VpcId", ⑬
    "ParameterValue": "vpc-<random_string>" ⑭
  }
]
```

① A short, representative cluster name to use for hostnames, etc.

② Specify the cluster name that you used when you generated the `install-config.yaml` file for the cluster.
The name for your cluster infrastructure that is encoded in your Ignition config files for the cluster.

4. Specify the infrastructure name that you extracted from the Ignition config file metadata, which has the format `<cluster-name>-<random-string>`.

5. The Route 53 public zone ID to register the targets with.

6. Specify the Route 53 public zone ID, which has a format similar to `Z21IXYZABCZ2A4`. You can obtain this value from the AWS console.

7. The Route 53 zone to register the targets with.

8. Specify the Route 53 base domain that you used when you generated the `install-config.yaml` file for the cluster. Do not include the trailing period (.) that is displayed in the AWS console.

9. The public subnets that you created for your VPC.

10. Specify the `PublicSubnetIds` value from the output of the CloudFormation template for the VPC.

11. The private subnets that you created for your VPC.

12. Specify the `PrivateSubnetIds` value from the output of the CloudFormation template for the VPC.

13. The VPC that you created for the cluster.

14. Specify the `VpcId` value from the output of the CloudFormation template for the VPC.

3. Copy the template from the CloudFormation template for the network and load balancers section of this topic and save it as a YAML file on your computer. This template describes the networking and load balancing objects that your cluster requires.

**IMPORTANT**

If you are deploying your cluster to an AWS government region, you must update the `InternalApiServerRecord` in the CloudFormation template to use `CNAME` records. Records of type `ALIAS` are not supported for AWS government regions.

4. Launch the CloudFormation template to create a stack of AWS resources that provide the networking and load balancing components:

**IMPORTANT**

You must enter the command on a single line.

```bash
$ aws cloudformation create-stack --stack-name <name> 1
  --template-body file://<template>.yaml 2
  --parameters file://<parameters>.json 3
  --capabilities CAPABILITY_NAMED_IAM 4
```
<name> is the name for the CloudFormation stack, such as cluster-dns. You need the name of this stack if you remove the cluster.

<template> is the relative path to and name of the CloudFormation template YAML file that you saved.

<parameters> is the relative path to and name of the CloudFormation parameters JSON file.

You must explicitly declare the CAPABILITY_NAMED_IAM capability because the provided template creates some AWS::IAM::Role resources.

Example output

```
arn:aws:cloudformation:us-east-1:269333783861:stack/cluster-dns/cd3e5de0-2fd4-11eb-5cf0-12be5c33a183
```

5. Confirm that the template components exist:

```
$ aws cloudformation describe-stacks --stack-name <name>
```

After the StackStatus displays CREATE_COMPLETE, the output displays values for the following parameters. You must provide these parameter values to the other CloudFormation templates that you run to create your cluster:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PrivateHostedZoneId</td>
<td>Hosted zone ID for the private DNS.</td>
</tr>
<tr>
<td>ExternalApiLoadBalancerName</td>
<td>Full name of the external API load balancer.</td>
</tr>
<tr>
<td>InternalApiLoadBalancerName</td>
<td>Full name of the internal API load balancer.</td>
</tr>
<tr>
<td>ApiServerDnsName</td>
<td>Full hostname of the API server.</td>
</tr>
<tr>
<td>RegisterNbIpTargetssLambda</td>
<td>Lambda ARN useful to help register/deregister IP targets for these load balancers.</td>
</tr>
<tr>
<td>ExternalApiTargetGroupArn</td>
<td>ARN of external API target group.</td>
</tr>
</tbody>
</table>
### 2.11.9.1. CloudFormation template for the network and load balancers

You can use the following CloudFormation template to deploy the networking objects and load balancers that you need for your OpenShift Container Platform cluster.

**Example 2.44. CloudFormation template for the network and load balancers**

```yaml
AWSTemplateFormatVersion: 2010-09-09
Description: Template for OpenShift Cluster Network Elements (Route53 & LBs)

Parameters:
  ClusterName:
    AllowedPattern: ^([a-zA-Z][a-zA-Z0-9-]{0,26})$
    MaxLength: 27
    MinLength: 1
    ConstraintDescription: Cluster name must be alphanumeric, start with a letter, and have a maximum of 27 characters.
    Description: A short, representative cluster name to use for host names and other identifying names.
    Type: String

  InfrastructureName:
    AllowedPattern: ^([a-zA-Z][a-zA-Z0-9-]{0,26})$
    MaxLength: 27
    MinLength: 1
    ConstraintDescription: Infrastructure name must be alphanumeric, start with a letter, and have a maximum of 27 characters.
    Description: A short, unique cluster ID used to tag cloud resources and identify items owned or used by the cluster.
    Type: String

  HostedZoneId:
    Description: The Route53 public zone ID to register the targets with, such as Z21IXYZABCZ2A4.
    Type: String

  HostedZoneName:
    Description: The Route53 zone to register the targets with, such as example.com. Omit the trailing period.
    Type: String
    Default: "example.com"

PublicSubnets:
  Type: List<AWS::EC2::Subnet::Id>

PrivateSubnets:
  Type: List<AWS::EC2::Subnet::Id>

VpcId:
```

Description: The VPC-scoped resources will belong to this VPC.
Type: AWS::EC2::VPC::Id

Metadata:
AWS::CloudFormation::Interface:
ParameterGroups:
- Label:
  default: "Cluster Information"
Parameters:
- ClusterName
- InfrastructureName
- Label:
  default: "Network Configuration"
Parameters:

          Runtime: "python3.7"
          Timeout: 120

RegisterPublicSubnetTags:
  Type: Custom::SubnetRegister
  Properties:
If you are deploying your cluster to an AWS government region, you must update the `InternalApiServerRecord` to use `CNAME` records. Records of type `ALIAS` are not supported for AWS government regions. For example:

```yaml
ServiceToken: !GetAtt RegisterSubnetTags.Arn
InfrastructureName: !Ref InfrastructureName
Subnets: !Ref PublicSubnets

RegisterPrivateSubnetTags:
  Type: Custom::SubnetRegister
  Properties:
    ServiceToken: !GetAtt RegisterSubnetTags.Arn
    InfrastructureName: !Ref InfrastructureName
    Subnets: !Ref PrivateSubnets

Outputs:
  PrivateHostedZoneld:
    Description: Hosted zone ID for the private DNS, which is required for private records.
    Value: !Ref IntDns
  ExternalApiLoadBalancerName:
    Description: Full name of the external API load balancer.
    Value: !GetAtt ExtApiElb.LoadBalancerFullName
  InternalApiLoadBalancerName:
    Description: Full name of the internal API load balancer.
    Value: !GetAtt IntApiElb.LoadBalancerFullName
  ApiServerDnsName:
    Description: Full hostname of the API server, which is required for the Ignition config files.
    Value: !Join [".", ["api-int", !Ref ClusterName, !Ref HostedZoneName]]
  RegisterNlbIpTargetsLambda:
    Description: Lambda ARN useful to help register or deregister IP targets for these load balancers.
    Value: !GetAtt RegisterNlbIpTargets.Arn
  ExternalApiTargetGroupArn:
    Description: ARN of the external API target group.
    Value: !Ref ExternalApiTargetGroup
  InternalApiTargetGroupArn:
    Description: ARN of the internal API target group.
    Value: !Ref InternalApiTargetGroup
  InternalServiceTargetGroupArn:
    Description: ARN of the internal service target group.
    Value: !Ref InternalServiceTargetGroup
```

Additional resources

- See [Listing public hosted zones](#) in the AWS documentation for more information about listing public hosted zones.
2.11.10. Creating security group and roles in AWS

You must create security groups and roles in Amazon Web Services (AWS) for your OpenShift Container Platform cluster to use.

You can use the provided CloudFormation template and a custom parameter file to create a stack of AWS resources. The stack represents the security groups and roles that your OpenShift Container Platform cluster requires.

**NOTE**

If you do not use the provided CloudFormation template to create your AWS infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

**Prerequisites**

- You configured an AWS account.
- You added your AWS keys and region to your local AWS profile by running `aws configure`.
- You generated the Ignition config files for your cluster.
- You created and configured a VPC and associated subnets in AWS.

**Procedure**

1. Create a JSON file that contains the parameter values that the template requires:

   ```json
   [  
   
   
   
   
   
   
   
   ]
   ```

   - The name for your cluster infrastructure that is encoded in your Ignition config files for the cluster.
   - Specify the infrastructure name that you extracted from the Ignition config file metadata, which has the format `<cluster-name>-<random_string>`. 
3. The CIDR block for the VPC.

4. Specify the CIDR block parameter that you used for the VPC that you defined in the form `x.x.x.x/16-24`.

5. The private subnets that you created for your VPC.

6. Specify the `PrivateSubnetIds` value from the output of the CloudFormation template for the VPC.

7. The VPC that you created for the cluster.

8. Specify the `VpcId` value from the output of the CloudFormation template for the VPC.

2. Copy the template from the CloudFormation template for security objects section of this topic and save it as a YAML file on your computer. This template describes the security groups and roles that your cluster requires.

3. Launch the CloudFormation template to create a stack of AWS resources that represent the security groups and roles:

   IMPORTANT

   You must enter the command on a single line.

   ```
   $ aws cloudformation create-stack --stack-name <name>  
   --template-body file://<template>.yaml  
   --parameters file://<parameters>.json  
   --capabilities CAPABILITY_NAMED_IAM
   ```

   - `<name>` is the name for the CloudFormation stack, such as `cluster-sec`. You need the name of this stack if you remove the cluster.
   - `<template>` is the relative path to and name of the CloudFormation template YAML file that you saved.
   - `<parameters>` is the relative path to and name of the CloudFormation parameters JSON file.
   - You must explicitly declare the `CAPABILITY_NAMED_IAM` capability because the provided template creates some `AWS::IAM::Role` and `AWS::IAM::InstanceProfile` resources.

   Example output

   ```
   arn:aws:cloudformation:us-east-1:269333783861:stack/cluster-sec/03bd4210-2ed7-11eb-6d7a-13fc0b61e9db
   ```

4. Confirm that the template components exist:

   ```
   $ aws cloudformation describe-stacks --stack-name <name>
   ```
After the StackStatus displays CREATE_COMPLETE, the output displays values for the following parameters. You must provide these parameter values to the other CloudFormation templates that you run to create your cluster:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MasterSecurityGroupId</td>
<td>Master Security Group ID</td>
</tr>
<tr>
<td>WorkerSecurityGroupId</td>
<td>Worker Security Group ID</td>
</tr>
<tr>
<td>MasterInstanceProfile</td>
<td>Master IAM Instance Profile</td>
</tr>
<tr>
<td>WorkerInstanceProfile</td>
<td>Worker IAM Instance Profile</td>
</tr>
</tbody>
</table>

2.11.10.1. CloudFormation template for security objects

You can use the following CloudFormation template to deploy the security objects that you need for your OpenShift Container Platform cluster.

Example 2.45. CloudFormation template for security objects

```yaml
AWSTemplateFormatVersion: 2010-09-09
Description: Template for OpenShift Cluster Security Elements (Security Groups & IAM)

Parameters:
InfrastructureName:
  AllowedPattern: ^([a-zA-Z][a-zA-Z0-9-]{0,26})$
  MaxLength: 27
  MinLength: 1
  ConstraintDescription: Infrastructure name must be alphanumeric, start with a letter, and have a maximum of 27 characters.
  Description: A short, unique cluster ID used to tag cloud resources and identify items owned or used by the cluster.
  Type: String
VpcCidr:
  AllowedPattern: ^((0-9|[1-9]0-9|10-9][0-9]2[0-4][0-9][25][0-5])\.[3]([0-9][1-9][0-9][10-9][2]2[0-4][0-9]|25[0-5])\(16-24\)$
  ConstraintDescription: CIDR block parameter must be in the form x.x.x.x/16-24.
  Default: 10.0.0.0/16
  Description: CIDR block for VPC.
  Type: String
VpcId:
  Description: The VPC-scoped resources will belong to this VPC.
  Type: AWS::EC2::VPC::Id
PrivateSubnets:
  Description: The internal subnets.
  Type: List<AWS::EC2::Subnet::Id>
```
Metadata:
AWS::CloudFormation::Interface:
  ParameterGroups:
  - Label:
    - default: "Cluster Information"
  Parameters:
    - InfrastructureName
  - Label:
    - default: "Network Configuration"
  Parameters:
    - VpcId
    - VpcCidr
    - PrivateSubnets
  ParameterLabels:
    InfrastructureName:
    - default: "Infrastructure Name"
    VpcId:
    - default: "VPC ID"
    VpcCidr:
    - default: "VPC CIDR"
    PrivateSubnets:
    - default: "Private Subnets"

2.11.11. RHCOS AMIs for the AWS infrastructure

Red Hat provides Red Hat Enterprise Linux CoreOS (RHCOS) AMIs valid for the various Amazon Web Services (AWS) zones you can specify for your OpenShift Container Platform nodes.

**NOTE**

You can also install to regions that do not have a RHCOS AMI published by importing your own AMI.

</table>
2.11.12. Creating the bootstrap node in AWS

You must create the bootstrap node in Amazon Web Services (AWS) to use during OpenShift Container Platform cluster initialization.

You can use the provided CloudFormation template and a custom parameter file to create a stack of AWS resources. The stack represents the bootstrap node that your OpenShift Container Platform installation requires.

NOTE
If you do not use the provided CloudFormation template to create your bootstrap node, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

Prerequisites

- You configured an AWS account.
- You added your AWS keys and region to your local AWS profile by running `aws configure`.
- You generated the Ignition config files for your cluster.
- You created and configured a VPC and associated subnets in AWS.
- You created and configured DNS, load balancers, and listeners in AWS.
- You created the security groups and roles required for your cluster in AWS.
Procedure

1. Provide a location to serve the `bootstrap.ign` Ignition config file to your cluster. This file is located in your installation directory. One way to do this is to create an S3 bucket in your cluster’s region and upload the Ignition config file to it.

   **IMPORTANT**

   The provided CloudFormation Template assumes that the Ignition config files for your cluster are served from an S3 bucket. If you choose to serve the files from another location, you must modify the templates.

   **IMPORTANT**

   If you are deploying to a region that has endpoints that differ from the AWS SDK, or you are providing your own custom endpoints, you must use a presigned URL for your S3 bucket instead of the `s3://` schema.

   **NOTE**

   The bootstrap Ignition config file does contain secrets, like X.509 keys. The following steps provide basic security for the S3 bucket. To provide additional security, you can enable an S3 bucket policy to allow only certain users, such as the OpenShift IAM user, to access objects that the bucket contains. You can avoid S3 entirely and serve your bootstrap Ignition config file from any address that the bootstrap machine can reach.

   a. Create the bucket:

   ```
   $ aws s3 mb s3://<cluster-name>-infra
   ```

   `cluster-name`-infra is the bucket name. When creating the `install-config.yaml` file, replace `<cluster-name>` with the name specified for the cluster.

   b. Upload the `bootstrap.ign` Ignition config file to the bucket:

   ```
   $ aws s3 cp <installation_directory>/bootstrap.ign s3://<cluster-name>-infra/bootstrap.ign
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   c. Verify that the file uploaded:

   ```
   $ aws s3 ls s3://<cluster-name>-infra/
   ```

   **Example output**

   ```
   2019-04-03 16:15:16   314878 bootstrap.ign
   ```

2. Create a JSON file that contains the parameter values that the template requires:
[{
  "ParameterKey": "InfrastructureName",
  "ParameterValue": "mycluster-<random_string>"
},
{
  "ParameterKey": "RhcosAmi",
  "ParameterValue": "ami-<random_string>"
},
{
  "ParameterKey": "AllowedBootstrapSshCidr",
  "ParameterValue": "0.0.0.0/0"
},
{
  "ParameterKey": "PublicSubnet",
  "ParameterValue": "subnet-<random_string>"
},
{
  "ParameterKey": "MasterSecurityGroupId",
  "ParameterValue": "sg-<random_string>"
},
{
  "ParameterKey": "VpcId",
  "ParameterValue": "vpc-<random_string>"
},
{
  "ParameterKey": "BootstrapIgnitionLocation",
  "ParameterValue": "s3://<bucket_name>/bootstrap.ign"
},
{
  "ParameterKey": "AutoRegisterELB",
  "ParameterValue": "yes"
},
{
  "ParameterKey": "RegisterNlbIpTargetsLambdaArn",
  "ParameterValue": "arn:aws:lambda:<region>:<account_number>:function:<dns_stack_name>-RegisterNlbIpTargets-<random_string>"
},
{
  "ParameterKey": "ExternalApiTargetGroupArn",
  "ParameterValue": "arn:aws:elasticloadbalancing:<region>:<account_number>:targetgroup/<dns_stack_name>-Exter-<random_string>"
},
{
  "ParameterKey": "InternalApiTargetGroupArn",
  "ParameterValue": "arn:aws:elasticloadbalancing:<region>:<account_number>:targetgroup/<dns_stack_name>-Inter-<random_string>"
},
{
  "ParameterKey": "InternalServiceTargetGroupArn",
  "ParameterValue": "arn:aws:elasticloadbalancing:<region>:
The name for your cluster infrastructure that is encoded in your Ignition config files for the cluster.

Specify the infrastructure name that you extracted from the Ignition config file metadata, which has the format `<cluster-name>_<random-string>`.

Current Red Hat Enterprise Linux CoreOS (RHCOS) AMI to use for the bootstrap node.

Specify a valid `AWS::EC2::Image::Id` value.

CIDR block to allow SSH access to the bootstrap node.

Specify a CIDR block in the format `x.x.x.x/16-24`.

The public subnet that is associated with your VPC to launch the bootstrap node into.

Specify the `PublicSubnetIds` value from the output of the CloudFormation template for the VPC.

The master security group ID (for registering temporary rules)

Specify the `MasterSecurityGroupId` value from the output of the CloudFormation template for the security group and roles.

The VPC created resources will belong to.

Specify the `VpcId` value from the output of the CloudFormation template for the VPC.

Location to fetch bootstrap Ignition config file from.

Specify the S3 bucket and file name in the form `s3://<bucket_name>/bootstrap.ign`.

Whether or not to register a network load balancer (NLB).

Specify `yes` or `no`. If you specify `yes`, you must provide a Lambda Amazon Resource Name (ARN) value.

The ARN for NLB IP target registration lambda group.

Specify the `RegisterNlbIpTargetsLambda` value from the output of the CloudFormation template for DNS and load balancing. Use `arn:aws-us-gov` if deploying the cluster to an AWS GovCloud region.

The ARN for external API load balancer target group.

Specify the `ExternalApiTargetGroupArn` value from the output of the CloudFormation template for DNS and load balancing. Use `arn:aws-us-gov` if deploying the cluster to an AWS GovCloud region.

The ARN for internal API load balancer target group.
Specify the `InternalApiTargetGroupArn` value from the output of the CloudFormation template for DNS and load balancing. Use `arn:aws-us-gov` if deploying the cluster to an

23 The ARN for internal service load balancer target group.

Specify the `InternalServiceTargetGroupArn` value from the output of the CloudFormation template for DNS and load balancing. Use `arn:aws-us-gov` if deploying the cluster to an AWS GovCloud region.

3. Copy the template from the CloudFormation template for the bootstrap machine section of this topic and save it as a YAML file on your computer. This template describes the bootstrap machine that your cluster requires.

4. Launch the CloudFormation template to create a stack of AWS resources that represent the bootstrap node:

   ![IMPORTANT](image)
   
   You must enter the command on a single line.

   ```
   $ aws cloudformation create-stack --stack-name <name>  
   --template-body file://<template>.yaml  
   --parameters file://<parameters>.json  
   --capabilities CAPABILITY_NAMED_IAM
   ```

   1 `<name>` is the name for the CloudFormation stack, such as `cluster-bootstrap`. You need the name of this stack if you remove the cluster.

   2 `<template>` is the relative path to and name of the CloudFormation template YAML file that you saved.

   3 `<parameters>` is the relative path to and name of the CloudFormation parameters JSON file.

   4 You must explicitly declare the `CAPABILITY_NAMED_IAM` capability because the provided template creates some `AWS::IAM::Role` and `AWS::IAM::InstanceProfile` resources.

   **Example output**

   ```
   arn:aws:cloudformation:us-east-1:269333783861:stack/cluster-bootstrap/12944486-2add-11eb-9dee-12dace8e3a83
   ```

5. Confirm that the template components exist:

   ```
   $ aws cloudformation describe-stacks --stack-name <name>
   ```

   After the StackStatus displays `CREATE_COMPLETE`, the output displays values for the following parameters. You must provide these parameter values to the other CloudFormation templates that you run to create your cluster:
<table>
<thead>
<tr>
<th><strong>Bootstrap InstanceId</strong></th>
<th>The bootstrap Instance ID.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Bootstrap PublicIp</strong></td>
<td>The bootstrap node public IP address.</td>
</tr>
<tr>
<td><strong>Bootstrap PrivateIp</strong></td>
<td>The bootstrap node private IP address.</td>
</tr>
</tbody>
</table>

### 2.11.12.1. CloudFormation template for the bootstrap machine

You can use the following CloudFormation template to deploy the bootstrap machine that you need for your OpenShift Container Platform cluster.

**Example 2.46. CloudFormation template for the bootstrap machine**

```yaml
AWSTemplateFormatVersion: 2010-09-09
Description: Template for OpenShift Cluster Bootstrap (EC2 Instance, Security Groups and IAM)

Parameters:
  InfrastructureName:
    AllowedPattern: ^([a-zA-Z][a-zA-Z0-9-]+)([0-26])$  
    MaxLength: 27
    MinLength: 1
    ConstraintDescription: Infrastructure name must be alphanumeric, start with a letter, and have a maximum of 27 characters.
    Description: A short, unique cluster ID used to tag cloud resources and identify items owned or used by the cluster.
    Type: String
  RhcosAmi:
    Description: Current Red Hat Enterprise Linux CoreOS AMI to use for bootstrap.
    Type: AWS::EC2::Image::Id
  AllowedBootstrapSshCidr:
    AllowedPattern:  \^((\[0-9\]|\[1-9]\[0-9\]|\[0-9-\]|2|0-4|2|0-9|25|0-5)\.\d\[3|0-9\]|1-9\[0-9\]|1\[0-9\]|2|0-4)\[0-9\]|25|0-5)\/(\[0-9\]|1-9\[0-9\]|2|0-9\]|3|0-2)\]$  
    ConstraintDescription: CIDR block parameter must be in the form x.x.x.x/0-32.
    Default: 0.0.0.0/0
    Description: CIDR block to allow SSH access to the bootstrap node.
    Type: String
  PublicSubnet:
    Description: The public subnet to launch the bootstrap node into.
    Type: AWS::EC2::Subnet::Id
  MasterSecurityGroupId:
    Description: The master security group ID for registering temporary rules.
    Type: AWS::EC2::SecurityGroup::Id
  VpcId:
    Description: The VPC-scoped resources will belong to this VPC.
    Type: AWS::EC2::VPC::Id
  BootstrapIgnitionLocation:
    Default: s3://my-s3-bucket/bootstrap.ign
    Description: Ignition config file location.
    Type: String
  AutoRegisterELB:
```

433
Default: "yes"
AllowedValues:
- "yes"
- "no"
Description: Do you want to invoke NLB registration, which requires a Lambda ARN parameter?
Type: String
RegisterNlbIpTargetsLambdaArn:
Description: ARN for NLB IP target registration lambda.
Type: String
ExternalApiTargetGroupArn:
Description: ARN for external API load balancer target group.
Type: String
InternalApiTargetGroupArn:
Description: ARN for internal API load balancer target group.
Type: String
InternalServiceTargetGroupArn:
Description: ARN for internal service load balancer target group.
Type: String

Additional resources

- See RHCOS AMIs for the AWS infrastructure for details about the Red Hat Enterprise Linux CoreOS (RHCOS) AMIs for the AWS zones.

2.11.13. Creating the control plane machines in AWS

You must create the control plane machines in Amazon Web Services (AWS) that your cluster will use.

You can use the provided CloudFormation template and a custom parameter file to create a stack of AWS resources that represent the control plane nodes.

**IMPORTANT**

The CloudFormation template creates a stack that represents three control plane nodes.

**NOTE**

If you do not use the provided CloudFormation template to create your control plane nodes, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

**Prerequisites**

- You configured an AWS account.
- You added your AWS keys and region to your local AWS profile by running `aws configure`.
- You generated the Ignition config files for your cluster.
- You created and configured a VPC and associated subnets in AWS.
- You created and configured DNS, load balancers, and listeners in AWS.
- You created the security groups and roles required for your cluster in AWS.
- You created the bootstrap machine.

**Procedure**

1. Create a JSON file that contains the parameter values that the template requires:
"ParameterKey": "AutoRegisterELB",  
  "ParameterValue": "yes"  
}, 

{  
  "ParameterKey": "RegisterNlbIpTargetsLambdaArn",  
  "ParameterValue": "arn:aws:lambda:<region>:<account_number>:function:<dns_stack_name>-RegisterNlbIpTargets-<random_string>"  
}, 

{  
  "ParameterKey": "ExternalApiTargetGroupArn",  
  "ParameterValue": "arn:aws:elasticloadbalancing:<region>:<account_number>:targetgroup/<dns_stack_name>-Exter-<random_string>"  
}, 

{  
  "ParameterKey": "InternalApiTargetGroupArn",  
  "ParameterValue": "arn:aws:elasticloadbalancing:<region>:<account_number>:targetgroup/<dns_stack_name>-Inter-<random_string>"  
}, 

{  
  "ParameterKey": "InternalServiceTargetGroupArn",  
  "ParameterValue": "arn:aws:elasticloadbalancing:<region>:<account_number>:targetgroup/<dns_stack_name>-Inter-<random_string>"  
}  
]  

1. The name for your cluster infrastructure that is encoded in your Ignition config files for the cluster.
2. Specify the infrastructure name that you extracted from the Ignition config file metadata, which has the format `<cluster-name>-<random-string>`.
3. Current Red Hat Enterprise Linux CoreOS (RHCOS) AMI to use for the control plane machines.
4. Specify an `AWS::EC2::Image::Id` value.
5. Whether or not to perform DNS etcd registration.
6. Specify `yes` or `no`. If you specify `yes`, you must provide hosted zone information.
7. The Route 53 private zone ID to register the etcd targets with.
8. Specify the `PrivateHostedZoneId` value from the output of the CloudFormation template for DNS and load balancing.
9. The Route 53 zone to register the targets with.
10. Specify `<cluster_name>.<domain_name>` where `<domain_name>` is the Route 53 base domain that you used when you generated `install-config.yaml` file for the cluster. Do not include the trailing period (.) that is displayed in the AWS console.
11. A subnet, preferably private, to launch the control plane machines on.
Specify a subnet from the **PrivateSubnets** value from the output of the CloudFormation template for DNS and load balancing.

The master security group ID to associate with control plane nodes (also known as the master nodes).

Specify the **MasterSecurityGroupId** value from the output of the CloudFormation template for the security group and roles.

The location to fetch control plane Ignition config file from.

Specify the generated Ignition config file location, `https://api-int.<cluster_name>.<domain_name>:22623/config/master`.

The base64 encoded certificate authority string to use.

Specify the value from the `master.ign` file that is in the installation directory. This value is the long string with the format `data:text/plain;charset=utf-8;base64,ABC…xYz==`.

The IAM profile to associate with control plane nodes.

Specify the **MasterInstanceProfile** parameter value from the output of the CloudFormation template for the security group and roles.

The type of AWS instance to use for the control plane machines.

**Allowed values:**

- m4.xlarge
- m4.2xlarge
- m4.4xlarge
- m4.8xlarge
- m4.10xlarge
- m4.16xlarge
- m5.xlarge
- m5.2xlarge
- m5.4xlarge
- m5.8xlarge
- m5.10xlarge
- m5.16xlarge
- m6i.xlarge
- c4.2xlarge
- c4.4xlarge
CHAPTER 2. INSTALLING ON AWS

- c4.8xlarge
- r4.xlarge
- r4.2xlarge
- r4.4xlarge
- r4.8xlarge
- r4.16xlarge

**IMPORTANT**

If m4 instance types are not available in your region, such as with eu-west-3, specify an m5 type, such as m5.xlarge, instead.

---

27. Whether or not to register a network load balancer (NLB).

28. Specify yes or no. If you specify yes, you must provide a Lambda Amazon Resource Name (ARN) value.

29. The ARN for NLB IP target registration lambda group.

30. Specify the `RegisterNlbIpTargetsLambda` value from the output of the CloudFormation template for DNS and load balancing. Use `arn:aws:us-gov` if deploying the cluster to an AWS GovCloud region.

31. The ARN for external API load balancer target group.

32. Specify the `ExternalApiTargetGroupArn` value from the output of the CloudFormation template for DNS and load balancing. Use `arn:aws:us-gov` if deploying the cluster to an AWS GovCloud region.

33. The ARN for internal API load balancer target group.

34. Specify the `InternalApiTargetGroupArn` value from the output of the CloudFormation template for DNS and load balancing. Use `arn:aws:us-gov` if deploying the cluster to an AWS GovCloud region.

35. The ARN for internal service load balancer target group.

36. Specify the `InternalServiceTargetGroupArn` value from the output of the CloudFormation template for DNS and load balancing. Use `arn:aws:us-gov` if deploying the cluster to an AWS GovCloud region.

---

2. Copy the template from the CloudFormation template for control plane machines section of this topic and save it as a YAML file on your computer. This template describes the control plane machines that your cluster requires.

3. If you specified an m5 instance type as the value for `MasterInstanceType`, add that instance type to the `MasterInstanceType.AllowedValues` parameter in the CloudFormation template.

4. Launch the CloudFormation template to create a stack of AWS resources that represent the control plane nodes:
IMPORTANT

You must enter the command on a single line.

```bash
$ aws cloudformation create-stack --stack-name <name>  
  --template-body file://<template>.yaml  
  --parameters file://<parameters>.json
```

1. `<name>` is the name for the CloudFormation stack, such as `cluster-control-plane`. You need the name of this stack if you remove the cluster.

2. `<template>` is the relative path to and name of the CloudFormation template YAML file that you saved.

3. `<parameters>` is the relative path to and name of the CloudFormation parameters JSON file.

Example output

```
arn:aws:cloudformation:us-east-1:269333783861:stack/cluster-control-plane/21c7e2b0-2ee2-11eb-c6f6-0aa34627df4b
```

NOTE

The CloudFormation template creates a stack that represents three control plane nodes.

5. Confirm that the template components exist:

   ```bash
   $ aws cloudformation describe-stacks --stack-name <name>
   ```

2.11.13.1. CloudFormation template for control plane machines

You can use the following CloudFormation template to deploy the control plane machines that you need for your OpenShift Container Platform cluster.

Example 2.47. CloudFormation template for control plane machines

```
AWSTemplateFormatVersion: 2010-09-09
Description: Template for OpenShift Cluster Node Launch (EC2 master instances)

Parameters:
InfrastructureName:
  AllowedPattern: ^([a-zA-Z][a-zA-Z0-9-]{0,26})$
  MaxLength: 27
  MinLength: 1
  ConstraintDescription: Infrastructure name must be alphanumeric, start with a letter, and have a maximum of 27 characters.
  Description: A short, unique cluster ID used to tag nodes for the kubelet cloud provider.
  Type: String
RhcosAmi:
```
Description: Current Red Hat Enterprise Linux CoreOS AMI to use for bootstrap.
Type: AWS::EC2::Image::Id
AutoRegisterDNS:
  Default: "yes"
  AllowedValues:
    - "yes"
    - "no"
  Description: Do you want to invoke DNS etcd registration, which requires Hosted Zone information?
  Type: String
PrivateHostedZoneId:
  Description: The Route53 private zone ID to register the etcd targets with, such as Z21IXYZABCZ2A4.
  Type: String
PrivateHostedZoneName:
  Description: The Route53 zone to register the targets with, such as cluster.example.com. Omit the trailing period.
  Type: String
Master0Subnet:
  Description: The subnets, recommend private, to launch the master nodes into.
  Type: AWS::EC2::Subnet::Id
Master1Subnet:
  Description: The subnets, recommend private, to launch the master nodes into.
  Type: AWS::EC2::Subnet::Id
Master2Subnet:
  Description: The subnets, recommend private, to launch the master nodes into.
  Type: AWS::EC2::Subnet::Id
MasterSecurityGroupId:
  Description: The master security group ID to associate with master nodes.
  Type: AWS::EC2::SecurityGroup::Id
IgnitionLocation:
  Default: https://api-int.$CLUSTER_NAME.$DOMAIN:22623/config/master
  Description: Ignition config file location.
  Type: String
CertificateAuthorities:
  Default: data:text/plain;charset=utf-8;base64,ABC...xYz==
  Description: Base64 encoded certificate authority string to use.
  Type: String
MasterInstanceProfileName:
  Description: IAM profile to associate with master nodes.
  Type: String
MasterInstanceType:
  Default: m5.xlarge
  Type: String
  AllowedValues:
    - "m4.xlarge"
    - "m4.2xlarge"
    - "m4.4xlarge"
    - "m4.10xlarge"
    - "m4.16xlarge"
    - "m5.xlarge"
    - "m5.2xlarge"
    - "m5.4xlarge"
    - "m5.8xlarge"
    - "m5.12xlarge"
    - "m5.16xlarge"
AutoRegisterELB:
Default: "yes"
AllowedValues:
- "yes"
- "no"

Description: Do you want to invoke NLB registration, which requires a Lambda ARN parameter?
Type: String

RegisterNlbIpTargetsLambdaArn:
Description: ARN for NLB IP target registration lambda. Supply the value from the cluster
infrastructure or select "no" for AutoRegisterELB.
Type: String

ExternalApiTargetGroupArn:
Description: ARN for external API load balancer target group. Supply the value from the cluster
infrastructure or select "no" for AutoRegisterELB.
Type: String
InternalApiTargetGroupArn:
  Description: ARN for internal API load balancer target group. Supply the value from the cluster infrastructure or select "no" for AutoRegisterELB.
  Type: String

InternalServiceTargetGroupArn:
  Description: ARN for internal service load balancer target group. Supply the value from the cluster infrastructure or select "no" for AutoRegisterELB.
  Type: String

Metadata:
AWS::CloudFormation::Interface:
  ParameterGroups:
    - Label: "Cluster Information"
      Parameters:
        - InfrastructureName
    - Label: "Host Information"
      Parameters:
        - MasterInstanceType
        - RhcosAmi
        - IgnitionLocation
        - CertificateAuthorities
        - MasterSecurityGroupId
        - MasterInstanceProfileName
    - Label: "Network Configuration"
      Parameters:
        - VpcId
        - AllowedBootstrapSshCidr
        - Master0Subnet
        - Master1Subnet
        - Master2Subnet
    - Label: "DNS"
      Parameters:
        - AutoRegisterDNS
        - PrivateHostedZoneName
        - PrivateHostedZoneId
    - Label: "Load Balancer Automation"
      Parameters:
        - AutoRegisterELB
        - RegisterNlbIpTargetsLambdaArn
        - ExternalApiTargetGroupArn
        - InternalApiTargetGroupArn
        - InternalServiceTargetGroupArn

ParameterLabels:
  InfrastructureName: "Infrastructure Name"
  VpcId: "VPC ID"
  Master0Subnet: "Master-0 Subnet"
  Master1Subnet: "Master-1 Subnet"
Master2Subnet:
  default: "Master-2 Subnet"

MasterInstanceType:
  default: "Master Instance Type"

MasterInstanceProfileName:
  default: "Master Instance Profile Name"

RhcosAmi:
  default: "Red Hat Enterprise Linux CoreOS AMI ID"

BootstrapIgnitionLocation:
  default: "Master Ignition Source"

CertificateAuthorities:
  default: "Ignition CA String"

MasterSecurityGroupId:
  default: "Master Security Group ID"

AutoRegisterDNS:
  default: "Use Provided DNS Automation"

Properties:
2.11.14. Creating the worker nodes in AWS

You can create worker nodes in Amazon Web Services (AWS) for your cluster to use.

You can use the provided CloudFormation template and a custom parameter file to create a stack of AWS resources that represent a worker node.

**IMPORTANT**

The CloudFormation template creates a stack that represents one worker node. You must create a stack for each worker node.

**NOTE**

If you do not use the provided CloudFormation template to create your worker nodes, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

**Prerequisites**

- You configured an AWS account.
- You added your AWS keys and region to your local AWS profile by running `aws configure`.
- You generated the Ignition config files for your cluster.
- You created and configured a VPC and associated subnets in AWS.
- You created and configured DNS, load balancers, and listeners in AWS.
- You created the security groups and roles required for your cluster in AWS.
- You created the bootstrap machine.
- You created the control plane machines.

**Procedure**

1. Create a JSON file that contains the parameter values that the CloudFormation template requires:

```json
[
  {
    "ParameterKey": "InfrastructureName",  ①
    "ParameterValue": "mycluster-<random_string>"  ②
  },
  {
    "ParameterKey": "RhcosAmi",  ③
    "ParameterValue": "ami-<random_string>"  ④
  },
  {
    "ParameterKey": "Subnet",  ⑤
    "ParameterValue": "subnet-<random_string>"  ⑥
  },
  {
    "ParameterKey": "WorkerSecurityGroupId",  ⑦
    "ParameterValue": "sg-<random_string>"  ⑧
  },
  {
    "ParameterKey": "IgnitionLocation",  ⑨
    "ParameterValue": "https://api-int.<cluster_name>.<domain_name>:22623/config/worker"  ⑩
  },
  {
    "ParameterKey": "CertificateAuthorities",  ⑪
    "ParameterValue": ""  ⑫
  },
  {
    "ParameterKey": "WorkerInstanceProfileName",  ⑬
    "ParameterValue": ""  ⑭
  },
  {
    "ParameterKey": "WorkerInstanceType",  ⑮
    "ParameterValue": "m4.large"  ⑯
  }
]
```

① The name for your cluster infrastructure that is encoded in your Ignition config files for the cluster.
Specify the infrastructure name that you extracted from the Ignition config file metadata, which has the format `<cluster-name>-<random-string>`.  

Current Red Hat Enterprise Linux CoreOS (RHCOS) AMI to use for the worker nodes.  

Specify an `AWS::EC2::Image::Id` value.  

A subnet, preferably private, to launch the worker nodes on.  

Specify a subnet from the `PrivateSubnets` value from the output of the CloudFormation template for DNS and load balancing.  

The worker security group ID to associate with worker nodes.  

Specify the `WorkerSecurityGroupId` value from the output of the CloudFormation template for the security group and roles.  

The location to fetch bootstrap Ignition config file from.  

Specify the generated Ignition config location, `https://api-int.<cluster_name>.<domain_name>:22623/config/worker`.  

Base64 encoded certificate authority string to use.  

Specify the value from the `worker.ign` file that is in the installation directory. This value is the long string with the format `data:text/plain;charset=utf-8;base64,ABC…xYz==`.  

The IAM profile to associate with worker nodes.  

Specify the `WorkerInstanceProfile` parameter value from the output of the CloudFormation template for the security group and roles.  

The type of AWS instance to use for the control plane machines.  

Allowed values:

- `m4.large`
- `m4.xlarge`
- `m4.2xlarge`
- `m4.4xlarge`
- `m4.8xlarge`
- `m4.10xlarge`
- `m4.16xlarge`
- `m5.large`
- `m5.xlarge`
- `m5.2xlarge`
- `m5.4xlarge`
• m5.8xlarge
• m5.10xlarge
• m5.16xlarge
• m6i.xlarge
• c4.2xlarge
• c4.4xlarge
• c4.8xlarge
• r4.large
• r4.xlarge
• r4.2xlarge
• r4.4xlarge
• r4.8xlarge
• r4.16xlarge

IMPORTANT
If m4 instance types are not available in your region, such as with eu-west-3, use m5 types instead.

2. Copy the template from the CloudFormation template for worker machines section of this topic and save it as a YAML file on your computer. This template describes the networking objects and load balancers that your cluster requires.

3. If you specified an m5 instance type as the value for WorkerInstanceType, add that instance type to the WorkerInstanceType.AllowedValues parameter in the CloudFormation template.

4. Launch the CloudFormation template to create a stack of AWS resources that represent a worker node:

IMPORTANT
You must enter the command on a single line.

```
$ aws cloudformation create-stack --stack-name <name> 1
   --template-body:////<template>.yaml 2
   --parameters file://<parameters>.json 3
```

1 <name> is the name for the CloudFormation stack, such as cluster-worker-1. You need the name of this stack if you remove the cluster.

2 <template> is the relative path to and name of the CloudFormation template YAML file that you saved.
<parameters> is the relative path to and name of the CloudFormation parameters JSON file.

Example output

```
```

**NOTE**

The CloudFormation template creates a stack that represents one worker node.

5. Confirm that the template components exist:

```bash
$ aws cloudformation describe-stacks --stack-name <name>
```

6. Continue to create worker stacks until you have created enough worker machines for your cluster. You can create additional worker stacks by referencing the same template and parameter files and specifying a different stack name.

**IMPORTANT**

You must create at least two worker machines, so you must create at least two stacks that use this CloudFormation template.

### 2.11.14.1. CloudFormation template for worker machines

You can use the following CloudFormation template to deploy the worker machines that you need for your OpenShift Container Platform cluster.

**Example 2.48. CloudFormation template for worker machines**

```yaml
AWSTemplateFormatVersion: 2010-09-09
Description: Template for OpenShift Cluster Node Launch (EC2 worker instance)

Parameters:
  InfrastructureName:
    AllowedPattern: ^[a-zA-Z][a-zA-Z0-9-]{0,26}$
    MaxLength: 27
    MinLength: 1
    ConstraintDescription: Infrastructure name must be alphanumeric, start with a letter, and have a maximum of 27 characters.
    Description: A short, unique cluster ID used to tag nodes for the kubelet cloud provider.
    Type: String
  RhcosAmi:
    Description: Current Red Hat Enterprise Linux CoreOS AMI to use for bootstrap.
    Type: AWS::EC2::Image::Id
  Subnet:
    Description: The subnets, recommend private, to launch the master nodes into.
    Type: AWS::EC2::Subnet::Id
  WorkerSecurityGroupId:
    Description: The master security group ID to associate with master nodes.
```
Type: AWS::EC2::SecurityGroup::Id
IgnitionLocation:
  Default: https://api-int.$CLUSTER_NAME.$DOMAIN:22623/config/worker
  Description: Ignition config file location.
  Type: String
CertificateAuthorities:
  Default: data:text/plain;charset=utf-8;base64,ABC...xYz==
  Description: Base64 encoded certificate authority string to use.
  Type: String
WorkerInstanceProfileName:
  Description: IAM profile to associate with master nodes.
  Type: String
WorkerInstanceType:
  Default: m5.large
  Type: String
  AllowedValues:
  - "m4.large"
  - "m4.xlarge"
  - "m4.2xlarge"
  - "m4.4xlarge"
  - "m4.10xlarge"
  - "m4.16xlarge"
  - "m5.large"
  - "m5.xlarge"
  - "m5.2xlarge"
  - "m5.4xlarge"
  - "m5.8xlarge"
  - "m5.12xlarge"
  - "m5.16xlarge"
  - "m5a.large"
  - "m5a.xlarge"
  - "m5a.2xlarge"
  - "m5a.4xlarge"
  - "m5a.8xlarge"
  - "m5a.10xlarge"
  - "m5a.16xlarge"
  - "c4.large"
  - "c4.xlarge"
  - "c4.2xlarge"
  - "c4.4xlarge"
  - "c4.8xlarge"
  - "c5.large"
  - "c5.xlarge"
  - "c5.2xlarge"
  - "c5.4xlarge"
  - "c5.9xlarge"
  - "c5.12xlarge"
  - "c5.18xlarge"
  - "c5.24xlarge"
  - "c5a.large"
  - "c5a.xlarge"
  - "c5a.2xlarge"
  - "c5a.4xlarge"
  - "c5a.8xlarge"
  - "c5a.12xlarge"
  - "c5a.16xlarge"
- "c5a.24xlarge"
- "r4.large"
- "r4.xlarge"
- "r4.2xlarge"
- "r4.4xlarge"
- "r4.8xlarge"
- "r4.16xlarge"
- "r5.large"
- "r5.xlarge"
- "r5.2xlarge"
- "r5.4xlarge"
- "r5.8xlarge"
- "r5.12xlarge"
- "r5.16xlarge"
- "r5.24xlarge"
- "r5a.large"
- "r5a.xlarge"
- "r5a.2xlarge"
- "r5a.4xlarge"
- "r5a.8xlarge"
- "r5a.12xlarge"
- "r5a.16xlarge"
- "r5a.24xlarge"
- "t3.large"
- "t3.xlarge"
- "t3.2xlarge"
- "t3a.large"
- "t3a.xlarge"
- "t3a.2xlarge"

Metadata:
AWS::CloudFormation::Interface:
  ParameterGroups:
  - Label: default: "Cluster Information"
    Parameters:
      - InfrastructureName
  - Label: default: "Host Information"
    Parameters:
      - WorkerInstanceType
      - RhcosAmi
      - IgnitionLocation
      - CertificateAuthorities
      - WorkerSecurityGroupIId
      - WorkerInstanceProfileName
  - Label: default: "Network Configuration"
    Parameters:
      - Subnet

ParameterLabels:
Subnet: default: "Subnet"
InfrastructureName: default: "Infrastructure Name"
WorkerInstanceType:
2.11.15. Initializing the bootstrap sequence on AWS with user-provisioned infrastructure

After you create all of the required infrastructure in Amazon Web Services (AWS), you can start the bootstrap sequence that initializes the OpenShift Container Platform control plane.

**Prerequisites**
• You configured an AWS account.
• You added your AWS keys and region to your local AWS profile by running `aws configure`.
• You generated the Ignition config files for your cluster.
• You created and configured a VPC and associated subnets in AWS.
• You created and configured DNS, load balancers, and listeners in AWS.
• You created the security groups and roles required for your cluster in AWS.
• You created the bootstrap machine.
• You created the control plane machines.
• You created the worker nodes.

Procedure

1. Change to the directory that contains the installation program and start the bootstrap process that initializes the OpenShift Container Platform control plane:

   ```
   $ ./openshift-install wait-for bootstrap-complete --dir <installation_directory> \  
      --log-level=info
   ```

   1 For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   2 To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

Example output

```INFO Waiting up to 20m0s for the Kubernetes API at https://api.mycluster.example.com:6443... INFO API v1.19.0+9f84db3 up INFO Waiting up to 30m0s for bootstrapping to complete... INFO It is now safe to remove the bootstrap resources INFO Time elapsed: 1s
```

If the command exits without a **FATAL** warning, your OpenShift Container Platform control plane has initialized.

**NOTE**

After the control plane initializes, it sets up the compute nodes and installs additional services in the form of Operators.

Additional resources

• See **Monitoring installation progress** for details about monitoring the installation, bootstrap, and control plane logs as an OpenShift Container Platform installation progresses.
- See Gathering bootstrap node diagnostic data for information about troubleshooting issues related to the bootstrap process.

### 2.11.16. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

**Procedure**

1. Export the **kubeadm** credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run **oc** commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   ```

   **Example output**

   ```
   system:admin
   ```

### 2.11.17. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

**Prerequisites**

- You added machines to your cluster.

**Procedure**

1. Confirm that the cluster recognizes the machines:

   ```bash
   $ oc get nodes
   ```

   **Example output**
The output lists all of the machines that you created.

NOTE

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

   ```
   $ oc get csr
   ```

**Example output**

```
NAME        AGE     REQUESTOR                                                           CONDITION
---         ---     ---------------------------------------------------------------          --------
csr-8b2br   15m     system:serviceaccount:openshift-machine-config-operator:node-bootstrapper   Pending

csr-8vnps   15m     system:serviceaccount:openshift-machine-config-operator:node-bootstrapper   Pending
...
```

In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

NOTE

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. Once the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.
NOTE
For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the `oc exec`, `oc rsh`, and `oc logs` commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the `node-bootstrapper` service account in the `system:node` or `system:admin` groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:
  
  ```bash
  $ oc adm certificate approve <csr_name>  
  ```

  `<csr_name>` is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

  ```bash
  $ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs --no-run-if-empty oc adm certificate approve
  ```

NOTE
Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```bash
$ oc get csr
```

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-c57lv</td>
<td>5m26s</td>
<td>system:node:ip-10-0-95-157.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td></td>
<td></td>
<td>...</td>
<td></td>
</tr>
</tbody>
</table>

5. If the remaining CSRs are not approved, and are in the `Pending` status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

  ```bash
  $ oc adm certificate approve <csr_name>  
  ```

  `<csr_name>` is the name of a CSR from the list of current CSRs.
To approve all pending CSRs, run the following command:

```bash
$ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs oc adm certificate approve
```

6. After all client and server CSRs have been approved, the machines have the Ready status. Verify this by running the following command:

```bash
$ oc get nodes
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>74m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>worker-0</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>worker-1</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.20.0</td>
</tr>
</tbody>
</table>

**NOTE**

It can take a few minutes after approval of the server CSRs for the machines to transition to the Ready status.

**Additional information**

- For more information on CSRs, see [Certificate Signing Requests](#).

### 2.11.18. Initial Operator configuration

After the control plane initializes, you must immediately configure some Operators so that they all become available.

**Prerequisites**

- Your control plane has initialized.

**Procedure**

1. Watch the cluster components come online:

```bash
$ watch -n5 oc get clusteroperators
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION AVAILABLE</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>
<th>SINCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>authentication</td>
<td>4.6.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>3h56m</td>
</tr>
<tr>
<td>cloud-credential</td>
<td>4.6.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>29h</td>
</tr>
<tr>
<td>cluster-autoscaler</td>
<td>4.6.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>29h</td>
</tr>
<tr>
<td>config-operator</td>
<td>4.6.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>6h39m</td>
</tr>
<tr>
<td>console</td>
<td>4.6.0</td>
<td>True</td>
<td>False</td>
<td>False</td>
<td>3h59m</td>
</tr>
</tbody>
</table>
2.11.18.1. Disabling the default OperatorHub sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

Procedure

- Disable the sources for the default catalogs by adding `disableAllDefaultSources: true` to the `OperatorHub` object:

  ```
  $ oc patch OperatorHub cluster --type json \
  -p '[{"op": "add", "path": "/spec/disableAllDefaultSources", "value": true}]'
  ```

**TIP**

Alternatively, you can use the web console to manage catalog sources. From the Administration → Cluster Settings → Global Configuration → OperatorHub page, click the Sources tab, where you can create, delete, disable, and enable individual sources.

2.11.18.2. Image registry storage configuration

Amazon Web Services provides default storage, which means the Image Registry Operator is available after installation. However, if the Registry Operator cannot create an S3 bucket and automatically configure storage, you must manually configure registry storage.
Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the **Recreate** rollout strategy during upgrades.

### 2.11.18.2.1. Configuring registry storage for AWS with user-provisioned infrastructure

During installation, your cloud credentials are sufficient to create an Amazon S3 bucket and the Registry Operator will automatically configure storage.

If the Registry Operator cannot create an S3 bucket and automatically configure storage, you can create an S3 bucket and configure storage with the following procedure.

**Prerequisites**

- You have a cluster on AWS with user-provisioned infrastructure.
- For Amazon S3 storage, the secret is expected to contain two keys:
  - `REGISTRY_STORAGE_S3_ACCESSKEY`
  - `REGISTRY_STORAGE_S3_SECRETKEY`

**Procedure**

Use the following procedure if the Registry Operator cannot create an S3 bucket and automatically configure storage.

1. Set up a **Bucket Lifecycle Policy** to abort incomplete multipart uploads that are one day old.

2. Fill in the storage configuration in `configs.imageregistry.operator.openshift.io/cluster`:

   ```
   $ oc edit configs.imageregistry.operator.openshift.io/cluster
   
   storage:
   s3:
     bucket: <bucket-name>
     region: <region-name>
   
   WARNING
   To secure your registry images in AWS, **block public access** to the S3 bucket.
   ```

### 2.11.18.2.2. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.
Procedure

- To set the image registry storage to an empty directory:

```bash
$ oc patch configs.imageregistry.operator.openshift.io cluster --type merge --patch '{"spec":
{"storage":{"emptyDir":[]}}}
```

**WARNING**

Configure this option for only non-production clusters.

If you run this command before the Image Registry Operator initializes its components, the `oc patch` command fails with the following error:

```
Error from server (NotFound): configs.imageregistry.operator.openshift.io "cluster" not found
```

Wait a few minutes and run the command again.

2.11.19. Deleting the bootstrap resources

After you complete the initial Operator configuration for the cluster, remove the bootstrap resources from Amazon Web Services (AWS).

**Prerequisites**

- You completed the initial Operator configuration for your cluster.

**Procedure**

1. Delete the bootstrap resources. If you used the CloudFormation template, delete its stack:

   - Delete the stack by using the AWS CLI:

     ```bash
     $ aws cloudformation delete-stack --stack-name <name>
     ```

     `<name>` is the name of your bootstrap stack.

   - Delete the stack by using the AWS CloudFormation console.

2.11.20. Creating the Ingress DNS Records

If you removed the DNS Zone configuration, manually create DNS records that point to the Ingress load balancer. You can create either a wildcard record or specific records. While the following procedure uses A records, you can use other record types that you require, such as CNAME or alias.

**Prerequisites**
• You deployed an OpenShift Container Platform cluster on Amazon Web Services (AWS) that uses infrastructure that you provisioned.

• You installed the OpenShift CLI (oc).

• You installed the jq package.

• You downloaded the AWS CLI and installed it on your computer. See Install the AWS CLI Using the Bundled Installer (Linux, macOS, or Unix).

Procedure

1. Determine the routes to create.

   • To create a wildcard record, use *.{apps.<cluster_name>.<domain_name>}, where <cluster_name> is your cluster name, and <domain_name> is the Route 53 base domain for your OpenShift Container Platform cluster.

   • To create specific records, you must create a record for each route that your cluster uses, as shown in the output of the following command:

     Example output

        $ oc get --all-namespaces -o jsonpath='{range .items[*]}{range .status.ingress[*]}{.host}
        "{\"n\"}{{end}{end}' routes

        oauth-openshift.apps.<cluster_name>.<domain_name>
        console-openshift-console.apps.<cluster_name>.<domain_name>
        downloads-openshift-console.apps.<cluster_name>.<domain_name>
        alertmanager-main-openshift-monitoring.apps.<cluster_name>.<domain_name>
        grafana-openshift-monitoring.apps.<cluster_name>.<domain_name>
        prometheus-k8s-openshift-monitoring.apps.<cluster_name>.<domain_name>

2. Retrieve the Ingress Operator load balancer status and note the value of the external IP address that it uses, which is shown in the EXTERNAL-IP column:

   Example output

        $ oc -n openshift-ingress get service router-default

        NAME             TYPE           CLUSTER-IP      EXTERNAL-IP                            PORT(S)
        AGE
        router-default   LoadBalancer   172.30.62.215   ab3...28.us-east-2.elb.amazonaws.com
        80:31499/TCP,443:30693/TCP   5m

3. Locate the hosted zone ID for the load balancer:

   Example output

        $ aws elb describe-load-balancers | jq -r '.LoadBalancerDescriptions[] | select(.DNSName == "<external_ip>").CanonicalHostedZoneNameID'

   1 For <external_ip>, specify the value of the external IP address of the Ingress Operator load balancer that you obtained.
Example output

```
Z3AADJGX6KTTL2
```

The output of this command is the load balancer hosted zone ID.

4. Obtain the public hosted zone ID for your cluster’s domain:

```
$ aws route53 list-hosted-zones-by-name
   --dns-name "<domain_name>"
   --query 'HostedZones?[? Config.PrivateZone != `true` && Name == `<domain_name>`.].Id'
   --output text
```

1 2 For `<domain_name>`, specify the Route 53 base domain for your OpenShift Container Platform cluster.

Example output

```
/hostedzone/Z3URY6TWQ91KV
```

The public hosted zone ID for your domain is shown in the command output. In this example, it is `Z3URY6TWQ91KV`.

5. Add the alias records to your private zone:

```
$ aws route53 change-resource-record-sets
   --hosted-zone-id "<private_hosted_zone_id>"
   --change-batch '{
     "Changes": [
       {
         "Action": "CREATE",
         "ResourceRecordSet": {
           "Name": "\052.apps.<cluster_domain>",
           "Type": "A",
           "AliasTarget": {
             "HostedZoneId": "<hosted_zone_id>",
             "DNSName": "<external_ip>",
             "EvaluateTargetHealth": false
           }
         }
       }
     ]
   }'
```

1 For `<private_hosted_zone_id>`, specify the value from the output of the CloudFormation template for DNS and load balancing.

2 For `<cluster_domain>`, specify the domain or subdomain that you use with your OpenShift Container Platform cluster.

3 For `<hosted_zone_id>`, specify the public hosted zone ID for the load balancer that you obtained.
For `<external_ip>`, specify the value of the external IP address of the Ingress Operator load balancer. Ensure that you include the trailing period (.) in this parameter value.

6. Add the records to your public zone:

```bash
$ aws route53 change-resource-record-sets --hosted-zone-id "<public_hosted_zone_id>" --change-batch '{
  "Changes": [
    {
      "Action": "CREATE",
      "ResourceRecordSet": {
        "Name": "\052.apps.<cluster_domain>",
        "Type": "A",
        "AliasTarget": {
          "HostedZoneId": "<hosted_zone_id>",
          "DNSName": "<external_ip>",
          "EvaluateTargetHealth": false
        }
      }
    }
  ]}
```

1. For `<public_hosted_zone_id>`, specify the public hosted zone for your domain.
2. For `<cluster_domain>`, specify the domain or subdomain that you use with your OpenShift Container Platform cluster.
3. For `<hosted_zone_id>`, specify the public hosted zone ID for the load balancer that you obtained.
4. For `<external_ip>`, specify the value of the external IP address of the Ingress Operator load balancer. Ensure that you include the trailing period (.) in this parameter value.

2.11.21. Completing an AWS installation on user-provisioned infrastructure

After you start the OpenShift Container Platform installation on Amazon Web Service (AWS) user-provisioned infrastructure, monitor the deployment to completion.

Prerequisites

- You removed the bootstrap node for an OpenShift Container Platform cluster on user-provisioned AWS infrastructure.
- You installed the `oc` CLI.

Procedure

1. From the directory that contains the installation program, complete the cluster installation:

   ```bash
   $ ./openshift-install --dir <installation_directory> wait-for install-complete
   ```
For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

Example output

INFO Waiting up to 40m0s for the cluster at https://api.mycluster.example.com:6443 to initialize...
INFO Waiting up to 10m0s for the openshift-console route to be created...
INFO Install complete!
INFO To access the cluster as the system:admin user when using `oc`, run `export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig`
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Fe5en-ymBEc-Wt6NL"
INFO Time elapsed: 1s

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

2. Register your cluster on the Cluster registration page.

**2.11.22. Logging in to the cluster by using the web console**

The `kubeadmin` user exists by default after an OpenShift Container Platform installation. You can log in to your cluster as the `kubeadmin` user by using the OpenShift Container Platform web console.

**Prerequisites**

- You have access to the installation host.

- You completed a cluster installation and all cluster Operators are available.

**Procedure**

1. Obtain the password for the `kubeadmin` user from the `kubeadmin-password` file on the installation host:

   ```bash
   $ cat <installation_directory>/auth/kubeadmin-password
   ```
2. List the OpenShift Container Platform web console route:

```
$ oc get routes -n openshift-console | grep 'console-openshift'
```

Example output

```
course     console-openshift-console.apps.<cluster_name>.<base_domain>            console
https   reencrypt/Redirect   None
```

3. Navigate to the route detailed in the output of the preceding command in a web browser and log in as the **kubeadmin** user.

**Additional resources**

- See [Accessing the web console](#) for more details about accessing and understanding the OpenShift Container Platform web console.

### 2.11.23. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.6, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to the **OpenShift Cluster Manager**.

After you confirm that your **OpenShift Cluster Manager** inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use `subscription watch` to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- See [About remote health monitoring](#) for more information about the Telemetry service

### 2.11.24. Additional resources

- See [Working with stacks](#) in the AWS documentation for more information about AWS CloudFormation stacks.

### 2.11.25. Next steps

- Validate an installation.
- Customize your cluster.
- Configure image streams for the Cluster Samples Operator and the **must-gather** tool.
Learn how to use Operator Lifecycle Manager (OLM) on restricted networks.

If the mirror registry that you used to install your cluster has a trusted CA, add it to the cluster by configuring additional trust stores.

If necessary, you can opt out of remote health reporting.

If necessary, you can remove cloud provider credentials.

### 2.12. UNINSTALLING A CLUSTER ON AWS

You can remove a cluster that you deployed to Amazon Web Services (AWS).

#### 2.12.1. Removing a cluster that uses installer-provisioned infrastructure

You can remove a cluster that uses installer-provisioned infrastructure from your cloud.

**NOTE**

After uninstallation, check your cloud provider for any resources not removed properly, especially with User Provisioned Infrastructure (UPI) clusters. There might be resources that the installer did not create or that the installer is unable to access.

**Prerequisites**

- Have a copy of the installation program that you used to deploy the cluster.
- Have the files that the installation program generated when you created your cluster.

**Procedure**

1. From the directory that contains the installation program on the computer that you used to install the cluster, run the following command:

   ```bash
   $ ./openshift-install destroy cluster \
   --dir <installation_directory> --log-level info
   ```

   **1** For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   **2** To view different details, specify `warn`, `debug`, or `error` instead of `info`.

   **NOTE**

   You must specify the directory that contains the cluster definition files for your cluster. The installation program requires the `metadata.json` file in this directory to delete the cluster.

2. Optional: Delete the `<installation_directory>` directory and the OpenShift Container Platform installation program.
CHAPTER 3. INSTALLING ON AZURE

3.1. CONFIGURING AN AZURE ACCOUNT

Before you can install OpenShift Container Platform, you must configure a Microsoft Azure account.

**IMPORTANT**

All Azure resources that are available through public endpoints are subject to resource name restrictions, and you cannot create resources that use certain terms. For a list of terms that Azure restricts, see Resolve reserved resource name errors in the Azure documentation.

3.1.1. Azure account limits

The OpenShift Container Platform cluster uses a number of Microsoft Azure components, and the default Azure subscription and service limits, quotas, and constraints affect your ability to install OpenShift Container Platform clusters.

**IMPORTANT**

Default limits vary by offer category types, such as Free Trial and Pay-As-You-Go, and by series, such as Dv2, F, and G. For example, the default for Enterprise Agreement subscriptions is 350 cores.

Check the limits for your subscription type and if necessary, increase quota limits for your account before you install a default cluster on Azure.

The following table summarizes the Azure components whose limits can impact your ability to install and run OpenShift Container Platform clusters.

<table>
<thead>
<tr>
<th>Component</th>
<th>Number of components required by default</th>
<th>Default Azure limit</th>
<th>Description</th>
</tr>
</thead>
</table>

OpenShift Container Platform 4.6 Installing
A default cluster requires 40 vCPUs, so you must increase the account limit.

By default, each cluster creates the following instances:

- One bootstrap machine, which is removed after installation
- Three control plane machines
- Three compute machines

Because the bootstrap machine uses **Standard_D4s_v3** machines, which use 4 vCPUs, the control plane machines use **Standard_D8s_v3** virtual machines, which use 8 vCPUs, and the worker machines use **Standard_D4s_v3** virtual machines, which use 4 vCPUs, a default cluster requires 40 vCPUs. The bootstrap node VM, which uses 4 vCPUs, is used only during installation.

To deploy more worker nodes, enable autoscaling, deploy large workloads, or use a different instance type, you must further increase the vCPU limit for your account to ensure that your cluster can deploy the machines that you require.

By default, the installation program distributes control plane and compute machines across all availability zones within a region. To ensure high availability for your cluster, select a region with at least three availability zones. If your region contains fewer than three availability zones, the installation program places more than one control plane machine in the available zones.
OS Disk  |  7  | Default Azure limit  | Description
-- | -- | -- | --
| VM OS disk must be able to sustain a minimum throughput of 5000 IOPS / 200MBps. This throughput can be provided by having a minimum of 1 TiB Premium SSD (P30). In Azure, disk performance is directly dependent on SSD disk sizes, so to achieve the throughput supported by Standard_D8s_v3, or other similar machine types available, and the target of 5000 IOPS, at least a P30 disk is required.

Host caching must be set to **ReadOnly** for low read latency and high read IOPS and throughput. The reads performed from the cache, which is present either in the VM memory or in the local SSD disk, are much faster than the reads from the data disk, which is in the blob storage.

VNet  |  1  | 1000 per region  | Each default cluster requires one Virtual Network (VNet), which contains two subnets.

Network interfaces  |  6  | 65,536 per region  | Each default cluster requires six network interfaces. If you create more machines or your deployed workloads create load balancers, your cluster uses more network interfaces.

Network security groups  |  2  | 5000  | Each default cluster Each cluster creates network security groups for each subnet in the VNet. The default cluster creates network security groups for the control plane and for the compute node subnets:

<table>
<thead>
<tr>
<th>role</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>control plane</strong></td>
<td>Allows the control plane machines to be reached on port 6443 from anywhere</td>
</tr>
<tr>
<td><strong>node</strong></td>
<td>Allows worker nodes to be reached from the Internet on ports 80 and 443</td>
</tr>
</tbody>
</table>
Network load balancers

Each cluster creates the following load balancers:

- **default**: Public IP address that load balances requests to ports 80 and 443 across worker machines.
- **internal**: Private IP address that load balances requests to ports 6443 and 22623 across control plane machines.
- **external**: Public IP address that load balances requests to port 6443 across control plane machines.

If your applications create more Kubernetes LoadBalancer service objects, your cluster uses more load balancers.

Public IP addresses

Each of the two public load balancers uses a public IP address. The bootstrap machine also uses a public IP address so that you can SSH into the machine to troubleshoot issues during installation. The IP address for the bootstrap node is used only during installation.

Private IP addresses

The internal load balancer, each of the three control plane machines, and each of the three worker machines each use a private IP address.

Spot VM vCPUs (optional)

This is an optional component. To use spot VMs, you must increase the Azure default limit to at least twice the number of compute nodes in your cluster.

### 3.1.2. Configuring a public DNS zone in Azure

To install OpenShift Container Platform, the Microsoft Azure account you use must have a dedicated public hosted DNS zone in your account. This zone must be authoritative for the domain. This service provides cluster DNS resolution and name lookup for external connections to the cluster.

**Procedure**
1. Identify your domain, or subdomain, and registrar. You can transfer an existing domain and registrar or obtain a new one through Azure or another source.

**NOTE**
For more information about purchasing domains through Azure, see [Buy a custom domain name for Azure App Service](#) in the Azure documentation.

2. If you are using an existing domain and registrar, migrate its DNS to Azure. See [Migrate an active DNS name to Azure App Service](#) in the Azure documentation.

3. Configure DNS for your domain. Follow the steps in the Tutorial: Host your domain in Azure DNS in the Azure documentation to create a public hosted zone for your domain or subdomain, extract the new authoritative name servers, and update the registrar records for the name servers that your domain uses.

   Use an appropriate root domain, such as `openshiftcorp.com`, or subdomain, such as `clusters.openshiftcorp.com`.

4. If you use a subdomain, follow your company’s procedures to add its delegation records to the parent domain.

### 3.1.3. Increasing Azure account limits

To increase an account limit, file a support request on the Azure portal.

**NOTE**
You can increase only one type of quota per support request.

**Procedure**

1. From the Azure portal, click **Help + support** in the lower left corner.

2. Click **New support request** and then select the required values:
   
   a. From the **Issue type** list, select **Service and subscription limits (quotas)**
   
   b. From the **Subscription** list, select the subscription to modify.
   
   c. From the **Quota type** list, select the quota to increase. For example, select **Compute-VM (cores-vCPUs) subscription limit increases** to increase the number of vCPUs, which is required to install a cluster.
   
   d. Click **Next: Solutions**.

3. On the **Problem Details** page, provide the required information for your quota increase:
   
   a. Click **Provide details** and provide the required details in the **Quota details** window.
   
   b. In the **SUPPORT METHOD** and **CONTACT INFO** sections, provide the issue severity and your contact details.

4. Click **Next: Review + create** and then click **Create**.

### 3.1.4. Required Azure roles
OpenShift Container Platform needs a service principal so it can manage Microsoft Azure resources. Before you can create a service principal, your Azure account subscription must have the following roles:

- **User Access Administrator**
- **Owner**

To set roles on the Azure portal, see the Manage access to Azure resources using RBAC and the Azure portal in the Azure documentation.

### 3.1.5. Creating a service principal

Because OpenShift Container Platform and its installation program must create Microsoft Azure resources through Azure Resource Manager, you must create a service principal to represent it.

#### Prerequisites

- Install or update the Azure CLI.
- Install the `jq` package.
- Your Azure account has the required roles for the subscription that you use.

#### Procedure

1. Log in to the Azure CLI:

   ```bash
   $ az login
   ``

   Log in to Azure in the web console by using your credentials.

2. If your Azure account uses subscriptions, ensure that you are using the right subscription.
   
   a. View the list of available accounts and record the `tenantId` value for the subscription you want to use for your cluster:

   ```bash
   $ az account list --refresh
   ```

   **Example output**

   ```json
   [
   {
   "cloudName": "AzureCloud",
   "id": "9bab1460-96d5-40b3-a78e-17b15e978a80",
   "isDefault": true,
   "name": "Subscription Name",
   "state": "Enabled",
   "tenantId": "6057c7e9-b3ae-489d-a54e-de3f6bf6a8ee",
   "user": {
   "name": "you@example.com",
   "type": "user"
   }
   }
   ]
   ```
b. View your active account details and confirm that the tenantId value matches the subscription you want to use:

```
$ az account show
```

**Example output**

```json
{
  "environmentName": "AzureCloud",
  "id": "9bab1460-96d5-40b3-a78e-17b15e978a80",
  "isDefault": true,
  "name": "Subscription Name",
  "state": "Enabled",
  "tenantId": "6057c7e9-b3ae-489d-a54e-de3f6bf6a8ee",
  "user": {
    "name": "you@example.com",
    "type": "user"
  }
}
```

1. Ensure that the value of the tenantId parameter is the UUID of the correct subscription.

c. If you are not using the right subscription, change the active subscription:

```
$ az account set -s <id>
```

1. Substitute the value of the id for the subscription that you want to use for <id>.

d. If you changed the active subscription, display your account information again:

```
$ az account show
```

**Example output**

```json
{
  "environmentName": "AzureCloud",
  "id": "33212d16-bdf6-45cb-b038-f6565b61edda",
  "isDefault": true,
  "name": "Subscription Name",
  "state": "Enabled",
  "tenantId": "8049c7e9-c3de-762d-a54e-dc3f6be6a7ee",
  "user": {
    "name": "you@example.com",
    "type": "user"
  }
}
```

3. Record the values of the tenantId and id parameters from the previous output. You need these values during OpenShift Container Platform installation.

4. Create the service principal for your account:
Replace `<service_principal>` with the name to assign to the service principal.

5. Record the values of the `appId` and `password` parameters from the previous output. You need these values during OpenShift Container Platform installation.

6. Grant additional permissions to the service principal.

   - You must always add the Contributor and User Access Administrator roles to the app registration service principal so the cluster can assign credentials for its components.

   - To operate the Cloud Credential Operator (CCO) in mint mode, the app registration service principal also requires the Azure Active Directory Graph/Application.ReadWrite.OwnedBy API permission.

   - To operate the CCO in passthrough mode, the app registration service principal does not require additional API permissions.

For more information about CCO modes, see the Cloud Credential Operator entry in the Red Hat Operators reference content.

   a. To assign the User Access Administrator role, run the following command:

      ```bash
      $ az role assignment create --role "User Access Administrator" \
        --assignee-object-id $(az ad sp list --filter "appId eq '<appId>'" \
        | jq '.[0].objectId' -r)
      ```

      Replace `<appld>` with the appld parameter value for your service principal.

   b. To assign the Azure Active Directory Graph permission, run the following command:

      ```bash
      $ az ad app permission add --id <appld> \ 
        --api 00000002-0000-0000-c000-000000000000 \ 
        --api-permissions 824c81eb-e3f8-4ee6-8f6d-de7f50d565b7=Role
      ```

      Replace `<appld>` with the `appld` parameter value for your service principal.
Example output

Invoking "az ad app permission grant --id 46d33abc-b8a3-46d8-8c84-f0fd58177435 --api 00000002-0000-0000-c000-000000000000" is needed to make the change effective

For more information about the specific permissions that you grant with this command, see the GUID Table for Windows Azure Active Directory Permissions.

c. Approve the permissions request. If your account does not have the Azure Active Directory tenant administrator role, follow the guidelines for your organization to request that the tenant administrator approve your permissions request.

```bash
$ az ad app permission grant --id <appId> \
  --api 00000002-0000-0000-c000-000000000000
```

1 Replace `<appId>` with the `appId` parameter value for your service principal.

3.1.6. Supported Azure regions

The installation program dynamically generates the list of available Microsoft Azure regions based on your subscription. The following Azure regions were tested and validated in OpenShift Container Platform version 4.6.1:

Supported Azure public regions

- **australiacentral** (Australia Central)
- **australiaeast** (Australia East)
- **australiasoutheast** (Australia South East)
- **brazilsouth** (Brazil South)
- **canadacentral** (Canada Central)
- **canadaeast** (Canada East)
- **centralindia** (Central India)
- **centralus** (Central US)
- **eastasia** (East Asia)
- **eastus** (East US)
- **eastus2** (East US 2)
- **francecentral** (France Central)
- **germanywestcentral** (Germany West Central)
- **japaneast** (Japan East)
- **japanwest** (Japan West)
- **koreacentral** (Korea Central)
- **koreasouth** (Korea South)
- **northcentralus** (North Central US)
- **northeurope** (North Europe)
- **norwayeast** (Norway East)
- **southafricanorth** (South Africa North)
- **southcentralus** (South Central US)
- **southeastasia** (Southeast Asia)
- **southindia** (South India)
- **switzerlandnorth** (Switzerland North)
- **uaenorth** (UAE North)
- **uksouth** (UK South)
- **ukwest** (UK West)
- **westcentralus** (West Central US)
- **westeurope** (West Europe)
- **westindia** (West India)
- **westus** (West US)
- **westus2** (West US 2)

**Supported Azure Government regions**
Support for the following Microsoft Azure Government (MAG) regions was added in OpenShift Container Platform version 4.6:

- **usgovtexas** (US Gov Texas)
- **usgovvirginia** (US Gov Virginia)

You can reference all available MAG regions in the Azure documentation. Other provided MAG regions are expected to work with OpenShift Container Platform, but have not been tested.

### 3.1.7. Next steps

- Install an OpenShift Container Platform cluster on Azure. You can install a customized cluster or quickly install a cluster with default options.

### 3.2. MANUALLY CREATING IAM FOR AZURE

In environments where the cloud identity and access management (IAM) APIs are not reachable, or the administrator prefers not to store an administrator-level credential secret in the cluster **kube-system** namespace, you can put the Cloud Credential Operator (CCO) into manual mode before you install the
3.2.1. Alternatives to storing administrator-level secrets in the kube-system project

The Cloud Credential Operator (CCO) manages cloud provider credentials as Kubernetes custom resource definitions (CRDs). You can configure the CCO to suit the security requirements of your organization by setting different values for the `credentialsMode` parameter in the `install-config.yaml` file.

If you prefer not to store an administrator-level credential secret in the cluster `kube-system` project, you can set the `credentialsMode` parameter for the CCO to `Manual` when installing OpenShift Container Platform and manage your cloud credentials manually.

Using manual mode allows each cluster component to have only the permissions it requires, without storing an administrator-level credential in the cluster. You can also use this mode if your environment does not have connectivity to the cloud provider public IAM endpoint. However, you must manually reconcile permissions with new release images for every upgrade. You must also manually supply credentials for every component that requests them.

Additional resources

- For a detailed description of all available CCO credential modes and their supported platforms, see the Cloud Credential Operator reference.

3.2.2. Manually create IAM

The Cloud Credential Operator (CCO) can be put into manual mode prior to installation in environments where the cloud identity and access management (IAM) APIs are not reachable, or the administrator prefers not to store an administrator-level credential secret in the cluster `kube-system` namespace.

Procedure

1. To generate the manifests, run the following command from the directory that contains the installation program:

   ```bash
   $ openshift-install create manifests --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

2. Insert a config map into the manifests directory so that the Cloud Credential Operator is placed in manual mode:

   ```yaml
   $ cat <<EOF > mycluster/manifests/cco-configmap.yaml
   apiVersion: v1
   kind: ConfigMap
   metadata:
     name: cloud-credential-operator-config
     namespace: openshift-cloud-credential-operator
   annotations:
     release.openshift.io/create-only: "true"
   EOF
   ```
3. Remove the admin credential secret created using your local cloud credentials. This removal prevents your admin credential from being stored in the cluster:

   $ rm mycluster/openshift/99_cloud-creds-secret.yaml

4. From the directory that contains the installation program, obtain details of the OpenShift Container Platform release image that your openshift-install binary is built to use:

   $ openshift-install version

   Example output

   release image quay.io/openshift-release-dev/ocp-release:4.y.z-x86_64

5. Locate all CredentialsRequest objects in this release image that target the cloud you are deploying on:

   $ oc adm release extract quay.io/openshift-release-dev/ocp-release:4.y.z-x86_64 --credentials-requests --cloud=azure

   This displays the details for each request.

   Sample CredentialsRequest object

   apiVersion: cloudcredential.openshift.io/v1
   kind: CredentialsRequest
   metadata:
     labels:
       controller-tools.k8s.io: "1.0"
   name: openshift-image-registry-azure
   namespace: openshift-image-registry-operator
   spec:
     secretRef:
       name: installer-cloud-credentials
       namespace: openshift-image-registry
   providerSpec:
     apiVersion: cloudcredential.openshift.io/v1
     kind: AzureProviderSpec
     roleBindings:
       - role: Contributor

6. Create YAML files for secrets in the openshift-install manifests directory that you generated previously. The secrets must be stored using the namespace and secret name defined in the spec.secretRef for each credentialsRequest. The format for the secret data varies for each cloud provider.

7. From the directory that contains the installation program, proceed with your cluster creation:

   $ openshift-install create cluster --dir <installation_directory>
IMPORTANT

Before upgrading a cluster that uses manually maintained credentials, you must ensure that the CCO is in an upgradeable state. For details, see the Upgrading clusters with manually maintained credentials section of the installation content for your cloud provider.

3.2.3. Admin credentials root secret format

Each cloud provider uses a credentials root secret in the `kube-system` namespace by convention, which is then used to satisfy all credentials requests and create their respective secrets. This is done either by minting new credentials, with mint mode, or by copying the credentials root secret, with passthrough mode.

The format for the secret varies by cloud, and is also used for each `CredentialsRequest` secret.

Microsoft Azure secret format

```yaml
apiVersion: v1
kind: Secret
metadata:
  namespace: kube-system
  name: azure-credentials
stringData:
  azure_subscription_id: <SubscriptionID>
  azure_client_id: <ClientID>
  azure_client_secret: <ClientSecret>
  azure_tenant_id: <TenantID>
  azure_resource_prefix: <ResourcePrefix>
  azure_resourcegroup: <ResourceGroup>
  azure_region: <Region>
```

On Microsoft Azure, the credentials secret format includes two properties that must contain the cluster’s infrastructure ID, generated randomly for each cluster installation. This value can be found after running create manifests:

```bash
$ cat .openshift_install_state.json | jq ".installconfig.ClusterID.InfraID" -r
```

Example output

```
mycluster-2mpcn
```

This value would be used in the secret data as follows:

```
  azure_resource_prefix: mycluster-2mpcn
  azure_resourcegroup: mycluster-2mpcn-rg
```

3.2.4. Upgrading clusters with manually maintained credentials

If credentials are added in a future release, the Cloud Credential Operator (CCO) upgradable status for a cluster with manually maintained credentials changes to false. For minor release, for example, from 4.5 to 4.6, this status prevents you from upgrading until you have addressed any updated permissions.
For z-stream releases, for example, from 4.5.10 to 4.5.11, the upgrade is not blocked, but the credentials must still be updated for the new release.

Use the **Administrator** perspective of the web console to determine if the CCO is upgradeable.

1. Navigate to **Administration → Cluster Settings**.
2. To view the CCO status details, click **cloud-credential** in the **Cluster Operators** list.
3. If the **Upgradeable** status in the **Conditions** section is **False**, examine the **credentialsRequests** for the new release and update the manually maintained credentials on your cluster to match before upgrading.

In addition to creating new credentials for the release image that you are upgrading to, you must review the required permissions for existing credentials and accommodate any new permissions requirements for existing components in the new release. The CCO cannot detect these mismatches and will not set **upgradable** to **false** in this case.

The *Manually creating IAM* section of the installation content for your cloud provider explains how to obtain and use the credentials required for your cloud.

### 3.2.5. Mint mode

Mint mode is the default and recommended Cloud Credential Operator (CCO) credentials mode for OpenShift Container Platform. In this mode, the CCO uses the provided administrator-level cloud credential to run the cluster. Mint mode is supported for AWS, GCP, and Azure.

In mint mode, the **admin** credential is stored in the **kube-system** namespace and then used by the CCO to process the **CredentialsRequest** objects in the cluster and create users for each with specific permissions.

The benefits of mint mode include:

- Each cluster component has only the permissions it requires
- Automatic, on-going reconciliation for cloud credentials, including additional credentials or permissions that might be required for upgrades

One drawback is that mint mode requires **admin** credential storage in a cluster **kube-system** secret.

### 3.2.6. Next steps

- Install an OpenShift Container Platform cluster:
  - Installing a cluster quickly on Azure with default options on installer-provisioned infrastructure
  - Install a cluster with cloud customizations on installer-provisioned infrastructure
  - Install a cluster with network customizations on installer-provisioned infrastructure

### 3.3. INSTALLING A CLUSTER QUICKLY ON AZURE

In OpenShift Container Platform version 4.6, you can install a cluster on Microsoft Azure that uses the default configuration options.
3.3.1. Prerequisites

- Review details about the OpenShift Container Platform installation and update processes.
- Configure an Azure account to host the cluster and determine the tested and validated region to deploy the cluster to.
- If you use a firewall, you must configure it to allow the sites that your cluster requires access to.
- If you do not allow the system to manage identity and access management (IAM), then a cluster administrator can manually create and maintain IAM credentials. Manual mode can also be used in environments where the cloud IAM APIs are not reachable.

3.3.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.6, you require access to the Internet to install your cluster.

You must have Internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

3.3.3. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your `ssh-agent` and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

**NOTE**

In a production environment, you require disaster recovery and debugging.

You can use this key to SSH into the master nodes as the user `core`. When you deploy the cluster, the key is added to the `core` user’s `~/.ssh/authorized_keys` list.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.
Procedure

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ ssh-keygen -t ed25519 -N " \\
   -f <path>/<file_name>  
   ```

   1 Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   Running this command generates an SSH key that does not require a password in the location that you specified.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the ssh-agent process as a background task:

   ```
   $ eval "$(ssh-agent -s)"
   ```

   **Example output**

   Agent pid 31874

   **NOTE**

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the ssh-agent:

   ```
   $ ssh-add <path>/<file_name>
   ```

   **Example output**

   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

   1 Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.
3.3.4. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on a local computer.

Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

   IMPORTANT

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   IMPORTANT

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ tar xvf openshift-install-linux.tar.gz
   ```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

3.3.5. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

   IMPORTANT

   You can run the create cluster command of the installation program only once, during initial installation.

Prerequisites
• Configure an account with the cloud platform that hosts your cluster.

• Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Change to the directory that contains the installation program and initialize the cluster deployment:

   ```bash
   $ ./openshift-install create cluster --dir <installation_directory> \ 
   --log-level=info
   ```

   1 For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

   2 To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

   **IMPORTANT**

   Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

Provide values at the prompts:

a. Optional: Select an SSH key to use to access your cluster machines.

   **NOTE**

   For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

b. Select `azure` as the platform to target.

c. If you do not have a Microsoft Azure profile stored on your computer, specify the following Azure parameter values for your subscription and service principal:

   • **azure subscription id** The subscription ID to use for the cluster. Specify the `id` value in your account output.

   • **azure tenant id** The tenant ID. Specify the `tenantId` value in your account output.

   • **azure service principal client id** The value of the `appId` parameter for the service principal.

   • **azure service principal client secret** The value of the `password` parameter for the service principal.

d. Select the region to deploy the cluster to.
e. Select the base domain to deploy the cluster to. The base domain corresponds to the Azure DNS Zone that you created for your cluster.

f. Enter a descriptive name for your cluster.

**IMPORTANT**

All Azure resources that are available through public endpoints are subject to resource name restrictions, and you cannot create resources that use certain terms. For a list of terms that Azure restricts, see Resolve reserved resource name errors in the Azure documentation.

g. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

**NOTE**

If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.

When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the **kubeadmin** user, display in your terminal.

**Example output**

```bash
... INFO Install complete! INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig' INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-Wt5AL" INFO Time elapsed: 36m22s
```

**NOTE**

The cluster access and credential information also outputs to `<installation_directory>/.openshift_install.log` when an installation succeeds.
IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

IMPORTANT

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

3.3.6. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) in order to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

IMPORTANT

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.6. Download and install the new version of oc.

3.3.6.1. Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.6 Linux Client entry and save the file.

4. Unpack the archive:

   $ tar xvzf <file>

5. Place the oc binary in a directory that is on your PATH.

To check your PATH, execute the following command:

   $ echo $PATH
After you install the OpenShift CLI, it is available using the `oc` command:

```bash
$ oc <command>
```

### 3.3.6.2. Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (`oc`) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.
3. Click **Download Now** next to the **OpenShift v4.6 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the `oc` binary to a directory that is on your PATH.
   To check your PATH, open the command prompt and execute the following command:

```bash
C:\> path
```

After you install the OpenShift CLI, it is available using the `oc` command:

```bash
C:\> oc <command>
```

### 3.3.6.3. Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (`oc`) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.
3. Click **Download Now** next to the **OpenShift v4.6 MacOSX Client** entry and save the file.
4. Unpack and unzip the archive.
5. Move the `oc` binary to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:

```bash
$ echo $PATH
```

After you install the OpenShift CLI, it is available using the `oc` command:

```bash
$ oc <command>
```
3.3.7. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

Procedure

1. Export the `kubeadm` credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   ``

   Example output

   ```
   system:admin
   ```

Additional resources

- See Accessing the web console for more details about accessing and understanding the OpenShift Container Platform web console.

3.3.8. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.6, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use `subscription watch` to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service

3.3.9. Next steps

- Customize your cluster.
If necessary, you can opt out of remote health reporting.

3.4. INSTALLING A CLUSTER ON AZURE WITH CUSTOMIZATIONS

In OpenShift Container Platform version 4.6, you can install a customized cluster on infrastructure that the installation program provisions on Microsoft Azure. To customize the installation, you modify parameters in the `install-config.yaml` file before you install the cluster.

3.4.1. Prerequisites

- Review details about the OpenShift Container Platform installation and update processes.
- Configure an Azure account to host the cluster and determine the tested and validated region to deploy the cluster to.
- If you use a firewall, you must configure it to allow the sites that your cluster requires access to.
- If you do not allow the system to manage identity and access management (IAM), then a cluster administrator can manually create and maintain IAM credentials. Manual mode can also be used in environments where the cloud IAM APIs are not reachable.

3.4.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.6, you require access to the Internet to install your cluster.

You must have Internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

3.4.3. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your `ssh-agent` and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

**NOTE**

In a production environment, you require disaster recovery and debugging.
You can use this key to SSH into the master nodes as the user `core`. When you deploy the cluster, the key is added to the `core` user’s `~/.ssh/authorized_keys` list.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

**Procedure**

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>  # 1
   ``

   Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

   Running this command generates an SSH key that does not require a password in the location that you specified.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the `x86_64` architecture, do not create a key that uses the `ed25519` algorithm. Instead, create a key that uses the `rsa` or `ecdsa` algorithm.

2. Start the `ssh-agent` process as a background task:

   ```bash
   $ eval "$(ssh-agent -s)"
   ``

   **Example output**

   ```
   Agent pid 31874
   ```

   **NOTE**

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the `ssh-agent`:

   ```bash
   $ ssh-add <path>/<file_name>  # 1
   ``

   **Example output**

   ```
   Identity added: /home/<you>/<path>/<file_name> (computer_name>
   ```
Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

3.4.4. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on a local computer.

Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

   **IMPORTANT**

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   **IMPORTANT**

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   $ tar xvf openshift-install-linux.tar.gz

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

3.4.5. Creating the installation configuration file
You can customize the OpenShift Container Platform cluster you install on Microsoft Azure.

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Create the `install-config.yaml` file.
   a. Change to the directory that contains the installation program and run the following command:

   ```bash
   $ ./openshift-install create install-config --dir <installation_directory>
   ```

   **IMPORTANT**
   Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

   b. At the prompts, provide the configuration details for your cloud:

   i. Optional: Select an SSH key to use to access your cluster machines.

   **NOTE**
   For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

   ii. Select `azure` as the platform to target.

   iii. If you do not have a Microsoft Azure profile stored on your computer, specify the following Azure parameter values for your subscription and service principal:

   - `azure subscription id` The subscription ID to use for the cluster. Specify the `id` value in your account output.

   - `azure tenant id` The tenant ID. Specify the `tenantId` value in your account output.

   - `azure service principal client id` The value of the `appId` parameter for the service principal.

   - `azure service principal client secret` The value of the `password` parameter for the service principal.
iv. Select the region to deploy the cluster to.

v. Select the base domain to deploy the cluster to. The base domain corresponds to the Azure DNS Zone that you created for your cluster.

vi. Enter a descriptive name for your cluster.

**IMPORTANT**

All Azure resources that are available through public endpoints are subject to resource name restrictions, and you cannot create resources that use certain terms. For a list of terms that Azure restricts, see Resolve reserved resource name errors in the Azure documentation.

vii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

2. Modify the `install-config.yaml` file. You can find more information about the available parameters in the Installation configuration parameters section.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

**IMPORTANT**

The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

### 3.4.5.1. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster’s platform. When you create the `install-config.yaml` installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the `install-config.yaml` file to provide more details about the platform.

**NOTE**

After installation, you cannot modify these parameters in the `install-config.yaml` file.

**IMPORTANT**

The `openshift-install` command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

### 3.4.5.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
</table>

OpenShift Container Platform 4.6 Installing
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is <code>v1</code>. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the <code>baseDomain</code> and <code>metadata.name</code> parameter values that uses the <code>&lt;metadata.name&gt;.&lt;baseDomain&gt;</code> format.</td>
<td>A fully-qualified domain or subdomain name, such as <code>example.com</code>.</td>
</tr>
<tr>
<td>metadata</td>
<td>Kubernetes resource <code>ObjectMeta</code>, from which only the <code>name</code> parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of <code>{{metadata.name}}.{{baseDomain}}</code>.</td>
<td>String of lowercase letters, hyphens (<code>-</code>), and periods (<code>.</code>), such as <code>dev</code>.</td>
</tr>
<tr>
<td>platform</td>
<td>The configuration for the specific platform upon which to perform the installation: <code>aws</code>, <code>baremetal</code>, <code>azure</code>, <code>openstack</code>, <code>ovirt</code>, <code>vsphere</code>. For additional information about <code>platform.&lt;platform&gt;</code> parameters, consult the following table for your specific platform.</td>
<td>Object</td>
</tr>
</tbody>
</table>
Pull Secret

Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.

```
{
  "auths":{
    "cloud.openshift.com":{
      "auth":"b3Blb=",
      "email":"you@example.com"
    },
    "quay.io":{
      "auth":"b3Blb=",
      "email":"you@example.com"
    }
  }
}
```

### 3.4.5.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

**Table 3.2. Network parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>networking</code></td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>NOTE</td>
<td></td>
</tr>
<tr>
<td></td>
<td>You cannot modify parameters specified by the <code>networking</code> object after installation.</td>
<td></td>
</tr>
<tr>
<td><code>networking.network</code></td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN.</td>
</tr>
<tr>
<td><code>networking.clusterNetwork</code></td>
<td>The IP address blocks for pods. The default value is 10.128.0.0/14 with a host prefix of /23. If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td>An array of objects. For example: networking: clusterNetwork: - cidr: 10.128.0.0/14 hostPrefix: 23</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td>networking.clusterNetwork.cidr</td>
<td>Required if you use networking.clusterNetwork. An IP address block. An IPv4 network.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td>networking.clusterNetwork.hostPrefix</td>
<td>The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given cidr. A hostPrefix value of 23 provides $2^{32 - 23} - 2$ pod IP addresses.</td>
<td>A subnet prefix. The default value is 23.</td>
</tr>
<tr>
<td>networking.serviceNetwork</td>
<td>The IP address block for services. The default value is 172.30.0.0/16. The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.</td>
<td>An array with an IP address block in CIDR format. For example: networking: serviceNetwork: - 172.30.0.0/16</td>
</tr>
<tr>
<td>networking.machineNetwork</td>
<td>The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td>An array of objects. For example: networking: machineNetwork: - cidr: 10.0.0.0/16</td>
</tr>
<tr>
<td>networking.machineNetwork.cidr</td>
<td>Required if you use networking.machineNetwork. An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24.</td>
<td>An IP network block in CIDR notation. For example, 10.0.0.0/16.</td>
</tr>
</tbody>
</table>

### 3.4.5.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

Table 3.3. Optional parameters
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of machine-pool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>compute.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td>compute.hyperthreading</td>
<td>Whether to enable or disable simultaneous multithreading, or <strong>hyperthreading</strong>, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td></td>
</tr>
<tr>
<td>compute.name</td>
<td>Required if you use <code>compute</code>. The name of the machine pool.</td>
<td>worker</td>
</tr>
<tr>
<td>compute.platform</td>
<td>Required if you use <code>compute</code>. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <code>controlPlane.platform</code> parameter value.</td>
<td><code>aws</code>, <code>azure</code>, <code>gcp</code>, <code>openstack</code>, <code>ovirt</code>, <code>vsphere</code>, or <code>{}</code></td>
</tr>
<tr>
<td>compute.replicas</td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
</tbody>
</table>

502
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlPlane</td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of MachinePool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>controlPlane.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are amd64 (the default).</td>
<td>String</td>
</tr>
<tr>
<td>controlPlane.hypertreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td></td>
</tr>
<tr>
<td>controlPlane.name</td>
<td>Required if you use controlPlane. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use controlPlane. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the compute.platform parameter value.</td>
<td>aws, azure, gcp, openstack, ovirt, vsphere, or{}</td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------</td>
</tr>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (&quot;&quot;&quot;).</td>
</tr>
</tbody>
</table>

**NOTE**

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Red Hat Operators reference content.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>fips</td>
<td>Enable or disable FIPS mode. The default is false (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</td>
<td>false or true</td>
</tr>
<tr>
<td>imageContentSources</td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects. Includes a <strong>source</strong> and, optionally, <strong>mirrors</strong>, as described in the following rows of this table.</td>
</tr>
<tr>
<td>imageContentSources.source</td>
<td>Required if you use <strong>imageContentSources</strong>. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td>imageContentSources.mirrors</td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
<tr>
<td>publish</td>
<td>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</td>
<td>Internal or External. To deploy a private cluster, which cannot be accessed from the internet, set <strong>publish</strong> to Internal. The default value is External.</td>
</tr>
</tbody>
</table>
The SSH key or keys to authenticate access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

One or more keys. For example:

```
sshKey:
  <key1>
  <key2>
  <key3>
```

### 3.4.5.1.4. Additional Azure configuration parameters

Additional Azure configuration parameters are described in the following table:

**Table 3.4. Additional Azure parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>compute.platform.azure.osDisk.diskSizeGB</code></td>
<td>The Azure disk size for the VM.</td>
<td>Integer that represents the size of the disk in GB. The default is 128.</td>
</tr>
<tr>
<td><code>compute.platform.azure.osDisk.diskType</code></td>
<td>Defines the type of disk.</td>
<td><code>standard_LRS</code>, <code>premium_LRS</code>, or <code>standardSSD_LRS</code>. The default is <code>premium_LRS</code>.</td>
</tr>
<tr>
<td><code>controlPlane.platform.azure.osDisk.diskSizeGB</code></td>
<td>The Azure disk size for the VM.</td>
<td>Integer that represents the size of the disk in GB. The default is 1024.</td>
</tr>
<tr>
<td><code>controlPlane.platform.azure.osDisk.diskType</code></td>
<td>Defines the type of disk.</td>
<td><code>premium_LRS</code> or <code>standardSSD_LRS</code>. The default is <code>premium_LRS</code>.</td>
</tr>
<tr>
<td><code>platform.azure.baseDomainResourceGroupName</code></td>
<td>The name of the resource group that contains the DNS zone for your base domain.</td>
<td>String, for example <code>production_cluster</code>.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>------------------------------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>platform.azure.outboundType</td>
<td>The outbound routing strategy used to connect your cluster to the internet. If you are using user-defined routing, you must have pre-existing networking available where the outbound routing has already been configured prior to installing a cluster. The installation program is not responsible for configuring user-defined routing.</td>
<td>LoadBalancer or UserDefinedRouting. The default is LoadBalancer.</td>
</tr>
<tr>
<td>platform.azure.region</td>
<td>The name of the Azure region that hosts your cluster.</td>
<td>Any valid region name, such as centralus.</td>
</tr>
<tr>
<td>platform.azure.zone</td>
<td>List of availability zones to place machines in. For high availability, specify at least two zones.</td>
<td>List of zones, for example [&quot;1&quot;, &quot;2&quot;, &quot;3&quot;].</td>
</tr>
<tr>
<td>platform.azure.networkResourceGroupName</td>
<td>The name of the resource group that contains the existing VNet that you want to deploy your cluster to. This name cannot be the same as the \texttt{platform.azure.baseDomainResourceGroupName}.</td>
<td>String.</td>
</tr>
<tr>
<td>platform.azure.virtualNetwork</td>
<td>The name of the existing VNet that you want to deploy your cluster to.</td>
<td>String.</td>
</tr>
<tr>
<td>platform.azure.controlPlaneSubnet</td>
<td>The name of the existing subnet in your VNet that you want to deploy your control plane machines to.</td>
<td>Valid CIDR, for example 10.0.0.0/16.</td>
</tr>
<tr>
<td>platform.azure.computeSubnet</td>
<td>The name of the existing subnet in your VNet that you want to deploy your compute machines to.</td>
<td>Valid CIDR, for example 10.0.0.0/16.</td>
</tr>
<tr>
<td>platform.azure.cloudName</td>
<td>The name of the Azure cloud environment that is used to configure the Azure SDK with the appropriate Azure API endpoints. If empty, the default value \texttt{AzurePublicCloud} is used.</td>
<td>Any valid cloud environment, such as AzurePublicCloud or AzureUSGovernmentCloud.</td>
</tr>
</tbody>
</table>

**NOTE**

You cannot customize Azure Availability Zones or Use tags to organize your Azure resources with an Azure cluster.
3.4.5.2. Sample customized `install-config.yaml` file for Azure

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

**IMPORTANT**

This sample YAML file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program and modify it.

```yaml
apiVersion: v1
baseDomain: example.com
controlPlane:  
  hyperthreading: Enabled
  name: master
  platform:
    azure:
      osDisk:
        diskSizeGB: 1024
        diskType: Premium_LRS
        type: Standard_D8s_v3
  replicas: 3
  compute:
    - hyperthreading: Enabled
      name: worker
      platform:
        azure:
          type: Standard_D2s_v3
          osDisk:
            diskSizeGB: 512
            diskType: Standard_LRS
          zones:
          - "1"
          - "2"
          - "3"
          replicas: 5
      metadata:
        name: test-cluster
  networking:
    clusterNetwork:
    - cidr: 10.128.0.0/14
      hostPrefix: 23
    machineNetwork:
    - cidr: 10.0.0.0/16
    networkType: OpenShiftSDN
    serviceNetwork:
    - 172.30.0.0/16
  platform:
    azure:
      baseDomainResourceGroupName: resource_group
      region: centralus
      resourceGroupName: existing_resource_group
      outboundType: Loadbalancer
```
1 Required. The installation program prompts you for this value.

2 If you do not provide these parameters and values, the installation program provides the default value.

3 The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, -, and the first line of the controlPlane section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

4 Whether to enable or disable simultaneous multithreading, or hyperthreading. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores. You can disable it by setting the parameter value to Disabled. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

   IMPORTANT

   If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger virtual machine types, such as Standard_D8s_v3, for your machines if you disable simultaneous multithreading.

5 You can specify the size of the disk to use in GB. Minimum recommendation for control plane nodes (also known as the master nodes) is 1024 GB.

6 Specify a list of zones to deploy your machines to. For high availability, specify at least two zones.

7 Specify the name of the resource group that contains the DNS zone for your base domain.

8 Specify the name of an already existing resource group to install your cluster to. If undefined, a new resource group is created for the cluster.

9 Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

   IMPORTANT

   The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

10 You can optionally provide the sshKey value that you use to access the machines in your cluster.
NOTE
For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

3.4.5.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

Prerequisites

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

NOTE
The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
     httpProxy: http://<username>:<pswd>@<ip>:<port> 1
     httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
     noProxy: example.com 3
   additionalTrustBundle:
     -----BEGIN CERTIFICATE-----
     <MY_TRUSTED_CA_CERT>
     -----END CERTIFICATE-----

   1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.
   2 A proxy URL to use for creating HTTPS connections outside the cluster.
   3 `noProxy` field.
   4 Additional trusted CA certificate.
   ```
A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For

If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace to hold the additional CA certificates. If you provide additionalTrustBundle and at least one proxy setting, the Proxy object is configured to reference the user-ca-bundle config map in the trustedCA field. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges the contents specified for the trustedCA parameter with the RHCOS trust bundle. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

NOTE
The installation program does not support the proxy readinessEndpoints field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

NOTE
Only the Proxy object named cluster is supported, and no additional proxies can be created.

3.4.6. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

IMPORTANT
You can run the create cluster command of the installation program only once, during initial installation.

Prerequisites

- Configure an account with the cloud platform that hosts your cluster.
- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Change to the directory that contains the installation program and initialize the cluster deployment:

   $ ./openshift-install create cluster --dir <installation_directory>  
   --log-level=info

2. For <installation_directory>, specify the location of your customized ./install-config.yaml file.
To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

**NOTE**

If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.

When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the `kubeadm` user, display in your terminal.

**Example output**

```plaintext
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadm", and password: "4vYBz-Ee6gm-ymBZj-Wi5AL"
INFO Time elapsed: 36m22s
```

**NOTE**

The cluster access and credential information also outputs to `<installation_directory>/openshift_install.log` when an installation succeeds.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

**IMPORTANT**

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

### 3.4.7. Installing the OpenShift CLI by downloading the binary

...
You can install the OpenShift CLI (oc) in order to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.6. Download and install the new version of oc.

### 3.4.7.1. Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.
3. Click **Download Now** next to the *OpenShift v4.6 Linux Client* entry and save the file.
4. Unpack the archive:

   ```bash
   $ tar xvzf <file>
   ```

5. Place the oc binary in a directory that is on your **PATH**.
   To check your **PATH**, execute the following command:

   ```bash
   $ echo $PATH
   ```

After you install the OpenShift CLI, it is available using the oc command:

```bash
$ oc <command>
```

### 3.4.7.2. Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.
3. Click **Download Now** next to the *OpenShift v4.6 Windows Client* entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the oc binary to a directory that is on your **PATH**.
   To check your **PATH**, open the command prompt and execute the following command:

   ```bash
   C:\> path
   ```
After you install the OpenShift CLI, it is available using the `oc` command:

```
C:\> oc <command>
```

### 3.4.7.3. Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (`oc`) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.

3. Click **Download Now** next to the **OpenShift v4.6 MacOSX Client** entry and save the file.

4. Unpack and unzip the archive.

5. Move the `oc` binary to a directory on your PATH. To check your `PATH`, open a terminal and execute the following command:

   ```
   $ echo $PATH
   ```

After you install the OpenShift CLI, it is available using the `oc` command:

```
$ oc <command>
```

### 3.4.8. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

   ```
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   **1** For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:
3.4.9. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.6, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources
- See About remote health monitoring for more information about the Telemetry service

3.4.10. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.

3.5. INSTALLING A CLUSTER ON AZURE WITH NETWORK CUSTOMIZATIONS

In OpenShift Container Platform version 4.6, you can install a cluster with a customized network configuration on infrastructure that the installation program provisions on Microsoft Azure. By customizing your network configuration, your cluster can coexist with existing IP address allocations in your environment and integrate with existing MTU and VXLAN configurations.

You must set most of the network configuration parameters during installation, and you can modify only kubeProxy configuration parameters in a running cluster.

3.5.1. Prerequisites

- Review details about the OpenShift Container Platform installation and update processes.
- Configure an Azure account to host the cluster and determine the tested and validated region to deploy the cluster to.
- If you use a firewall, you must configure it to allow the sites that your cluster requires access to.
If you do not allow the system to manage identity and access management (IAM), then a cluster administrator can manually create and maintain IAM credentials. Manual mode can also be used in environments where the cloud IAM APIs are not reachable.

### 3.5.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.6, you require access to the Internet to install your cluster.

You must have Internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

### 3.5.3. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your `ssh-agent` and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

**NOTE**

In a production environment, you require disaster recovery and debugging.

You can use this key to SSH into the master nodes as the user `core`. When you deploy the cluster, the key is added to the `core` user’s `~/.ssh/authorized_keys` list.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

**Procedure**

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>
   ```
Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

Running this command generates an SSH key that does not require a password in the location that you specified.

**NOTE**

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the `ssh-agent` process as a background task:

   ```
   $ eval "$(ssh-agent -s)"
   ``

   **Example output**

   ```
   Agent pid 31874
   ```

   **NOTE**

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the `ssh-agent`:

   ```
   $ ssh-add <path>/<file_name>
   ```

   **Example output**

   ```
   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
   ```

   **Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`**

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

**3.5.4. Obtaining the installation program**

Before you install OpenShift Container Platform, download the installation file on a local computer.

**Prerequisites**

- You have a computer that runs Linux or macOS, with 500 MB of local disk space
Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

   **IMPORTANT**
   
   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   **IMPORTANT**
   
   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ tar xvf openshift-install-linux.tar.gz
   $ ./openshift-install create install-config --dir <installation_directory>
   ```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

3.5.5. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Microsoft Azure.

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Create the `install-config.yaml` file.

   a. Change to the directory that contains the installation program and run the following command:

   ```
   $ ./openshift-install create install-config --dir <installation_directory>
   ```
For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

**IMPORTANT**

Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

b. At the prompts, provide the configuration details for your cloud:

i. Optional: Select an SSH key to use to access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

ii. Select `azure` as the platform to target.

iii. If you do not have a Microsoft Azure profile stored on your computer, specify the following Azure parameter values for your subscription and service principal:

- `azure subscription id` The subscription ID to use for the cluster. Specify the `id` value in your account output.
- `azure tenant id` The tenant ID. Specify the `tenantId` value in your account output.
- `azure service principal client id` The value of the `appId` parameter for the service principal.
- `azure service principal client secret` The value of the `password` parameter for the service principal.

iv. Select the region to deploy the cluster to.

v. Select the base domain to deploy the cluster to. The base domain corresponds to the Azure DNS Zone that you created for your cluster.

vi. Enter a descriptive name for your cluster.

**IMPORTANT**

All Azure resources that are available through public endpoints are subject to resource name restrictions, and you cannot create resources that use certain terms. For a list of terms that Azure restricts, see `Resolve reserved resource name errors` in the Azure documentation.

vii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.
2. Modify the `install-config.yaml` file. You can find more information about the available parameters in the **Installation configuration parameters** section.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

**IMPORTANT**

The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

### 3.5.5.1. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster’s platform. When you create the `install-config.yaml` installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the `install-config.yaml` file to provide more details about the platform.

**NOTE**

After installation, you cannot modify these parameters in the `install-config.yaml` file.

**IMPORTANT**

The `openshift-install` command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

#### 3.5.5.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

**Table 3.5. Required parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is v1. The installer may also support older API versions.</td>
<td>String</td>
</tr>
</tbody>
</table>

OpenShift Container Platform 4.6 Installing
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
</tr>
<tr>
<td></td>
<td>routes to your OpenShift Container Platform cluster components. The full DNS</td>
<td></td>
</tr>
<tr>
<td></td>
<td>name for your cluster is a combination of the baseDomain and metadata.name</td>
<td></td>
</tr>
<tr>
<td></td>
<td>parameter values that uses the &lt;metadata.name&gt;, &lt;baseDomain&gt; format.</td>
<td></td>
</tr>
<tr>
<td>metadata</td>
<td>Kubernetes resource ObjectMeta, from which only the name parameter is</td>
<td>Object</td>
</tr>
<tr>
<td></td>
<td>consumed.</td>
<td></td>
</tr>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of</td>
<td>String of lowercase letters, hyphens (-), and periods (.), such as dev.</td>
</tr>
<tr>
<td></td>
<td>{{.metadata.name}}. {{.baseDomain}}.</td>
<td></td>
</tr>
<tr>
<td>platform</td>
<td>The configuration for the specific platform upon which to perform the</td>
<td>Object</td>
</tr>
<tr>
<td></td>
<td>installation: aws, baremetal, azure, openstack, ovirt, vsphere. For</td>
<td></td>
</tr>
<tr>
<td></td>
<td>additional information about platform.&lt;platform&gt; parameters, consult the</td>
<td></td>
</tr>
<tr>
<td></td>
<td>following table for your specific platform.</td>
<td></td>
</tr>
<tr>
<td>pullSecret</td>
<td>Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate</td>
<td>{ &quot;auths&quot;:{ &quot;cloud.openshift.com&quot;:{&quot;auth&quot;:&quot;b3Blb=&quot;, &quot;email&quot;:&quot;<a href="mailto:you@example.com">you@example.com</a>&quot; }, &quot;quay.io&quot;:{&quot;auth&quot;:&quot;b3Blb=&quot;, &quot;email&quot;:&quot;<a href="mailto:you@example.com">you@example.com</a>&quot; } } }</td>
</tr>
<tr>
<td></td>
<td>downloading container images for OpenShift Container Platform components from</td>
<td></td>
</tr>
<tr>
<td></td>
<td>services such as Quay.io.</td>
<td></td>
</tr>
</tbody>
</table>
3.5.5.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

Table 3.6. Network parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong> You cannot modify parameters specified by the <code>networking</code> object after installation.</td>
<td></td>
</tr>
<tr>
<td>networking.network.Type</td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN.</td>
</tr>
<tr>
<td>networking.clusterNetwork</td>
<td>The IP address blocks for pods.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td>The default value is <code>10.128.0.0/14</code> with a host prefix of <code>/23</code>.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td></td>
</tr>
<tr>
<td>networking.clusterNetwork.cidr</td>
<td>Required if you use <code>networking.clusterNetwork</code>. An IP address block.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>An IPv4 network.</td>
<td></td>
</tr>
<tr>
<td>networking.clusterNetwork.hostPrefix</td>
<td>The subnet prefix length to assign to each individual node. For example, if <code>hostPrefix</code> is set to <code>23</code> then each node is assigned a <code>/23</code> subnet out of the given <code>cidr</code>. A <code>hostPrefix</code> value of <code>23</code> provides <code>510 (2^(32 - 23) - 2)</code> pod IP addresses.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>A subnet prefix.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>The default value is <code>23</code>.</td>
<td></td>
</tr>
</tbody>
</table>
The IP address block for services. The default value is 172.30.0.0/16.

The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.

An array with an IP address block in CIDR format. For example:

```
networking:
  serviceNetwork:
    - 172.30.0.0/16
```

The IP address blocks for machines.

If you specify multiple IP address blocks, the blocks must not overlap.

An array of objects. For example:

```
networking:
  machineNetwork:
    - cidr: 10.0.0.0/16
```

Required if you use `networking.machineNetwork`. An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24.

An IP network block in CIDR notation. For example, 10.0.0.0/16.

**NOTE**
Set the `networking.machineNetwork` to match the CIDR that the preferred NIC resides in.

3.5.5.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

**Table 3.7. Optional parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of machine-pool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-----------------------------</td>
</tr>
<tr>
<td>compute.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td>compute.hyperthreading</td>
<td>Whether to enable or disable simultaneous multithreading, or <strong>hyperthreading</strong>, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td><strong>Enabled</strong> or <strong>Disabled</strong></td>
</tr>
<tr>
<td>compute.name</td>
<td>Required if you use <strong>compute</strong>. The name of the machine pool.</td>
<td><strong>worker</strong></td>
</tr>
<tr>
<td>compute.platform</td>
<td>Required if you use <strong>compute</strong>. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <strong>controlPlane.platform</strong> parameter value.</td>
<td>aws, azure, gcp, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td>compute.replicas</td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td>controlPlane</td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of <strong>MachinePool</strong> objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>---------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>----------------</td>
</tr>
<tr>
<td>controlPlane.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td>controlPlane.hypertreading</td>
<td>Whether to enable or disable simultaneous multithreading, or <em>hyperthreading</em>, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td></td>
</tr>
<tr>
<td>controlPlane.name</td>
<td>Required if you use <code>controlPlane</code>. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use <code>controlPlane</code>. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the <code>compute.platform</code> parameter value.</td>
<td><code>aws</code>, <code>azure</code>, <code>gcp</code>, <code>openstack</code>, <code>ovirt</code>, <code>vsphere</code>, or <code>{}</code></td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is <code>3</code>, which is the default value.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>---------------------------------------</td>
</tr>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (&quot;&quot;&quot;).</td>
</tr>
<tr>
<td>fips</td>
<td>Enable or disable FIPS mode. The default is false (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</td>
<td>false or true</td>
</tr>
</tbody>
</table>

**NOTE**

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Red Hat Operators reference content.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.
Sources and repositories for the release-image content. Array of objects. Includes a source and, optionally, mirrors, as described in the following rows of this table.

Required if you use imageContentSources. Specify the repository that users refer to, for example, in image pull specifications.

Specify one or more repositories that may also contain the same images.

How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes. Internal or External. To deploy a private cluster, which cannot be accessed from the internet, set publish to Internal. The default value is External.

The SSH key or keys to authenticate access your cluster machines.

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

### 3.5.5.1.4. Additional Azure configuration parameters

Additional Azure configuration parameters are described in the following table:

#### Table 3.8. Additional Azure parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>compute.platform.azure.osDisk.diskSize GB</td>
<td>The Azure disk size for the VM.</td>
<td>Integer that represents the size of the disk in GB. The default is 128.</td>
</tr>
<tr>
<td>compute.platform.azure.osDisk.diskType</td>
<td>Defines the type of disk.</td>
<td>standard_LRS, premium_LRS, or standardSSD_LRS. The default is premium_LRS.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td><code>controlPlane.platform.azure.osDisk.diskSizeGB</code></td>
<td>The Azure disk size for the VM.</td>
<td>Integer that represents the size of the disk in GB. The default is 1024.</td>
</tr>
<tr>
<td><code>controlPlane.platform.azure.osDisk.diskType</code></td>
<td>Defines the type of disk.</td>
<td><code>premium_LRS</code> or <code>standardSSD_LRS</code>. The default is <code>premium_LRS</code>.</td>
</tr>
<tr>
<td><code>platform.azure.baseDomainResourceGroupName</code></td>
<td>The name of the resource group that contains the DNS zone for your base domain.</td>
<td>String, for example <code>production_cluster</code>.</td>
</tr>
<tr>
<td><code>platform.azure.outboundType</code></td>
<td>The outbound routing strategy used to connect your cluster to the internet. If you are using user-defined routing, you must have pre-existing networking available where the outbound routing has already been configured prior to installing a cluster. The installation program is not responsible for configuring user-defined routing.</td>
<td><code>LoadBalancer</code> or <code>UserDefinedRouting</code>. The default is <code>LoadBalancer</code>.</td>
</tr>
<tr>
<td><code>platform.azure.region</code></td>
<td>The name of the Azure region that hosts your cluster.</td>
<td>Any valid region name, such as <code>centralus</code>.</td>
</tr>
<tr>
<td><code>platform.azure.zone</code></td>
<td>List of availability zones to place machines in. For high availability, specify at least two zones.</td>
<td>List of zones, for example <code>&quot;1&quot;, &quot;2&quot;, &quot;3&quot;</code>.</td>
</tr>
<tr>
<td><code>platform.azure.networkResourceGroupName</code></td>
<td>The name of the resource group that contains the existing VNet that you want to deploy your cluster to. This name cannot be the same as the <code>platform.azure.baseDomainResourceGroupName</code>.</td>
<td>String.</td>
</tr>
<tr>
<td><code>platform.azure.virtualNetwork</code></td>
<td>The name of the existing VNet that you want to deploy your cluster to.</td>
<td>String.</td>
</tr>
<tr>
<td><code>platform.azure.controlPlaneSubnet</code></td>
<td>The name of the existing subnet in your VNet that you want to deploy your control plane machines to.</td>
<td>Valid CIDR, for example <code>10.0.0.0/16</code>.</td>
</tr>
<tr>
<td><code>platform.azure.computeSubnet</code></td>
<td>The name of the existing subnet in your VNet that you want to deploy your compute machines to.</td>
<td>Valid CIDR, for example <code>10.0.0.0/16</code>.</td>
</tr>
</tbody>
</table>
### Parameter table

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>platform.azure.cloud Name</td>
<td>The name of the Azure cloud environment that is used to configure the Azure SDK with the appropriate Azure API endpoints. If empty, the default value AzurePublicCloud is used.</td>
<td>Any valid cloud environment, such as AzurePublicCloud or AzureUSGovernmentCloud.</td>
</tr>
</tbody>
</table>

### NOTE

You cannot customize Azure Availability Zones or Use tags to organize your Azure resources with an Azure cluster.

### 3.5.5.2. Sample customized install-config.yaml file for Azure

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

### IMPORTANT

This sample YAML file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program and modify it.

```yaml
apiVersion: v1
baseDomain: example.com
controlPlane: 
  hyperthreading: Enabled
  name: master
  platform:
    azure:
      osDisk:
        diskSizeGB: 1024
        diskType: Premium_LRS
        type: Standard_D8s_v3
      replicas: 3
      compute:
        - hyperthreading: Enabled
        - name: worker
          platform:
            azure:
              type: Standard_D2s_v3
              osDisk:
                diskSizeGB: 512
                diskType: Standard_LRS
              zones:
                - "1"
                - "2"
                - "3"
              replicas: 5
```

---

**CHAPTER 3. INSTALLING ON AZURE**

529
Required. The installation program prompts you for this value.

If you do not provide these parameters and values, the installation program provides the default value.

The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, -, and the first line of the controlPlane section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading, or hyperthreading. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to Disabled. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

IMPORTANT

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger virtual machine types, such as Standard_D8s_v3, for your machines if you disable simultaneous multithreading.

You can specify the size of the disk to use in GB. Minimum recommendation for control plane nodes (also known as the master nodes) is 1024 GB.

Specify a list of zones to deploy your machines to. For high availability, specify at least two zones.

Specify the name of the resource group that contains the DNS zone for your base domain.

Specify the name of an already existing resource group to install your cluster to. If undefined, a new resource group is created for the cluster.
Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

You can optionally provide the `sshKey` value that you use to access the machines in your cluster.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

### 3.5.5.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**Prerequisites**

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

**Procedure**

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port>  
  httpsProxy: https://<username>:<pswd>@<ip>:<port>  
```
A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.

A proxy URL to use for creating HTTPS connections outside the cluster.

A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.

If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace to hold the additional CA certificates. If you provide additionalTrustBundle and at least one proxy setting, the Proxy object is configured to reference the user-ca-bundle config map in the trustedCA field. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges the contents specified for the trustedCA parameter with the RHCOS trust bundle. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

**NOTE**

The installation program does not support the proxy readinessEndpoints field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

**NOTE**

Only the Proxy object named cluster is supported, and no additional proxies can be created.

### 3.5.6. Network configuration phases

When specifying a cluster configuration prior to installation, there are several phases in the installation procedures when you can modify the network configuration:

**Phase 1**

After entering the openshift-install create install-config command. In the install-config.yaml file, you can customize the following network-related fields:

- networking.networkType
- networking.clusterNetwork

```bash
noProxy: example.com
additionalTrustBundle:

-----BEGIN CERTIFICATE-----
<MY_TRUSTED_CA_CERT>
-----END CERTIFICATE-----
...
For more information on these fields, refer to "Installation configuration parameters".

**NOTE**

Set the `networking.machineNetwork` to match the CIDR that the preferred NIC resides in.

**Phase 2**

After entering the `openshift-install create manifests` command. If you must specify advanced network configuration, during this phase you can define a customized Cluster Network Operator manifest with only the fields you want to modify.

You cannot override the values specified in phase 1 in the `install-config.yaml` file during phase 2. However, you can further customize the cluster network provider during phase 2.

### 3.5.7. Specifying advanced network configuration

You can use advanced configuration customization to integrate your cluster into your existing network environment by specifying additional configuration for your cluster network provider. You can specify advanced network configuration only before you install the cluster.

**IMPORTANT**

Modifying the OpenShift Container Platform manifest files created by the installation program is not supported. Applying a manifest file that you create, as in the following procedure, is supported.

**Prerequisites**

- Create the `install-config.yaml` file and complete any modifications to it.

**Procedure**

1. Change to the directory that contains the installation program and create the manifests:

   ```bash
   $ ./openshift-install create manifests --dir <installation_directory>
   ```

   where:

   `<installation_directory>`
   
   Specifies the name of the directory that contains the `install-config.yaml` file for your cluster.

2. Create a stub manifest file for the advanced network configuration that is named `cluster-network-03-config.yml` in the `<installation_directory>/manifests/` directory:

   ```bash
   $ cat <<EOF > <installation_directory>/manifests/cluster-network-03-config.yml
   apiVersion: operator.openshift.io/v1
   kind: Network
   metadata:
   ```
where:

<installation_directory>

Specifies the directory name that contains the manifests/ directory for your cluster.

3. Open the cluster-network-03-config.yml file in an editor and specify the advanced network configuration for your cluster, such as in the following example:

```
Specify a different VXLAN port for the OpenShift SDN network provider
```

```yaml
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
  name: cluster
spec:
  defaultNetwork:
    openshiftSDNConfig:
      vxlanPort: 4800
```

4. Save the cluster-network-03-config.yml file and quit the text editor.

5. Optional: Back up the manifests/cluster-network-03-config.yml file. The installation program deletes the manifests/ directory when creating the cluster.

### 3.5.8. Cluster Network Operator configuration

The configuration for the cluster network is specified as part of the Cluster Network Operator (CNO) configuration and stored in a custom resource (CR) object that is named cluster. The CR specifies the fields for the Network API in the operator.openshift.io API group.

The CNO configuration inherits the following fields during cluster installation from the Network API in the Network.config.openshift.io API group and these fields cannot be changed:

- **clusterNetwork**
  IP address pools from which pod IP addresses are allocated.

- **serviceNetwork**
  IP address pool for services.

- **defaultNetwork.type**
  Cluster network provider, such as OpenShift SDN or OVN-Kubernetes.

You can specify the cluster network provider configuration for your cluster by setting the fields for the defaultNetwork object in the CNO object named cluster.

### 3.5.8.1. Cluster Network Operator configuration object

The fields for the Cluster Network Operator (CNO) are described in the following table:

```
Table 3.9. Cluster Network Operator configuration object
```
### defaultNetwork object configuration

The values for the `defaultNetwork` object are defined in the following table:

#### Table 3.10. defaultNetwork object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>metadata.name</td>
<td>string</td>
<td>The name of the CNO object. This name is always <code>cluster</code>.</td>

<td>- 172.30.0.0/14</td>
</tr>
<tr>
<td></td>
<td></td>
<td>This value is ready-only and specified in the <code>install-config.yaml</code> file.</td>
</tr>
<tr>
<td>spec.defaultNetwork</td>
<td>object</td>
<td>Configures the Container Network Interface (CNI) cluster network provider for the cluster network.</td>
</tr>
<tr>
<td>spec.kubeProxyConfig</td>
<td>object</td>
<td>The fields for this object specify the kube-proxy configuration. If you are using the OVN-Kubernetes cluster network provider, the kube-proxy configuration has no effect.</td>
</tr>
</tbody>
</table>
Either OpenShiftSDN or OVNKubernetes. The cluster network provider is selected during installation. This value cannot be changed after cluster installation.

NOTE
OpenShift Container Platform uses the OpenShift SDN Container Network Interface (CNI) cluster network provider by default.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>string</td>
<td>Either OpenShiftSDN or OVNKubernetes. The cluster network provider is selected during installation. This value cannot be changed after cluster installation.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>openshiftSDNConfig</td>
<td>object</td>
<td>This object is only valid for the OpenShift SDN cluster network provider.</td>
</tr>

<td>object</td>
<td>This object is only valid for the OVN-Kubernetes cluster network provider.</td>
</tr>
</tbody>
</table>

Configuration for the OpenShift SDN CNI cluster network provider
The following table describes the configuration fields for the OpenShift SDN Container Network Interface (CNI) cluster network provider.

Table 3.11. openshiftSDNConfig object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mode</td>
<td>string</td>
<td>Configures the network isolation mode for OpenShift SDN. The default value is NetworkPolicy. The values Multitenant and Subnet are available for backwards compatibility with OpenShift Container Platform 3.x but are not recommended. This value cannot be changed after cluster installation.</td>
</tr>
</tbody>
</table>
The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.

If the auto-detected value is not what you expected it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.

If your cluster requires different MTU values for different nodes, you must set this value to 50 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1450.

This value cannot be changed after cluster installation.

The port to use for all VXLAN packets. The default value is 4789. This value cannot be changed after cluster installation.

If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number.

On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port 9000 and port 9999.

---

### Example OpenShift SDN configuration

```yaml
defaultNetwork:
  type: OpenShiftSDN
  openshiftSDNConfig:
    mode: NetworkPolicy
    mtu: 1450
    vxlanPort: 4789
```

### Configuration for the OVN-Kubernetes CNI cluster network provider

The following table describes the configuration fields for the OVN-Kubernetes CNI cluster network provider.

#### Table 3.12. ovnKubernetesConfig object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mtu</td>
<td>integer</td>
<td>The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU. If the auto-detected value is not what you expected it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes. If your cluster requires different MTU values for different nodes, you must set this value to 50 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1450. This value cannot be changed after cluster installation.</td>
</tr>
<tr>
<td>vxlanPort</td>
<td>integer</td>
<td>The port to use for all VXLAN packets. The default value is 4789. This value cannot be changed after cluster installation. If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number. On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port 9000 and port 9999.</td>
</tr>
</tbody>
</table>
The maximum transmission unit (MTU) for the Geneve (Generic Network Virtualization Encapsulation) overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.

If the auto-detected value is not what you expected it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.

If your cluster requires different MTU values for different nodes, you must set this value to 100 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1400.

This value cannot be changed after cluster installation.

genevePort

The port to use for all Geneve packets. The default value is 6081. This value cannot be changed after cluster installation.

Example OVN-Kubernetes configuration

defaultNetwork:
  type: OVNKubernetes
ovnKubernetesConfig:
  mtu: 1400
genevePort: 6081

kubeProxyConfig object configuration

The values for the kubeProxyConfig object are defined in the following table:

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mtu</td>
<td>integer</td>
<td>The maximum transmission unit (MTU) for the Geneve (Generic Network Virtualization Encapsulation) overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU. If the auto-detected value is not what you expected it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes. If your cluster requires different MTU values for different nodes, you must set this value to 100 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1400. This value cannot be changed after cluster installation.</td>
</tr>
<tr>
<td>genevePort</td>
<td>integer</td>
<td>The port to use for all Geneve packets. The default value is 6081. This value cannot be changed after cluster installation.</td>
</tr>
</tbody>
</table>
### Field Name: `iptablesSyncPeriod`

**Type:** `string`

The refresh period for `iptables` rules. The default value is `30s`. Valid suffixes include `s`, `m`, and `h` and are described in the Go `time` package documentation.

**NOTE**
Because of performance improvements introduced in OpenShift Container Platform 4.3 and greater, adjusting the `iptablesSyncPeriod` parameter is no longer necessary.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>iptablesSyncPeriod</code></td>
<td>string</td>
<td>The refresh period for <code>iptables</code> rules. The default value is <code>30s</code>. Valid suffixes include <code>s</code>, <code>m</code>, and <code>h</code> and are described in the Go <code>time</code> package documentation.</td>
</tr>
</tbody>
</table>

### Field Name: `proxyArguments.iptables-min-sync-period`

**Type:** `array`

The minimum duration before refreshing `iptables` rules. This field ensures that the refresh does not happen too frequently. Valid suffixes include `s`, `m`, and `h` and are described in the Go `time` package. The default value is:

```yaml
kubeProxyConfig:
  proxyArguments:
    iptables-min-sync-period:
      - 0s
```

### 3.5.9. Configuring hybrid networking with OVN-Kubernetes

You can configure your cluster to use hybrid networking with OVN-Kubernetes. This allows a hybrid cluster that supports different node networking configurations. For example, this is necessary to run both Linux and Windows nodes in a cluster.

**IMPORTANT**
You must configure hybrid networking with OVN-Kubernetes during the installation of your cluster. You cannot switch to hybrid networking after the installation process.

**Prerequisites**

- You defined `OVNKubernetes` for the `networking.networkType` parameter in the `install-config.yaml` file. See the installation documentation for configuring OpenShift Container Platform network customizations on your chosen cloud provider for more information.

**Procedure**
1. Change to the directory that contains the installation program and create the manifests:

```
$ ./openshift-install create manifests --dir <installation_directory>
```

where:

```
<installation_directory>
```

Specifies the name of the directory that contains the `install-config.yaml` file for your cluster.

2. Create a stub manifest file for the advanced network configuration that is named `cluster-network-03-config.yml` in the `<installation_directory>/manifests/` directory:

```
$ cat <<EOF > <installation_directory>/manifests/cluster-network-03-config.yml
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
  name: cluster
spec:
EOF
```

where:

```
<installation_directory>
```

Specifies the directory name that contains the `manifests/` directory for your cluster.

3. Open the `cluster-network-03-config.yml` file in an editor and configure OVN-Kubernetes with hybrid networking, such as in the following example:

**Specify a hybrid networking configuration**

```
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
  name: cluster
spec:
  defaultNetwork:
    ovnKubernetesConfig:
      hybridOverlayConfig:
        hybridClusterNetwork: 1
        - cidr: 10.132.0.0/14
          hostPrefix: 23
        hybridOverlayVXLANPort: 9898 2
```

1. Specify the CIDR configuration used for nodes on the additional overlay network. The `hybridClusterNetwork` CIDR cannot overlap with the `clusterNetwork` CIDR.

2. Specify a custom VXLAN port for the additional overlay network. This is required for running Windows nodes in a cluster installed on vSphere, and must not be configured for any other cloud provider. The custom port can be any open port excluding the default 4789 port. For more information on this requirement, see the Microsoft documentation on Pod-to-pod connectivity between hosts is broken.
4. Save the `cluster-network-03-config.yml` file and quit the text editor.

5. Optional: Back up the `manifests/cluster-network-03-config.yml` file. The installation program deletes the `manifests/` directory when creating the cluster.

**NOTE**

For more information on using Linux and Windows nodes in the same cluster, see [Understanding Windows container workloads](#).

### 3.5.10. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

**Prerequisites**

- Configure an account with the cloud platform that hosts your cluster.
- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Change to the directory that contains the installation program and initialize the cluster deployment:

   ```bash
   $ ./openshift-install create cluster --dir <installation_directory> \  
   --log-level=info 
   ```

   **1** For `<installation_directory>`, specify the location of your customized `./install-config.yaml` file.

   **2** To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

   **NOTE**

   If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.

   When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the `kubeadmin` user, display in your terminal.

   **Example output**

   ```
   …
   INFO Install complete!
   ```
NOTE
The cluster access and credential information also outputs to
<installation_directory>/.openshift_install.log when an installation succeeds.

IMPORTANT
- The Ignition config files that the installation program generates contain
  certificates that expire after 24 hours, which are then renewed at that time. If
  the cluster is shut down before renewing the certificates and the cluster is
  later restarted after the 24 hours have elapsed, the cluster automatically
  recovers the expired certificates. The exception is that you must manually
  approve the pending node-bootstrapper certificate signing requests (CSRs)
  to recover kubelet certificates. See the documentation for Recovering from
  expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they
  are generated because the 24-hour certificate rotates from 16 to 22 hours
  after the cluster is installed. By using the Ignition config files within 12 hours,
  you can avoid installation failure if the certificate update runs during
  installation.

IMPORTANT
You must not delete the installation program or the files that the installation
program creates. Both are required to delete the cluster.

3.5.11. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) in order to interact with OpenShift Container Platform from a
command-line interface. You can install oc on Linux, Windows, or macOS.

IMPORTANT
If you installed an earlier version of oc, you cannot use it to complete all of the commands
in OpenShift Container Platform 4.6. Download and install the new version of oc.

3.5.11.1. Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure

2. Select the appropriate version in the **Version** drop-down menu.

3. Click **Download Now** next to the **OpenShift v4.6 Linux Client** entry and save the file.

4. Unpack the archive:

   ```
   $ tar xzvf <file>
   ```

5. Place the **oc** binary in a directory that is on your **PATH**.

   To check your **PATH**, execute the following command:

   ```
   $ echo $PATH
   ```

After you install the OpenShift CLI, it is available using the **oc** command:

```
$ oc <command>
```

### 3.5.11.2. Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (**oc**) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.

3. Click **Download Now** next to the **OpenShift v4.6 Windows Client** entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the **oc** binary to a directory that is on your **PATH**.

   To check your **PATH**, open the command prompt and execute the following command:

   ```
   C:\> path
   ```

After you install the OpenShift CLI, it is available using the **oc** command:

```
C:\> oc <command>
```
4. Unpack and unzip the archive.

5. Move the `oc` binary to a directory on your PATH. To check your PATH, open a terminal and execute the following command:

   ```
   $ echo $PATH
   ```

After you install the OpenShift CLI, it is available using the `oc` command:

   ```
   $ oc <command>
   ```

### 3.5.12. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

   ```
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```
   $ oc whoami
   ```

   **Example output**

   ```
   system:admin
   ```

**Additional resources**

- See [Accessing the web console](#) for more details about accessing and understanding the OpenShift Container Platform web console.

### 3.5.13. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.6, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).
After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service

3.5.14. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.

3.6. INSTALLING A CLUSTER ON AZURE INTO AN EXISTING VNET

In OpenShift Container Platform version 4.6, you can install a cluster into an existing Azure Virtual Network (VNet) on Microsoft Azure. The installation program provisions the rest of the required infrastructure, which you can further customize. To customize the installation, you modify parameters in the `install-config.yaml` file before you install the cluster.

3.6.1. Prerequisites

- Review details about the OpenShift Container Platform installation and update processes.
- Configure an Azure account to host the cluster and determine the tested and validated region to deploy the cluster to.
- If you use a firewall, you must configure it to allow the sites that your cluster requires access to.
- If you do not allow the system to manage identity and access management (IAM), then a cluster administrator can manually create and maintain IAM credentials. Manual mode can also be used in environments where the cloud IAM APIs are not reachable.

3.6.2. About reusing a VNet for your OpenShift Container Platform cluster

In OpenShift Container Platform 4.6, you can deploy a cluster into an existing Azure Virtual Network (VNet) in Microsoft Azure. If you do, you must also use existing subnets within the VNet and routing rules.

By deploying OpenShift Container Platform into an existing Azure VNet, you might be able to avoid service limit constraints in new accounts or more easily abide by the operational constraints that your company’s guidelines set. This is a good option to use if you cannot obtain the infrastructure creation permissions that are required to create the VNet.

3.6.2.1. Requirements for using your VNet

When you deploy a cluster by using an existing VNet, you must perform additional network configuration before you install the cluster. In installer-provisioned infrastructure clusters, the installer usually creates the following components, but it does not create them when you install into an existing VNet:

- Subnets
- Route tables
- V Nets
- Network Security Groups

If you use a custom VNet, you must correctly configure it and its subnets for the installation program and the cluster to use. The installation program cannot subdivide network ranges for the cluster to use, set route tables for the subnets, or set VNet options like DHCP, so you must do so before you install the cluster.

The cluster must be able to access the resource group that contains the existing VNet and subnets. While all of the resources that the cluster creates are placed in a separate resource group that it creates, some network resources are used from a separate group. Some cluster Operators must be able to access resources in both resource groups. For example, the Machine API controller attaches NICS for the virtual machines that it creates to subnets from the networking resource group.

Your VNet must meet the following characteristics:

- The VNet’s CIDR block must contain the `Networking.MachineCIDR` range, which is the IP address pool for cluster machines.
- The VNet and its subnets must belong to the same resource group, and the subnets must be configured to use Azure-assigned DHCP IP addresses instead of static IP addresses.

You must provide two subnets within your VNet, one for the control plane machines and one for the compute machines. Because Azure distributes machines in different availability zones within the region that you specify, your cluster will have high availability by default.

To ensure that the subnets that you provide are suitable, the installation program confirms the following data:

- All the specified subnets exist.
- There are two private subnets, one for the control plane machines and one for the compute machines.
- The subnet CIDRs belong to the machine CIDR that you specified. Machines are not provisioned in availability zones that you do not provide private subnets for. If required, the installation program creates public load balancers that manage the control plane and worker nodes, and Azure allocates a public IP address to them.

**NOTE**

If you destroy a cluster that uses an existing VNet, the VNet is not deleted.

### 3.6.2.1.1. Network security group requirements

The network security groups for the subnets that host the compute and control plane machines require specific access to ensure that the cluster communication is correct. You must create rules to allow access to the required cluster communication ports.

**IMPORTANT**

The network security group rules must be in place before you install the cluster. If you attempt to install a cluster without the required access, the installation program cannot reach the Azure APIs, and installation fails.
Table 3.14. Required ports

<table>
<thead>
<tr>
<th>Port</th>
<th>Description</th>
<th>Control plane</th>
<th>Compute</th>
</tr>
</thead>
<tbody>
<tr>
<td>80</td>
<td>Allows HTTP traffic</td>
<td></td>
<td>x</td>
</tr>
<tr>
<td>443</td>
<td>Allows HTTPS traffic</td>
<td></td>
<td>x</td>
</tr>
<tr>
<td>6443</td>
<td>Allows communication to the control plane machines</td>
<td>x</td>
<td></td>
</tr>
<tr>
<td>22623</td>
<td>Allows communication to the machine config server</td>
<td></td>
<td>x</td>
</tr>
</tbody>
</table>

**NOTE**

Since cluster components do not modify the user-provided network security groups, which the Kubernetes controllers update, a pseudo-network security group is created for the Kubernetes controller to modify without impacting the rest of the environment.

### 3.6.2.2. Division of permissions

Starting with OpenShift Container Platform 4.3, you do not need all of the permissions that are required for an installation program-provisioned infrastructure cluster to deploy a cluster. This change mimics the division of permissions that you might have at your company: some individuals can create different resources in your clouds than others. For example, you might be able to create application-specific items, like instances, storage, and load balancers, but not networking-related components such as V Nets, subnet, or ingress rules.

The Azure credentials that you use when you create your cluster do not need the networking permissions that are required to make V Nets and core networking components within the V Net, such as subnets, routing tables, internet gateways, NAT, and VPN. You still need permission to make the application resources that the machines within the cluster require, such as load balancers, security groups, storage accounts, and nodes.

### 3.6.2.3. Isolation between clusters

Because the cluster is unable to modify network security groups in an existing subnet, there is no way to isolate clusters from each other on the V Net.

### 3.6.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.6, you require access to the Internet to install your cluster.

You must have Internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.
IMPORTANT

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

3.6.4. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your ssh-agent and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

NOTE

In a production environment, you require disaster recovery and debugging.

You can use this key to SSH into the master nodes as the user core. When you deploy the cluster, the key is added to the core user’s ~/.ssh/authorized_keys list.

NOTE

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

Procedure

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ ssh-keygen -t ed25519 -N "" 
   -f <path>/<file_name>
   ```

   Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   Running this command generates an SSH key that does not require a password in the location that you specified.

   NOTE

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the ssh-agent process as a background task:
NOTE
If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the ssh-agent:

    $ ssh-add <path>/<file_name>

Example output

    Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

3.6.5. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on a local computer.

Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.
IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar xvf openshift-install-linux.tar.gz
```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

3.6.6. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Microsoft Azure.

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Create the `install-config.yaml` file.

   a. Change to the directory that contains the installation program and run the following command:

   ```
   $ ./openshift-install create install-config --dir <installation_directory> 1
   ```

   1 For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

   IMPORTANT

   Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

   b. At the prompts, provide the configuration details for your cloud:

      i. Optional: Select an SSH key to use to access your cluster machines.
NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

ii. Select azure as the platform to target.

iii. If you do not have a Microsoft Azure profile stored on your computer, specify the following Azure parameter values for your subscription and service principal:
   - azure subscription id The subscription ID to use for the cluster. Specify the id value in your account output.
   - azure tenant id The tenant ID. Specify the tenantId value in your account output.
   - azure service principal client id The value of the appId parameter for the service principal.
   - azure service principal client secret The value of the password parameter for the service principal.

iv. Select the region to deploy the cluster to.

v. Select the base domain to deploy the cluster to. The base domain corresponds to the Azure DNS Zone that you created for your cluster.

vi. Enter a descriptive name for your cluster.

IMPORTANT

All Azure resources that are available through public endpoints are subject to resource name restrictions, and you cannot create resources that use certain terms. For a list of terms that Azure restricts, see Resolve reserved resource name errors in the Azure documentation.

vii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

2. Modify the install-config.yaml file. You can find more information about the available parameters in the Installation configuration parameters section.

3. Back up the install-config.yaml file so that you can use it to install multiple clusters.

IMPORTANT

The install-config.yaml file is consumed during the installation process. If you want to reuse the file, you must back it up now.

3.6.6.1. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster’s platform. When you create the install-config.yaml installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the install-config.yaml file to provide more details about the platform.
NOTE
After installation, you cannot modify these parameters in the `install-config.yaml` file.

IMPORTANT
The `openshift-install` command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

3.6.6.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

Table 3.15. Required parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is v1. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the baseDomain and metadata.name parameter values that uses the <code>&lt;metadata.name&gt;</code>, <code>&lt;baseDomain&gt;</code> format.</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
</tr>
<tr>
<td>metadata</td>
<td>Kubernetes resource <code>ObjectMeta</code>, from which only the name parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of <code>{{.metadata.name}}. {{.baseDomain}}</code>.</td>
<td>String of lowercase letters, hyphens (-), and periods (.), such as dev.</td>
</tr>
</tbody>
</table>
The configuration for the specific platform upon which to perform the installation: **aws**, **baremetal**, **azure**, **openstack**, **ovirt**, **vsphere**. For additional information about platform.<platform> parameters, consult the following table for your specific platform.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>platform</strong></td>
<td>The configuration for the specific platform upon which to perform the installation: <strong>aws</strong>, <strong>baremetal</strong>, <strong>azure</strong>, <strong>openstack</strong>, <strong>ovirt</strong>, <strong>vsphere</strong>. For additional information about platform.&lt;platform&gt; parameters, consult the following table for your specific platform.</td>
<td>Object</td>
</tr>
</tbody>
</table>

For additional information about platform.<platform> parameters, consult the following table for your specific platform.

```
{  
"auths":{
  "cloud.openshift.com":{
    "auth":"b3Blb=",
    "email":"you@example.com"
  },
  "quay.io":{
    "auth":"b3Blb=",
    "email":"you@example.com"
  }
}
```

### 3.6.6.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

#### Table 3.16. Network parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>networking</strong></td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
</tbody>
</table>

**NOTE**

You cannot modify parameters specified by the **networking** object after installation.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking.network Type</td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN.</td>
</tr>
<tr>
<td>networking.clusterNetwork</td>
<td>The IP address blocks for pods.</td>
<td>An array of objects. For example:</td>
</tr>
</tbody>
</table>
|                                   | The default value is 10.128.0.0/14 with a host prefix of /23.              | networking:
|                                   | If you specify multiple IP address blocks, the blocks must not overlap.    |    | clusterNetwork: |
|                                   |                                                                          | - cidr: 10.128.0.0/14                                                  |
|                                   |                                                                          |  hostPrefix: 23                                                        |
| networking.clusterNetwork.cidr    | Required if you use networking.clusterNetwork. An IP address block.         | An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32. |
|                                   | An IPv4 network.                                                          |                                                                        |
| networking.clusterNetwork.hostPrefix | The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given cidr. A hostPrefix value of 23 provides 510 (2^(32 - 23) - 2) pod IP addresses. | A subnet prefix.                                                        |
|                                   |                                                                          | The default value is 23.                                                |
| networking.serviceNetwork         | The IP address block for services. The default value is 172.30.0.0/16.     | An array with an IP address block in CIDR format. For example:           |
|                                   | The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network. | networking:
|                                   |                                                                          |    | serviceNetwork:
|                                   |                                                                          | - 172.30.0.0/16                                                        |
| networking.machineNetwork         | The IP address blocks for machines.                                         | An array of objects. For example:                                       |
|                                   | If you specify multiple IP address blocks, the blocks must not overlap.    | networking:
|                                   |                                                                          |    | machineNetwork:
|                                   |                                                                          | - cidr: 10.0.0.0/16                                                    |
Network.cidr

Required if you use networking.machineNetwork. An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24.

An IP network block in CIDR notation. For example, 10.0.0.0/16.

NOTE

Set the networking.machineNetwork to match the CIDR that the preferred NIC resides in.

3.6.6.13. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

Table 3.17. Optional parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of machine-pool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>compute.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are amd64 (the default).</td>
<td>String</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-------------------------------</td>
</tr>
<tr>
<td>compute.hyperthreading</td>
<td>Whether to enable or disable simultaneous multithreading, or <strong>hyperthreading</strong>, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td><strong>Enabled</strong> or <strong>Disabled</strong></td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td></td>
</tr>
<tr>
<td>compute.name</td>
<td>Required if you use <strong>compute</strong>. The name of the machine pool.</td>
<td><strong>worker</strong></td>
</tr>
<tr>
<td>compute.platform</td>
<td>Required if you use <strong>compute</strong>. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <strong>controlPlane.platform</strong> parameter value.</td>
<td><strong>aws, azure, gcp, openstack, ovirt, vsphere</strong>, or {}</td>
</tr>
<tr>
<td>compute.replicas</td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td>controlPlane</td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of <strong>MachinePool</strong> objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>controlPlane.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <strong>amd64</strong> (the default).</td>
<td>String</td>
</tr>
</tbody>
</table>
### Parameter Description

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlPlane.hypertreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>controlPlane.name</td>
<td>Required if you use controlPlane. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use controlPlane. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the compute.platform parameter value.</td>
<td>aws, azure, gcp, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
</tbody>
</table>
The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.

NOTE

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Red Hat Operators reference content.
Enable or disable FIPS mode. The default is **false** (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the **x86_64** architecture.

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>fips</strong></td>
<td>Enable or disable FIPS mode.</td>
<td><strong>false</strong> or <strong>true</strong></td>
</tr>
<tr>
<td><strong>imageContentSources</strong></td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects. Includes a <strong>source</strong> and, optionally, <strong>mirrors</strong>, as described in the following rows of this table.</td>
</tr>
<tr>
<td><strong>imageContentSources.source</strong></td>
<td>Required if you use <strong>imageContentSources</strong>. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td><strong>String</strong></td>
</tr>
<tr>
<td><strong>imageContentSources.mirrors</strong></td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
<tr>
<td><strong>publish</strong></td>
<td>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</td>
<td><strong>Internal</strong> or <strong>External</strong>. To deploy a private cluster, which cannot be accessed from the internet, set <strong>publish</strong> to <strong>Internal</strong>. The default value is <strong>External</strong>.</td>
</tr>
</tbody>
</table>
### sshKey

The SSH key or keys to authenticate access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

One or more keys. For example:

```
sshKey:
<key1>
<key2>
<key3>
```

---

### 3.6.6.1.4. Additional Azure configuration parameters

Additional Azure configuration parameters are described in the following table:

#### Table 3.18. Additional Azure parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>compute.platform.azure.osDisk.diskSize GB</code></td>
<td>The Azure disk size for the VM.</td>
<td>Integer that represents the size of the disk in GB. The default is 128.</td>
</tr>
<tr>
<td><code>compute.platform.azure.osDisk.diskType</code></td>
<td>Defines the type of disk.</td>
<td><code>standard_LRS</code>, <code>premium_LRS</code>, or <code>standardSSD_LRS</code>. The default is <code>premium_LRS</code>.</td>
</tr>
<tr>
<td><code>controlPlane.platform.azure.osDisk.diskSizeGB</code></td>
<td>The Azure disk size for the VM.</td>
<td>Integer that represents the size of the disk in GB. The default is 1024.</td>
</tr>
<tr>
<td><code>controlPlane.platform.azure.osDisk.diskType</code></td>
<td>Defines the type of disk.</td>
<td><code>premium_LRS</code> or <code>standardSSD_LRS</code>. The default is <code>premium_LRS</code>.</td>
</tr>
<tr>
<td><code>platform.azure.baseDomainResourceGroupName</code></td>
<td>The name of the resource group that contains the DNS zone for your base domain.</td>
<td>String, for example <code>production_cluster</code>.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td>platform.azure.outboundType</td>
<td>The outbound routing strategy used to connect your cluster to the internet. If you are using user-defined routing, you must have pre-existing networking available where the outbound routing has already been configured prior to installing a cluster. The installation program is not responsible for configuring user-defined routing.</td>
<td>LoadBalancer or UserDefinedRouting. The default is LoadBalancer.</td>
</tr>
<tr>
<td>platform.azure.region</td>
<td>The name of the Azure region that hosts your cluster.</td>
<td>Any valid region name, such as centralus.</td>
</tr>
<tr>
<td>platform.azure.zone</td>
<td>List of availability zones to place machines in. For high availability, specify at least two zones.</td>
<td>List of zones, for example [&quot;1&quot;, &quot;2&quot;, &quot;3&quot;].</td>
</tr>
<tr>
<td>platform.azure.networkResourceGroupName</td>
<td>The name of the resource group that contains the existing VNet that you want to deploy your cluster to. This name cannot be the same as the platform.azure.baseDomainResourceGroupName.</td>
<td>String.</td>
</tr>
<tr>
<td>platform.azure.virtualNetwork</td>
<td>The name of the existing VNet that you want to deploy your cluster to.</td>
<td>String.</td>
</tr>
<tr>
<td>platform.azure.controlPlaneSubnet</td>
<td>The name of the existing subnet in your VNet that you want to deploy your control plane machines to.</td>
<td>Valid CIDR, for example 10.0.0.0/16.</td>
</tr>
<tr>
<td>platform.azure.computeSubnet</td>
<td>The name of the existing subnet in your VNet that you want to deploy your compute machines to.</td>
<td>Valid CIDR, for example 10.0.0.0/16.</td>
</tr>
<tr>
<td>platform.azure.cloudName</td>
<td>The name of the Azure cloud environment that is used to configure the Azure SDK with the appropriate Azure API endpoints. If empty, the default value AzurePublicCloud is used.</td>
<td>Any valid cloud environment, such as AzurePublicCloud or AzureUSGovernmentCloud.</td>
</tr>
</tbody>
</table>

**NOTE**

You cannot customize Azure Availability Zones or Use tags to organize your Azure resources with an Azure cluster.

3.6.6.2. Sample customized install-config.yaml file for Azure
You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

**IMPORTANT**

This sample YAML file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program and modify it.

```yaml
apiVersion: v1
baseDomain: example.com
controlPlane:
  hyperthreading: Enabled
  name: master
  platform:
    azure:
      osDisk:
        diskSizeGB: 1024
        diskType: Premium_LRS
        type: Standard_D8s_v3
        replicas: 3
    compute: - hyperthreading: Enabled
      name: worker
      platform:
        azure:
          type: Standard_D2s_v3
        osDisk:
          diskSizeGB: 512
          diskType: Standard_LRS
      zones: - "1"
        - "2"
        - "3"
      replicas: 5
metadata:
  name: test-cluster
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
      hostPrefix: 23
  machineNetwork:
    - cidr: 10.0.0.0/16
  networkType: OpenShiftSDN
  serviceNetwork:
    - 172.30.0.0/16
platform:
  azure:
    baseDomainResourceGroupName: resource_group
    region: centralus
    resourceGroupName: existing_resource_group
    networkResourceGroupName: vnet_resource_group
    virtualNetwork: vnet
    controlPlaneSubnet: control_plane_subnet
```
CHAPTER 3. INSTALLING ON AZURE

computeSubnet: compute_subnet
outboundType: Loadbalancer
cloudName: AzurePublicCloud
pullSecret: '{"auths": ...}'
fips: false
sshKey: ssh-ed25519 AAAA...

1. Required. The installation program prompts you for this value.
2. If you do not provide these parameters and values, the installation program provides the default value.
3. The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, -, and the first line of the controlPlane section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.
4. Whether to enable or disable simultaneous multithreading, or hyperthreading. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores. You can disable it by setting the parameter value to Disabled. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger virtual machine types, such as Standard_D8s_v3, for your machines if you disable simultaneous multithreading.

5. You can specify the size of the disk to use in GB. Minimum recommendation for control plane nodes (also known as the master nodes) is 1024 GB.
6. Specify a list of zones to deploy your machines to. For high availability, specify at least two zones.
7. Specify the name of the resource group that contains the DNS zone for your base domain.
8. Specify the name of an already existing resource group to install your cluster to. If undefined, a new resource group is created for the cluster.
9. If you use an existing VNet, specify the name of the resource group that contains it.
10. If you use an existing VNet, specify its name.
11. If you use an existing VNet, specify the name of the subnet to host the control plane machines.
12. If you use an existing VNet, specify the name of the subnet to host the compute machines.
13. Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.
IMPORTANT

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the `x86_64` architecture.

You can optionally provide the `sshKey` value that you use to access the machines in your cluster.

NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

3.6.6.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

Prerequisites

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

NOTE

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port> ¹
  httpsProxy: https://<username>:<pswd>@<ip>:<port> ²
noProxy: example.com ³
additionalTrustBundle: | ⁴
     -----BEGIN CERTIFICATE-----
```

¹
²
³
⁴
A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.

A proxy URL to use for creating HTTPS connections outside the cluster.

A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with `.` to match subdomains only. For example, `.y.com` matches `x.y.com`, but not `y.com`. Use `*` to bypass the proxy for all destinations.

If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace to hold the additional CA certificates. If you provide `additionalTrustBundle` and at least one proxy setting, the `Proxy` object is configured to reference the `user-ca-bundle` config map in the `trustedCA` field. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges the contents specified for the `trustedCA` parameter with the RHCOS trust bundle. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

**NOTE**

The installation program does not support the proxy `readinessEndpoints` field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster` `Proxy` object is still created, but it will have a nil `spec`.

**NOTE**

Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

### 3.6.7. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

**Prerequisites**

- Configure an account with the cloud platform that hosts your cluster.
- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.
Procedure

1. Change to the directory that contains the installation program and initialize the cluster deployment:

   ```bash
   $ ./openshift-install create cluster --dir <installation_directory> \ 
   --log-level=info
   ```

   1. For `<installation_directory>`, specify the location of your customized `.install-config.yaml` file.

   2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

   **NOTE**

   If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.

   When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the `kubeadmin` user, display in your terminal.

   **Example output**

   ```bash
   INFO Install complete!
   INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
   INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
   INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-Wt5AL"
   INFO Time elapsed: 36m22s
   ```

   **NOTE**

   The cluster access and credential information also outputs to `<installation_directory>/.openshift_install.log` when an installation succeeds.
IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

IMPORTANT

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

3.6.8. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) in order to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

IMPORTANT

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.6. Download and install the new version of oc.

3.6.8.1. Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.6 Linux Client entry and save the file.

4. Unpack the archive:

   $ tar xzvf <file>

5. Place the oc binary in a directory that is on your PATH. To check your PATH, execute the following command:

   $ echo $PATH
After you install the OpenShift CLI, it is available using the `oc` command:

```
$ oc <command>
```

### 3.6.8.2. Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (`oc`) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.
3. Click **Download Now** next to the **OpenShift v4.6 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the `oc` binary to a directory that is on your `PATH`.

   To check your `PATH`, open the command prompt and execute the following command:

```
C:\> path
```

After you install the OpenShift CLI, it is available using the `oc` command:

```
C:\> oc <command>
```

### 3.6.8.3. Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (`oc`) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.
3. Click **Download Now** next to the **OpenShift v4.6 MacOSX Client** entry and save the file.
4. Unpack and unzip the archive.
5. Move the `oc` binary to a directory on your `PATH`.

   To check your `PATH`, open a terminal and execute the following command:

```
$ echo $PATH
```

After you install the OpenShift CLI, it is available using the `oc` command:

```
$ oc <command>
```
3.6.9. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

Procedure

1. Export the `kubeadmin` credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ``

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   ``

   **Example output**

   system:admin

Additional resources

- See [Accessing the web console](#) for more details about accessing and understanding the OpenShift Container Platform web console.

3.6.10. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.6, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use `subscription watch` to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

3.6.11. Next steps

- Customize your cluster.
• If necessary, you can opt out of remote health reporting.

3.7. INSTALLING A PRIVATE CLUSTER ON AZURE

In OpenShift Container Platform version 4.6, you can install a private cluster into an existing Azure Virtual Network (VNet) on Microsoft Azure. The installation program provisions the rest of the required infrastructure, which you can further customize. To customize the installation, you modify parameters in the install-config.yaml file before you install the cluster.

3.7.1. Prerequisites

• Review details about the OpenShift Container Platform installation and update processes.

• Configure an Azure account to host the cluster and determine the tested and validated region to deploy the cluster to.

• If you use a firewall, you must configure it to allow the sites that your cluster requires access to.

• If you do not allow the system to manage identity and access management (IAM), then a cluster administrator can manually create and maintain IAM credentials. Manual mode can also be used in environments where the cloud IAM APIs are not reachable.

3.7.2. Private clusters

You can deploy a private OpenShift Container Platform cluster that does not expose external endpoints. Private clusters are accessible from only an internal network and are not visible to the Internet.

By default, OpenShift Container Platform is provisioned to use publicly-accessible DNS and endpoints. A private cluster sets the DNS, Ingress Controller, and API server to private when you deploy your cluster. This means that the cluster resources are only accessible from your internal network and are not visible to the internet.

To deploy a private cluster, you must use existing networking that meets your requirements. Your cluster resources might be shared between other clusters on the network.

Additionally, you must deploy a private cluster from a machine that has access the API services for the cloud you provision to, the hosts on the network that you provision, and to the internet to obtain installation media. You can use any machine that meets these access requirements and follows your company's guidelines. For example, this machine can be a bastion host on your cloud network or a machine that has access to the network through a VPN.

3.7.2.1. Private clusters in Azure

To create a private cluster on Microsoft Azure, you must provide an existing private VNet and subnets to host the cluster. The installation program must also be able to resolve the DNS records that the cluster requires. The installation program configures the Ingress Operator and API server for only internal traffic.

Depending how your network connects to the private VNET, you might need to use a DNS forwarder in order to resolve the cluster’s private DNS records. The cluster’s machines use 168.63.129.16 internally for DNS resolution. For more information, see What is Azure Private DNS? and What is IP address 168.63.129.16? in the Azure documentation.

The cluster still requires access to Internet to access the Azure APIs.
The following items are not required or created when you install a private cluster:

- A **BaseDomainResourceGroup**, since the cluster does not create public records
- Public IP addresses
- Public DNS records
- Public endpoints

The cluster is configured so that the Operators do not create public records for the cluster and all cluster machines are placed in the private subnets that you specify.

### 3.7.2.1.1. Limitations

Private clusters on Azure are subject to only the limitations that are associated with the use of an existing VNet.

### 3.7.2.2. User-defined outbound routing

In OpenShift Container Platform, you can choose your own outbound routing for a cluster to connect to the Internet. This allows you to skip the creation of public IP addresses and the public load balancer.

You can configure user-defined routing by modifying parameters in the `install-config.yaml` file before installing your cluster. A pre-existing VNet is required to use outbound routing when installing a cluster; the installation program is not responsible for configuring this.

When configuring a cluster to use user-defined routing, the installation program does not create the following resources:

- Outbound rules for access to the Internet.
- Public IPs for the public load balancer.
- Kubernetes Service object to add the cluster machines to the public load balancer for outbound requests.

You must ensure the following items are available before setting user-defined routing:

- Egress to the Internet is possible to pull container images, unless using an internal registry mirror.
- The cluster can access Azure APIs.
- Various allowlist endpoints are configured. You can reference these endpoints in the *Configuring your firewall* section.

There are several pre-existing networking setups that are supported for Internet access using user-defined routing.

**Private cluster with network address translation**

You can use **Azure VNET network address translation (NAT)** to provide outbound Internet access for the subnets in your cluster. You can reference *Create a NAT gateway using Azure CLI* in the Azure documentation for configuration instructions.
When using a VNet setup with Azure NAT and user-defined routing configured, you can create a private cluster with no public endpoints.

**Private cluster with Azure Firewall**
You can use Azure Firewall to provide outbound routing for the VNet used to install the cluster. You can learn more about providing user-defined routing with Azure Firewall in the Azure documentation.

When using a VNet setup with Azure Firewall and user-defined routing configured, you can create a private cluster with no public endpoints.

**Private cluster with a proxy configuration**
You can use a proxy with user-defined routing to allow egress to the Internet. You must ensure that cluster Operators do not access Azure APIs using a proxy; Operators must have access to Azure APIs outside of the proxy.

When using the default route table for subnets, with 0.0.0.0/0 populated automatically by Azure, all Azure API requests are routed over Azure’s internal network even though the IP addresses are public. As long as the Network Security Group rules allow egress to Azure API endpoints, proxies with user-defined routing configured allow you to create private clusters with no public endpoints.

**Private cluster with no Internet access**
You can have VNets with no access to the Internet if your cluster has access to the following:

- An internal registry mirror that allows for pulling container images
- Access to Azure APIs

With these requirements available, you can use user-defined routing to create private clusters with no public endpoints.

### 3.7.3. About reusing a VNet for your OpenShift Container Platform cluster

In OpenShift Container Platform 4.6, you can deploy a cluster into an existing Azure Virtual Network (VNet) in Microsoft Azure. If you do, you must also use existing subnets within the VNet and routing rules.

By deploying OpenShift Container Platform into an existing Azure VNet, you might be able to avoid service limit constraints in new accounts or more easily abide by the operational constraints that your company’s guidelines set. This is a good option to use if you cannot obtain the infrastructure creation permissions that are required to create the VNet.

### 3.7.3.1. Requirements for using your VNet

When you deploy a cluster by using an existing VNet, you must perform additional network configuration before you install the cluster. In installer-provisioned infrastructure clusters, the installer usually creates the following components, but it does not create them when you install into an existing VNet:

- Subnets
- Route tables
- VNets
- Network Security Groups

If you use a custom VNet, you must correctly configure it and its subnets for the installation program and the cluster to use. The installation program cannot subdivide network ranges for the cluster to use,
set route tables for the subnets, or set VNet options like DHCP, so you must do so before you install the cluster.

The cluster must be able to access the resource group that contains the existing VNet and subnets. While all of the resources that the cluster creates are placed in a separate resource group that it creates, some network resources are used from a separate group. Some cluster Operators must be able to access resources in both resource groups. For example, the Machine API controller attaches NICS for the virtual machines that it creates to subnets from the networking resource group.

Your VNet must meet the following characteristics:

- The VNet’s CIDR block must contain the **Networking.MachineCIDR** range, which is the IP address pool for cluster machines.
- The VNet and its subnets must belong to the same resource group, and the subnets must be configured to use Azure-assigned DHCP IP addresses instead of static IP addresses.

You must provide two subnets within your VNet, one for the control plane machines and one for the compute machines. Because Azure distributes machines in different availability zones within the region that you specify, your cluster will have high availability by default.

To ensure that the subnets that you provide are suitable, the installation program confirms the following data:

- All the specified subnets exist.
- There are two private subnets, one for the control plane machines and one for the compute machines.
- The subnet CIDRs belong to the machine CIDR that you specified. Machines are not provisioned in availability zones that you do not provide private subnets for.

**NOTE**

If you destroy a cluster that uses an existing VNet, the VNet is not deleted.

### 3.7.3.1.1. Network security group requirements

The network security groups for the subnets that host the compute and control plane machines require specific access to ensure that the cluster communication is correct. You must create rules to allow access to the required cluster communication ports.

**IMPORTANT**

The network security group rules must be in place before you install the cluster. If you attempt to install a cluster without the required access, the installation program cannot reach the Azure APIs, and installation fails.

**Table 3.19. Required ports**

<table>
<thead>
<tr>
<th>Port</th>
<th>Description</th>
<th>Control plane</th>
<th>Compute</th>
</tr>
</thead>
<tbody>
<tr>
<td>80</td>
<td>Allows HTTP traffic</td>
<td></td>
<td>x</td>
</tr>
</tbody>
</table>
### Port Description

<table>
<thead>
<tr>
<th>Port</th>
<th>Description</th>
<th>Control plane</th>
<th>Compute</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>Allows HTTPS traffic</td>
<td></td>
<td>x</td>
</tr>
<tr>
<td>6443</td>
<td>Allows communication to the control plane machines</td>
<td>x</td>
<td></td>
</tr>
<tr>
<td>22623</td>
<td>Allows communication to the machine config server</td>
<td>x</td>
<td></td>
</tr>
</tbody>
</table>

**NOTE**

Since cluster components do not modify the user-provided network security groups, which the Kubernetes controllers update, a pseudo-network security group is created for the Kubernetes controller to modify without impacting the rest of the environment.

#### 3.7.3.2. Division of permissions

Starting with OpenShift Container Platform 4.3, you do not need all of the permissions that are required for an installation program-provisioned infrastructure cluster to deploy a cluster. This change mimics the division of permissions that you might have at your company: some individuals can create different resources in your clouds than others. For example, you might be able to create application-specific items, like instances, storage, and load balancers, but not networking-related components such as Vnets, subnet, or ingress rules.

The Azure credentials that you use when you create your cluster do not need the networking permissions that are required to make Vnets and core networking components within the VNet, such as subnets, routing tables, internet gateways, NAT, and VPN. You still need permission to make the application resources that the machines within the cluster require, such as load balancers, security groups, storage accounts, and nodes.

#### 3.7.3.3. Isolation between clusters

Because the cluster is unable to modify network security groups in an existing subnet, there is no way to isolate clusters from each other on the VNet.

#### 3.7.4. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.6, you require access to the Internet to install your cluster.

You must have Internet access to:

- Access [OpenShift Cluster Manager](#) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](#) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.
IMPORTANT

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

3.7.5. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your ssh-agent and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

NOTE

In a production environment, you require disaster recovery and debugging.

You can use this key to SSH into the master nodes as the user core. When you deploy the cluster, the key is added to the core user’s ~/.ssh/authorized_keys list.

NOTE

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

Procedure

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   $ ssh-keygen -t ed25519 -N "\  
   -f <path>/<file_name>  

   Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   Running this command generates an SSH key that does not require a password in the location that you specified.

   NOTE

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the ssh-agent process as a background task:
NOTE
If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the `ssh-agent`:

```bash
$ ssh-add /path/to/file
```

Example output

```
Identity added: /path/to/file (computer_name)
```

Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

3.7.6. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on a local computer.

Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.
4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar xvf openshift-install-linux.tar.gz
```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 3.7.7. Manually creating the installation configuration file

For installations of a private OpenShift Container Platform cluster that are only accessible from an internal network and are not visible to the Internet, you must manually generate your installation configuration file.

**Prerequisites**

- Obtain the OpenShift Container Platform installation program and the access token for your cluster.

**Procedure**

1. Create an installation directory to store your required installation assets in:

   ```
   $ mkdir <installation_directory>
   ```

   **IMPORTANT**

   You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the following `install-config.yaml` file template and save it in the `<installation_directory>`.

   **NOTE**

   You must name this configuration file `install-config.yaml`.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.
3.7.7.1. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster’s platform. When you create the `install-config.yaml` installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the `install-config.yaml` file to provide more details about the platform.

### IMPORTANT

The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.

### NOTE

After installation, you cannot modify these parameters in the `install-config.yaml` file.

### IMPORTANT

The `openshift-install` command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

#### 3.7.7.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is v1. The installer may also support older API versions.</td>
<td>String</td>
</tr>
</tbody>
</table>
| baseDomain    | The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the baseDomain and metadata.name parameter values that uses the `<metadata.name>`.<baseDomain> format. | A fully-qualified domain or subdomain name, such as example.com.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>metadata</td>
<td>Kubernetes resource <strong>ObjectMeta</strong>, from which only the <strong>name</strong> parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of <code>{{.metadata.name}}.{{.baseDomain}}</code>.</td>
<td>String of lowercase letters, hyphens (-), and periods (.), such as <code>dev</code>.</td>
</tr>
<tr>
<td>platform</td>
<td>The configuration for the specific platform upon which to perform the installation: <code>aws</code>, <code>baremetal</code>, <code>azure</code>, <code>openstack</code>, <code>ovirt</code>, <code>vsphere</code>. For additional information about <code>platform.&lt;platform&gt;</code> parameters, consult the following table for your specific platform.</td>
<td>Object</td>
</tr>
</tbody>
</table>
| pullSecret | Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io. | ```json
{
  "auths":{
    "cloud.openshift.com":{
      "auth":"b3Blb=",
      "email":"you@example.com"
    },
    "quay.io":{
      "auth":"b3Blb=",
      "email":"you@example.com"
    }
  }
}
``` |

### 3.7.7.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

**Table 3.21. Network parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
</table>

579
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td>networking.network Type</td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN.</td>
</tr>
<tr>
<td>networking.clusterNetwork</td>
<td>The IP address blocks for pods.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td>networking.clusterNetwork.cidr</td>
<td>Required if you use networking.clusterNetwork. An IP address block.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td>networking.clusterNetwork.hostPrefix</td>
<td>The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given cidr. A hostPrefix value of 23 provides 510 (2^(32 - 23) - 2) pod IP addresses.</td>
<td>A subnet prefix. The default value is 23.</td>
</tr>
<tr>
<td>networking.serviceNetwork</td>
<td>The IP address block for services. The default value is 172.30.0.0/16.</td>
<td>An array with an IP address block in CIDR format. For example:</td>
</tr>
<tr>
<td>networking.machineNetwork</td>
<td>The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td>An array of objects. For example:</td>
</tr>
</tbody>
</table>
networking.machine
Network.cidr

Required if you use networking.machineNetwork. An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24.

An IP network block in CIDR notation. For example, 10.0.0.0/16.

NOTE
Set the networking.machineNetwork to match the CIDR that the preferred NIC resides in.

3.7.7.13. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

Table 3.22. Optional parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of machine-pool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>compute.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are amd64 (the default).</td>
<td>String</td>
</tr>
</tbody>
</table>
Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.

<table>
<thead>

</tbody>
</table>
Enable or disable FIPS mode. The default is false (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**
The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

**NOTE**
If you are using Azure File storage, you cannot enable FIPS mode.

<table>
<thead>
<tr>

<td>imageContentSources.source</td>
<td>Required if you use imageContentSources. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td>imageContentSources.mirs</td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
<tr>
<td>publish</td>
<td>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</td>
<td>Internal or External. To deploy a private cluster, which cannot be accessed from the internet, set publish to Internal. The default value is External.</td>
</tr>
</tbody>
</table>
The SSH key or keys to authenticate access your cluster machines.

**NOTE**
For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

One or more keys. For example:

```
sshKey:
  <key1>
  <key2>
  <key3>
```

### 3.7.7.14. Additional Azure configuration parameters

Additional Azure configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>compute.platform.azure.osDisk.diskSize GB</code></td>
<td>The Azure disk size for the VM.</td>
<td>Integer that represents the size of the disk in GB. The default is 128.</td>
</tr>
<tr>
<td><code>compute.platform.azure.osDisk.diskType</code></td>
<td>Defines the type of disk.</td>
<td>standard_LRS, premium_LRS, or standardSSD_LRS, The default is premium_LRS.</td>
</tr>
<tr>
<td><code>controlPlane.platform.azure.osDisk.diskSizeGB</code></td>
<td>The Azure disk size for the VM.</td>
<td>Integer that represents the size of the disk in GB. The default is 1024.</td>
</tr>
<tr>
<td><code>controlPlane.platform.azure.osDisk.diskType</code></td>
<td>Defines the type of disk.</td>
<td>premium_LRS or standardSSD_LRS, The default is premium_LRS.</td>
</tr>
<tr>
<td><code>platform.azure.baseDomainResourceGroupName</code></td>
<td>The name of the resource group that contains the DNS zone for your base domain.</td>
<td>String, for example production_cluster.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>platform.azure.outboundType</td>
<td>The outbound routing strategy used to connect your cluster to the internet. If you are using user-defined routing, you must have pre-existing networking available where the outbound routing has already been configured prior to installing a cluster. The installation program is not responsible for configuring user-defined routing.</td>
<td>LoadBalancer or UserDefinedRouting. The default is LoadBalancer.</td>
</tr>
<tr>
<td>platform.azure.region</td>
<td>The name of the Azure region that hosts your cluster.</td>
<td>Any valid region name, such as centralus.</td>
</tr>
<tr>
<td>platform.azure.zone</td>
<td>List of availability zones to place machines in. For high availability, specify at least two zones.</td>
<td>List of zones, for example [&quot;1&quot;, &quot;2&quot;, &quot;3&quot;].</td>
</tr>
<tr>
<td>platform.azure.networkResourceGroupName</td>
<td>The name of the resource group that contains the existing VNet that you want to deploy your cluster to. This name cannot be the same as the platform.azure.baseDomainResourceGroupName.</td>
<td>String.</td>
</tr>
<tr>
<td>platform.azure.virtualNetwork</td>
<td>The name of the existing VNet that you want to deploy your cluster to.</td>
<td>String.</td>
</tr>
<tr>
<td>platform.azure.controlPlaneSubnet</td>
<td>The name of the existing subnet in your VNet that you want to deploy your control plane machines to.</td>
<td>Valid CIDR, for example 10.0.0.0/16.</td>
</tr>
<tr>
<td>platform.azure.computeSubnet</td>
<td>The name of the existing subnet in your VNet that you want to deploy your compute machines to.</td>
<td>Valid CIDR, for example 10.0.0.0/16.</td>
</tr>
<tr>
<td>platform.azure.cloudName</td>
<td>The name of the Azure cloud environment that is used to configure the Azure SDK with the appropriate Azure API endpoints. If empty, the default value AzurePublicCloud is used.</td>
<td>Any valid cloud environment, such as AzurePublicCloud or AzureUSGovernmentCloud.</td>
</tr>
</tbody>
</table>

**NOTE**

You cannot customize Azure Availability Zones or Use tags to organize your Azure resources with an Azure cluster.

3.7.7.2. Sample customized install-config.yaml file for Azure
You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster's platform or modify the values of the required parameters.

**IMPORTANT**

This sample YAML file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program and modify it.

```yaml
apiVersion: v1
baseDomain: example.com
controlPlane:
  hyperthreading: Enabled
  name: master
  platform:
    azure:
      osDisk:
        diskSizeGB: 1024
        diskType: Premium_LRS
        type: Standard_D8s_v3
      replicas: 3
compute:
  - hyperthreading: Enabled
  name: worker
  platform:
    azure:
      type: Standard_D2s_v3
      osDisk:
        diskSizeGB: 512
        diskType: Standard_LRS
      zones:
        - "1"
        - "2"
        - "3"
      replicas: 5
metadata:
  name: test-cluster
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
      hostPrefix: 23
  machineNetwork:
    - cidr: 10.0.0.0/16
  networkType: OpenShiftSDN
  serviceNetwork:
    - 172.30.0.0/16
platform:
  azure:
    baseDomainResourceGroupName: resource_group
    region: centralus
    resourceGroupName: existing_resource_group
    networkResourceGroupName: vnet_resource_group
    virtualNetwork: vnet
    controlPlaneSubnet: control_plane_subnet
```
computeSubnet: compute_subnet
outboundType: UserDefinedRouting
cloudName: AzurePublicCloud
pullSecret: {'"auths": ...'}
fips: false
sshKey: ssh-ed25519 AAAA...
publish: Internal

1. Required. The installation program prompts you for this value.
2. If you do not provide these parameters and values, the installation program provides the default value.
3. The `controlPlane` section is a single mapping, but the `compute` section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the `compute` section must begin with a hyphen, `-`, and the first line of the `controlPlane` section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.
4. Whether to enable or disable simultaneous multithreading, or hyperthreading. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores. You can disable it by setting the parameter value to `Disabled`. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger virtual machine types, such as `Standard_D8s_v3`, for your machines if you disable simultaneous multithreading.

5. You can specify the size of the disk to use in GB. Minimum recommendation for control plane nodes (also known as the master nodes) is 1024 GB.
6. Specify a list of zones to deploy your machines to. For high availability, specify at least two zones.
7. Specify the name of the resource group that contains the DNS zone for your base domain.
8. Specify the name of an already existing resource group to install your cluster to. If undefined, a new resource group is created for the cluster.
9. If you use an existing VNet, specify the name of the resource group that contains it.
10. If you use an existing VNet, specify its name.
11. If you use an existing VNet, specify the name of the subnet to host the control plane machines.
12. If you use an existing VNet, specify the name of the subnet to host the compute machines.
13. You can customize your own outbound routing. Configuring user-defined routing prevents exposing external endpoints in your cluster. User-defined routing for egress requires deploying your cluster to an existing VNet.
14. Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container...
Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

You can optionally provide the `sshKey` value that you use to access the machines in your cluster.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

How to publish the user-facing endpoints of your cluster. Set `publish` to `Internal` to deploy a private cluster, which cannot be accessed from the Internet. The default value is `External`.

### 3.7.7.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**Prerequisites**

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

**Procedure**

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

```yaml
apiVersion: v1
template:
  metadata:
    labels:
      cluster-openshift-4.x.tangaroa.com/openshift-cluster: default-openshift
spec:
  machineConfig:
    imagePullSecrets:
    - name: openshift-image-pull-secret
      nodename: node1
    metadata:
      labels:
        cluster-openshift-4.x.tangaroa.com/openshift-cluster: default-openshift
      containerImagePolicy:
        useOpenShiftBuilds: true
    osImage:
      name: rhcos-4.6.1
    serviceNetwork:
      cidr: 10.96.0.0/14
```

2. After updating the configuration, you can deploy the cluster using the `oc` command:

   ```bash
   oc new-project $(oc whoami)
   ``
proxy:
httpProxy: http://<username>:<pswd>@<ip>:<port>  
httpsProxy: https://<username>:<pswd>@<ip>:<port>  
nopxy: example.com  
additionalTrustBundle: |  
      -----BEGIN CERTIFICATE-----  
      <MY_TRUSTED_CA_CERT>  
      -----END CERTIFICATE-----  

1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.

2. A proxy URL to use for creating HTTPS connections outside the cluster.

3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.

4. If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace to hold the additional CA certificates. If you provide additionalTrustBundle and at least one proxy setting, the Proxy object is configured to reference the user-ca-bundle config map in the trustedCA field. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges the contents specified for the trustedCA parameter with the RHCOS trust bundle. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

NOTE
The installation program does not support the proxy readinessEndpoints field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

NOTE
Only the Proxy object named cluster is supported, and no additional proxies can be created.

3.7.8. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

IMPORTANT
You can run the create cluster command of the installation program only once, during initial installation.
Prerequisites

- Configure an account with the cloud platform that hosts your cluster.
- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Change to the directory that contains the installation program and initialize the cluster deployment:

   $ ./openshift-install create cluster --dir <installation_directory> \  
   --log-level=info

   1 For <installation_directory>, specify the
   2 To view different installation details, specify warn, debug, or error instead of info.

   **NOTE**
   
   If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.

   When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the kubeadmin user, display in your terminal.

   **Example output**

   ...  
   INFO Install complete!  
   INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'  
   INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com  
   INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-Wt5AL"  
   INFO Time elapsed: 36m22s

   **NOTE**
   
   The cluster access and credential information also outputs to <installation_directory>/openshift_install.log when an installation succeeds.
The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

3.7.9. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) in order to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.6. Download and install the new version of oc.

3.7.9.1. Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.6 Linux Client entry and save the file.

4. Unpack the archive:

   $ tar xzvf <file>

5. Place the oc binary in a directory that is on your PATH. To check your PATH, execute the following command:

   $ echo $PATH
After you install the OpenShift CLI, it is available using the `oc` command:

```
$ oc <command>
```

### 3.7.9.2. Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (`oc`) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.
3. Click **Download Now** next to the **OpenShift v4.6 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the `oc` binary to a directory that is on your **PATH**.
   
   To check your **PATH**, open the command prompt and execute the following command:

   ```
   C:\> path
   ```

After you install the OpenShift CLI, it is available using the `oc` command:

```
C:\> oc <command>
```

### 3.7.9.3. Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (`oc`) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.
3. Click **Download Now** next to the **OpenShift v4.6 MacOSX Client** entry and save the file.
4. Unpack and unzip the archive.
5. Move the `oc` binary to a directory on your **PATH**.
   
   To check your **PATH**, open a terminal and execute the following command:

   ```
   $ echo $PATH
   ```

After you install the OpenShift CLI, it is available using the `oc` command:

```
$ oc <command>
```
3.7.10. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster kubeconfig file. The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the oc CLI.

Procedure

1. Export the kubeadm credentials:

   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig

   For <installation_directory>, specify the path to the directory that you stored the installation files in.

2. Verify you can run oc commands successfully using the exported configuration:

   $ oc whoami

   Example output

   system:admin

Additional resources

- See Accessing the web console for more details about accessing and understanding the OpenShift Container Platform web console.

3.7.11. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.6, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service

3.7.12. Next steps

- Customize your cluster.
If necessary, you can opt out of remote health reporting.

3.8. INSTALLING A CLUSTER ON AZURE INTO A GOVERNMENT REGION

In OpenShift Container Platform version 4.6, you can install a cluster on Microsoft Azure into a government region. To configure the government region, you modify parameters in the `install-config.yaml` file before you install the cluster.

3.8.1. Prerequisites

- Review details about the OpenShift Container Platform installation and update processes.
- Configure an Azure account to host the cluster and determine the tested and validated government region to deploy the cluster to.
- If you use a firewall, you must configure it to allow the sites that your cluster requires access to.
- If you do not allow the system to manage identity and access management (IAM), then a cluster administrator can manually create and maintain IAM credentials. Manual mode can also be used in environments where the cloud IAM APIs are not reachable.

3.8.2. Azure government regions

OpenShift Container Platform supports deploying a cluster to Microsoft Azure Government (MAG) regions. MAG is specifically designed for US government agencies at the federal, state, and local level, as well as contractors, educational institutions, and other US customers that must run sensitive workloads on Azure. MAG is composed of government-only data center regions, all granted an Impact Level 5 Provisional Authorization.

Installing to a MAG region requires manually configuring the Azure Government dedicated cloud instance and region in the `install-config.yaml` file. You must also update your service principal to reference the appropriate government environment.

**NOTE**

The Azure government region cannot be selected using the guided terminal prompts from the installation program. You must define the region manually in the `install-config.yaml` file. Remember to also set the dedicated cloud instance, like `AzureUSGovernmentCloud`, based on the region specified.

3.8.3. Private clusters

You can deploy a private OpenShift Container Platform cluster that does not expose external endpoints. Private clusters are accessible from only an internal network and are not visible to the Internet.

By default, OpenShift Container Platform is provisioned to use publicly-accessible DNS and endpoints. A private cluster sets the DNS, Ingress Controller, and API server to private when you deploy your cluster. This means that the cluster resources are only accessible from your internal network and are not visible to the internet.

To deploy a private cluster, you must use existing networking that meets your requirements. Your cluster resources might be shared between other clusters on the network.
Additionally, you must deploy a private cluster from a machine that has access the API services for the cloud you provision to, the hosts on the network that you provision, and to the internet to obtain installation media. You can use any machine that meets these access requirements and follows your company’s guidelines. For example, this machine can be a bastion host on your cloud network or a machine that has access to the network through a VPN.

3.8.3.1. Private clusters in Azure

To create a private cluster on Microsoft Azure, you must provide an existing private VNet and subnets to host the cluster. The installation program must also be able to resolve the DNS records that the cluster requires. The installation program configures the Ingress Operator and API server for only internal traffic.

Depending how your network connects to the private VNET, you might need to use a DNS forwarder in order to resolve the cluster’s private DNS records. The cluster’s machines use 168.63.129.16 internally for DNS resolution. For more information, see What is Azure Private DNS? and What is IP address 168.63.129.16? in the Azure documentation.

The cluster still requires access to Internet to access the Azure APIs.

The following items are not required or created when you install a private cluster:

- A BaseDomainResourceGroup, since the cluster does not create public records
- Public IP addresses
- Public DNS records
- Public endpoints

The cluster is configured so that the Operators do not create public records for the cluster and all cluster machines are placed in the private subnets that you specify.

3.8.3.1. Limitations

Private clusters on Azure are subject to only the limitations that are associated with the use of an existing VNet.

3.8.3.2. User-defined outbound routing

In OpenShift Container Platform, you can choose your own outbound routing for a cluster to connect to the Internet. This allows you to skip the creation of public IP addresses and the public load balancer.

You can configure user-defined routing by modifying parameters in the install-config.yaml file before installing your cluster. A pre-existing VNet is required to use outbound routing when installing a cluster; the installation program is not responsible for configuring this.

When configuring a cluster to use user-defined routing, the installation program does not create the following resources:

- Outbound rules for access to the Internet.
- Public IPs for the public load balancer.
- Kubernetes Service object to add the cluster machines to the public load balancer for outbound requests.
You must ensure the following items are available before setting user-defined routing:

- Egress to the Internet is possible to pull container images, unless using an internal registry mirror.
- The cluster can access Azure APIs.
- Various allowlist endpoints are configured. You can reference these endpoints in the Configuring your firewall section.

There are several pre-existing networking setups that are supported for Internet access using user-defined routing.

**Private cluster with network address translation**

You can use Azure VNET network address translation (NAT) to provide outbound Internet access for the subnets in your cluster. You can reference Create a NAT gateway using Azure CLI in the Azure documentation for configuration instructions.

When using a VNet setup with Azure NAT and user-defined routing configured, you can create a private cluster with no public endpoints.

**Private cluster with Azure Firewall**

You can use Azure Firewall to provide outbound routing for the VNet used to install the cluster. You can learn more about providing user-defined routing with Azure Firewall in the Azure documentation.

When using a VNet setup with Azure Firewall and user-defined routing configured, you can create a private cluster with no public endpoints.

**Private cluster with a proxy configuration**

You can use a proxy with user-defined routing to allow egress to the Internet. You must ensure that cluster Operators do not access Azure APIs using a proxy; Operators must have access to Azure APIs outside of the proxy.

When using the default route table for subnets, with 0.0.0.0/0 populated automatically by Azure, all Azure API requests are routed over Azure’s internal network even though the IP addresses are public. As long as the Network Security Group rules allow egress to Azure API endpoints, proxies with user-defined routing configured allow you to create private clusters with no public endpoints.

**Private cluster with no Internet access**

You can have VNets with no access to the Internet if your cluster has access to the following:

- An internal registry mirror that allows for pulling container images
- Access to Azure APIs

With these requirements available, you can use user-defined routing to create private clusters with no public endpoints.

### 3.8.4. About reusing a VNet for your OpenShift Container Platform cluster

In OpenShift Container Platform 4.6, you can deploy a cluster into an existing Azure Virtual Network (VNet) in Microsoft Azure. If you do, you must also use existing subnets within the VNet and routing rules.

By deploying OpenShift Container Platform into an existing Azure VNet, you might be able to avoid service limit constraints in new accounts or more easily abide by the operational constraints that your company’s guidelines set. This is a good option to use if you cannot obtain the infrastructure creation
permissions that are required to create the VNet.

### 3.8.4.1. Requirements for using your VNet

When you deploy a cluster by using an existing VNet, you must perform additional network configuration before you install the cluster. In installer-provisioned infrastructure clusters, the installer usually creates the following components, but it does not create them when you install into an existing VNet:

- Subnets
- Route tables
- VNets
- Network Security Groups

If you use a custom VNet, you must correctly configure it and its subnets for the installation program and the cluster to use. The installation program cannot subdivide network ranges for the cluster to use, set route tables for the subnets, or set VNet options like DHCP, so you must do so before you install the cluster.

The cluster must be able to access the resource group that contains the existing VNet and subnets. While all of the resources that the cluster creates are placed in a separate resource group that it creates, some network resources are used from a separate group. Some cluster Operators must be able to access resources in both resource groups. For example, the Machine API controller attaches NICS for the virtual machines that it creates to subnets from the networking resource group.

Your VNet must meet the following characteristics:

- The VNet’s CIDR block must contain the `Networking.MachineCIDR` range, which is the IP address pool for cluster machines.
- The VNet and its subnets must belong to the same resource group, and the subnets must be configured to use Azure-assigned DHCP IP addresses instead of static IP addresses.

You must provide two subnets within your VNet, one for the control plane machines and one for the compute machines. Because Azure distributes machines in different availability zones within the region that you specify, your cluster will have high availability by default.

To ensure that the subnets that you provide are suitable, the installation program confirms the following data:

- All the specified subnets exist.
- There are two private subnets, one for the control plane machines and one for the compute machines.
- The subnet CIDRs belong to the machine CIDR that you specified. Machines are not provisioned in availability zones that you do not provide private subnets for. If required, the installation program creates public load balancers that manage the control plane and worker nodes, and Azure allocates a public IP address to them.

**NOTE**

If you destroy a cluster that uses an existing VNet, the VNet is not deleted.
3.8.4.1. Network security group requirements

The network security groups for the subnets that host the compute and control plane machines require specific access to ensure that the cluster communication is correct. You must create rules to allow access to the required cluster communication ports.

**IMPORTANT**

The network security group rules must be in place before you install the cluster. If you attempt to install a cluster without the required access, the installation program cannot reach the Azure APIs, and installation fails.

### Table 3.24. Required ports

<table>
<thead>
<tr>
<th>Port</th>
<th>Description</th>
<th>Control plane</th>
<th>Compute</th>
</tr>
</thead>
<tbody>
<tr>
<td>80</td>
<td>Allows HTTP traffic</td>
<td></td>
<td>x</td>
</tr>
<tr>
<td>443</td>
<td>Allows HTTPS traffic</td>
<td></td>
<td>x</td>
</tr>
<tr>
<td>6443</td>
<td>Allows communication to the control plane machines</td>
<td>x</td>
<td></td>
</tr>
<tr>
<td>22623</td>
<td>Allows communication to the machine config server</td>
<td></td>
<td>x</td>
</tr>
</tbody>
</table>

**NOTE**

Since cluster components do not modify the user-provided network security groups, which the Kubernetes controllers update, a pseudo-network security group is created for the Kubernetes controller to modify without impacting the rest of the environment.

3.8.4.2. Division of permissions

Starting with OpenShift Container Platform 4.3, you do not need all of the permissions that are required for an installation program-provisioned infrastructure cluster to deploy a cluster. This change mimics the division of permissions that you might have at your company: some individuals can create different resources in your clouds than others. For example, you might be able to create application-specific items, like instances, storage, and load balancers, but not networking-related components such as VNets, subnet, or ingress rules.

The Azure credentials that you use when you create your cluster do not need the networking permissions that are required to make VNets and core networking components within the VNet, such as subnets, routing tables, internet gateways, NAT, and VPN. You still need permission to make the application resources that the machines within the cluster require, such as load balancers, security groups, storage accounts, and nodes.

3.8.4.3. Isolation between clusters

Because the cluster is unable to modify network security groups in an existing subnet, there is no way to isolate clusters from each other on the VNet.

3.8.5. Internet access for OpenShift Container Platform
In OpenShift Container Platform 4.6, you require access to the Internet to install your cluster.

You must have Internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- Access Quay.io to obtain the packages that are required to install your cluster.

- Obtain the packages that are required to perform cluster updates.

IMPORTANT

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

3.8.6. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your `ssh-agent` and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

NOTE

In a production environment, you require disaster recovery and debugging.

You can use this key to SSH into the master nodes as the user `core`. When you deploy the cluster, the key is added to the `core` user’s `~/.ssh/authorized_keys` list.

NOTE

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

Procedure

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "\n              -f <path>/<file_name> 1
```

Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.
Running this command generates an SSH key that does not require a password in the location that you specified.

**NOTE**

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the **ssh-agent** process as a background task:

```
$ eval "$(ssh-agent -s)"
```

**Example output**

```
Agent pid 31874
```

**NOTE**

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the **ssh-agent**:

```
$ ssh-add <path>/<file_name>
```

**Example output**

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

1. Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

**3.8.7. Obtaining the installation program**

Before you install OpenShift Container Platform, download the installation file on a local computer.

**Prerequisites**

- You have a computer that runs Linux or macOS, with 500 MB of local disk space

**Procedure**

1. Access the **Infrastructure Provider** page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.
2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

   **IMPORTANT**
   
   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   **IMPORTANT**
   
   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ tar xvf openshift-install-linux.tar.gz
   ```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 3.8.8. Manually creating the installation configuration file

When installing OpenShift Container Platform on Microsoft Azure into a government region, you must manually generate your installation configuration file.

**Prerequisites**

- Obtain the OpenShift Container Platform installation program and the access token for your cluster.

**Procedure**

1. Create an installation directory to store your required installation assets in:

   ```
   $ mkdir <installation_directory>
   ```
IMPORTANT
You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the following install-config.yaml file template and save it in the <installation_directory>.

NOTE
You must name this configuration file install-config.yaml.

3. Back up the install-config.yaml file so that you can use it to install multiple clusters.

IMPORTANT
The install-config.yaml file is consumed during the next step of the installation process. You must back it up now.

3.8.8.1. Installation configuration parameters
Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster’s platform. When you create the install-config.yaml installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the install-config.yaml file to provide more details about the platform.

NOTE
After installation, you cannot modify these parameters in the install-config.yaml file.

IMPORTANT
The openshift-install command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

3.8.8.1.1. Required configuration parameters
Required installation configuration parameters are described in the following table:

Table 3.25. Required parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is v1. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the <code>baseDomain</code> and <code>metadata.name</code> parameter values that uses the <code>&lt;metadata.name&gt;</code>, <code>&lt;baseDomain&gt;</code> format.</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
</tr>
<tr>
<td>metadata</td>
<td>Kubernetes resource <code>ObjectMeta</code>, from which only the <code>name</code> parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of <code>{.metadata.name}.{.baseDomain}</code>.</td>
<td>String of lowercase letters, hyphens (-), and periods (.), such as dev.</td>
</tr>
<tr>
<td>platform</td>
<td>The configuration for the specific platform upon which to perform the installation: aws, baremetal, azure, openstack, ovirt, vsphere. For additional information about <code>platform.&lt;platform&gt;</code> parameters, consult the following table for your specific platform.</td>
<td>Object</td>
</tr>
</tbody>
</table>
Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.

```
{
  "auths":{
    "cloud.openshift.com":{

      "email":"you@example.com"
    }
  }
}
```

### 3.8.8.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

**Table 3.26. Network parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td><strong>NOTE</strong></td>
<td>You cannot modify parameters specified by the networking object after installation.</td>
<td></td>
</tr>
<tr>
<td>networking.networkType</td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN.</td>
</tr>
<tr>
<td>networking.clusterNetwork</td>
<td>The IP address blocks for pods.</td>
<td>An array of objects. For example: networking:</td>
</tr>
<tr>
<td></td>
<td>The default value is <strong>10.128.0.0/14</strong> with a host prefix of <strong>/23</strong>.</td>
<td>clusterNetwork:</td>
</tr>
</tbody>
</table>
|                        | If you specify multiple IP address blocks, the blocks must not overlap. | - cidr: **10.128.0.0/14**  
|                        |                                                        | hostPrefix: **23** |

</tr>
<tr>
<td>controlPlane.name</td>
<td>Required if you use controlPlane. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use controlPlane. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the compute.platform parameter value.</td>
<td><code>aws, azure, gcp, openstack, ovirt, vsphere</code>, or {}</td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
</tbody>
</table>
The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.

**NOTE**

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Red Hat Operators reference content.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (&quot;&quot;).</td>
</tr>
</tbody>
</table>
### fips

Enable or disable FIPS mode. The default is **false** (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the **x86_64** architecture.

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>imageContentSources</td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects. Includes a <code>source</code> and, optionally, <code>mirrors</code>, as described in the following rows of this table.</td>
</tr>
<tr>
<td>imageContentSources.source</td>
<td>Required if you use <code>imageContentSources</code>. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td>imageContentSources.mirrors</td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
<tr>
<td>publish</td>
<td>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</td>
<td><strong>Internal</strong> or <strong>External</strong>. To deploy a private cluster, which cannot be accessed from the internet, set <code>publish</code> to <strong>Internal</strong>. The default value is <strong>External</strong>.</td>
</tr>
</tbody>
</table>
The SSH key or keys to authenticate access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

One or more keys. For example:

```plaintext
sshKey:
<key1>
<key2>
<key3>
```

### 3.8.8.1.4. Additional Azure configuration parameters

Additional Azure configuration parameters are described in the following table:

**Table 3.28. Additional Azure parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>compute.platform.azure.osDisk.diskSize GB</code></td>
<td>The Azure disk size for the VM.</td>
<td>Integer that represents the size of the disk in GB. The default is 128.</td>
</tr>
<tr>
<td><code>compute.platform.azure.osDisk.diskType</code></td>
<td>Defines the type of disk.</td>
<td>standard_LRS, premium_LRS, or standardSSD_LRS. The default is premium_LRS.</td>
</tr>
<tr>
<td><code>controlPlane.platform.azure.osDisk.diskSizeGB</code></td>
<td>The Azure disk size for the VM.</td>
<td>Integer that represents the size of the disk in GB. The default is 1024.</td>
</tr>
<tr>
<td><code>controlPlane.platform.azure.osDisk.diskType</code></td>
<td>Defines the type of disk.</td>
<td>premium_LRS or standardSSD_LRS. The default is premium_LRS.</td>
</tr>
<tr>
<td><code>platform.azure.baseDomainResourceGroupName</code></td>
<td>The name of the resource group that contains the DNS zone for your base domain.</td>
<td>String, for example production_cluster.</td>
</tr>
</tbody>
</table>
| Parameter                                      | Description                                                                 | Values                                                                 
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>platform.azure.outboundType</td>
<td>The outbound routing strategy used to connect your cluster to the internet. If you are using user-defined routing, you must have pre-existing networking available where the outbound routing has already been configured prior to installing a cluster. The installation program is not responsible for configuring user-defined routing.</td>
<td>LoadBalancer or UserDefinedRouting. The default is LoadBalancer.</td>
</tr>
<tr>
<td>platform.azure.region</td>
<td>The name of the Azure region that hosts your cluster.</td>
<td>Any valid region name, such as centralus.</td>
</tr>
<tr>
<td>platform.azure.zone</td>
<td>List of availability zones to place machines in. For high availability, specify at least two zones.</td>
<td>List of zones, for example [&quot;1&quot;, &quot;2&quot;, &quot;3&quot;].</td>
</tr>
<tr>
<td>platform.azure.networkResourceGroupName</td>
<td>The name of the resource group that contains the existing VNet that you want to deploy your cluster to. This name cannot be the same as the platform.azure.baseDomainResourceGroupName.</td>
<td>String.</td>
</tr>
<tr>
<td>platform.azure.virtualNetwork</td>
<td>The name of the existing VNet that you want to deploy your cluster to.</td>
<td>String.</td>
</tr>
<tr>
<td>platform.azure.controlPlaneSubnet</td>
<td>The name of the existing subnet in your VNet that you want to deploy your control plane machines to.</td>
<td>Valid CIDR, for example 10.0.0.0/16.</td>
</tr>
<tr>
<td>platform.azure.computeSubnet</td>
<td>The name of the existing subnet in your VNet that you want to deploy your compute machines to.</td>
<td>Valid CIDR, for example 10.0.0.0/16.</td>
</tr>
<tr>
<td>platform.azure.cloudName</td>
<td>The name of the Azure cloud environment that is used to configure the Azure SDK with the appropriate Azure API endpoints. If empty, the default value AzurePublicCloud is used.</td>
<td>Any valid cloud environment, such as AzurePublicCloud or AzureUSGovernmentCloud.</td>
</tr>
</tbody>
</table>

**NOTE**

You cannot customize Azure Availability Zones or Use tags to organize your Azure resources with an Azure cluster.
3.8.8.2. Sample customized install-config.yaml file for Azure

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

**IMPORTANT**

This sample YAML file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program and modify it.

```yaml
apiVersion: v1
baseDomain: example.com
controlPlane:
  hyperthreading: Enabled
  name: master
  platform:
    azure:
      osDisk:
        diskSizeGB: 1024
        diskType: Premium_LRS
        type: Standard_D8s_v3
      replicas: 3
      compute: 6
      - hyperthreading: Enabled
        name: worker
        platform:
          azure:
            type: Standard_D2s_v3
            osDisk:
              diskSizeGB: 512
              diskType: Standard_LRS
            zones: 9
            - "1"
            - "2"
            - "3"
      replicas: 5
  metadata:
    name: test-cluster
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
      hostPrefix: 23
  machineNetwork:
    - cidr: 10.0.0.0/16
  networkType: OpenShiftSDN
  serviceNetwork:
    - 172.30.0.0/16
  platform:
    azure:
      baseDomainResourceGroupName: resource_group
      region: usgovvirginia
      resourceGroupName: existing_resource_group
      networkResourceGroupName: vnet_resource_group
```
If you do not provide these parameters and values, the installation program provides the default value.

The `controlPlane` section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the `compute` section must begin with a hyphen, `-`, and the first line of the `controlPlane` section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading, or hyperthreading. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to `Disabled`. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger virtual machine types, such as `Standard_D8s_v3`, for your machines if you disable simultaneous multithreading.

You can specify the size of the disk to use in GB. Minimum recommendation for control plane nodes (also known as the master nodes) is 1024 GB.

Specify a list of zones to deploy your machines to. For high availability, specify at least two zones.

Specify the name of the resource group that contains the DNS zone for your base domain.

Specify the name of an already existing resource group to install your cluster to. If undefined, a new resource group is created for the cluster.

If you use an existing VNet, specify the name of the resource group that contains it.

If you use an existing VNet, specify its name.

If you use an existing VNet, specify the name of the subnet to host the control plane machines.

If you use an existing VNet, specify the name of the subnet to host the compute machines.

You can customize your own outbound routing. Configuring user-defined routing prevents exposing external endpoints in your cluster. User-defined routing for egress requires deploying your cluster to an existing VNet.
Specify the name of the Azure cloud environment to deploy your cluster to. Set `AzureUSGovernmentCloud` to deploy to a Microsoft Azure Government (MAG) region. The

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

You can optionally provide the `sshKey` value that you use to access the machines in your cluster.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

How to publish the user-facing endpoints of your cluster. Set `publish` to `Internal` to deploy a private cluster, which cannot be accessed from the Internet. The default value is `External`.

### 3.8.8.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**Prerequisites**

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

**Procedure**
1. Edit your `install-config.yaml` file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port> 1
  httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
  noProxy: example.com 3
additionalTrustBundle: |
  -----BEGIN CERTIFICATE-----
  <MY_TRUSTED_CA_CERT>
  -----END CERTIFICATE-----
...
```

1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.

2. A proxy URL to use for creating HTTPS connections outside the cluster.

3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, `.y.com` matches `x.y.com`, but not `y.com`. Use `*` to bypass the proxy for all destinations.

4. If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace to hold the additional CA certificates. If you provide `additionalTrustBundle` and at least one proxy setting, the `Proxy` object is configured to reference the `user-ca-bundle` config map in the `trustedCA` field. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges the contents specified for the `trustedCA` parameter with the RHCOS trust bundle. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

**NOTE**

The installation program does not support the proxy `readinessEndpoints` field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

**NOTE**

Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

3.8.9. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.
IMPORTANT

You can run the `create cluster` command of the installation program only once, during initial installation.

Prerequisites

- Configure an account with the cloud platform that hosts your cluster.
- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Change to the directory that contains the installation program and initialize the cluster deployment:

   ```sh
   $ ./openshift-install create cluster --dir <installation_directory> --log-level=info
   ```

   For `<installation_directory>`, specify the location of your customized `./install-config.yaml` file.

   To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

   NOTE

   If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.

   When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the `kubeadmin` user, display in your terminal.

   Example output

   ```
   ... INFO Install complete!
   INFO To access the cluster as the system:admin user when using 'oc', run 'export
   KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
   INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
   INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-Wi5AL"
   INFO Time elapsed: 36m22s
   ```

   NOTE

   The cluster access and credential information also outputs to `<installation_directory>/openshift_install.log` when an installation succeeds.
IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

IMPORTANT

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

3.8.10. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) in order to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

IMPORTANT

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.6. Download and install the new version of oc.

3.8.10.1. Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.6 Linux Client entry and save the file.

4. Unpack the archive:

   ```
   $ tar xvzf <file>
   ```

5. Place the oc binary in a directory that is on your PATH.
   To check your PATH, execute the following command:

   ```
   $ echo $PATH
   ```
After you install the OpenShift CLI, it is available using the `oc` command:

```
$ oc <command>
```

### 3.8.10.2. Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (`oc`) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.
3. Click **Download Now** next to the **OpenShift v4.6 Windows Client** entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the `oc` binary to a directory that is on your **PATH**.
   To check your **PATH**, open the command prompt and execute the following command:

```
C:\> path
```

After you install the OpenShift CLI, it is available using the `oc` command:

```
C:\> oc <command>
```

### 3.8.10.3. Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (`oc`) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.
3. Click **Download Now** next to the **OpenShift v4.6 MacOSX Client** entry and save the file.
4. Unpack and unzip the archive.
5. Move the `oc` binary to a directory on your **PATH**.
   To check your **PATH**, open a terminal and execute the following command:

```
$ echo $PATH
```

After you install the OpenShift CLI, it is available using the `oc` command:

```
$ oc <command>
```
3.8.11. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

Procedure

1. Export the `kubeadmin` credentials:
   
   ```
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```
   
   1 For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:
   
   ```
   $ oc whoami
   ```
   
   Example output
   
   ```
   system:admin
   ```

Additional resources

- See Accessing the web console for more details about accessing and understanding the OpenShift Container Platform web console.

3.8.12. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.6, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use `subscription watch` to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service

3.8.13. Next steps

- Customize your cluster.
If necessary, you can opt out of remote health reporting.

3.9. INSTALLING A CLUSTER ON AZURE USING ARM TEMPLATES

In OpenShift Container Platform version 4.6, you can install a cluster on Microsoft Azure by using infrastructure that you provide.

Several Azure Resource Manager (ARM) templates are provided to assist in completing these steps or to help model your own.

**IMPORTANT**

The steps for performing a user-provisioned infrastructure installation are provided as an example only. Installing a cluster with infrastructure you provide requires knowledge of the cloud provider and the installation process of OpenShift Container Platform. Several ARM templates are provided to assist in completing these steps or to help model your own. You are also free to create the required resources through other methods; the templates are just an example.

### 3.9.1. Prerequisites

- Review details about the OpenShift Container Platform installation and update processes.
- Configure an Azure account to host the cluster.
- Download the Azure CLI and install it on your computer. See Install the Azure CLI in the Azure documentation. The documentation below was last tested using version 2.2.0 of the Azure CLI. Azure CLI commands might perform differently based on the version you use.
- If you use a firewall and plan to use telemetry, you must configure the firewall to allow the sites that your cluster requires access to.
- If you do not allow the system to manage identity and access management (IAM), then a cluster administrator can manually create and maintain IAM credentials. Manual mode can also be used in environments where the cloud IAM APIs are not reachable.

**NOTE**

Be sure to also review this site list if you are configuring a proxy.

### 3.9.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.6, you require access to the Internet to install your cluster.

You must have Internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.
IMPORTANT

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

3.9.3. Configuring your Azure project

Before you can install OpenShift Container Platform, you must configure an Azure project to host it.

IMPORTANT

All Azure resources that are available through public endpoints are subject to resource name restrictions, and you cannot create resources that use certain terms. For a list of terms that Azure restricts, see Resolve reserved resource name errors in the Azure documentation.

3.9.3.1. Azure account limits

The OpenShift Container Platform cluster uses a number of Microsoft Azure components, and the default Azure subscription and service limits, quotas, and constraints affect your ability to install OpenShift Container Platform clusters.

IMPORTANT

Default limits vary by offer category types, such as Free Trial and Pay-As-You-Go, and by series, such as Dv2, F, and G. For example, the default for Enterprise Agreement subscriptions is 350 cores.

Check the limits for your subscription type and if necessary, increase quota limits for your account before you install a default cluster on Azure.

The following table summarizes the Azure components whose limits can impact your ability to install and run OpenShift Container Platform clusters.

<table>
<thead>
<tr>
<th>Component</th>
<th>Number of components required by default</th>
<th>Default Azure limit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
A default cluster requires 40 vCPUs, so you must increase the account limit.

By default, each cluster creates the following instances:

- One bootstrap machine, which is removed after installation
- Three control plane machines
- Three compute machines

Because the bootstrap machine uses Standard_D4s_v3 machines, which use 4 vCPUs, the control plane machines use Standard_D8s_v3 virtual machines, which use 8 vCPUs, and the worker machines use Standard_D4s_v3 virtual machines, which use 4 vCPUs, a default cluster requires 40 vCPUs. The bootstrap node VM, which uses 4 vCPUs, is used only during installation.

To deploy more worker nodes, enable autoscaling, deploy large workloads, or use a different instance type, you must further increase the vCPU limit for your account to ensure that your cluster can deploy the machines that you require.

By default, the installation program distributes control plane and compute machines across all availability zones within a region. To ensure high availability for your cluster, select a region with at least three availability zones. If your region contains fewer than three availability zones, the installation program places more than one control plane machine in the available zones.
OS Disk
VM OS disk must be able to sustain a minimum throughput of 5000 IOPS / 200MBps. This throughput can be provided by having a minimum of 1 TiB Premium SSD (P30). In Azure, disk performance is directly dependent on SSD disk sizes, so to achieve the throughput supported by Standard_D8s_v3, or other similar machine types available, and the target of 5000 IOPS, at least a P30 disk is required.

Host caching must be set to ReadOnly for low read latency and high read IOPS and throughput. The reads performed from the cache, which is present either in the VM memory or in the local SSD disk, are much faster than the reads from the data disk, which is in the blob storage.

VNet
Each default cluster requires one Virtual Network (VNet), which contains two subnets.

Network interfaces
Each default cluster requires six network interfaces. If you create more machines or your deployed workloads create load balancers, your cluster uses more network interfaces.

Network security groups
Each default cluster Each cluster creates network security groups for each subnet in the VNet. The default cluster creates network security groups for the control plane and for the compute node subnets:

| control plane | Allows the control plane machines to be reached on port 6443 from anywhere |
| node          | Allows worker nodes to be reached from the Internet on ports 80 and 443 |

### Component | Number of components required by default | Default Azure limit | Description |

<td></td>
<td></td>
</tr>
</tbody>
</table>
Network load balancers

Each cluster creates the following load balancers:

- **default**: Public IP address that load balances requests to ports 80 and 443 across worker machines.
- **internal**: Private IP address that load balances requests to ports 6443 and 22623 across control plane machines.
- **external**: Public IP address that load balances requests to port 6443 across control plane machines.

If your applications create more Kubernetes LoadBalancer service objects, your cluster uses more load balancers.

Public IP addresses

Each of the two public load balancers uses a public IP address. The bootstrap machine also uses a public IP address so that you can SSH into the machine to troubleshoot issues during installation. The IP address for the bootstrap node is used only during installation.

Private IP addresses

The internal load balancer, each of the three control plane machines, and each of the three worker machines each use a private IP address.

Spot VM vCPUs (optional)

This is an optional component. To use spot VMs, you must increase the Azure default limit to at least twice the number of compute nodes in your cluster.

### 3.9.3.2. Configuring a public DNS zone in Azure

To install OpenShift Container Platform, the Microsoft Azure account you use must have a dedicated public hosted DNS zone in your account. This zone must be authoritative for the domain. This service provides cluster DNS resolution and name lookup for external connections to the cluster.

Procedure
1. Identify your domain, or subdomain, and registrar. You can transfer an existing domain and registrar or obtain a new one through Azure or another source.

**NOTE**

For more information about purchasing domains through Azure, see [Buy a custom domain name for Azure App Service](#) in the Azure documentation.

2. If you are using an existing domain and registrar, migrate its DNS to Azure. See [Migrate an active DNS name to Azure App Service](#) in the Azure documentation.

3. Configure DNS for your domain. Follow the steps in the [Tutorial: Host your domain in Azure DNS](#) in the Azure documentation to create a public hosted zone for your domain or subdomain, extract the new authoritative name servers, and update the registrar records for the name servers that your domain uses.

   Use an appropriate root domain, such as `openshiftcorp.com`, or subdomain, such as `clusters.openshiftcorp.com`.

4. If you use a subdomain, follow your company’s procedures to add its delegation records to the parent domain.

   You can view Azure’s DNS solution by visiting this [example for creating DNS zones](#).

### 3.9.3.3. Increasing Azure account limits

To increase an account limit, file a support request on the Azure portal.

**NOTE**

You can increase only one type of quota per support request.

**Procedure**

1. From the Azure portal, click Help + support in the lower left corner.

2. Click New support request and then select the required values:
   a. From the Issue type list, select Service and subscription limits (quotas).
   b. From the Subscription list, select the subscription to modify.
   c. From the Quota type list, select the quota to increase. For example, select **Compute-VM (cores-vCPUs) subscription limit increases** to increase the number of vCPUs, which is required to install a cluster.
   d. Click Next: Solutions.

3. On the Problem Details page, provide the required information for your quota increase:
   a. Click Provide details and provide the required details in the Quota details window.
   b. In the SUPPORT METHOD and CONTACT INFO sections, provide the issue severity and your contact details.

4. Click Next: Review + create and then click Create.
3.9.3.4. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The `kube-controller-manager` only approves the kubelet client CSRs. The `machine-approver` cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

3.9.3.5. Required Azure roles

OpenShift Container Platform needs a service principal so it can manage Microsoft Azure resources. Before you can create a service principal, your Azure account subscription must have the following roles:

- User Access Administrator
- Owner

To set roles on the Azure portal, see the Manage access to Azure resources using RBAC and the Azure portal in the Azure documentation.

3.9.3.6. Creating a service principal

Because OpenShift Container Platform and its installation program must create Microsoft Azure resources through Azure Resource Manager, you must create a service principal to represent it.

**Prerequisites**

- Install or update the Azure CLI.
- Install the `jq` package.
- Your Azure account has the required roles for the subscription that you use.

**Procedure**

1. Log in to the Azure CLI:

   
   ```
   $ az login
   $ az account list --refresh
   
   Log in to Azure in the web console by using your credentials.
   ```

2. If your Azure account uses subscriptions, ensure that you are using the right subscription.
   a. View the list of available accounts and record the `tenantId` value for the subscription you want to use for your cluster:

   ```
   $ az account list --refresh
   
   Example output
   ```

   ```
   [ 
    {  
      "cloudName": "AzureCloud",
   ```
b. View your active account details and confirm that the `tenantId` value matches the subscription you want to use:

```
$ az account show
```

**Example output**

```
{
  "environmentName": "AzureCloud",
  "id": "9bab1460-96d5-40b3-a78e-17b15e978a80",
  "isDefault": true,
  "name": "Subscription Name",
  "state": "Enabled",
  "tenantId": "6057c7e9-b3ae-489d-a54e-de3f6bf6a8ee",
  "user": {
    "name": "you@example.com",
    "type": "user"
  }
}
```

1. Ensure that the value of the `tenantId` parameter is the UUID of the correct subscription.

c. If you are not using the right subscription, change the active subscription:

```
$ az account set -s <id> 1
```

1. Substitute the value of the `id` for the subscription that you want to use for `<id>`.

d. If you changed the active subscription, display your account information again:

```
$ az account show
```

**Example output**

```
{
  "environmentName": "AzureCloud",
  "id": "33212d16-bdf6-45cb-b038-f6565b61edda",
  "isDefault": true,
  "name": "Subscription Name",
  "tenantId": "6057c7e9-b3ae-489d-a54e-de3f6bf6a8ee",
  "user": {
    "name": "you@example.com",
    "type": "user"
  }
}
```
3. Record the values of the **tenantId** and **id** parameters from the previous output. You need these values during OpenShift Container Platform installation.

4. Create the service principal for your account:

   ```bash
   $ az ad sp create-for-rbac --role Contributor --name <service_principal>  
   ```

   Replace `<service_principal>` with the name to assign to the service principal.

   **Example output**

   ```json
   Changing "<service_principal>" to a valid URI of "http://<service_principal>", which is the required format used for service principal names
   Retrying role assignment creation: 1/36
   Retrying role assignment creation: 2/36
   Retrying role assignment creation: 3/36
   Retrying role assignment creation: 4/36
   ```

5. Record the values of the **appId** and **password** parameters from the previous output. You need these values during OpenShift Container Platform installation.

6. Grant additional permissions to the service principal.

   - You must always add the **Contributor** and **User Access Administrator** roles to the app registration service principal so the cluster can assign credentials for its components.

   - To operate the Cloud Credential Operator (CCO) in **mint mode**, the app registration service principal also requires the **Azure Active Directory Graph/Application.ReadWrite.OwnedBy** API permission.

   - To operate the CCO in **passthrough mode**, the app registration service principal does not require additional API permissions.

   For more information about CCO modes, see the **Cloud Credential Operator** entry in the **Red Hat Operators reference** content.

   a. To assign the **User Access Administrator** role, run the following command:
$ az role assignment create --role "User Access Administrator" \\ --assignee-object-id $(az ad sp list --filter "appId eq '<appId>'" \\ | jq '.[0].objectId' -r) 

Replace <appId> with the appId parameter value for your service principal.

b. To assign the **Azure Active Directory Graph** permission, run the following command:

```
$ az ad app permission add --id <appId> \
  --api 00000002-0000-0000-c000-000000000000 \
  --api-permissions 824c81eb-e3f8-4ee6-8f6d-de7f50d565b7=Role
```

Replace <appId> with the appId parameter value for your service principal.

Example output

Invoking "az ad app permission grant --id 46d33abc-b8a3-46d8-8c84-f0fd58177435 --api 00000002-0000-0000-c000-000000000000" is needed to make the change effective

For more information about the specific permissions that you grant with this command, see the [GUID Table for Windows Azure Active Directory Permissions](#).

c. Approve the permissions request. If your account does not have the Azure Active Directory tenant administrator role, follow the guidelines for your organization to request that the tenant administrator approve your permissions request.

```
$ az ad app permission grant --id <appId> \
  --api 00000002-0000-0000-c000-000000000000
```

Replace <appId> with the appId parameter value for your service principal.

### 3.9.3.7. Supported Azure regions

The installation program dynamically generates the list of available Microsoft Azure regions based on your subscription. The following Azure regions were tested and validated in OpenShift Container Platform version 4.6.1:

**Supported Azure public regions**

- **australiacentral** (Australia Central)
- **australiaeast** (Australia East)
- **australiasoutheast** (Australia South East)
- **brazilsouth** (Brazil South)
- **canadacentral** (Canada Central)
- **canadaeast** (Canada East)
- **centralindia** (Central India)
- **centralus** (Central US)
- **eastasia** (East Asia)
- **eastus** (East US)
- **eastus2** (East US 2)
- **francecentral** (France Central)
- **germanywestcentral** (Germany West Central)
- **japaneast** (Japan East)
- **japanwest** (Japan West)
- **koreacentral** (Korea Central)
- **koreasouth** (Korea South)
- **northcentralus** (North Central US)
- **northeurope** (North Europe)
- **norwayeast** (Norway East)
- **southafricanorth** (South Africa North)
- **southcentralus** (South Central US)
- **southeastasia** (Southeast Asia)
- **southindia** (South India)
- **switzerlandnorth** (Switzerland North)
- **uabenorth** (UAE North)
- **uksouth** (UK South)
- **ukwest** (UK West)
- **westcentralus** (West Central US)
- **westeurope** (West Europe)
- **westindia** (West India)
- **westus** (West US)
- **westus2** (West US 2)

**Supported Azure Government regions**
Support for the following Microsoft Azure Government (MAG) regions was added in OpenShift Container Platform version 4.6:

- **usgovtexas** (US Gov Texas)
You can reference all available MAG regions in the Azure documentation. Other provided MAG regions are expected to work with OpenShift Container Platform, but have not been tested.

3.9.4. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on a local computer.

Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

   **IMPORTANT**

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   **IMPORTANT**

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ tar xvf openshift-install-linux.tar.gz
   ```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

3.9.5. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your ssh-agent and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.
NOTE

In a production environment, you require disaster recovery and debugging.

You can use this key to SSH into the master nodes as the user core. When you deploy the cluster, the key is added to the core user’s ~/.ssh/authorized_keys list.

NOTE

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

Procedure

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N "" \
   -f <path>/<file_name>  \n   ```

   1 Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   Running this command generates an SSH key that does not require a password in the location that you specified.

   NOTE

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the ssh-agent process as a background task:

   ```bash
   $ eval "$(ssh-agent -s)"
   ```

   Example output

   Agent pid 31874

   NOTE

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the ssh-agent:

   ```bash
   $ ssh-add <path>/file_name>  \n   ```

   1
Example output

Specify the path and file name for your SSH private key, such as 

```
/home/<you>/<path>/<file_name> (<computer_name>)
```

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program. If you install a cluster on infrastructure that you provision, you must provide this key to your cluster’s machines.

3.9.6. Creating the installation files for Azure

To install OpenShift Container Platform on Microsoft Azure using user-provisioned infrastructure, you must generate the files that the installation program needs to deploy your cluster and modify them so that the cluster creates only the machines that it will use. You generate and customize the `install-config.yaml` file, Kubernetes manifests, and Ignition config files. You also have the option to first set up a separate `var` partition during the preparation phases of installation.

3.9.6.1. Optional: Creating a separate `/var` partition

It is recommended that disk partitioning for OpenShift Container Platform be left to the installer. However, there are cases where you might want to create separate partitions in a part of the filesystem that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the `/var` partition or a subdirectory of `/var`. For example:

- `/var/lib/containers`: Holds container-related content that can grow as more images and containers are added to a system.
- `/var/lib/etcd`: Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.
- `/var`: Holds data that you might want to keep separate for purposes such as auditing.

Storing the contents of a `/var` directory separately makes it easier to grow storage for those areas as needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

Because `/var` must be in place before a fresh installation of Red Hat Enterprise Linux CoreOS (RHCOS), the following procedure sets up the separate `/var` partition by creating a machine config that is inserted during the `openshift-install` preparation phases of an OpenShift Container Platform installation.

**IMPORTANT**

If you follow the steps to create a separate `/var` partition in this procedure, it is not necessary to create the Kubernetes manifest and Ignition config files again as described later in this section.

Procedure
1. Create a directory to hold the OpenShift Container Platform installation files:

   $ mkdir $HOME/clusterconfig

2. Run `openshift-install` to create a set of files in the `manifest` and `openshift` subdirectories. Answer the system questions as you are prompted:

   $ openshift-install create manifests --dir $HOME/clusterconfig

**Example output**

```
? SSH Public Key ...
INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
INFO Consuming Install Config from target directory
INFO Manifests created in: $HOME/clusterconfig/manifests and $HOME/clusterconfig/openshift
```

3. Optional: Confirm that the installation program created manifests in the `clusterconfig/openshift` directory:

   $ ls $HOME/clusterconfig/openshift/

**Example output**

```
99_kubeadmin-password-secret.yaml
99_openshift-cluster-api_master-machines-0.yaml
99_openshift-cluster-api_master-machines-1.yaml
99_openshift-cluster-api_master-machines-2.yaml
...
```

4. Create a `MachineConfig` object and add it to a file in the `openshift` directory. For example, name the file `98-var-partition.yaml`, change the disk device name to the name of the storage device on the `worker` systems, and set the storage size as appropriate. This example places the `/var` directory on a separate partition:

```yaml
apiVersion: machineconfiguration.openshift.io/v1
kind: MachineConfig
metadata:
  labels:
    machineconfiguration.openshift.io/role: worker
name: 98-var-partition
spec:
  config:
    ignition:
      version: 3.1.0
    storage:
      disks:
        - device: /dev/<device_name> 1
          partitions:
            - label: var
              startMiB: <partition_start_offset> 2
              sizeMiB: <partition_size> 3
          filesystems:
```
The storage device name of the disk that you want to partition.

When adding a data partition to the boot disk, a minimum value of 25000 MiB (Mebibytes) is recommended. The root file system is automatically resized to fill all available space up to the specified offset. If no value is specified, or if the specified value is smaller than the recommended minimum, the resulting root file system will be too small, and future reinstalls of RHCOS might overwrite the beginning of the data partition.

The size of the data partition in mebibytes.

The name of the mount unit must match the directory specified in the Where= directive. For example, for a filesystem mounted on /var/lib/containers, the unit must be named var-lib-containers.mount.

The prjquota mount option must be enabled for filesystems used for container storage.

NOTE

When creating a separate /var partition, you cannot use different instance types for worker nodes, if the different instance types do not have the same device name.

5. Run openshift-install again to create Ignition configs from a set of files in the manifest and openshift subdirectories:

```bash
$ openshift-install create ignition-configs --dir $HOME/clusterconfig
$ ls $HOME/clusterconfig/
auth bootstrap.ign master.ign metadata.json worker.ign
```

Now you can use the Ignition config files as input to the installation procedures to install Red Hat Enterprise Linux CoreOS (RHCOS) systems.

3.9.6.2. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Microsoft Azure.
Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Create the `install-config.yaml` file.

   a. Change to the directory that contains the installation program and run the following command:

   ```bash
   $ ./openshift-install create install-config --dir <installation_directory>
   ```

   IMPORTANT

   Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

   For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

   b. At the prompts, provide the configuration details for your cloud:

      i. Optional: Select an SSH key to use to access your cluster machines.

      IMPORTANT

      For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

      ii. Select `azure` as the platform to target.

      iii. If you do not have a Microsoft Azure profile stored on your computer, specify the following Azure parameter values for your subscription and service principal:

         - `azure subscription id` The subscription ID to use for the cluster. Specify the `id` value in your account output.

         - `azure tenant id` The tenant ID. Specify the `tenantId` value in your account output.

         - `azure service principal client id` The value of the `appId` parameter for the service principal.

         - `azure service principal client secret` The value of the `password` parameter for the service principal.

      iv. Select the region to deploy the cluster to.
v. Select the base domain to deploy the cluster to. The base domain corresponds to the Azure DNS Zone that you created for your cluster.

vi. Enter a descriptive name for your cluster.

**IMPORTANT**

All Azure resources that are available through public endpoints are subject to resource name restrictions, and you cannot create resources that use certain terms. For a list of terms that Azure restricts, see [Resolve reserved resource name errors](#) in the Azure documentation.

vii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

**IMPORTANT**

All Azure resources that are available through public endpoints are subject to resource name restrictions, and you cannot create resources that use certain terms. For a list of terms that Azure restricts, see [Resolve reserved resource name errors](#) in the Azure documentation.

**IMPORTANT**

All Azure resources that are available through public endpoints are subject to resource name restrictions, and you cannot create resources that use certain terms. For a list of terms that Azure restricts, see [Resolve reserved resource name errors](#) in the Azure documentation.

**IMPORTANT**

All Azure resources that are available through public endpoints are subject to resource name restrictions, and you cannot create resources that use certain terms. For a list of terms that Azure restricts, see [Resolve reserved resource name errors](#) in the Azure documentation.

**IMPORTANT**

All Azure resources that are available through public endpoints are subject to resource name restrictions, and you cannot create resources that use certain terms. For a list of terms that Azure restricts, see [Resolve reserved resource name errors](#) in the Azure documentation.

**IMPORTANT**

All Azure resources that are available through public endpoints are subject to resource name restrictions, and you cannot create resources that use certain terms. For a list of terms that Azure restricts, see [Resolve reserved resource name errors](#) in the Azure documentation.

2. Optional: If you do not want the cluster to provision compute machines, empty the compute pool by editing the resulting `install-config.yaml` file to set `replicas` to 0 for the `compute` pool:

   ```yaml
   compute:
     - hyperthreading: Enabled
       name: worker
       platform: {}
       replicas: 0
   ``

   Set to 0.

3. Modify the `install-config.yaml` file. You can find more information about the available parameters in the [Installation configuration parameters](#) section.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

**IMPORTANT**

The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

### 3.9.6.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**Prerequisites**

- You have an existing `install-config.yaml` file.

- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.
NOTE

The Proxy object status.noProxy field is populated with the values of the networking.machineNetwork[].cidr, networking.clusterNetwork[].cidr, and networking.serviceNetwork[] fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object status.noProxy field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your install-config.yaml file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port>
  httpsProxy: https://<username>:<pswd>@<ip>:<port>
  noProxy: example.com
additionalTrustBundle: |
  -----BEGIN CERTIFICATE-----
  <MY_TRUSTED_CA_CERT>
  -----END CERTIFICATE-----
...
```

   1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.
   2. A proxy URL to use for creating HTTPS connections outside the cluster.
   3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.
   4. If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace to hold the additional CA certificates. If you provide additionalTrustBundle and at least one proxy setting, the Proxy object is configured to reference the user-ca-bundle config map in the trustedCA field. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges the contents specified for the trustedCA parameter with the RHCOS trust bundle. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

NOTE

The installation program does not support the proxy readinessEndpoints field.

2. Save the file and reference it when installing OpenShift Container Platform.
The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

**NOTE**
Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

### 3.9.6.4. Exporting common variables for ARM templates

You must export a common set of variables that are used with the provided Azure Resource Manager (ARM) templates used to assist in completing a user-provided infrastructure install on Microsoft Azure.

**NOTE**
Specific ARM templates can also require additional exported variables, which are detailed in their related procedures.

#### Prerequisites
- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

#### Procedure

1. Export common variables found in the `install-config.yaml` to be used by the provided ARM templates:

```
$ export CLUSTER_NAME=<cluster_name>  
$ export AZURE_REGION=<azure_region>  
$ export SSH_KEY=<ssh_key>  
$ export BASE_DOMAIN=<base_domain>  
$ export BASE_DOMAIN_RESOURCE_GROUP=<base_domain_resource_group>
```

   1. The value of the `.metadata.name` attribute from the `install-config.yaml` file.
   2. The region to deploy the cluster into, for example `centralus`. This is the value of the `.platform.azure.region` attribute from the `install-config.yaml` file.
   3. The SSH RSA public key file as a string. You must enclose the SSH key in quotes since it contains spaces. This is the value of the `.sshKey` attribute from the `install-config.yaml` file.
   4. The base domain to deploy the cluster to. The base domain corresponds to the public DNS zone that you created for your cluster. This is the value of the `.baseDomain` attribute from the `install-config.yaml` file.
   5. The resource group where the public DNS zone exists. This is the value of the `.platform.azure.baseDomainResourceGroupName` attribute from the `install-config.yaml` file.

For example:

-
$ export CLUSTER_NAME=test-cluster
$ export AZURE_REGION=centralus
$ export SSH_KEY="ssh-rsa xxx/xxx/xxx= user@email.com"
$ export BASE_DOMAIN=example.com
$ export BASE_DOMAIN_RESOURCE_GROUP=ocp-cluster

2. Export the kubeadmin credentials:

   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

### 3.9.6.5. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to make its machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to create the cluster.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

**Prerequisites**

- You obtained the OpenShift Container Platform installation program.

- You created the `install-config.yaml` installation configuration file.

**Procedure**

1. Change to the directory that contains the installation program and generate the Kubernetes manifests for the cluster:

   $ ./openshift-install create manifests --dir <installation_directory>

   **Example output**
For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.

2. Remove the Kubernetes manifest files that define the control plane machines:

   ```
   $ rm -f <installation_directory>/openshift/99_openshift-cluster-api_master-machines-*.yaml
   ```

   By removing these files, you prevent the cluster from automatically generating control plane machines.

3. Remove the Kubernetes manifest files that define the worker machines:

   ```
   $ rm -f <installation_directory>/openshift/99_openshift-cluster-api_worker-machineset-*.yaml
   ```

   Because you create and manage the worker machines yourself, you do not need to initialize these machines.

4. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:

   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.

   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.

   c. Save and exit the file.

5. Optional: If you do not want the Ingress Operator to create DNS records on your behalf, remove the `privateZone` and `publicZone` sections from the `<installation_directory>/manifests/cluster-dns-02-config.yml` DNS configuration file:

   ```yaml
   apiVersion: config.openshift.io/v1
   kind: DNS
   metadata:
     creationTimestamp: null
   name: cluster
   spec:
     baseDomain: example.openshift.com
     privateZone: 1
     id: mycluster-100419-private-zone
     publicZone: 2
     id: example.openshift.com
   status: {}
   ```

   Remove this section completely.

   If you do so, you must add ingress DNS records manually in a later step.
6. When configuring Azure on user-provisioned infrastructure, you must export some common variables defined in the manifest files to use later in the Azure Resource Manager (ARM) templates:

a. Export the infrastructure ID by using the following command:

   ```bash
   $ export INFRA_ID=<infra_id>
   ```

   The OpenShift Container Platform cluster has been assigned an identifier (INFRA_ID) in the form of `<cluster_name>_<random_string>`. This will be used as the base name for most resources created using the provided ARM templates. This is the value of the `.status.infrastructureName` attribute from the `manifests/cluster-infrastructure-02-config.yml` file.

b. Export the resource group by using the following command:

   ```bash
   $ export RESOURCE_GROUP=<resource_group>
   ```

   All resources created in this Azure deployment exists as part of a resource group. The resource group name is also based on the INFRA_ID, in the form of `<cluster_name>_<random_string>-rg`. This is the value of the `.status.platformStatus.azure.resourceGroupName` attribute from the `manifests/cluster-infrastructure-02-config.yml` file.

7. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

   ```bash
   $ ./openshift-install create ignition-configs --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the same installation directory.

The following files are generated in the directory:

```
├── auth
│   ├── kubeadmin-password
│   └── kubeconfig
└── bootstrap.ign
    └── master.ign
        └── metadata.json
            └── worker.ign
```

3.9.7. Creating the Azure resource group and identity

You must create a Microsoft Azure resource group and an identity for that resource group. These are both used during the installation of your OpenShift Container Platform cluster on Azure.

**Prerequisites**

- Configure an Azure account.
- Generate the Ignition config files for your cluster.
Procedure

1. Create the resource group in a supported Azure region:

```bash
$ az group create --name ${RESOURCE_GROUP} --location ${AZURE_REGION}
```

2. Create an Azure identity for the resource group:

```bash
$ az identity create -g ${RESOURCE_GROUP} -n ${INFRA_ID}-identity
```

This is used to grant the required access to Operators in your cluster. For example, this allows the Ingress Operator to create a public IP and its load balancer. You must assign the Azure identity to a role.

3. Grant the Contributor role to the Azure identity:

   a. Export the following variables required by the Azure role assignment:

```bash
$ export PRINCIPAL_ID=`az identity show -g ${RESOURCE_GROUP} -n ${INFRA_ID}-identity --query principalId --out tsv`

$ export RESOURCE_GROUP_ID=`az group show -g ${RESOURCE_GROUP} --query id --out tsv`
```

   b. Assign the Contributor role to the identity:

```bash
$ az role assignment create --assignee "$PRINCIPAL_ID" --role 'Contributor' --scope "$RESOURCE_GROUP_ID"
```

3.9.8. Uploading the RHCOS cluster image and bootstrap Ignition config file

The Azure client does not support deployments based on files existing locally; therefore, you must copy and store the RHCOS virtual hard disk (VHD) cluster image and bootstrap Ignition config file in a storage container so they are accessible during deployment.

Prerequisites

- Configure an Azure account.
- Generate the Ignition config files for your cluster.

Procedure

1. Create an Azure storage account to store the VHD cluster image:

```bash
$ az storage account create -g ${RESOURCE_GROUP} --location ${AZURE_REGION} --name ${CLUSTER_NAME}sa --kind Storage --sku Standard_LRS
```
2. Export the storage account key as an environment variable:

```
$ export ACCOUNT_KEY=`az storage account keys list -g ${RESOURCE_GROUP} --account-name ${CLUSTER_NAME}sa --query '[0].value' -o tsv`
```

3. Choose the RHCOS version to use and export the URL of its VHD to an environment variable:

```
$ export VHD_URL=`curl -s https://raw.githubusercontent.com/openshift/installer/release-4.6/data/data/rhcos.json | jq -r .azure.url`
```

4. Copy the chosen VHD to a blob:

```
$ az storage container create --name vhd --account-name ${CLUSTER_NAME}sa --account-key ${ACCOUNT_KEY}

$ az storage blob copy start --account-name ${CLUSTER_NAME}sa --account-key ${ACCOUNT_KEY} --destination-blob "rhcos.vhd" --destination-container vhd --source-uri "$VHD_URL"
```

To track the progress of the VHD copy task, run this script:

```
status="unknown"
while [ "$status" != "success" ]
    do
        status=`az storage blob show --container-name vhd --name "rhcos.vhd" --account-name ${CLUSTER_NAME}sa --account-key ${ACCOUNT_KEY} -o tsv --query properties.copy.status`
        echo $status
    done
```

5. Create a blob storage container and upload the generated `bootstrap.ign` file:
3.9.9. Example for creating DNS zones

DNS records are required for clusters that use user-provisioned infrastructure. You should choose the DNS strategy that fits your scenario.

For this example, Azure’s DNS solution is used, so you will create a new public DNS zone for external (internet) visibility and a private DNS zone for internal cluster resolution.

NOTE

The public DNS zone is not required to exist in the same resource group as the cluster deployment and might already exist in your organization for the desired base domain. If that is the case, you can skip creating the public DNS zone; be sure the installation config you generated earlier reflects that scenario.

Prerequisites

- Configure an Azure account.
- Generate the Ignition config files for your cluster.

Procedure

1. Create the new public DNS zone in the resource group exported in the BASE_DOMAIN_RESOURCE_GROUP environment variable:

   ```
   $ az network dns zone create -g ${BASE_DOMAIN_RESOURCE_GROUP} -n ${CLUSTER_NAME}.${BASE_DOMAIN}
   
   You can skip this step if you are using a public DNS zone that already exists.
   
   2. Create the private DNS zone in the same resource group as the rest of this deployment:

   ```
   
   $ az network private-dns zone create -g ${RESOURCE_GROUP} -n ${CLUSTER_NAME}.${BASE_DOMAIN}
   
   You can learn more about configuring a public DNS zone in Azure by visiting that section.

3.9.10. Creating a VNet in Azure

You must create a virtual network (VNet) in Microsoft Azure for your OpenShift Container Platform cluster to use. You can customize the VNet to meet your requirements. One way to create the VNet is to modify the provided Azure Resource Manager (ARM) template.
NOTE

If you do not use the provided ARM template to create your Azure infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

Prerequisites

- Configure an Azure account.
- Generate the Ignition config files for your cluster.

Procedure

1. Copy the template from the ARM template for the VNet section of this topic and save it as 01_vnet.json in your cluster's installation directory. This template describes the VNet that your cluster requires.

2. Create the deployment by using the az CLI:

   ```bash
   $ az deployment group create -g ${RESOURCE_GROUP} \
   --template-file "<installation_directory>/01_vnet.json" \
   --parameters baseName="${INFRA_ID}"  
   ``

   The base name to be used in resource names; this is usually the cluster’s infrastructure ID.

3. Link the VNet template to the private DNS zone:

   ```bash
   $ az network private-dns link vnet create -g ${RESOURCE_GROUP} -z 
   ${CLUSTER_NAME}.${BASE_DOMAIN} -n ${INFRA_ID}-network-link -v "${INFRA_ID}-vnet" 
   -e false
   ```

3.9.10.1. ARM template for the VNet

You can use the following Azure Resource Manager (ARM) template to deploy the VNet that you need for your OpenShift Container Platform cluster:

Example 3.1. 01_vnet.json ARM template

```json
{
  "contentVersion" : "1.0.0.0",
  "parameters" : {
    "baseName" : {
      "type" : "string",
      "minLength" : 1,
      "metadata" : {
        "description" : "Base name to be used in resource names (usually the cluster's Infra ID)"
      }
    }
  }
}
```
"variables" : {
  "location" : "[resourceGroup().location]",
  "virtualNetworkName" : "[concat(parameters('baseName'), '-vnet')]",
  "addressPrefix" : "10.0.0.0/16",
  "masterSubnetName" : "[concat(parameters('baseName'), '-master-subnet')]",
  "masterSubnetPrefix" : "10.0.0.0/24",
  "nodeSubnetName" : "[concat(parameters('baseName'), '-worker-subnet')]",
  "nodeSubnetPrefix" : "10.0.1.0/24",
  "clusterNsgName" : "[concat(parameters('baseName'), '-nsg')]",
},
"resources" : [
{
  "apiVersion" : "2018-12-01",
  "type" : "Microsoft.Network/virtualNetworks",
  "name" : "[variables('virtualNetworkName')]",
  "location" : "[variables('location')]",
  "dependsOn" : [
    "[concat('Microsoft.Network/networkSecurityGroups/', variables('clusterNsgName'))]"
  ],
  "properties" : {
    "addressSpace" : {
      "addressPrefixes" : [
        "[variables('addressPrefix')]
      ]
    },
    "subnets" : [
      {
        "name" : "[variables('masterSubnetName')]",
        "properties" : {
          "addressPrefix" : "[variables('masterSubnetPrefix')]",
          "serviceEndpoints" : [],
          "networkSecurityGroup" : {
            "id" : "[resourceId('Microsoft.Network/networkSecurityGroups', variables('clusterNsgName'))]"
          }
        }
      },
      {
        "name" : "[variables('nodeSubnetName')]",
        "properties" : {
          "addressPrefix" : "[variables('nodeSubnetPrefix')]",
          "serviceEndpoints" : [],
          "networkSecurityGroup" : {
            "id" : "[resourceId('Microsoft.Network/networkSecurityGroups', variables('clusterNsgName'))]"
          }
        }
      }
    ]
  }
}
3.9.11. Deploying the RHCOS cluster image for the Azure infrastructure

You must use a valid Red Hat Enterprise Linux CoreOS (RHCOS) image for Microsoft Azure for your OpenShift Container Platform nodes.

Prerequisites

- Configure an Azure account.
- Generate the Ignition config files for your cluster.
- Store the RHCOS virtual hard disk (VHD) cluster image in an Azure storage container.
- Store the bootstrap Ignition config file in an Azure storage container.

Procedure

1. Copy the template from the **ARM template for image storage** section of this topic and save it as `02_storage.json` in your cluster’s installation directory. This template describes the image storage that your cluster requires.

2. Export the RHCOS VHD blob URL as a variable:

   ```bash
   $ export VHD_BLOB_URL=`az storage blob url --account-name ${CLUSTER_NAME}sa --account-key ${ACCOUNT_KEY} -c vhd -n "rhcos.vhd" -o tsv`
   
3. Deploy the cluster image:

   ```bash
   $ az deployment group create -g ${RESOURCE_GROUP} \
   --template-file "<installation_directory>/02_storage.json" \
   --parameters vhdBlobURL="${VHD_BLOB_URL}"  \
   --parameters baseName="${INFRA_ID}"
   ```
The blob URL of the RHCOS VHD to be used to create master and worker machines.

The base name to be used in resource names; this is usually the cluster's infrastructure ID.

3.9.11.1. ARM template for image storage

You can use the following Azure Resource Manager (ARM) template to deploy the stored Red Hat Enterprise Linux CoreOS (RHCOS) image that you need for your OpenShift Container Platform cluster:

Example 3.2. 02_storage.json ARM template

```json
{
    "$schema": "https://schema.management.azure.com/schemas/2015-01-01/deploymentTemplate.json#",
    "contentVersion": "1.0.0.0",
    "parameters": {
        "baseName": {

    ]
}
```
3.9.12. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require network in initramfs during boot to fetch Ignition config from the machine config server.

You must configure the network connectivity between machines to allow cluster components to communicate. Each machine must be able to resolve the host names of all other machines in the cluster.

Network topology requirements

The infrastructure that you provision for your cluster must meet the following network topology requirements.
IMPORTANT

OpenShift Container Platform requires all nodes to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

Load balancers

Before you install OpenShift Container Platform, you must provision two load balancers that meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.
   - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

   **IMPORTANT**

   Do not configure session persistence for an API load balancer.

Configure the following ports on both the front and back of the load balancers:

**Table 3.32. API load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the <code>/readyz</code> endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>

**NOTE**

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the `/readyz` endpoint to the removal of the API server instance from the pool. Within the time frame after `/readyz` returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.
2. **Application Ingress load balancer**: Provides an Ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the Ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

Configure the following ports on both the front and back of the load balancers:

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress router pods, compute, or worker, by default.</td>
<td>✗</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress router pods, compute, or worker, by default.</td>
<td>X</td>
<td>✗</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>

**TIP**

If the true IP address of the client can be seen by the load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

**NOTE**

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

### 3.9.13. Creating networking and load balancing components in Azure

You must configure networking and load balancing in Microsoft Azure for your OpenShift Container Platform cluster to use. One way to create these components is to modify the provided Azure Resource Manager (ARM) template.

**NOTE**

If you do not use the provided ARM template to create your Azure infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

**Prerequisites**

- Configure an Azure account.
- Generate the Ignition config files for your cluster.
- Create and configure a VNet and associated subnets in Azure.
Procedure

1. Copy the template from the ARM template for the network and load balancers section of this topic and save it as 03_infra.json in your cluster’s installation directory. This template describes the networking and load balancing objects that your cluster requires.

2. Create the deployment by using the az CLI:

```
$ az deployment group create -g ${RESOURCE_GROUP} \
   --template-file "<installation_directory>/03_infra.json" \
   --parameters privateDNSZoneName="${CLUSTER_NAME}.${BASE_DOMAIN}" 1 \
   --parameters baseName="${INFRA_ID}" 2
```

1. The name of the private DNS zone.
2. The base name to be used in resource names; this is usually the cluster’s infrastructure ID.

3. Create an api DNS record in the public zone for the API public load balancer. The `${BASE_DOMAIN_RESOURCE_GROUP}` variable must point to the resource group where the public DNS zone exists.
   a. Export the following variable:
      ```
      $ export PUBLIC_IP=`az network public-ip list -g ${RESOURCE_GROUP} --query "][?name=='${INFRA_ID}-master-pip'] | [0].ipAddress" -o tsv`
      ```
   b. Create the DNS record in a new public zone:
      ```
      $ az network dns record-set a add-record -g ${BASE_DOMAIN_RESOURCE_GROUP} -z ${CLUSTER_NAME}.${BASE_DOMAIN} -n api -a ${PUBLIC_IP} --ttl 60
      ```
   c. If you are adding the cluster to an existing public zone, you can create the DNS record in it instead:
      ```
      $ az network dns record-set a add-record -g ${BASE_DOMAIN_RESOURCE_GROUP} -z ${BASE_DOMAIN} -n api.${CLUSTER_NAME} -a ${PUBLIC_IP} --ttl 60
      ```

3.9.13.1. ARM template for the network and load balancers

You can use the following Azure Resource Manager (ARM) template to deploy the networking objects and load balancers that you need for your OpenShift Container Platform cluster:

**Example 3.3. 03_infra.json ARM template**

```
{
"contentVersion" : "1.0.0.0",
"parameters" : {
"baseName" : {
"type" : "string",
"minLength" : 1,
"metadata" : {
```
"description" : "Base name to be used in resource names (usually the cluster's Infra ID)"
},
"privateDNSZoneName" : {
  "type" : "string",
  "metadata" : {
    "description" : "Name of the private DNS zone"
  }
},
"variables" : {
  "location" : "[resourceGroup().location]",
  "virtualNetworkName" : "{concat(parameters('baseName'), '-vnet')}",
  "virtualNetworkID" : "{resourceId('Microsoft.Network/virtualNetworks', variables('virtualNetworkName'))}",
  "masterSubnetName" : "{concat(parameters('baseName'), '-master-subnet')}",
  "masterSubnetRef" : "{concat(variables('virtualNetworkID'), '/subnets/', variables('masterSubnetName'))}",
  "masterPublicIpAddressName" : "{concat(parameters('baseName'), '-master-pip')}",
  "masterPublicIpAddressID" : "{resourceId('Microsoft.Network/publicIPAddresses', variables('masterPublicIpAddressName'))}",
  "masterLoadBalancerName" : "{concat(parameters('baseName'), '-public-lb')}",
  "masterLoadBalancerID" : "{resourceId('Microsoft.Network/loadBalancers', variables('masterLoadBalancerName'))}",
  "internalLoadBalancerName" : "{concat(parameters('baseName'), '-internal-lb')}",
  "internalLoadBalancerID" : "{resourceId('Microsoft.Network/loadBalancers', variables('internalLoadBalancerName'))}",
  "skuName" : "Standard"
},
"resources" : [
  {
    "apiVersion" : "2018-12-01",

    }
  ]}

You must create the bootstrap machine in Microsoft Azure to use during OpenShift Container Platform cluster initialization. One way to create this machine is to modify the provided Azure Resource Manager (ARM) template.

NOTE

If you do not use the provided ARM template to create your bootstrap machine, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

Prerequisites

- Configure an Azure account.
- Generate the Ignition config files for your cluster.
- Create and configure a VNet and associated subnets in Azure.
- Create and configure networking and load balancers in Azure.
- Create control plane and compute roles.

Procedure

1. Copy the template from the ARM template for the bootstrap machine section of this topic and save it as 04_bootstrap.json in your cluster’s installation directory. This template describes the bootstrap machine that your cluster requires.
2. Export the following variables required by the bootstrap machine deployment:

```bash
$ export BOOTSTRAP_URL=`az storage blob url --account-name ${CLUSTER_NAME}sa --account-key ${ACCOUNT_KEY} -c "files" -n "bootstrap.ign" -o tsv`
$ export BOOTSTRAP_IGNITION=`jq -rcnM --arg v "3.1.0" --arg url ${BOOTSTRAP_URL} '{ignition:{version:$v,config:{replace:{source:$url}}}}' | base64 | tr -d "n```

3. Create the deployment by using the `az` CLI:

```bash
$ az deployment group create -g ${RESOURCE_GROUP} \
  --template-file "<installation_directory>/04_bootstrap.json" \
  --parameters bootstrapIgnition="${BOOTSTRAP_IGNITION}" \
  --parameters sshKeyData="${SSH_KEY}" \
  --parameters baseName="${INFRA_ID}" \
  --parameters bootstrapIgnition="${BOOTSTRAP_IGNITION}"
```

1. The bootstrap Ignition content for the bootstrap cluster.
2. The SSH RSA public key file as a string.
3. The base name to be used in resource names; this is usually the cluster’s infrastructure ID.

3.9.14.1. ARM template for the bootstrap machine

You can use the following Azure Resource Manager (ARM) template to deploy the bootstrap machine that you need for your OpenShift Container Platform cluster:

**Example 3.4. 04_bootstrap.json ARM template**

```json
{
  "$schema": "https://schema.management.azure.com/schemas/2015-01-01/deploymentTemplate.json#",
  "contentVersion": "1.0.0.0",
  "parameters": {
    "baseName": {
      "type": "string",
      "minLength": 1,
      "metadata": {
        "description": "Base name to be used in resource names (usually the cluster’s Infra ID)"
      }
    },
    "bootstrapIgnition": {
      "type": "string",
      "minLength": 1,
      "metadata": {
        "description": "Bootstrap ignition content for the bootstrap cluster"
      }
    },
    "sshKeyData": {
      "type": "securestring",
      "metadata": {
        "description": "SSH RSA public key file as a string."
      }
    }
  }
}
```
"bootstrapVMSize" : {
"type" : "string",

3.9.15. Creating the control plane machines in Azure

You must create the control plane machines in Microsoft Azure for your cluster to use. One way to create these machines is to modify the provided Azure Resource Manager (ARM) template.

NOTE
If you do not use the provided ARM template to create your control plane machines, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

Prerequisites

- Configure an Azure account.
- Generate the Ignition config files for your cluster.
- Create and configure a VNet and associated subnets in Azure.
- Create and configure networking and load balancers in Azure.
- Create control plane and compute roles.
- Create the bootstrap machine.

Procedure

1. Copy the template from the ARM template for control plane machines section of this topic and save it as 05_masters.json in your cluster’s installation directory. This template describes the control plane machines that your cluster requires.

2. Export the following variable needed by the control plane machine deployment:

   $ export MASTER_IGNITION=`cat <installation_directory>/master.ign | base64 | tr -d "\n"

3. Create the deployment by using the az CLI:

   $ az deployment group create -g ${RESOURCE_GROUP} \
   --template-file "<installation_directory>/05_masters.json" \
   --parameters masterIgnition="${MASTER_IGNITION}" \  
   --parameters sshKeyData="${SSH_KEY}" \  
   --parameters privateDNSZoneName="${CLUSTER_NAME}.${BASE_DOMAIN}" \  
   --parameters baseName="${INFRA_ID}"

   - The Ignition content for the control plane nodes (also known as the master nodes).
   - The SSH RSA public key file as a string.
The name of the private DNS zone to which the control plane nodes are attached.

The base name to be used in resource names; this is usually the cluster’s infrastructure ID.

### 3.9.15.1. ARM template for control plane machines

You can use the following Azure Resource Manager (ARM) template to deploy the control plane machines that you need for your OpenShift Container Platform cluster:

**Example 3.5. 05_masters.json ARM template**

```json
{
  "$schema": "https://schema.management.azure.com/schemas/2015-01-01/deploymentTemplate.json#",
  "contentVersion": "1.0.0.0",
  "parameters": {
    "baseName": {
      "type": "string",
      "minLength": 1,
      "metadata": {
        "description": "Base name to be used in resource names (usually the cluster's Infra ID)"
      }
    },
    "masterIgnition": {
      "type": "string",
      "metadata": {
        "description": "Ignition content for the master nodes"
      }
    },
    "numberOfMasters": {
      "type": "int",
      "defaultValue": 3,
      "minValue": 2,
      "maxValue": 30,
      "metadata": {
        "description": "Number of OpenShift masters to deploy"
      }
    },
    "sshKeyData": {
      "type": "securestring",
      "metadata": {
        "description": "SSH RSA public key file as a string"
      }
    },
    "privateDNSZoneName": {
      "type": "string",
      "metadata": {
        "description": "Name of the private DNS zone the master nodes are going to be attached to"
      }
    },
    "masterVMSize": {
      "type": "string",
      "defaultValue": "Standard_D8s_v3",
      "allowedValues": [
        "Standard_A2",
        "Standard_A2v3",
        "Standard_A2v4"
      ]
    }
  }
}
```

"OpenShift Container Platform 4.6 Installing
3.9.16. Wait for bootstrap completion and remove bootstrap resources in Azure

After you create all of the required infrastructure in Microsoft Azure, wait for the bootstrap process to complete on the machines that you provisioned by using the Ignition config files that you generated with the installation program.

**Prerequisites**

- Configure an Azure account.
- Generate the Ignition config files for your cluster.
- Create and configure a VNet and associated subnets in Azure.
- Create and configure networking and load balancers in Azure.
- Create control plane and compute roles.
- Create the bootstrap machine.
- Create the control plane machines.

**Procedure**
1. Change to the directory that contains the installation program and run the following command:

   $ ./openshift-install wait-for bootstrap-complete --dir <installation_directory> \  
   --log-level info

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

   If the command exits without a `FATAL` warning, your production control plane has initialized.

2. Delete the bootstrap resources:

   $ az network nsgrule delete -g ${RESOURCE_GROUP} --nsg-name ${INFRA_ID}-nsg --name bootstrap_ssh_in
   $ az vm stop -g ${RESOURCE_GROUP} --name ${INFRA_ID}-bootstrap
   $ az vm deallocate -g ${RESOURCE_GROUP} --name ${INFRA_ID}-bootstrap
   $ az vm delete -g ${RESOURCE_GROUP} --name ${INFRA_ID}-bootstrap --yes
   $ az disk delete -g ${RESOURCE_GROUP} --name ${INFRA_ID}-bootstrap_OSDisk --no-wait --yes
   $ az network nic delete -g ${RESOURCE_GROUP} --name ${INFRA_ID}-bootstrap-nic --no-wait
   $ az storage blob delete --account-key ${ACCOUNT_KEY} --account-name  
   ${CLUSTER_NAME}sa --container-name files --name bootstrap.ign
   $ az network public-ip delete -g ${RESOURCE_GROUP} --name ${INFRA_ID}-bootstrap-ssh-pip

3.9.17. Creating additional worker machines in Azure

You can create worker machines in Microsoft Azure for your cluster to use by launching individual instances discretely or by automated processes outside the cluster, such as auto scaling groups. You can also take advantage of the built-in cluster scaling mechanisms and the machine API in OpenShift Container Platform.

In this example, you manually launch one instance by using the Azure Resource Manager (ARM) template. Additional instances can be launched by including additional resources of type `06_workers.json` in the file.

**NOTE**

If you do not use the provided ARM template to create your worker machines, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

**Prerequisites**

- Configure an Azure account.
- Generate the Ignition config files for your cluster.
- Create and configure a VNet and associated subnets in Azure.
Create and configure networking and load balancers in Azure.

Create control plane and compute roles.

Create the bootstrap machine.

Create the control plane machines.

Procedure

1. Copy the template from the ARM template for worker machines section of this topic and save it as 06_workers.json in your cluster’s installation directory. This template describes the worker machines that your cluster requires.

2. Export the following variable needed by the worker machine deployment:

   ```
   $ export WORKER_IGNITION=`cat <installation_directory>/worker.ign | base64 | tr -d "\n"
   ```

3. Create the deployment by using the az CLI:

   ```
   $ az deployment group create -g ${RESOURCE_GROUP} \\    --template-file "<installation_directory>/06_workers.json" \\    --parameters workerIgnition="${WORKER_IGNITION}" \\    --parameters sshKeyData="${SSH_KEY}" \\    --parameters baseName="${INFRA_ID}" \\
   ```

   1. The Ignition content for the worker nodes.
   2. The SSH RSA public key file as a string.
   3. The base name to be used in resource names; this is usually the cluster’s infrastructure ID.

3.9.17.1. ARM template for worker machines

You can use the following Azure Resource Manager (ARM) template to deploy the worker machines that you need for your OpenShift Container Platform cluster:

Example 3.6. 06_workers.json ARM template

```json
{
  "$schema": "https://schema.management.azure.com/schemas/2015-01-01/deploymentTemplate.json#",
  "contentVersion": "1.0.0.0",
  "parameters": {

CHAPTER 3. INSTALLING ON AZURE
3.9.18. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) in order to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.6. Download and install the new version of oc.

3.9.18.1. Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.6 Linux Client entry and save the file.

4. Unpack the archive:

   ```
   $ tar xvzf <file>
   ```

5. Place the oc binary in a directory that is on your PATH.

   To check your PATH, execute the following command:

   ```
   $ echo $PATH
   ```

After you install the OpenShift CLI, it is available using the oc command:

```
$ oc <command>
```  

3.9.18.2. Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.6 Windows Client entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the oc binary to a directory that is on your PATH.

   To check your PATH, open the command prompt and execute the following command:

   ```
   $ oc <command>
   ```
After you install the OpenShift CLI, it is available using the `oc` command:

```bash
C:\> oc <command>
```

### 3.9.18.3. Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (`oc`) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.
3. Click **Download Now** next to the **OpenShift v4.6 MacOSX Client** entry and save the file.
4. Unpack and unzip the archive.
5. Move the `oc` binary to a directory on your PATH.

To check your **PATH**, open a terminal and execute the following command:

```bash
$ echo $PATH
```

After you install the OpenShift CLI, it is available using the `oc` command:

```bash
$ oc <command>
```

### 3.9.19. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

```bash
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig
```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.
2. Verify you can run `oc` commands successfully using the exported configuration:

```
$ oc whoami
```

**Example output**

```
system:admin
```

### 3.9.20. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

**Prerequisites**

- You added machines to your cluster.

**Procedure**

1. Confirm that the cluster recognizes the machines:

```
$ oc get nodes
```

**Example output**

```
NAME      STATUS    ROLES   AGE  VERSION
master-0  Ready     master  63m  v1.19.0
master-1  Ready     master  63m  v1.19.0
master-2  Ready     master  64m  v1.19.0
```

The output lists all of the machines that you created.

**NOTE**

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

```
$ oc get csr
```

**Example output**

```
NAME        AGE     REQUESTOR                                                                   CONDITION
csr-8b2br   15m     system:serviceaccount:openshift-machine-config-operator:node-bootstrapper   Pending
csr-8vnps   15m     system:serviceaccount:openshift-machine-config-operator:node-bootstrapper   Pending
...```

680
In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

   **NOTE**

   Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. Once the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine-approver** if the Kubelet requests a new certificate with identical parameters.

   **NOTE**

   For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrapper** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

   - To approve them individually, run the following command for each valid CSR:

     ```bash
     $ oc adm certificate approve <csr_name>  
     ```

     `<csr_name>` is the name of a CSR from the list of current CSRs.

   - To approve all pending CSRs, run the following command:

     ```bash
     $ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
     ```

     **NOTE**

     Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

   ```bash
   $ oc get csr
   ```

   **Example output**
5. If the remaining CSRs are not approved, and are in the pending status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

  ```bash
  $ oc adm certificate approve <csr_name>
  ``

  `<csr_name>` is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

  ```bash
  $ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs oc adm certificate approve
  ```

6. After all client and server CSRs have been approved, the machines have the Ready status. Verify this by running the following command:

```bash
$ oc get nodes
```

## Example output

```
NAME      STATUS    ROLES   AGE  VERSION
master-0  Ready     master  73m  v1.20.0
master-1  Ready     master  73m  v1.20.0
master-2  Ready     master  74m  v1.20.0
worker-0  Ready     worker  11m  v1.20.0
worker-1  Ready     worker  11m  v1.20.0
```

### NOTE

It can take a few minutes after approval of the server CSRs for the machines to transition to the Ready status.

### Additional information

- For more information on CSRs, see Certificate Signing Requests.

## 3.9.21. Adding the Ingress DNS records

If you removed the DNS Zone configuration when creating Kubernetes manifests and generating Ignition configs, you must manually create DNS records that point at the Ingress load balancer. You can create either a wildcard `*.apps.{baseDomain}`, or specific records. You can use A, CNAME, and other records per your requirements.

### Prerequisites
You deployed an OpenShift Container Platform cluster on Microsoft Azure by using infrastructure that you provisioned.

- Install the OpenShift CLI (oc).
- Install the jq package.
- Install or update the Azure CLI.

**Procedure**

1. Confirm the Ingress router has created a load balancer and populated the **EXTERNAL-IP** field:

   ```
   $ oc -n openshift-ingress get service router-default
   ```

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>CLUSTER-IP</th>
<th>EXTERNAL-IP</th>
<th>PORT(S)</th>
<th>AGE</th>
</tr>
</thead>
<tbody>
<tr>
<td>router-default</td>
<td>LoadBalancer</td>
<td>172.30.20.10</td>
<td>35.130.120.110</td>
<td>80:32288/TCP,443:31215/TCP</td>
<td>20</td>
</tr>
</tbody>
</table>

2. Export the Ingress router IP as a variable:

   ```
   $ export PUBLIC_IP_ROUTER=`oc -n openshift-ingress get service router-default --no-headers | awk '{print $4}'`
   ```

3. Add a **.apps** record to the public DNS zone.
   a. If you are adding this cluster to a new public zone, run:

   ```
   $ az network dns record-set a add-record -g ${BASE_DOMAIN_RESOURCE_GROUP} -z ${CLUSTER_NAME}.${BASE_DOMAIN} -n *.apps -a ${PUBLIC_IP_ROUTER} --ttl 300
   ```
   b. If you are adding this cluster to an already existing public zone, run:

   ```
   $ az network dns record-set a add-record -g ${BASE_DOMAIN_RESOURCE_GROUP} -z ${BASE_DOMAIN} -n *.apps.${CLUSTER_NAME} -a ${PUBLIC_IP_ROUTER} --ttl 300
   ```

4. Add a **.apps** record to the private DNS zone:
   a. Create a **.apps** record by using the following command:

   ```
   $ az network private-dns record-set a create -g ${RESOURCE_GROUP} -z ${CLUSTER_NAME}.${BASE_DOMAIN} -n *.apps --ttl 300
   ```
   b. Add the **.apps** record to the private DNS zone by using the following command:

   ```
   $ az network private-dns record-set a add-record -g ${RESOURCE_GROUP} -z ${CLUSTER_NAME}.${BASE_DOMAIN} -n *.apps -a ${PUBLIC_IP_ROUTER}
   ```

If you prefer to add explicit domains instead of using a wildcard, you can create entries for each of the cluster’s current routes:
3.9.22. Completing an Azure installation on user-provisioned infrastructure

After you start the OpenShift Container Platform installation on Microsoft Azure user-provisioned infrastructure, you can monitor the cluster events until the cluster is ready.

Prerequisites

- Deploy the bootstrap machine for an OpenShift Container Platform cluster on user-provisioned Azure infrastructure.
- Install the `oc` CLI and log in.

Procedure

- Complete the cluster installation:

  ```
  $ ./openshift-install --dir <installation_directory> wait-for install-complete
  ```

  Example output

  ```
  INFO Waiting up to 30m0s for the cluster to initialize...
  ```

  For `<installation_directory>`, specify the path to the directory that you stored the installation files in.
3.9.23. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.6, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service

3.10. UNINSTALLING A CLUSTER ON AZURE

You can remove a cluster that you deployed to Microsoft Azure.

3.10.1. Removing a cluster that uses installer-provisioned infrastructure

You can remove a cluster that uses installer-provisioned infrastructure from your cloud.

**NOTE**

After uninstallation, check your cloud provider for any resources not removed properly, especially with User Provisioned Infrastructure (UPI) clusters. There might be resources that the installer did not create or that the installer is unable to access.

Prerequisites

- Have a copy of the installation program that you used to deploy the cluster.
- Have the files that the installation program generated when you created your cluster.

Procedure
1. From the directory that contains the installation program on the computer that you used to install the cluster, run the following command:

```bash
$ ./openshift-install destroy cluster \
--dir <installation_directory> --log-level info 1 2
```

1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. To view different details, specify `warn`, `debug`, or `error` instead of `info`.

**NOTE**

You must specify the directory that contains the cluster definition files for your cluster. The installation program requires the `metadata.json` file in this directory to delete the cluster.

2. Optional: Delete the `<installation_directory>` directory and the OpenShift Container Platform installation program.
CHAPTER 4. INSTALLING ON GCP

4.1. CONFIGURING A GCP PROJECT

Before you can install OpenShift Container Platform, you must configure a Google Cloud Platform (GCP) project to host it.

4.1.1. Creating a GCP project

To install OpenShift Container Platform, you must create a project in your Google Cloud Platform (GCP) account to host the cluster.

Procedure

- Create a project to host your OpenShift Container Platform cluster. See Creating and Managing Projects in the GCP documentation.

**IMPORTANT**

Your GCP project must use the Premium Network Service Tier if you are using installer-provisioned infrastructure. The Standard Network Service Tier is not supported for clusters installed using the installation program. The installation program configures internal load balancing for the `api-int.<cluster_name>.<base_domain>` URL; the Premium Tier is required for internal load balancing.

4.1.2. Enabling API services in GCP

Your Google Cloud Platform (GCP) project requires access to several API services to complete OpenShift Container Platform installation.

**Prerequisites**

- You created a project to host your cluster.

**Procedure**

- Enable the following required API services in the project that hosts your cluster. See Enabling services in the GCP documentation.

<table>
<thead>
<tr>
<th>API service</th>
<th>Console service name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compute Engine API</td>
<td>compute.googleapis.com</td>
</tr>
<tr>
<td>Google Cloud APIs</td>
<td>cloudapis.googleapis.com</td>
</tr>
<tr>
<td>Cloud Resource Manager API</td>
<td>cloudresourcemanager.googleapis.com</td>
</tr>
<tr>
<td>Google DNS API</td>
<td>dns.googleapis.com</td>
</tr>
</tbody>
</table>
4.1.3. Configuring DNS for GCP

To install OpenShift Container Platform, the Google Cloud Platform (GCP) account you use must have a dedicated public hosted zone in the same project that you host the OpenShift Container Platform cluster. This zone must be authoritative for the domain. The DNS service provides cluster DNS resolution and name lookup for external connections to the cluster.

Procedure

1. Identify your domain, or subdomain, and registrar. You can transfer an existing domain and registrar or obtain a new one through GCP or another source.

   **NOTE**
   
   If you purchase a new domain, it can take time for the relevant DNS changes to propagate. For more information about purchasing domains through Google, see Google Domains.

2. Create a public hosted zone for your domain or subdomain in your GCP project. See Creating public zones in the GCP documentation.  
   Use an appropriate root domain, such as openshiftcorp.com, or subdomain, such as clusters.openshiftcorp.com.

3. Extract the new authoritative name servers from the hosted zone records. See Look up your Cloud DNS name servers in the GCP documentation. You typically have four name servers.

4. Update the registrar records for the name servers that your domain uses. For example, if you registered your domain to Google Domains, see the following topic in the Google Domains Help: How to switch to custom name servers.

5. If you migrated your root domain to Google Cloud DNS, migrate your DNS records. See Migrating to Cloud DNS in the GCP documentation.

<table>
<thead>
<tr>
<th>API service</th>
<th>Console service name</th>
</tr>
</thead>
<tbody>
<tr>
<td>IAM Service Account Credentials API</td>
<td>iamcredentials.googleapis.com</td>
</tr>
<tr>
<td>Identity and Access Management (IAM) API</td>
<td>iam.googleapis.com</td>
</tr>
<tr>
<td>Service Management API</td>
<td>servicemanagement.googleapis.com</td>
</tr>
<tr>
<td>Service Usage API</td>
<td>serviceusage.googleapis.com</td>
</tr>
<tr>
<td>Google Cloud Storage JSON API</td>
<td>storage-api.googleapis.com</td>
</tr>
<tr>
<td>Cloud Storage</td>
<td>storage-component.googleapis.com</td>
</tr>
</tbody>
</table>
6. If you use a subdomain, follow your company’s procedures to add its delegation records to the parent domain. This process might include a request to your company’s IT department or the division that controls the root domain and DNS services for your company.

4.1.4. GCP account limits

The OpenShift Container Platform cluster uses a number of Google Cloud Platform (GCP) components, but the default Quotas do not affect your ability to install a default OpenShift Container Platform cluster.

A default cluster, which contains three compute and three control plane machines, uses the following resources. Note that some resources are required only during the bootstrap process and are removed after the cluster deploys.

Table 4.2. GCP resources used in a default cluster

<table>
<thead>
<tr>
<th>Service</th>
<th>Component</th>
<th>Location</th>
<th>Total resources required</th>
<th>Resources removed after bootstrap</th>
</tr>
</thead>
<tbody>
<tr>
<td>Service account</td>
<td>IAM</td>
<td>Global</td>
<td>5</td>
<td>0</td>
</tr>
<tr>
<td>Firewall rules</td>
<td>Compute</td>
<td>Global</td>
<td>11</td>
<td>1</td>
</tr>
<tr>
<td>Forwarding rules</td>
<td>Compute</td>
<td>Global</td>
<td>2</td>
<td>0</td>
</tr>
<tr>
<td>In-use global IP addresses</td>
<td>Compute</td>
<td>Global</td>
<td>4</td>
<td>1</td>
</tr>
<tr>
<td>Health checks</td>
<td>Compute</td>
<td>Global</td>
<td>3</td>
<td>0</td>
</tr>
<tr>
<td>Images</td>
<td>Compute</td>
<td>Global</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>Networks</td>
<td>Compute</td>
<td>Global</td>
<td>2</td>
<td>0</td>
</tr>
<tr>
<td>Static IP addresses</td>
<td>Compute</td>
<td>Region</td>
<td>4</td>
<td>1</td>
</tr>
<tr>
<td>Routers</td>
<td>Compute</td>
<td>Global</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>Routes</td>
<td>Compute</td>
<td>Global</td>
<td>2</td>
<td>0</td>
</tr>
<tr>
<td>Subnetworks</td>
<td>Compute</td>
<td>Global</td>
<td>2</td>
<td>0</td>
</tr>
<tr>
<td>Target pools</td>
<td>Compute</td>
<td>Global</td>
<td>3</td>
<td>0</td>
</tr>
<tr>
<td>CPUs</td>
<td>Compute</td>
<td>Region</td>
<td>28</td>
<td>4</td>
</tr>
<tr>
<td>Persistent disk SSD (GB)</td>
<td>Compute</td>
<td>Region</td>
<td>896</td>
<td>128</td>
</tr>
</tbody>
</table>
NOTE

If any of the quotas are insufficient during installation, the installation program displays an error that states both which quota was exceeded and the region.

Be sure to consider your actual cluster size, planned cluster growth, and any usage from other clusters that are associated with your account. The CPU, static IP addresses, and persistent disk SSD (storage) quotas are the ones that are most likely to be insufficient.

If you plan to deploy your cluster in one of the following regions, you will exceed the maximum storage quota and are likely to exceed the CPU quota limit:

- asia-east2
- asia-northeast2
- asia-south1
- australia-southeast1
- europe-north1
- europe-west2
- europe-west3
- europe-west6
- northamerica-northeast1
- southamerica-east1
- us-west2

You can increase resource quotas from the GCP console, but you might need to file a support ticket. Be sure to plan your cluster size early so that you can allow time to resolve the support ticket before you install your OpenShift Container Platform cluster.

4.1.5. Creating a service account in GCP

OpenShift Container Platform requires a Google Cloud Platform (GCP) service account that provides authentication and authorization to access data in the Google APIs. If you do not have an existing IAM service account that contains the required roles in your project, you must create one.

Prerequisites

- You created a project to host your cluster.

Procedure

1. Create a service account in the project that you use to host your OpenShift Container Platform cluster. See Creating a service account in the GCP documentation.

2. Grant the service account the appropriate permissions. You can either grant the individual permissions that follow or assign the Owner role to it. See Granting roles to a service account for specific resources.
NOTE

While making the service account an owner of the project is the easiest way to gain the required permissions, it means that service account has complete control over the project. You must determine if the risk that comes from offering that power is acceptable.

3. Create the service account key in JSON format. See Creating service account keys in the GCP documentation.
   The service account key is required to create a cluster.

4.1.5.1. Required GCP permissions

When you attach the Owner role to the service account that you create, you grant that service account all permissions, including those that are required to install OpenShift Container Platform. To deploy an OpenShift Container Platform cluster, the service account requires the following permissions. If you deploy your cluster into an existing VPC, the service account does not require certain networking permissions, which are noted in the following lists:

**Required roles for the installation program**

- Compute Admin
- Security Admin
- Service Account Admin
- Service Account User
- Storage Admin

**Required roles for creating network resources during installation**

- DNS Administrator

**Optional roles**

For the cluster to create new limited credentials for its Operators, add the following role:

- Service Account Key Admin

The roles are applied to the service accounts that the control plane and compute machines use:

<table>
<thead>
<tr>
<th>Account</th>
<th>Roles</th>
</tr>
</thead>
<tbody>
<tr>
<td>Control Plane</td>
<td><code>roles/compute.instanceAdmin</code></td>
</tr>
<tr>
<td></td>
<td><code>roles/compute.networkAdmin</code></td>
</tr>
<tr>
<td></td>
<td><code>roles/compute.securityAdmin</code></td>
</tr>
<tr>
<td></td>
<td><code>roles/storage.admin</code></td>
</tr>
</tbody>
</table>
### 4.1.6. Supported GCP regions

You can deploy an OpenShift Container Platform cluster to the following Google Cloud Platform (GCP) regions:

- **asia-east1** (Changhua County, Taiwan)
- **asia-east2** (Hong Kong)
- **asia-northeast1** (Tokyo, Japan)
- **asia-northeast2** (Osaka, Japan)
- **asia-northeast3** (Seoul, South Korea)
- **asia-south1** (Mumbai, India)
- **asia-southeast1** (Jurong West, Singapore)
- **asia-southeast2** (Jakarta, Indonesia)
- **australia-southeast1** (Sydney, Australia)
- **europe-north1** (Hamina, Finland)
- **europe-west1** (St. Ghislain, Belgium)
- **europe-west2** (London, England, UK)
- **europe-west3** (Frankfurt, Germany)
- **europe-west4** (Eemshaven, Netherlands)
- **europe-west6** (Zürich, Switzerland)
- **northamerica-northeast1** (Montréal, Québec, Canada)
- **southamerica-east1** (São Paulo, Brazil)
- **us-central1** (Council Bluffs, Iowa, USA)
- **us-east1** (Moncks Corner, South Carolina, USA)
- **us-east4** (Ashburn, Northern Virginia, USA)
- **us-west1** (The Dalles, Oregon, USA)
4.1.7. Next steps

- Install an OpenShift Container Platform cluster on GCP. You can install a customized cluster or quickly install a cluster with default options.

4.2. MANUALLY CREATING IAM FOR GCP

In environments where the cloud identity and access management (IAM) APIs are not reachable, or the administrator prefers not to store an administrator-level credential secret in the cluster `kube-system` namespace, you can put the Cloud Credential Operator (CCO) into manual mode before you install the cluster.

4.2.1. Alternatives to storing administrator-level secrets in the `kube-system` project

The Cloud Credential Operator (CCO) manages cloud provider credentials as Kubernetes custom resource definitions (CRDs). You can configure the CCO to suit the security requirements of your organization by setting different values for the `credentialsMode` parameter in the `install-config.yaml` file.

If you prefer not to store an administrator-level credential secret in the cluster `kube-system` project, you can set the `credentialsMode` parameter for the CCO to `Manual` when installing OpenShift Container Platform and manage your cloud credentials manually.

Using manual mode allows each cluster component to have only the permissions it requires, without storing an administrator-level credential in the cluster. You can also use this mode if your environment does not have connectivity to the cloud provider public IAM endpoint. However, you must manually reconcile permissions with new release images for every upgrade. You must also manually supply credentials for every component that requests them.

Additional resources

- Rotating or removing cloud provider credentials.

For a detailed description of all available CCO credential modes and their supported platforms, see the Cloud Credential Operator reference.

4.2.2. Manually create IAM

The Cloud Credential Operator (CCO) can be put into manual mode prior to installation in environments where the cloud identity and access management (IAM) APIs are not reachable, or the administrator prefers not to store an administrator-level credential secret in the cluster `kube-system` namespace.

Procedure

1. To generate the manifests, run the following command from the directory that contains the installation program:
$ openshift-install create manifests --dir <installation_directory> ①

For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

2. Insert a config map into the manifests directory so that the Cloud Credential Operator is placed in manual mode:

   $ cat <<EOF > mycluster/manifests/cco-configmap.yaml
   apiVersion: v1
   kind: ConfigMap
   metadata:
     name: cloud-credential-operator-config
     namespace: openshift-cloud-credential-operator
   annotations:
     release.openshift.io/create-only: "true"
   data:
     disabled: "true"
   EOF

3. Remove the admin credential secret created using your local cloud credentials. This removal prevents your admin credential from being stored in the cluster:

   $ rm mycluster/openshift/99_cloud-creds-secret.yaml

4. From the directory that contains the installation program, obtain details of the OpenShift Container Platform release image that your `openshift-install` binary is built to use:

   $ openshift-install version

   Example output

   release image quay.io/openshift-release-dev/ocp-release:4.y.z-x86_64

5. Locate all `CredentialsRequest` objects in this release image that target the cloud you are deploying on:

   $ oc adm release extract quay.io/openshift-release-dev/ocp-release:4.y.z-x86_64 --credentials-requests --cloud=gcp

   This displays the details for each request.

Sample `CredentialsRequest` object

```yaml
apiVersion: cloudcredential.openshift.io/v1
kind: CredentialsRequest
metadata:
  labels:
    controller-tools.k8s.io: "1.0"
name: openshift-image-registry-gcs
namespace: openshift-cloud-credential-operator
spec:
```
6. Create YAML files for secrets in the `openshift-install` manifests directory that you generated previously. The secrets must be stored using the namespace and secret name defined in the `spec.secretRef` for each `credentialsRequest`. The format for the secret data varies for each cloud provider.

7. From the directory that contains the installation program, proceed with your cluster creation:

   ```bash
   $ openshift-install create cluster --dir <installation_directory>
   ```

**IMPORTANT**

Before upgrading a cluster that uses manually maintained credentials, you must ensure that the CCO is in an upgradeable state. For details, see the *Upgrading clusters with manually maintained credentials* section of the installation content for your cloud provider.

### 4.2.3. Admin credentials root secret format

Each cloud provider uses a credentials root secret in the `kube-system` namespace by convention, which is then used to satisfy all credentials requests and create their respective secrets. This is done either by minting new credentials, with *mint mode*, or by copying the credentials root secret, with *passthrough mode*.

The format for the secret varies by cloud, and is also used for each `CredentialsRequest` secret.

**Google Cloud Platform (GCP) secret format**

```yaml
apiVersion: v1
kind: Secret
metadata:
  namespace: kube-system
  name: gcp-credentials
stringData:
  service_account.json: <ServiceAccount>
```

### 4.2.4. Upgrading clusters with manually maintained credentials

If credentials are added in a future release, the Cloud Credential Operator (CCO) `upgradable` status for a cluster with manually maintained credentials changes to `false`. For minor release, for example, from 4.5 to 4.6, this status prevents you from upgrading until you have addressed any updated permissions. For z-stream releases, for example, from 4.5.10 to 4.5.11, the upgrade is not blocked, but the credentials must still be updated for the new release.
Use the **Administrator** perspective of the web console to determine if the CCO is upgradeable.

1. Navigate to **Administration → Cluster Settings**.

2. To view the CCO status details, click **cloud-credential** in the **Cluster Operators** list.

3. If the **Upgradeable** status in the **Conditions** section is **False**, examine the **credentialsRequests** for the new release and update the manually maintained credentials on your cluster to match before upgrading.

In addition to creating new credentials for the release image that you are upgrading to, you must review the required permissions for existing credentials and accommodate any new permissions requirements for existing components in the new release. The CCO cannot detect these mismatches and will not set **upgradable** to **false** in this case.

The *Manually creating IAM* section of the installation content for your cloud provider explains how to obtain and use the credentials required for your cloud.

### 4.2.5. Mint mode

Mint mode is the default and recommended Cloud Credential Operator (CCO) credentials mode for OpenShift Container Platform. In this mode, the CCO uses the provided administrator-level cloud credential to run the cluster. Mint mode is supported for AWS, GCP, and Azure.

In mint mode, the **admin** credential is stored in the **kube-system** namespace and then used by the CCO to process the **CredentialsRequest** objects in the cluster and create users for each with specific permissions.

The benefits of mint mode include:

- Each cluster component has only the permissions it requires
- Automatic, on-going reconciliation for cloud credentials, including additional credentials or permissions that might be required for upgrades

One drawback is that mint mode requires **admin** credential storage in a cluster **kube-system** secret.

### 4.2.6. Mint Mode with removal or rotation of the admin credential

Currently, this mode is only supported on AWS.

In this mode, a user installs OpenShift Container Platform with an **admin** credential just like the normal mint mode. However, this mode removes the **admin** credential secret from the cluster post-installation.

The administrator can have the Cloud Credential Operator make its own request for a read-only credential that allows it to verify if all **CredentialsRequest** objects have their required permissions, thus the **admin** credential is not required unless something needs to be changed. After the associated credential is removed, it can be destroyed on the underlying cloud, if desired.

Prior to upgrade, the **admin** credential should be restored. In the future, upgrade might be blocked if the credential is not present.

The **admin** credential is not stored in the cluster permanently.

This mode still requires the **admin** credential in the cluster for brief periods of time. It also requires manually re-instating the secret with **admin** credentials for each upgrade.
4.2.7. Next steps

- Install an OpenShift Container Platform cluster:
  - Installing a cluster quickly on GCP with default options on installer-provisioned infrastructure
  - Install a cluster with cloud customizations on installer-provisioned infrastructure
  - Install a cluster with network customizations on installer-provisioned infrastructure

4.3. INSTALLING A CLUSTER QUICKLY ON GCP

In OpenShift Container Platform version 4.6, you can install a cluster on Google Cloud Platform (GCP) that uses the default configuration options.

4.3.1. Prerequisites

- Review details about the OpenShift Container Platform installation and update processes.
- Configure a GCP account to host the cluster.
- If you use a firewall, you must configure it to allow the sites that your cluster requires access to.
- If you do not allow the system to manage identity and access management (IAM), then a cluster administrator can manually create and maintain IAM credentials. Manual mode can also be used in environments where the cloud IAM APIs are not reachable.

4.3.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.6, you require access to the Internet to install your cluster.

You must have Internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

4.3.3. Generating an SSH private key and adding it to the agent
If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your `ssh-agent` and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

**NOTE**

In a production environment, you require disaster recovery and debugging.

You can use this key to SSH into the master nodes as the user `core`. When you deploy the cluster, the key is added to the `core` user's `~/.ssh/authorized_keys` list.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

**Procedure**

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N '' -f <path>/<file_name>
   ``

   Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.

   Running this command generates an SSH key that does not require a password in the location that you specified.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the `x86_64` architecture, do not create a key that uses the `ed25519` algorithm. Instead, create a key that uses the `rsa` or `ecdsa` algorithm.

2. Start the `ssh-agent` process as a background task:

   ```bash
   $ eval "$(ssh-agent -s)"
   ``

   **Example output**

   Agent pid 31874

   **NOTE**

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.
3. Add your SSH private key to the `ssh-agent`:

```
$ ssh-add <path>/<file_name>  # 1
```

**Example output**

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)  # 1
```

Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`.

4. Set the `GOOGLE_APPLICATION_CREDENTIALS` environment variable to the full path to your service account private key file.

```
$ export GOOGLE_APPLICATION_CREDENTIALS="<your_service_account_file>"
```

5. Verify that the credentials were applied.

```
$ gcloud auth list
```

**Next steps**
- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

**4.3.4. Obtaining the installation program**

Before you install OpenShift Container Platform, download the installation file on a local computer.

**Prerequisites**
- You have a computer that runs Linux or macOS, with 500 MB of local disk space

**Procedure**

1. Access the [Infrastructure Provider](#) page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.
Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```bash
$ tar xvf openshift-install-linux.tar.gz
```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 4.3.5. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

**Prerequisites**

- Configure an account with the cloud platform that hosts your cluster.
- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Remove any existing GCP credentials that do not use the service account key for the GCP account that you configured for your cluster and that are stored in the following locations:

   - The `GOOGLE_CREDENTIALS`, `GOOGLE_CLOUD_KEYFILE_JSON`, or `GCloud_KEYFILE_JSON` environment variables
   - The `~/.gcp/osServiceAccount.json` file
   - The `gcloud cli` default credentials

2. Change to the directory that contains the installation program and initialize the cluster deployment:

   ```bash
   $ ./openshift-install create cluster --dir <installation_directory> \
   --log-level=info
   ```

   **1** For `<installation_directory>`, specify the directory name to store the files that the installation program creates.
To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

**IMPORTANT**

Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

Provide values at the prompts:

a. Optional: Select an SSH key to use to access your cluster machines.

   **NOTE**
   
   For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

b. Select `gcp` as the platform to target.

c. If you have not configured the service account key for your GCP account on your computer, you must obtain it from GCP and paste the contents of the file or enter the absolute path to the file.

d. Select the project ID to provision the cluster in. The default value is specified by the service account that you configured.

e. Select the region to deploy the cluster to.

f. Select the base domain to deploy the cluster to. The base domain corresponds to the public DNS zone that you created for your cluster.

g. Enter a descriptive name for your cluster. If you provide a name that is longer than 6 characters, only the first 6 characters will be used in the infrastructure ID that is generated from the cluster name.

h. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

   **NOTE**
   
   If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.

When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the `kubeadmin` user, display in your terminal.

**Example output**

...
NOTE
The cluster access and credential information also outputs to
<installation_directory>/.openshift_install.log when an installation succeeds.

IMPORTANT
- The Ignition config files that the installation program generates contain
certificates that expire after 24 hours, which are then renewed at that time. If
the cluster is shut down before renewing the certificates and the cluster is
later restarted after the 24 hours have elapsed, the cluster automatically
recovers the expired certificates. The exception is that you must manually
approve the pending node-bootstrapper certificate signing requests (CSRs)
to recover kubelet certificates. See the documentation for Recovering from
expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they
are generated because the 24-hour certificate rotates from 16 to 22 hours
after the cluster is installed. By using the Ignition config files within 12 hours,
you can avoid installation failure if the certificate update runs during
installation.

IMPORTANT
You must not delete the installation program or the files that the installation
program creates. Both are required to delete the cluster.

3. Optional: You can reduce the number of permissions for the service account that you used to
install the cluster.
   - If you assigned the Owner role to your service account, you can remove that role and
     replace it with the Viewer role.
   - If you included the Service Account Key Admin role, you can remove it.

4.3.6. Installing the OpenShift CLI by downloading the binary
You can install the OpenShift CLI (oc) in order to interact with OpenShift Container Platform from a
command-line interface. You can install oc on Linux, Windows, or macOS.

IMPORTANT
If you installed an earlier version of oc, you cannot use it to complete all of the commands
in OpenShift Container Platform 4.6. Download and install the new version of oc.
4.3.6.1. Installing the OpenShift CLI on Linux
You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.
3. Click Download Now next to the OpenShift v4.6 Linux Client entry and save the file.
4. Unpack the archive:

   $ tar xzvf <file>

5. Place the oc binary in a directory that is on your PATH. To check your PATH, execute the following command:

   $ echo $PATH

After you install the OpenShift CLI, it is available using the oc command:

   $ oc <command>

4.3.6.2. Installing the OpenShift CLI on Windows
You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.
3. Click Download Now next to the OpenShift v4.6 Windows Client entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the oc binary to a directory that is on your PATH. To check your PATH, open the command prompt and execute the following command:

   C:\> path

After you install the OpenShift CLI, it is available using the oc command:

   C:\> oc <command>

4.3.6.3. Installing the OpenShift CLI on macOS
You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.
Procedure

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.6 MacOSX Client entry and save the file.

4. Unpack and unzip the archive.

5. Move the oc binary to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:

   ```
   $ echo $PATH
   ```

After you install the OpenShift CLI, it is available using the oc command:

```
$ oc <command>
```

4.3.7. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster kubeconfig file. The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the oc CLI.

Procedure

1. Export the kubeadmin credentials:

   ```
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For <installation_directory>, specify the path to the directory that you stored the installation files in.

2. Verify you can run oc commands successfully using the exported configuration:

   ```
   $ oc whoami
   ```

   **Example output**

   ```
   system:admin
   ```

   **Additional resources**
See Accessing the web console for more details about accessing and understanding the OpenShift Container Platform web console.

### 4.3.8. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.6, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](https://openshift.io/cluster-manager/).

After you confirm that your [OpenShift Cluster Manager](https://openshift.io/cluster-manager/) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- See About remote health monitoring for more information about the Telemetry service

### 4.3.9. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.

### 4.4. INSTALLING A CLUSTER ON GCP WITH CUSTOMIZATIONS

In OpenShift Container Platform version 4.6, you can install a customized cluster on infrastructure that the installation program provisions on Google Cloud Platform (GCP). To customize the installation, you modify parameters in the `install-config.yaml` file before you install the cluster.

#### 4.4.1. Prerequisites

- Configure a GCP account to host the cluster.
- If you use a firewall, you must configure it to allow the sites that your cluster requires access to.
- If you do not allow the system to manage identity and access management (IAM), then a cluster administrator can manually create and maintain IAM credentials. Manual mode can also be used in environments where the cloud IAM APIs are not reachable.

#### 4.4.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.6, you require access to the Internet to install your cluster.

You must have Internet access to:

- Access [OpenShift Cluster Manager](https://openshift.io/cluster-manager/) to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access [Quay.io](https://quay.io) to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.
IMPORTANT

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

4.4.3. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your ssh-agent and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

NOTE

In a production environment, you require disaster recovery and debugging.

You can use this key to SSH into the master nodes as the user core. When you deploy the cluster, the key is added to the core user’s ~/.ssh/authorized_keys list.

NOTE

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

Procedure

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   $ ssh-keygen -t ed25519 -N "\n   -f <path>/<file_name>  
   1

   Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   Running this command generates an SSH key that does not require a password in the location that you specified.

   NOTE

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the ssh-agent process as a background task:
NOTE
If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the `ssh-agent`:

   ```
   $ ssh-add <path>/<file_name>
   ```

   Example output

   ```
   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
   ```

   Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

4. Set the `GOOGLE_APPLICATION_CREDENTIALS` environment variable to the full path to your service account private key file.

   ```
   $ export GOOGLE_APPLICATION_CREDENTIALS="<your_service_account_file>"
   ```

5. Verify that the credentials were applied.

   ```
   $ gcloud auth list
   ```

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

4.4.4. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on a local computer.

Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space

Procedure

1. Access the [Infrastructure Provider] page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.
3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

**IMPORTANT**

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```
$ tar xvf openshift-install-linux.tar.gz
```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 4.4.5. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Google Cloud Platform (GCP).

**Prerequisites**

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Create the `install-config.yaml` file.

   a. Change to the directory that contains the installation program and run the following command:

```
$ ./openshift-install create install-config --dir <installation_directory>
```

   1 For `<installation_directory>`, specify the directory name to store the files that the installation program creates.
IMPORTANT

Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

b. At the prompts, provide the configuration details for your cloud:
   i. Optional: Select an SSH key to use to access your cluster machines.

   **NOTE**
   For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your *ssh-agent* process uses.

   ii. Select `gcp` as the platform to target.

   iii. If you have not configured the service account key for your GCP account on your computer, you must obtain it from GCP and paste the contents of the file or enter the absolute path to the file.

   iv. Select the project ID to provision the cluster in. The default value is specified by the service account that you configured.

   v. Select the region to deploy the cluster to.

   vi. Select the base domain to deploy the cluster to. The base domain corresponds to the public DNS zone that you created for your cluster.

   vii. Enter a descriptive name for your cluster.

   viii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

2. Modify the `install-config.yaml` file. You can find more information about the available parameters in the Installation configuration parameters section.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

IMPORTANT

The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

4.4.5.1. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster’s platform. When you create the `install-config.yaml` installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the `install-config.yaml` file to provide more details about the platform.
After installation, you cannot modify these parameters in the `install-config.yaml` file.

The `openshift-install` command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

### 4.4.5.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>apiVersion</code></td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is <code>v1</code>. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td><code>baseDomain</code></td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the <code>baseDomain</code> and <code>metadata.name</code> parameter values that uses the <code>&lt;metadata.name&gt;</code>, <code>&lt;baseDomain&gt;</code> format.</td>
<td>A fully-qualified domain or subdomain name, such as <code>example.com</code>.</td>
</tr>
<tr>
<td><code>metadata</code></td>
<td>Kubernetes resource <code>ObjectMeta</code>, from which only the <code>name</code> parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td><code>metadata.name</code></td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of <code>{{.metadata.name}}</code>. <code>{{.baseDomain}}</code>.</td>
<td>String of lowercase letters, hyphens (-), and periods (.), such as <code>dev</code>.</td>
</tr>
</tbody>
</table>
### platform

The configuration for the specific platform upon which to perform the installation: **aws**, **baremetal**, **azure**, **openstack**, **ovirt**, **vsphere**. For additional information about `platform.<platform>` parameters, consult the following table for your specific platform.

### pullSecret

Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.

```json
{
  "auths":{
    "cloud.openshift.com":{
      "auth":"b3Blb=",
      "email":"you@example.com"
    },
    "quay.io":{
      "auth":"b3Blb=",
      "email":"you@example.com"
    }
  }
}
```

#### 4.4.5.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

### Table 4.5. Network parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
</tbody>
</table>

**NOTE**

You cannot modify parameters specified by the `networking` object after installation.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking.network Type</td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN.</td>
</tr>
<tr>
<td>networking.clusterNetwork</td>
<td>The IP address blocks for pods.</td>
<td>An array of objects. For example: networking: clusterNetwork: - cidr: 10.128.0.0/14 hostPrefix: 23</td>
</tr>
<tr>
<td>networking.clusterNetwork.cidr</td>
<td>Required if you use networking.clusterNetwork. An IP address block.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td>networking.clusterNetwork.hostPrefix</td>
<td>The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given cidr. A hostPrefix value of 23 provides 510 (2^((32 - 23) - 2)) pod IP addresses.</td>
<td>A subnet prefix. The default value is 23.</td>
</tr>
<tr>
<td>networking.serviceNetwork</td>
<td>The IP address block for services. The default value is 172.30.0.0/16.</td>
<td>An array with an IP address block in CIDR format. For example: networking: serviceNetwork: - 172.30.0.0/16</td>
</tr>
<tr>
<td>networking.machineNetwork</td>
<td>The IP address blocks for machines.</td>
<td>An array of objects. For example: networking: machineNetwork: - cidr: 10.0.0.0/16</td>
</tr>
</tbody>
</table>
4.4.5.13. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

Table 4.6. Optional parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking.machineNetwork.cidr</td>
<td>Required if you use networking.machineNetwork. An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24.</td>
<td>An IP network block in CIDR notation. For example, 10.0.0.0/16.</td>
</tr>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of machine-pool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>compute.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are amd64 (the default).</td>
<td>String</td>
</tr>
</tbody>
</table>
### Parameter Description Values

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>compute.hyperthreading</code></td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td><strong>IMPORTANT</strong></td>
<td>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td></td>
</tr>
<tr>
<td><code>compute.name</code></td>
<td>Required if you use <code>compute</code>. The name of the machine pool.</td>
<td><code>worker</code></td>
</tr>
<tr>
<td><code>compute.platform</code></td>
<td>Required if you use <code>compute</code>. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <code>controlPlane.platform</code> parameter value.</td>
<td><code>aws, azure, gcp, openstack, ovirt, vsphere, or{}</code></td>
</tr>
<tr>
<td><code>compute.replicas</code></td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td><code>controlPlane</code></td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of <code>MachinePool</code> objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td><code>controlPlane.architecture</code></td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>----------------------</td>
<td>------------------------------------------------------------------------------</td>
<td>-------------------------</td>
</tr>
<tr>
<td>controlPlane.hypertreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>controlPlane.name</td>
<td>Required if you use controlPlane. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use controlPlane. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the compute.platform parameter value.</td>
<td>aws, azure, gcp, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (&quot;&quot;&quot;).</td>
</tr>
</tbody>
</table>

**NOTE**

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Red Hat Operators reference content.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>fips</td>
<td>Enable or disable FIPS mode. The default is <strong>false</strong> (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</td>
<td><strong>false</strong> or <strong>true</strong></td>
</tr>
</tbody>
</table>

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the **x86_64** architecture.

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>imageContentSources</td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects. Includes a <strong>source</strong> and, optionally, <strong>mirrors</strong>, as described in the following rows of this table.</td>
</tr>
<tr>
<td>imageContentSources.source</td>
<td>Required if you use <strong>imageContentSources</strong>. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td><strong>String</strong></td>
</tr>
<tr>
<td>imageContentSources.mirrors</td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
<tr>
<td>publish</td>
<td>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</td>
<td><strong>Internal</strong> or <strong>External</strong>. To deploy a private cluster, which cannot be accessed from the internet, set <strong>publish</strong> to <strong>Internal</strong>. The default value is <strong>External</strong>.</td>
</tr>
</tbody>
</table>
### sshKey

The SSH key or keys to authenticate access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

- **Values**: One or more keys. For example:
  - `sshKey: <key1>`
  - `<key2>`
  - `<key3>`

---

### 4.4.5.1.4. Additional Google Cloud Platform (GCP) configuration parameters

Additional GCP configuration parameters are described in the following table:

**Table 4.7. Additional GCP parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>platform.gcp.network</code></td>
<td>The name of the existing VPC that you want to deploy your cluster to.</td>
<td>String.</td>
</tr>
<tr>
<td><code>platform.gcp.region</code></td>
<td>The name of the GCP region that hosts your cluster.</td>
<td>Any valid region name, such as <code>us-central1</code>.</td>
</tr>
<tr>
<td><code>platform.gcp.type</code></td>
<td>The GCP machine type.</td>
<td>The GCP machine type.</td>
</tr>
<tr>
<td><code>platform.gcp.zones</code></td>
<td>The availability zones where the installation program creates machines for the specified MachinePool.</td>
<td>A list of valid GCP availability zones, such as <code>us-central1-a</code>, in a YAML sequence.</td>
</tr>
<tr>
<td><code>platform.gcp.controlPlaneSubnet</code></td>
<td>The name of the existing subnet in your VPC that you want to deploy your control plane machines to.</td>
<td>The subnet name.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td>platform.gcp.computeSubnet</td>
<td>The name of the existing subnet in your VPC that you want to deploy your compute machines to.</td>
<td>The subnet name.</td>
</tr>
<tr>
<td>platform.gcp.licenses</td>
<td>A list of license URLs that must be applied to the compute images.</td>
<td>Any license available with the license API, such as the license to enable nested virtualization. You cannot use this parameter with a mechanism that generates pre-built images. Using a license URL forces the installer to copy the source image before use.</td>
</tr>
<tr>
<td>platform.gcp.osDisk.diskSizeGB</td>
<td>The size of the disk in gigabytes (GB).</td>
<td>Any size between 16 GB and 65536 GB.</td>
</tr>
<tr>
<td>platform.gcp.osDisk.diskType</td>
<td>The type of disk.</td>
<td>Either the default pd-ssd or the pd-standard disk type. The control plane nodes must be the pd-ssd disk type. The worker nodes can be either type.</td>
</tr>
</tbody>
</table>

### 4.4.5.2. Sample customized install-config.yaml file for GCP

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

**IMPORTANT**

This sample YAML file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program and modify it.

```yaml
apiVersion: v1
baseDomain: example.com
controlPlane: 2 3
  hyperthreading: Enabled 4
name: master
platform: gcp:
```
Required. The installation program prompts you for this value.

If you do not provide these parameters and values, the installation program provides the default value.

The **controlPlane** section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, `-`, and the first line of the **controlPlane** section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading, or **hypervthreading**. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to **Disabled**. If you disable simultaneous
multithreading in some cluster machines, you must disable it in all cluster machines.

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger machine types, such as `n1-standard-8`, for your machines if you disable simultaneous multithreading.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the `x86_64` architecture.

You can optionally provide the `sshKey` value that you use to access the machines in your cluster.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

### 4.4.5.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**Prerequisites**

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.
NOTE

The Proxy object status.noProxy field is populated with the values of the networking.machineNetwork[].cidr, networking.clusterNetwork[].cidr, and networking.serviceNetwork[] fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object status.noProxy field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your install-config.yaml file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port>
  httpsProxy: https://<username>:<pswd>@<ip>:<port>
  noProxy: example.com
additionalTrustBundle: |
    -----BEGIN CERTIFICATE-----
    <MY_TRUSTED_CA_CERT>
    -----END CERTIFICATE-----
```

   1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.
   2 A proxy URL to use for creating HTTPS connections outside the cluster.
   3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.
   4 If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace to hold the additional CA certificates. If you provide additionalTrustBundle and at least one proxy setting, the Proxy object is configured to reference the user-ca-bundle config map in the trustedCA field. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges the contents specified for the trustedCA parameter with the RHCOS trust bundle. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

NOTE

The installation program does not support the proxy readinessEndpoints field.

2. Save the file and reference it when installing OpenShift Container Platform.
The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

**NOTE**

Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

### 4.4.6. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

**Prerequisites**

- Configure an account with the cloud platform that hosts your cluster.
- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Remove any existing GCP credentials that do not use the service account key for the GCP account that you configured for your cluster and that are stored in the following locations:
   
   - The `GOOGLE_CREDENTIALS`, `GOOGLE_CLOUD_KEYFILE_JSON`, or `GCloud_KEYFILE_JSON` environment variables
   - The `~/.gcp/osServiceAccount.json` file
   - The `gcloud cli` default credentials

2. Change to the directory that contains the installation program and initialize the cluster deployment:

   ```bash
   $ ./openshift-install create cluster --dir <installation_directory> \
   --log-level=info
   ```

   1. For `<installation_directory>`, specify the location of your customized `./install-config.yaml` file.
   2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

   **NOTE**

   If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.
When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the **kubeadmin** user, display in your terminal.

**Example output**

```plaintext
... INFO Install complete! INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig' INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-Wt5AL" INFO Time elapsed: 36m22s
```

**NOTE**

The cluster access and credential information also outputs to `<installation_directory>/openshift_install.log` when an installation succeeds.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

**IMPORTANT**

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

3. Optional: You can reduce the number of permissions for the service account that you used to install the cluster.

- If you assigned the **Owner** role to your service account, you can remove that role and replace it with the **Viewer** role.

- If you included the **Service Account Key Admin** role, you can remove it.

### 4.4.7. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) in order to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.
IMPORTANT

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.6. Download and install the new version of oc.

4.4.7.1. Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

**Procedure**

2. Select the appropriate version in the Version drop-down menu.
3. Click Download Now next to the OpenShift v4.6 Linux Client entry and save the file.
4. Unpack the archive:
   ```bash
   $ tar xvzf <file>
   ```
5. Place the oc binary in a directory that is on your PATH. To check your PATH, execute the following command:
   ```bash
   $ echo $PATH
   $$
   ```

After you install the OpenShift CLI, it is available using the oc command:

```bash
$ oc <command>
```

4.4.7.2. Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version in the Version drop-down menu.
3. Click Download Now next to the OpenShift v4.6 Windows Client entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the oc binary to a directory that is on your PATH. To check your PATH, open the command prompt and execute the following command:
   ```bash
   C:\> path
   ```

After you install the OpenShift CLI, it is available using the oc command:
4.4.7.3. Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version in the Version drop-down menu.
3. Click Download Now next to the OpenShift v4.6 MacOSX Client entry and save the file.
4. Unpack and unzip the archive.
5. Move the oc binary to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:

   ```bash
   $ echo $PATH
   ``

After you install the OpenShift CLI, it is available using the oc command:

```bash
$ oc <command>
```

4.4.8. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster kubeconfig file. The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the oc CLI.

**Procedure**

1. Export the kubeadmin credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run oc commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   ```
4.4.9. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.6, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources
- See About remote health monitoring for more information about the Telemetry service.

4.4.10. Next steps
- Customize your cluster.
- If necessary, you can opt out of remote health reporting.

4.5. INSTALLING A CLUSTER ON GCP WITH NETWORK CUSTOMIZATIONS

In OpenShift Container Platform version 4.6, you can install a cluster with a customized network configuration on infrastructure that the installation program provisions on Google Cloud Platform (GCP). By customizing your network configuration, your cluster can coexist with existing IP address allocations in your environment and integrate with existing MTU and VXLAN configurations. To customize the installation, you modify parameters in the install-config.yaml file before you install the cluster.

You must set most of the network configuration parameters during installation, and you can modify only kubeProxy configuration parameters in a running cluster.

4.5.1. Prerequisites
- Review details about the OpenShift Container Platform installation and update processes.
- Configure a GCP account to host the cluster.
- If you use a firewall, you must configure it to allow the sites that your cluster requires access to.
- If you do not allow the system to manage identity and access management (IAM), then a cluster administrator can manually create and maintain IAM credentials. Manual mode can also be used in environments where the cloud IAM APIs are not reachable.
4.5.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.6, you require access to the Internet to install your cluster.

You must have Internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

4.5.3. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your `ssh-agent` and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

**NOTE**

In a production environment, you require disaster recovery and debugging.

You can use this key to SSH into the master nodes as the user `core`. When you deploy the cluster, the key is added to the `core` user’s `~/.ssh/authorized_keys` list.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

**Procedure**

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>
   ```

   Specify the path and file name, such as `~/.ssh/id_rsa`, of the new SSH key. If you have an existing key pair, ensure your public key is in the your `~/.ssh` directory.
Running this command generates an SSH key that does not require a password in the location that you specified.

**NOTE**

If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the `ssh-agent` process as a background task:

```bash
$ eval "$(ssh-agent -s)"
```

**Example output**

```
Agent pid 31874
```

**NOTE**

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the `ssh-agent`:

```bash
$ ssh-add <path>/<file_name>
```

**Example output**

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

4. Set the `GOOGLE_APPLICATION_CREDENTIALS` environment variable to the full path to your service account private key file.

```bash
$ export GOOGLE_APPLICATION_CREDENTIALS="<your_service_account_file>"
```

5. Verify that the credentials were applied.

```bash
$ gcloud auth list
```

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

### 4.5.4. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on a local computer.
**Prerequisites**

- You have a computer that runs Linux or macOS, with 500 MB of local disk space

**Procedure**

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

**IMPORTANT**

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ tar xvf openshift-install-linux.tar.gz
   ```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

**4.5.5. Creating the installation configuration file**

You can customize the OpenShift Container Platform cluster you install on Google Cloud Platform (GCP).

**Prerequisites**

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Create the `install-config.yaml` file.
1. Change to the directory that contains the installation program and run the following command:

```
$ ./openshift-install create install-config --dir <installation_directory> 1
```

For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

**IMPORTANT**

Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. At the prompts, provide the configuration details for your cloud:

   i. Optional: Select an SSH key to use to access your cluster machines.

      **NOTE**

      For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

   ii. Select `gcp` as the platform to target.

   iii. If you have not configured the service account key for your GCP account on your computer, you must obtain it from GCP and paste the contents of the file or enter the absolute path to the file.

   iv. Select the project ID to provision the cluster in. The default value is specified by the service account that you configured.

   v. Select the region to deploy the cluster to.

   vi. Select the base domain to deploy the cluster to. The base domain corresponds to the public DNS zone that you created for your cluster.

   vii. Enter a descriptive name for your cluster.

   viii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

3. Modify the `install-config.yaml` file. You can find more information about the available parameters in the Installation configuration parameters section.

4. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.
IMPORTANT

The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

4.5.5.1. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster’s platform. When you create the `install-config.yaml` installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the `install-config.yaml` file to provide more details about the platform.

NOTE

After installation, you cannot modify these parameters in the `install-config.yaml` file.

IMPORTANT

The `openshift-install` command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

4.5.5.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

Table 4.8. Required parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is v1. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the <code>baseDomain</code> and <code>metadata.name</code> parameter values that uses the <code>&lt;metadata.name&gt;.&lt;baseDomain&gt;</code> format.</td>
<td>A fully-qualified domain or subdomain name, such as <code>example.com</code>.</td>
</tr>
</tbody>
</table>
Parameter | Description | Values
---|---|---
metadata | Kubernetes resource **ObjectMeta**, from which only the name parameter is consumed. | Object
metadata.name | The name of the cluster. DNS records for the cluster are all subdomains of {{.metadata.name}}.{{.baseDomain}}. | String of lowercase letters, hyphens (-), and periods (.), such as dev.
platform | The configuration for the specific platform upon which to perform the installation: aws, baremetal, azure, openstack, ovirt, vsphere. For additional information about **platform.<platform>** parameters, consult the following table for your specific platform. | Object
pullSecret | Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io. | 

```json
{
  "auths":{
    "cloud.openshift.com":{
      "auth":"b3Blb=",
      "email":"you@example.com"
    },
    "quay.io":{
      "auth":"b3Blb=",
      "email":"you@example.com"
    }
  }
}
```

4.5.5.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

**Table 4.9. Network parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>

</tbody>
</table>
### 4.5.5.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>AdditionalTrustBundle</strong></td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes' trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td><strong>compute</strong></td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of machine-pool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td><strong>compute.architecture</strong></td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <strong>amd64</strong> (the default).</td>
<td>String</td>
</tr>
</tbody>
</table>
Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>compute.hyperthreading</code></td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td><code>compute.name</code></td>
<td>Required if you use <code>compute</code>. The name of the machine pool.</td>
<td><code>worker</code></td>
</tr>
<tr>
<td><code>compute.platform</code></td>
<td>Required if you use <code>compute</code>. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <code>controlPlane.platform</code> parameter value.</td>
<td><code>aws, azure, gcp, openstack, ovirt, vsphere, or {}</code></td>
</tr>
<tr>
<td><code>compute.replicas</code></td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td><code>controlPlane</code></td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of MachinePool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td><code>controlPlane.architecture</code></td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-------------------------</td>
</tr>
<tr>
<td>controlPlane.hypertreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td></td>
</tr>
<tr>
<td>controlPlane.name</td>
<td>Required if you use controlPlane. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use controlPlane. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the compute.platform parameter value.</td>
<td>aws, azure, gcp, openstack, ovirt, vsphere, or{}</td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>--------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (&quot;&quot;).</td>
</tr>
</tbody>
</table>
Enable or disable FIPS mode. The default is `false` (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the `x86_64` architecture.

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>fips</strong></td>
<td>Enable or disable FIPS mode. The default is <code>false</code> (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</td>
<td><code>false</code> or <code>true</code></td>
</tr>
<tr>
<td><strong>imageContentSources</strong></td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects. Includes a <code>source</code> and, optionally, <code>mirrors</code>, as described in the following rows of this table.</td>
</tr>
<tr>
<td><strong>imageContentSources.source</strong></td>
<td>Required if you use <code>imageContentSources</code>. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td><strong>imageContentSources.mirrors</strong></td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
</tbody>
</table>
**publish**

How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.

Internal or External. To deploy a private cluster, which cannot be accessed from the internet, set publish to Internal. The default value is External.

**sshKey**

The SSH key or keys to authenticate access your cluster machines.

NOTE

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

One or more keys. For example:

```
sshKey:
  <key1>
  <key2>
  <key3>
```

### 4.5.5.1.4. Additional Google Cloud Platform (GCP) configuration parameters

Additional GCP configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>platform.gcp.network</strong></td>
<td>The name of the existing VPC that you want to deploy your cluster to.</td>
<td>String.</td>
</tr>
<tr>
<td><strong>platform.gcp.region</strong></td>
<td>The name of the GCP region that hosts your cluster.</td>
<td>Any valid region name, such as us-central1.</td>
</tr>
<tr>
<td><strong>platform.gcp.type</strong></td>
<td>The GCP machine type.</td>
<td>The GCP machine type.</td>
</tr>
<tr>
<td><strong>platform.gcp.zones</strong></td>
<td>The availability zones where the installation program creates machines for the specified MachinePool.</td>
<td>A list of valid GCP availability zones, such as us-central1-a, in a YAML sequence.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------</td>
</tr>
<tr>
<td>platform.gcp.controlPlaneSubnet</td>
<td>The name of the existing subnet in your VPC that you want to deploy your control plane machines to.</td>
<td>The subnet name.</td>
</tr>
<tr>
<td>platform.gcp.computeSubnet</td>
<td>The name of the existing subnet in your VPC that you want to deploy your compute machines to.</td>
<td>The subnet name.</td>
</tr>
<tr>
<td>platform.gcp.licenses</td>
<td>A list of license URLs that must be applied to the compute images.</td>
<td>Any license available with the license API, such as the license to enable nested virtualization. You cannot use this parameter with a mechanism that generates pre-built images. Using a license URL forces the installer to copy the source image before use.</td>
</tr>
<tr>
<td>platform.gcp.osDisk.disk.SizeGB</td>
<td>The size of the disk in gigabytes (GB).</td>
<td>Any size between 16 GB and 65536 GB.</td>
</tr>
<tr>
<td>platform.gcp.osDisk.disk.Type</td>
<td>The type of disk.</td>
<td>Either the default <strong>pd-ssd</strong> or the <strong>pd-standard</strong> disk type. The control plane nodes must be the <strong>pd-ssd</strong> disk type. The worker nodes can be either type.</td>
</tr>
</tbody>
</table>

### 4.5.5.2. Sample customized install-config.yaml file for GCP

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

**IMPORTANT**

This sample YAML file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program and modify it.
| `apiVersion: v1` | Required. The installation program prompts you for this value. |
| `baseDomain: example.com` | |
| `controlPlane:` | If you do not provide these parameters and values, the installation program provides the default value. |
| `hyperthreading: Enabled` | |
| `name: master` | |
| `platform:` | The `controlPlane` section is a single mapping, but the compute section is a sequence of mappings. |
| `gcp:` | |
| `- type: n2-standard-4` | |
| `- zones:` | |
| `- us-central1-a` | |
| `- us-central1-c` | |
| `osDisk:` | |
| `diskType: pd-ssd` | |
| `diskSizeGB: 1024` | |
| `replicas: 3` | |
| `compute:` | |
| `- hyperthreading: Enabled` | |
| `name: worker` | |
| `platform:` | |
| `gcp:` | |
| `- type: n2-standard-4` | |
| `- zones:` | |
| `- us-central1-a` | |
| `- us-central1-c` | |
| `osDisk:` | |
| `diskType: pd-standard` | |
| `diskSizeGB: 128` | |
| `replicas: 3` | |
| `metadata:` | |
| `name: test-cluster` | |
| `networking:` | |
| `clusterNetwork:` | |
| `- cidr: 10.128.0.0/14` | |
| `- hostPrefix: 23` | |
| `machineNetwork:` | |
| `- cidr: 10.0.0.0/16` | |
| `networkType: OpenShiftSDN` | |
| `serviceNetwork:` | |
| `- 172.30.0.0/16` | |
| `platform:` | |
| `gcp:` | |
| `- projectID: openshift-production` | |
| `- region: us-central1` | |
| `pullSecret: '{"auths": ...}'` | |
| `fips: false` | |
| `sshKey: ssh-ed25519 AAAA...` | |
Whether to enable or disable simultaneous multithreading, or **hyperthreading**. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger machine types, such as **n1-standard-8**, for your machines if you disable simultaneous multithreading.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the **x86_64** architecture.

You can optionally provide the **sshKey** value that you use to access the machines in your cluster.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your **ssh-agent** process uses.

### 4.5.5.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the **install-config.yaml** file.

**Prerequisites**

- You have an existing **install-config.yaml** file.

- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the **Proxy** object’s **spec.noProxy** field to bypass the proxy if necessary.
NOTE

The Proxy object status.noProxy field is populated with the values of the networking.machineNetwork[].cidr, networking.clusterNetwork[].cidr, and networking.serviceNetwork[] fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object status.noProxy field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your install-config.yaml file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
     httpProxy: http://<username>:<pswd>@<ip>:<port> 1
     httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
     noProxy: example.com 3
   additionalTrustBundle: |
     -----BEGIN CERTIFICATE-----
     <MY_TRUSTED_CA_CERT>
     -----END CERTIFICATE-----
     ...
   
   1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.
   2 A proxy URL to use for creating HTTPS connections outside the cluster.
   3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.
   4 If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace to hold the additional CA certificates. If you provide additionalTrustBundle and at least one proxy setting, the Proxy object is configured to reference the user-ca-bundle config map in the trustedCA field. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges the contents specified for the trustedCA parameter with the RH COS trust bundle. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RH COS trust bundle.

NOTE

The installation program does not support the proxy readinessEndpoints field.

2. Save the file and reference it when installing OpenShift Container Platform.
The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

**NOTE**

Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

### 4.5.6. Network configuration phases

When specifying a cluster configuration prior to installation, there are several phases in the installation procedures when you can modify the network configuration:

**Phase 1**

After entering the `openshift-install create install-config` command. In the `install-config.yaml` file, you can customize the following network-related fields:

- `networking.networkType`
- `networking.clusterNetwork`
- `networking.serviceNetwork`
- `networking.machineNetwork`

For more information on these fields, refer to "Installation configuration parameters".

**NOTE**

Set the `networking.machineNetwork` to match the CIDR that the preferred NIC resides in.

**Phase 2**

After entering the `openshift-install create manifests` command. If you must specify advanced network configuration, during this phase you can define a customized Cluster Network Operator manifest with only the fields you want to modify.

You cannot override the values specified in phase 1 in the `install-config.yaml` file during phase 2. However, you can further customize the cluster network provider during phase 2.

### 4.5.7. Specifying advanced network configuration

You can use advanced configuration customization to integrate your cluster into your existing network environment by specifying additional configuration for your cluster network provider. You can specify advanced network configuration only before you install the cluster.

**IMPORTANT**

Modifying the OpenShift Container Platform manifest files created by the installation program is not supported. Applying a manifest file that you create, as in the following procedure, is supported.

**Prerequisites**
Create the `install-config.yaml` file and complete any modifications to it.

**Procedure**

1. Change to the directory that contains the installation program and create the manifests:

   ```bash
   $ ./openshift-install create manifests --dir <installation_directory>
   ``

   where:

   `<installation_directory>`
   
   Specifies the name of the directory that contains the `install-config.yaml` file for your cluster.

2. Create a stub manifest file for the advanced network configuration that is named `cluster-network-03-config.yml` in the `<installation_directory>/manifests/` directory:

   ```bash
   $ cat <<EOF > <installation_directory>/manifests/cluster-network-03-config.yml
   apiVersion: operator.openshift.io/v1
   kind: Network
   metadata:
     name: cluster
   spec:
   EOF
   
   where:

   `<installation_directory>`
   
   Specifies the directory name that contains the `manifests/` directory for your cluster.

3. Open the `cluster-network-03-config.yml` file in an editor and specify the advanced network configuration for your cluster, such as in the following example:

   **Specify a different VXLAN port for the OpenShift SDN network provider**

   ```yaml
   apiVersion: operator.openshift.io/v1
   kind: Network
   metadata:
     name: cluster
   spec:
     defaultNetwork:
       openshiftSDNConfig:
         vxlanPort: 4800
   ```

4. Save the `cluster-network-03-config.yml` file and quit the text editor.

5. Optional: Back up the `manifests/cluster-network-03-config.yml` file. The installation program deletes the `manifests/` directory when creating the cluster.

**4.5.8. Cluster Network Operator configuration**

The configuration for the cluster network is specified as part of the Cluster Network Operator (CNO) configuration and stored in a custom resource (CR) object that is named `cluster`. The CR specifies the fields for the `Network` API in the `operator.openshift.io` API group.
The CNO configuration inherits the following fields during cluster installation from the Network API in the Network.config.openshift.io API group and these fields cannot be changed:

**clusterNetwork**
- IP address pools from which pod IP addresses are allocated.

**serviceNetwork**
- IP address pool for services.

**defaultNetwork.type**
- Cluster network provider, such as OpenShift SDN or OVN-Kubernetes.

You can specify the cluster network provider configuration for your cluster by setting the fields for the **defaultNetwork** object in the CNO object named **cluster**.

### 4.5.8.1. Cluster Network Operator configuration object

The fields for the Cluster Network Operator (CNO) are described in the following table:

#### Table 4.12. Cluster Network Operator configuration object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>metadata.name</td>
<td>string</td>
<td>The name of the CNO object. This name is always <strong>cluster</strong>.</td>
</tr>
<tr>
<td>spec.clusterNetwork</td>
<td>array</td>
<td>A list specifying the blocks of IP addresses from which pod IP addresses are allocated and the subnet prefix length assigned to each individual node in the cluster. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>spec:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>clusterNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- cidr: 10.128.0.0/19</td>
</tr>
<tr>
<td></td>
<td></td>
<td>hostPrefix: 23</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- cidr: 10.128.32.0/19</td>
</tr>
<tr>
<td></td>
<td></td>
<td>hostPrefix: 23</td>
</tr>
<tr>
<td></td>
<td></td>
<td>This value is ready-only and specified in the <strong>install-config.yaml</strong> file.</td>
</tr>
<tr>
<td>spec.serviceNetwork</td>
<td>array</td>
<td>A block of IP addresses for services. The OpenShift SDN and OVN-Kubernetes Container Network Interface (CNI) network providers support only a single IP address block for the service network. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>spec:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>serviceNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- 172.30.0.0/14</td>
</tr>
<tr>
<td></td>
<td></td>
<td>This value is ready-only and specified in the <strong>install-config.yaml</strong> file.</td>
</tr>
<tr>
<td>spec.defaultNetwork</td>
<td>object</td>
<td>Configures the Container Network Interface (CNI) cluster network provider for the cluster network.</td>
</tr>
</tbody>
</table>
The fields for this object specify the kube-proxy configuration. If you are using the OVN-Kubernetes cluster network provider, the kube-proxy configuration has no effect.

**defaultNetwork object configuration**

The values for the `defaultNetwork` object are defined in the following table:

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>type</code></td>
<td>string</td>
<td>Either OpenShiftSDN or OVNKubernetes. The cluster network provider is selected during installation. This value cannot be changed after cluster installation.</td>
</tr>
</tbody>
</table>

**NOTE**

OpenShift Container Platform uses the OpenShift SDN Container Network Interface (CNI) cluster network provider by default.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>openshiftSDNConfig</code></td>
<td>object</td>
<td>This object is only valid for the OpenShift SDN cluster network provider.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ovnKubernetesConfig</code></td>
<td>object</td>
<td>This object is only valid for the OVN-Kubernetes cluster network provider.</td>
</tr>
</tbody>
</table>

**Configuration for the OpenShift SDN CNI cluster network provider**

The following table describes the configuration fields for the OpenShift SDN Container Network Interface (CNI) cluster network provider.

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>mode</code></td>
<td>string</td>
<td>Configures the network isolation mode for OpenShift SDN. The default value is <code>NetworkPolicy</code>. The values <code>Multitenant</code> and <code>Subnet</code> are available for backwards compatibility with OpenShift Container Platform 3.x but are not recommended. This value cannot be changed after cluster installation.</td>
</tr>
</tbody>
</table>
The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.

If the auto-detected value is not what you expected it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.

If your cluster requires different MTU values for different nodes, you must set this value to 50 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1450.

This value cannot be changed after cluster installation.

The port to use for all VXLAN packets. The default value is 4789. This value cannot be changed after cluster installation.

If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number.

On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port 9000 and port 9999.

Example OpenShift SDN configuration

```yaml
defaultNetwork:
  type: OpenShiftSDN
  openshiftSDNConfig:
    mode: NetworkPolicy
    mtu: 1450
    vxlanPort: 4789
```

Configuration for the OVN-Kubernetes CNI cluster network provider

The following table describes the configuration fields for the OVN-Kubernetes CNI cluster network provider.

Table 4.15. ovnKubernetesConfig object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mtu</td>
<td>integer</td>
<td>The maximum transmission unit (MTU) for the VXLAN overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU. If the auto-detected value is not what you expected it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes. If your cluster requires different MTU values for different nodes, you must set this value to 50 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1450. This value cannot be changed after cluster installation.</td>
</tr>
<tr>
<td>vxlanPort</td>
<td>integer</td>
<td>The port to use for all VXLAN packets. The default value is 4789. This value cannot be changed after cluster installation. If you are running in a virtualized environment with existing nodes that are part of another VXLAN network, then you might be required to change this. For example, when running an OpenShift SDN overlay on top of VMware NSX-T, you must select an alternate port for the VXLAN, because both SDNs use the same default VXLAN port number. On Amazon Web Services (AWS), you can select an alternate port for the VXLAN between port 9000 and port 9999.</td>
</tr>
</tbody>
</table>
mtu | integer | The maximum transmission unit (MTU) for the Geneve (Generic Network Virtualization Encapsulation) overlay network. This is detected automatically based on the MTU of the primary network interface. You do not normally need to override the detected MTU.

If the auto-detected value is not what you expected it to be, confirm that the MTU on the primary network interface on your nodes is correct. You cannot use this option to change the MTU value of the primary network interface on the nodes.

If your cluster requires different MTU values for different nodes, you must set this value to 100 less than the lowest MTU value in your cluster. For example, if some nodes in your cluster have an MTU of 9001, and some have an MTU of 1500, you must set this value to 1400.

This value cannot be changed after cluster installation.

genevePort | integer | The port to use for all Geneve packets. The default value is 6081. This value cannot be changed after cluster installation.

Example OVN–Kubernetes configuration

defaultNetwork:
type: OVNKubernetes
ovnKubernetesConfig:
  mtu: 1400
genevePort: 6081

kubeProxyConfig object configuration
The values for the kubeProxyConfig object are defined in the following table:

Table 4.16. kubeProxyConfig object

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>iptablesSyncPeriod</td>
<td>string</td>
<td>The refresh period for iptables rules. The default value is 30s. Valid suffixes include s, m, and h and are described in the Go time package documentation.</td>
</tr>
</tbody>
</table>

NOTE
Because of performance improvements introduced in OpenShift Container Platform 4.3 and greater, adjusting the iptablesSyncPeriod parameter is no longer necessary.
### Field: proxyArguments.iptables-min-sync-period

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>proxyArguments.iptables-min-sync-period</td>
<td>array</td>
<td>The minimum duration before refreshing <code>iptables</code> rules. This field ensures that the refresh does not happen too frequently. Valid suffixes include <code>s</code>, <code>m</code>, and <code>h</code> and are described in the <code>Go time</code> package. The default value is: kubeProxyConfig: proxyArguments: iptables-min-sync-period: -0s</td>
</tr>
</tbody>
</table>

#### 4.5.9. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the `create cluster` command of the installation program only once, during initial installation.

**Prerequisites**

- Configure an account with the cloud platform that hosts your cluster.
- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Change to the directory that contains the installation program and initialize the cluster deployment:

   ```bash
   $ ./openshift-install create cluster --dir <installation_directory> \  
   --log-level=info
   ``

   **1** For `<installation_directory>`, specify the
   **2** To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

   **NOTE**

   If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.

   When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the `kubeadmin` user, display in your terminal.

   **Example output**
NOTE

The cluster access and credential information also outputs to `<installation_directory>/openshift_install.log` when an installation succeeds.

IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

IMPORTANT

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

4.5.10. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (`oc`) in order to interact with OpenShift Container Platform from a command-line interface. You can install `oc` on Linux, Windows, or macOS.

IMPORTANT

If you installed an earlier version of `oc`, you cannot use it to complete all of the commands in OpenShift Container Platform 4.6. Download and install the new version of `oc`.

4.5.10.1. Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (`oc`) binary on Linux by using the following procedure.

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.6 Linux Client entry and save the file.

4. Unpack the archive:

   ```
   $ tar xvzf <file>
   ```

5. Place the `oc` binary in a directory that is on your PATH.

   To check your PATH, execute the following command:

   ```
   $ echo $PATH
   ```

After you install the OpenShift CLI, it is available using the `oc` command:

```
$ oc <command>
```

### 4.5.10.2. Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (`oc`) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.6 Windows Client entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the `oc` binary to a directory that is on your PATH.

   To check your PATH, open the command prompt and execute the following command:

   ```
   C:\> path
   ```

After you install the OpenShift CLI, it is available using the `oc` command:

```
C:\> oc <command>
```

### 4.5.10.3. Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (`oc`) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.6 MacOSX Client entry and save the file.

4. Unpack and unzip the archive.

5. Move the oc binary to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:

   ```
   $ echo $PATH
   ```

   After you install the OpenShift CLI, it is available using the oc command:

   ```
   $ oc <command>
   ```

4.5.11. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster kubeconfig file. The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the oc CLI.

**Procedure**

1. Export the kubeadmin credentials:

   ```
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run oc commands successfully using the exported configuration:

   ```
   $ oc whoami
   ```

   Example output

   ```
   system:admin
   ```

**Additional resources**

- See Accessing the web console for more details about accessing and understanding the OpenShift Container Platform web console.

4.5.12. Telemetry access for OpenShift Container Platform
In OpenShift Container Platform 4.6, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service

4.5.13. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.

4.6. INSTALLING A CLUSTER ON GCP IN A RESTRICTED NETWORK

In OpenShift Container Platform 4.6, you can install a cluster on Google Cloud Platform (GCP) in a restricted network by creating an internal mirror of the installation release content on an existing Google Virtual Private Cloud (VPC).

**IMPORTANT**

You can install an OpenShift Container Platform cluster by using mirrored installation release content, but your cluster will require internet access to use the GCP APIs.

4.6.1. Prerequisites

- You mirrored the images for a disconnected installation to your registry and obtained the imageContentSources data for your version of OpenShift Container Platform.

**IMPORTANT**

Because the installation media is on the mirror host, you can use that computer to complete all installation steps.

- You have an existing VPC in GCP. While installing a cluster in a restricted network that uses installer-provisioned infrastructure, you cannot use the installer-provisioned VPC. You must use a user-provisioned VPC that satisfies one of the following requirements:
  - Contains the mirror registry
  - Has firewall rules or a peering connection to access the mirror registry hosted elsewhere
- You reviewed details about the OpenShift Container Platform installation and update processes.
- If you use a firewall, you must configure it to allow the sites that your cluster requires access to. While you might need to grant access to more sites, you must grant access to *.googleapis.com and accounts.google.com.
If you do not allow the system to manage identity and access management (IAM), then a cluster administrator can manually create and maintain IAM credentials. Manual mode can also be used in environments where the cloud IAM APIs are not reachable.

**4.6.2. About installations in restricted networks**

In OpenShift Container Platform 4.6, you can perform an installation that does not require an active connection to the Internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service’s IAM service, require Internet access, so you might still require Internet access. Depending on your network, you might require less Internet access for an installation on bare metal hardware or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift Container Platform registry and contains the installation media. You can create this registry on a mirror host, which can access both the Internet and your closed network, or by using other methods that meet your restrictions.

**4.6.2.1. Additional limits**

Clusters in restricted networks have the following additional limitations and restrictions:

- The ClusterVersion status includes an Unable to retrieve available updates error.
- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

**4.6.3. Internet access for OpenShift Container Platform**

In OpenShift Container Platform 4.6, you require access to the Internet to obtain the images that are necessary to install your cluster.

You must have Internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.
4.6.4. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your ssh-agent and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

**NOTE**

In a production environment, you require disaster recovery and debugging.

You can use this key to SSH into the master nodes as the user core. When you deploy the cluster, the key is added to the core user’s ~/.ssh/authorized_keys list.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

**Procedure**

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```bash
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>
   ```

   Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   Running this command generates an SSH key that does not require a password in the location that you specified.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the ssh-agent process as a background task:

   ```bash
   $ eval "$(ssh-agent -s)"
   ```

   **Example output**

   ```bash
   Agent pid 31874
   ```
NOTE

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the $ssh-agent$:

```
$ ssh-add <path>/<file_name>
```

Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

4. Set the $GOOGLE_APPLICATION_CREDENTIALS$ environment variable to the full path to your service account private key file.

```
$ export GOOGLE_APPLICATION_CREDENTIALS="<your_service_account_file>"
```

5. Verify that the credentials were applied.

```
$ gcloud auth list
```

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

4.6.5. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Google Cloud Platform (GCP).

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster. For a restricted network installation, these files are on your mirror host.

- Have the $imageContentSources$ values that were generated during mirror registry creation.

- Obtain the contents of the certificate for your mirror registry.

Procedure

1. Create the $install-config.yaml$ file.

   a. Change to the directory that contains the installation program and run the following command:

```
$ ./openshift-install create install-config --dir <installation_directory>
```
For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

**IMPORTANT**

Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

b. At the prompts, provide the configuration details for your cloud:

i. Optional: Select an SSH key to use to access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

ii. Select `gcp` as the platform to target.

iii. If you have not configured the service account key for your GCP account on your computer, you must obtain it from GCP and paste the contents of the file or enter the absolute path to the file.

iv. Select the project ID to provision the cluster in. The default value is specified by the service account that you configured.

v. Select the region to deploy the cluster to.

vi. Select the base domain to deploy the cluster to. The base domain corresponds to the public DNS zone that you created for your cluster.

vii. Enter a descriptive name for your cluster.

viii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

2. Edit the `install-config.yaml` file to provide the additional information that is required for an installation in a restricted network.

a. Update the `pullSecret` value to contain the authentication information for your registry:

```yaml
pullSecret: {
  "<mirror_host_name>:5000": {
    "auth": "$<credentials>",
    "email": 
    "you@example.com"
  }
}
```

For `<mirror_host_name>`, specify the registry domain name that you specified in the certificate for your mirror registry, and for `<credentials>`, specify the base64-encoded user name and password for your mirror registry.

b. Add the `additionalTrustBundle` parameter and value.
The value must be the contents of the certificate file that you used for your mirror registry, which can be an existing, trusted certificate authority or the self-signed certificate that you generated for the mirror registry.

c. Define the network and subnets for the VPC to install the cluster in under the parent `platform.gcp` field:

```
network: <existing_vpc>
controlPlaneSubnet: <control_plane_subnet>
computeSubnet: <compute_subnet>
```

For `platform.gcp.network`, specify the name for the existing Google VPC. For `platform.gcp.controlPlaneSubnet` and `platform.gcp.computeSubnet`, specify the existing subnets to deploy the control plane machines and compute machines, respectively.

d. Add the image content resources, which look like this excerpt:

```
imageContentSources:
- mirrors:
  - `<mirror_host_name>:5000/<repo_name>/release`
    source: quay.example.com/openshift-release-dev/ocp-release
  - mirrors:
    - `<mirror_host_name>:5000/<repo_name>/release`
      source: registry.example.com/ocp/release
```

To complete these values, use the `imageContentSources` that you recorded during mirror registry creation.

3. Make any other modifications to the `install-config.yaml` file that you require. You can find more information about the available parameters in the Installation configuration parameters section.

4. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

**IMPORTANT**

The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

### 4.6.5.1. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster’s platform. When you create the `install-config.yaml` installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the `install-config.yaml` file to provide more details about the platform.
NOTE
After installation, you cannot modify these parameters in the `install-config.yaml` file.

IMPORTANT
The `openshift-install` command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

4.6.5.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

Table 4.17. Required parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is v1. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the baseDomain and metadata.name parameter values that uses the <code>&lt;metadata.name&gt;.&lt;baseDomain&gt;</code> format.</td>
<td>A fully-qualified domain or subdomain name, such as <code>example.com</code>.</td>
</tr>
<tr>
<td>metadata</td>
<td>Kubernetes resource <code>ObjectMeta</code>, from which only the <code>name</code> parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of <code>{{.metadata.name}}.{{.baseDomain}}</code>.</td>
<td>String of lowercase letters, hyphens (-), and periods (.), such as <code>dev</code>.</td>
</tr>
</tbody>
</table>
The configuration for the specific platform upon which to perform the installation: **aws**, **baremetal**, **azure**, **openstack**, **ovirt**, **vsphere**. For additional information about **platform.<platform>** parameters, consult the following table for your specific platform.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>platform</td>
<td>The configuration for the specific platform upon which to perform the installation: <strong>aws</strong>, <strong>baremetal</strong>, <strong>azure</strong>, <strong>openstack</strong>, <strong>ovirt</strong>, <strong>vsphere</strong>. For additional information about <strong>platform.&lt;platform&gt;</strong> parameters, consult the following table for your specific platform.</td>
<td>Object</td>
</tr>
</tbody>
</table>

Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.

```json
{
  "auths":{
    "cloud.openshift.com":{
      "auth":"b3Blb=",
      "email":"you@example.com"
    },
    "quay.io":{
      "auth":"b3Blb=",
      "email":"you@example.com"
    }
  }
}
```

### 4.6.5.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

**Table 4.18. Network parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
</tbody>
</table>

**NOTE**

You cannot modify parameters specified by the **networking** object after installation.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking.network Type</td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN.</td>
</tr>
<tr>
<td>networking.clusterNetwork</td>
<td>The IP address blocks for pods. The default value is 10.128.0.0/14 with a host prefix of /23. If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td>An array of objects. For example: networking: clusterNetwork: - cidr: 10.128.0.0/14 hostPrefix: 23</td>
</tr>
<tr>
<td>networking.clusterNetwork.cidr</td>
<td>Required if you use networking.clusterNetwork. An IP address block. An IPv4 network.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td>networking.clusterNetwork.hostPrefix</td>
<td>The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given cidr. A hostPrefix value of 23 provides 510 (2^((32 - 23) - 2)) pod IP addresses.</td>
<td>A subnet prefix. The default value is 23.</td>
</tr>
<tr>
<td>networking.serviceNetwork</td>
<td>The IP address block for services. The default value is 172.30.0.0/16. The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.</td>
<td>An array with an IP address block in CIDR format. For example: networking: serviceNetwork: - 172.30.0.0/16</td>
</tr>
<tr>
<td>networking.machineNetwork</td>
<td>The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td>An array of objects. For example: networking: machineNetwork: - cidr: 10.0.0.0/16</td>
</tr>
</tbody>
</table>
networking.machineNetwork.cidr

Required if you use networking.machineNetwork. An IP address block. The default value is **10.0.0.0/16** for all platforms other than libvirt. For libvirt, the default value is **192.168.126.0/24**.

An IP network block in CIDR notation.
For example, **10.0.0.0/16**.

**NOTE**
Set the networking.machineNetwork to match the CIDR that the preferred NIC resides in.

4.6.5.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

**Table 4.19. Optional parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of machine-pool objects. For details, see the following “Machine-pool” table.</td>
</tr>
<tr>
<td>compute.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <strong>amd64</strong> (the default).</td>
<td>String</td>
</tr>
</tbody>
</table>
Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.

**IMPORTANT**
If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>compute.hyperthreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>compute.name</td>
<td>Required if you use compute. The name of the machine pool.</td>
<td>worker</td>
</tr>
<tr>
<td>compute.platform</td>
<td>Required if you use compute. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the controlPlane.platform parameter value.</td>
<td>aws, azure, gcp, openstack, ovirt, vsphere, or{}</td>
</tr>
<tr>
<td>compute.replicas</td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td>controlPlane</td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of MachinePool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>controlPlane.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are amd64 (the default).</td>
<td>String</td>
</tr>
</tbody>
</table>
### Parameter

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlPlane.hyperthreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>controlPlane.name</td>
<td>Required if you use <code>controlPlane</code>. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use <code>controlPlane</code>. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the <code>compute.platform</code> parameter value.</td>
<td><code>aws</code>, <code>azure</code>, <code>gcp</code>, <code>openstack</code>, <code>ovirt</code>, <code>vsphere</code>, or <code>{}</code></td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
</tbody>
</table>
The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.

NOTE
Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Red Hat Operators reference content.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (&quot;&quot;&quot;).</td>
</tr>
</tbody>
</table>
Enable or disable FIPS mode. The default is `false` (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the `x86_64` architecture.

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>fips</strong></td>
<td>Enable or disable FIPS mode. The default is <code>false</code> (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</td>
<td><code>false</code> or <code>true</code></td>
</tr>
<tr>
<td><strong>imageContentSources</strong></td>
<td>Sources and repositories for the release-image content.</td>
<td>Array of objects. Includes a <code>source</code> and, optionally, <code>mirrors</code>, as described in the following rows of this table.</td>
</tr>
<tr>
<td><strong>imageContentSources.source</strong></td>
<td>Required if you use <code>imageContentSources</code>. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td><strong>imageContentSources.mirrors</strong></td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
<tr>
<td><strong>publish</strong></td>
<td>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</td>
<td><code>Internal</code> or <code>External</code>. To deploy a private cluster, which cannot be accessed from the internet, set <code>publish</code> to <code>Internal</code>. The default value is <code>External</code>.</td>
</tr>
</tbody>
</table>
The SSH key or keys to authenticate access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

One or more keys. For example:

```
sshKey:
  <key1>
  <key2>
  <key3>
```

### 4.6.5.1.4. Additional Google Cloud Platform (GCP) configuration parameters

Additional GCP configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>platform.gcp.network</code></td>
<td>The name of the existing VPC that you want to deploy your cluster to.</td>
<td>String.</td>
</tr>
<tr>
<td><code>platform.gcp.region</code></td>
<td>The name of the GCP region that hosts your cluster.</td>
<td>Any valid region name, such as <code>us-central1</code>.</td>
</tr>
<tr>
<td><code>platform.gcp.type</code></td>
<td>The GCP machine type.</td>
<td>The GCP machine type.</td>
</tr>
<tr>
<td><code>platform.gcp.zones</code></td>
<td>The availability zones where the installation program creates machines for the specified MachinePool.</td>
<td>A list of valid GCP availability zones, such as <code>us-central1-a</code>, in a YAMl sequence.</td>
</tr>
<tr>
<td><code>platform.gcp.controlPlaneSubnet</code></td>
<td>The name of the existing subnet in your VPC that you want to deploy your control plane machines to.</td>
<td>The subnet name.</td>
</tr>
</tbody>
</table>
### Parameter Description Values

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>platform.gcp.computeSubnet</code></td>
<td>The name of the existing subnet in your VPC that you want to deploy your compute machines to.</td>
<td>The subnet name.</td>
</tr>
<tr>
<td><code>platform.gcp.licenses</code></td>
<td>A list of license URLs that must be applied to the compute images.</td>
<td>Any license available with the license API, such as the license to enable nested virtualization. You cannot use this parameter with a mechanism that generates pre-built images. Using a license URL forces the installer to copy the source image before use.</td>
</tr>
<tr>
<td><strong>IMPORTANT</strong></td>
<td>The licenses parameter is a deprecated field and nested virtualization is enabled by default. It is not recommended to use this field.</td>
<td></td>
</tr>
<tr>
<td><code>platform.gcp.osDisk.diskSizeGB</code></td>
<td>The size of the disk in gigabytes (GB).</td>
<td>Any size between 16 GB and 65536 GB.</td>
</tr>
<tr>
<td><code>platform.gcp.osDisk.diskType</code></td>
<td>The type of disk.</td>
<td>Either the default <strong>pd-ssd</strong> or the <strong>pd-standard</strong> disk type. The control plane nodes must be the <strong>pd-ssd</strong> disk type. The worker nodes can be either type.</td>
</tr>
</tbody>
</table>

### 4.6.5.2. Sample customized `install-config.yaml` file for GCP

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

**IMPORTANT**

This sample YAML file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program and modify it.

```yaml
apiVersion: v1
baseDomain: example.com
controlPlane:
  hyperthreading: Enabled
  name: master
platform:
gcp:
```
CHAPTER 4. INSTALLING ON GCP

type: n2-standard-4
zones:
- us-central1-a
- us-central1-c
osDisk:
  diskType: pd-ssd
diskSizeGB: 1024
replicas: 3
compute:
- hyperthreading: Enabled
name: worker
platform:
gcp:
  type: n2-standard-4
  zones:
  - us-central1-a
  - us-central1-c
  osDisk:
    diskType: pd-standard
diskSizeGB: 128
replicas: 3
metadata:
  name: test-cluster
networking:
  clusterNetwork:
  - cidr: 10.128.0.0/14
  hostPrefix: 23
  machineNetwork:
  - cidr: 10.0.0.0/16
  networkType: OpenShiftSDN
  serviceNetwork:
  - 172.30.0.0/16
platform:
gcp:
  projectId: openshift-production
  region: us-central1
  network: existing_vpc
  controlPlaneSubnet: control_plane_subnet
  computeSubnet: compute_subnet
  pullSecret: '{"auths":{"<local_registry>": {"auth": "<credentials>","email": "you@example.com"}}}'}
fips: false
sshKey: ssh-ed25519 AAAA...
additionalTrustBundle: |
  -----BEGIN CERTIFICATE-----
  <MY_TRUSTED_CA_CERT>
  -----END CERTIFICATE-----
imageContentSources:
  - mirrors:
    - <local_registry>/<local_repository_name>/release
      source: quay.io/openshift-release-dev/ocp-release
  - mirrors:
    - <local_registry>/<local_repository_name>/release
      source: quay.io/openshift-release-dev/ocp-v4.0-art-dev
1. **Required.** The installation program prompts you for this value.

2. If you do not provide these parameters and values, the installation program provides the default value.

3. The `controlPlane` section is a single mapping, but the compute section is a sequence of mappings. The `compute` section must begin with a hyphen, `-`, and the `controlPlane` section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

4. Whether to enable or disable simultaneous multithreading, or **hyperthreading**. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to **Disabled**. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

   **IMPORTANT**

   If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger machine types, such as `n1-standard-8`, for your machines if you disable simultaneous multithreading.

5. Specify the name of an existing VPC.

6. Specify the name of the existing subnet to deploy the control plane machines to. The subnet must belong to the VPC that you specified.

7. Specify the name of the existing subnet to deploy the compute machines to. The subnet must belong to the VPC that you specified.

8. For `<local_registry>`, specify the registry domain name, and optionally the port, that your mirror registry uses to serve content. For example, `registry.example.com` or `registry.example.com:5000`. For `<credentials>`, specify the base64-encoded user name and password for your mirror registry.

9. Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

   **IMPORTANT**

   The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the `x86_64` architecture.

10. You can optionally provide the **sshKey** value that you use to access the machines in your cluster.

   **NOTE**

   For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.
Provide the contents of the certificate file that you used for your mirror registry.

Provide the `imageContentSources` section from the output of the command to mirror the repository.

4.6.5.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

Prerequisites

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

NOTE

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port> 1
  httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
  noProxy: example.com 3
additionalTrustBundle: | 4
-----BEGIN CERTIFICATE-----
<MY_TRUSTED_CA_CERT>
-----END CERTIFICATE-----
...
```

1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.

2. A proxy URL to use for creating HTTPS connections outside the cluster.

3. A comma-separated list of destination domain names, IP addresses, or other network

---
4. If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace to hold the additional CA certificates. If you provide

```
NOTE
The installation program does not support the proxy `readinessEndpoints` field.
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

```
NOTE
Only the Proxy object named `cluster` is supported, and no additional proxies can be created.
```

4.6.6. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

```
IMPORTANT
You can run the `create cluster` command of the installation program only once, during initial installation.
```

Prerequisites

- Configure an account with the cloud platform that hosts your cluster.
- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Remove any existing GCP credentials that do not use the service account key for the GCP account that you configured for your cluster and that are stored in the following locations:
   - The `GOOGLE_CREDENTIALS`, `GOOGLE_CLOUD_KEYFILE_JSON`, or `GCLOUD_KEYFILE_JSON` environment variables
   - The `~/.gcp/osServiceAccount.json` file
   - The `gcloud cli` default credentials

2. Change to the directory that contains the installation program and initialize the cluster deployment:

```
$ ./openshift-install create cluster --dir <installation_directory> \  
--log-level=info
```

1. For `<installation_directory>`, specify the location of your customized `.install-config.yaml` file.

2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

**NOTE**

If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.

When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the `kubeadmin` user, display in your terminal.

**Example output**

```
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-Wt5AL".
INFO Time elapsed: 36m22s
```

**NOTE**

The cluster access and credential information also outputs to `<installation_directory>/openshift_install.log` when an installation succeeds.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for *Recovering from expired control plane certificates* for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

**IMPORTANT**

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.
3. Optional: You can reduce the number of permissions for the service account that you used to install the cluster.
   - If you assigned the Owner role to your service account, you can remove that role and replace it with the Viewer role.
   - If you included the Service Account Key Admin role, you can remove it.

4.6.7. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) in order to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.6. Download and install the new version of oc.

4.6.7.1. Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

**Procedure**

2. Select the appropriate version in the Version drop-down menu.
3. Click Download Now next to the OpenShift v4.6 Linux Client entry and save the file.
4. Unpack the archive:

   ```
   $ tar xvzf <file>
   ```

5. Place the oc binary in a directory that is on your PATH.
   To check your PATH, execute the following command:

   ```
   $ echo $PATH
   ```

After you install the OpenShift CLI, it is available using the oc command:

```
$ oc <command>
```}

4.6.7.2. Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.6 Windows Client entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the oc binary to a directory that is on your PATH.
   To check your PATH, open the command prompt and execute the following command:

   ```
   C:\> path
   ```

   After you install the OpenShift CLI, it is available using the oc command:

   ```
   C:\> oc <command>
   ```

### 4.6.7.3. Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.6 MacOSX Client entry and save the file.

4. Unpack and unzip the archive.

5. Move the oc binary to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:

   ```
   $ echo $PATH
   ```

   After you install the OpenShift CLI, it is available using the oc command:

   ```
   $ oc <command>
   ```

### 4.6.8. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster kubeconfig file. The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the oc CLI.

**Procedure**

```csharp
C:\> path
```
1. Export the `kubeadmin` credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   ```bash
   $ oc whoami
   ```

   Example output
   ```
   system:admin
   ```

4.6.9. Disabling the default OperatorHub sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

Procedure

- Disable the sources for the default catalogs by adding `disableAllDefaultSources: true` to the `OperatorHub` object:

  ```bash
  $ oc patch OperatorHub cluster --type json \
  -p '[{"op": "add", "path": "/spec/disableAllDefaultSources", "value": true}]'
  ```

TIP

Alternatively, you can use the web console to manage catalog sources. From the Administration → Cluster Settings → Global Configuration → OperatorHub page, click the Sources tab, where you can create, delete, disable, and enable individual sources.

4.6.10. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.6, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use `subscription watch` to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service

4.6.11. Next steps
• Validate an installation.
• Customize your cluster.
• Configure image streams for the Cluster Samples Operator and the must-gather tool.
• Learn how to use Operator Lifecycle Manager (OLM) on restricted networks.
• If the mirror registry that you used to install your cluster has a trusted CA, add it to the cluster by configuring additional trust stores.
• If necessary, you can opt out of remote health reporting.

4.7. INSTALLING A CLUSTER ON GCP INTO AN EXISTING VPC

In OpenShift Container Platform version 4.6, you can install a cluster into an existing Virtual Private Cloud (VPC) on Google Cloud Platform (GCP). The installation program provisions the rest of the required infrastructure, which you can further customize. To customize the installation, you modify parameters in the install-config.yaml file before you install the cluster.

4.7.1. Prerequisites

• Review details about the OpenShift Container Platform installation and update processes.
• Configure a GCP account to host the cluster.
• If you use a firewall, you must configure it to allow the sites that your cluster requires access to.
• If you do not allow the system to manage identity and access management (IAM), then a cluster administrator can manually create and maintain IAM credentials. Manual mode can also be used in environments where the cloud IAM APIs are not reachable.

4.7.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.6, you require access to the Internet to install your cluster.

You must have Internet access to:

• Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
• Access Quay.io to obtain the packages that are required to install your cluster.
• Obtain the packages that are required to perform cluster updates.

IMPORTANT

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.
4.7.3. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your ssh-agent and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

**NOTE**

In a production environment, you require disaster recovery and debugging.

You can use this key to SSH into the master nodes as the user core. When you deploy the cluster, the key is added to the core user’s ~/.ssh/authorized_keys list.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

**Procedure**

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ ssh-keygen -t ed25519 -N "" \
   -f <path>/<file_name>
   ``

   Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   Running this command generates an SSH key that does not require a password in the location that you specified.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the ssh-agent process as a background task:

   ```
   $ eval "$(ssh-agent -s)"
   ``

   **Example output**

   Agent pid 31874
3. Add your SSH private key to the `ssh-agent`:

   ```bash
   $ ssh-add <path>/<file_name>
   ```

   **Example output**

   ```bash
   Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
   ```

   **1** Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

4. Set the `GOOGLE_APPLICATION_CREDENTIALS` environment variable to the full path to your service account private key file.

   ```bash
   $ export GOOGLE_APPLICATION_CREDENTIALS="<your_service_account_file>"
   ```

5. Verify that the credentials were applied.

   ```bash
   $ gcloud auth list
   ```

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

### 4.7.4. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on a local computer.

**Prerequisites**

- You have a computer that runs Linux or macOS, with 500 MB of local disk space

**Procedure**

1. Access the **Infrastructure Provider** page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

---

**NOTE**

If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.
IMPORTANT

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

IMPORTANT

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   $ tar xvf openshift-install-linux.tar.gz

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

4.7.5. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Google Cloud Platform (GCP).

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure

1. Create the install-config.yaml file.

   a. Change to the directory that contains the installation program and run the following command:

      $ ./openshift-install create install-config --dir <installation_directory> 1

   1 For <installation_directory>, specify the directory name to store the files that the installation program creates.
b. At the prompts, provide the configuration details for your cloud:

i. Optional: Select an SSH key to use to access your cluster machines.

NOTE
For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

ii. Select gcp as the platform to target.

iii. If you have not configured the service account key for your GCP account on your computer, you must obtain it from GCP and paste the contents of the file or enter the absolute path to the file.

iv. Select the project ID to provision the cluster in. The default value is specified by the service account that you configured.

v. Select the region to deploy the cluster to.

vi. Select the base domain to deploy the cluster to. The base domain corresponds to the public DNS zone that you created for your cluster.

vii. Enter a descriptive name for your cluster.

viii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

2. Modify the install-config.yaml file. You can find more information about the available parameters in the Installation configuration parameters section.

3. Back up the install-config.yaml file so that you can use it to install multiple clusters.

IMPORTANT
The install-config.yaml file is consumed during the installation process. If you want to reuse the file, you must back it up now.

4.7.5.1. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster’s platform. When you create the install-config.yaml installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the install-config.yaml file to provide more details about the platform.
NOTE
After installation, you cannot modify these parameters in the `install-config.yaml` file.

IMPORTANT
The `openshift-install` command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

4.7.5.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

Table 4.21. Required parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is v1. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the <code>baseDomain</code> and <code>metadata.name</code> parameter values that uses the <code>&lt;metadata.name&gt;.&lt;baseDomain&gt;</code> format.</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
</tr>
<tr>
<td>metadata</td>
<td>Kubernetes resource <code>ObjectMeta</code>, from which only the <code>name</code> parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of <code>{{.metadata.name}}. {{.baseDomain}}</code>.</td>
<td>String of lowercase letters, hyphens (-), and periods (.), such as dev.</td>
</tr>
</tbody>
</table>
The configuration for the specific platform upon which to perform the installation: **aws, baremetal, azure, openstack, ovirt, vsphere.**

For additional information about platform.<platform> parameters, consult the following table for your specific platform.

### Object

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>pullSecret</td>
<td>Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.</td>
<td><code>{  &quot;auths&quot;:{  &quot;cloud.openshift.com&quot;:{  &quot;auth&quot;:&quot;b3Blb=&quot;,  &quot;email&quot;:&quot;you@example.com&quot;  },  &quot;quay.io&quot;:{  &quot;auth&quot;:&quot;b3Blb=&quot;,  &quot;email&quot;:&quot;you@example.com&quot;  }  }  }</code></td>
</tr>
</tbody>
</table>

#### 4.7.5.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

**Table 4.22. Network parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>

<td>The IP address block for services. The default value is 172.30.0.0/16.</td>
<td>An array with an IP address block in CIDR format. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>networking: serviceNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- 172.30.0.0/16</td>
</tr>
<tr>
<td>networking.machineNetwork</td>
<td>The IP address blocks for machines.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>networking: machineNetwork:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- cidr: 10.0.0.0/16</td>
</tr>
</tbody>
</table>
### Parameter Description Values

**networking.machineNetwork.cidr**

Required if you use `networking.machineNetwork`. An IP address block. The default value is `10.0.0.0/16` for all platforms other than libvirt. For libvirt, the default value is `192.168.126.0/24`.

An IP network block in CIDR notation.

For example, `10.0.0.0/16`.

**NOTE**

Set the `networking.machineNetwork` to match the CIDR that the preferred NIC resides in.

---

#### 4.7.5.13. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

**Table 4.23. Optional parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>additionalTrustBundle</code></td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes' trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td><code>compute</code></td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of machine-pool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td><code>compute.architecture</code></td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
</tbody>
</table>
Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>compute.hyperthreading</code></td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td><code>compute.name</code></td>
<td>Required if you use <code>compute</code>. The name of the machine pool.</td>
<td>worker</td>
</tr>
<tr>
<td><code>compute.platform</code></td>
<td>Required if you use <code>compute</code>. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <code>controlPlane.platform</code> parameter value.</td>
<td>aws, azure, gcp, openstack, ovirt, vsphere, or{}</td>
</tr>
<tr>
<td><code>compute.replicas</code></td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td><code>controlPlane</code></td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of MachinePool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td><code>controlPlane.architecture</code></td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-----------------------------</td>
</tr>
<tr>
<td><code>controlPlane.hypertreading</code></td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td></td>
</tr>
<tr>
<td><code>controlPlane.name</code></td>
<td>Required if you use <code>controlPlane</code>. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td><code>controlPlane.platform</code></td>
<td>Required if you use <code>controlPlane</code>. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the <code>compute.platform</code> parameter value.</td>
<td><code>aws, azure, gcp, openstack, ovirt, vsphere, {}</code></td>
</tr>
<tr>
<td><code>controlPlane.replicas</code></td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>--------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------</td>
</tr>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (“”).</td>
</tr>
</tbody>
</table>

**NOTE**

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Red Hat Operators reference content.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>fips</td>
<td>Enable or disable FIPS mode. The default is false (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.</td>
<td>false or true</td>
</tr>
</tbody>
</table>

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.

<table>
<thead>
<tr>
<th>imageContentSources</th>
<th>Sources and repositories for the release–image content.</th>
<th>Array of objects. Includes a source and, optionally, mirrors, as described in the following rows of this table.</th>
</tr>
</thead>
<tbody>
<tr>
<td>imageContentSources.source</td>
<td>Required if you use imageContentSources. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td>imageContentSources.mirrors</td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
<tr>
<td>publish</td>
<td>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</td>
<td>Internal or External. To deploy a private cluster, which cannot be accessed from the internet, set publish to Internal. The default value is External.</td>
</tr>
</tbody>
</table>
### sshKey

The SSH key or keys to authenticate access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

One or more keys. For example:

```
sshKey:
  <key1>
  <key2>
  <key3>
```

### 4.7.5.1.4. Additional Google Cloud Platform (GCP) configuration parameters

Additional GCP configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>platform.gcp.network</code></td>
<td>The name of the existing VPC that you want to deploy your cluster to.</td>
<td>String.</td>
</tr>
<tr>
<td><code>platform.gcp.region</code></td>
<td>The name of the GCP region that hosts your cluster.</td>
<td>Any valid region name, such as <code>us-central1</code>.</td>
</tr>
<tr>
<td><code>platform.gcp.type</code></td>
<td>The GCP machine type.</td>
<td>The GCP machine type.</td>
</tr>
<tr>
<td><code>platform.gcp.zones</code></td>
<td>The availability zones where the installation program creates machines for the specified MachinePool.</td>
<td>A list of valid GCP availability zones, such as <code>us-central1-a</code>, in a YAML sequence.</td>
</tr>
<tr>
<td><code>platform.gcp.controlPlaneSubnet</code></td>
<td>The name of the existing subnet in your VPC that you want to deploy your control plane machines to.</td>
<td>The subnet name.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td>platform.gcp.computeSubnet</td>
<td>The name of the existing subnet in your VPC that you want to deploy your compute machines to.</td>
<td>The subnet name.</td>
</tr>
<tr>
<td>platform.gcp.licenses</td>
<td>A list of license URLs that must be applied to the compute images.</td>
<td>Any license available with the license API, such as the license to enable nested virtualization. You cannot use this parameter with a mechanism that generates pre-built images. Using a license URL forces the installer to copy the source image before use.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

The `licenses` parameter is a deprecated field and nested virtualization is enabled by default. It is not recommended to use this field.

<table>
<thead>
<tr>
<th>platform.gcp.osDisk.diskSizeG</th>
<th>The size of the disk in gigabytes (GB).</th>
<th>Any size between 16 GB and 65536 GB.</th>
</tr>
</thead>
<tbody>
<tr>
<td>platform.gcp.osDisk.diskType</td>
<td>The type of disk.</td>
<td>Either the default <code>pd-ssd</code> or the <code>pd-standard</code> disk type. The control plane nodes must be the <code>pd-ssd</code> disk type. The worker nodes can be either type.</td>
</tr>
</tbody>
</table>

### 4.7.5.2. Sample customized install-config.yaml file for GCP

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

**IMPORTANT**

This sample YAML file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program and modify it.

```yaml
apiVersion: v1
baseDomain: example.com
controlPlane:
hyperthreading: Enabled
name: master
platform:
gcp:
```
Required. The installation program prompts you for this value.

If you do not provide these parameters and values, the installation program provides the default value.

The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, `-`, and the first line of the controlPlane section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.
Whether to enable or disable simultaneous multithreading, or hyperthreading. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You

IMPORTANT
If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger machine types, such as **n1-standard-8**, for your machines if you disable simultaneous multithreading.

Specify the name of an existing VPC.

Specify the name of the existing subnet to deploy the control plane machines to. The subnet must belong to the VPC that you specified.

Specify the name of the existing subnet to deploy the compute machines to. The subnet must belong to the VPC that you specified.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

IMPORTANT
The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

You can optionally provide the `sshKey` value that you use to access the machines in your cluster.

NOTE
For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

4.7.5.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

Prerequisites

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.
NOTE

The Proxy object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port> 1
  httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
  noProxy: example.com 3
additionalTrustBundle: |
  -----BEGIN CERTIFICATE-----
  <MY_TRUSTED_CA_CERT>
  -----END CERTIFICATE-----
... 4
```

1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.

2. A proxy URL to use for creating HTTPS connections outside the cluster.

3. A comma-separated list of destination domain names, IP addresses, or other network CIDRS to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.

4. If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace to hold the additional CA certificates. If you provide `additionalTrustBundle` and at least one proxy setting, the Proxy object is configured to reference the `user-ca-bundle` config map in the `trustedCA` field. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges the contents specified for the `trustedCA` parameter with the RH COS trust bundle. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RH COS trust bundle.

NOTE

The installation program does not support the proxy `readinessEndpoints` field.

2. Save the file and reference it when installing OpenShift Container Platform.
The installation program creates a cluster-wide proxy that is named **cluster** that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a **cluster Proxy** object is still created, but it will have a nil **spec**.

**NOTE**

Only the **Proxy** object named **cluster** is supported, and no additional proxies can be created.

### 4.7.6. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the **create cluster** command of the installation program only once, during initial installation.

**Prerequisites**

- Configure an account with the cloud platform that hosts your cluster.
- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Remove any existing GCP credentials that do not use the service account key for the GCP account that you configured for your cluster and that are stored in the following locations:
   - The `GOOGLE_CREDENTIALS`, `GOOGLE_CLOUD_KEYFILE_JSON`, or `GCLOUD_KEYFILE_JSON` environment variables
   - The `~/.gcp/osServiceAccount.json` file
   - The `gcloud cli` default credentials

2. Change to the directory that contains the installation program and initialize the cluster deployment:

   ```shell
   $ ./openshift-install create cluster --dir <installation_directory> \ 1
   --log-level=info 2
   ```

   1. For `<installation_directory>`, specify the location of your customized `./install-config.yaml` file.
   2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

**NOTE**

If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.
When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the **kubeadmin** user, display in your terminal.

**Example output**

```
... 
INFO Install complete! 
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-Wt5AL"
INFO Time elapsed: 36m22s
```

**NOTE**

The cluster access and credential information also outputs to `<installation_directory>/.openshift_install.log` when an installation succeeds.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

**IMPORTANT**

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

3. Optional: You can reduce the number of permissions for the service account that you used to install the cluster.

- If you assigned the **Owner** role to your service account, you can remove that role and replace it with the **Viewer** role.

- If you included the **Service Account Key Admin** role, you can remove it.

### 4.7.7. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (**oc**) in order to interact with OpenShift Container Platform from a command-line interface. You can install **oc** on Linux, Windows, or macOS.
4.7.7.1. Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.
3. Click Download Now next to the OpenShift v4.6 Linux Client entry and save the file.
4. Unpack the archive:
   $ tar xvzf <file>
5. Place the oc binary in a directory that is on your PATH.
   To check your PATH, execute the following command:
   $ echo $PATH

After you install the OpenShift CLI, it is available using the oc command:

$ oc <command>

4.7.7.2. Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.
3. Click Download Now next to the OpenShift v4.6 Windows Client entry and save the file.
4. Unzip the archive with a ZIP program.
5. Move the oc binary to a directory that is on your PATH.
   To check your PATH, open the command prompt and execute the following command:
   C:\> path

After you install the OpenShift CLI, it is available using the oc command:
4.7.7.3. Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.
3. Click Download Now next to the OpenShift v4.6 MacOSX Client entry and save the file.
4. Unpack and unzip the archive.
5. Move the oc binary to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:

   $ echo $PATH

After you install the OpenShift CLI, it is available using the oc command:

$ oc <command>

4.7.8. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster kubeconfig file. The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the oc CLI.

Procedure

1. Export the kubeadmin credentials:

   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig

   For <installation_directory>, specify the path to the directory that you stored the installation files in.

2. Verify you can run oc commands successfully using the exported configuration:

   $ oc whoami
Example output

```
  system:admin
```

Additional resources

- See [Accessing the web console](#) for more details about accessing and understanding the OpenShift Container Platform web console.

### 4.7.9. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.6, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to [OpenShift Cluster Manager](#).

After you confirm that your [OpenShift Cluster Manager](#) inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use `subscription watch` to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See [About remote health monitoring](#) for more information about the Telemetry service

### 4.7.10. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.

### 4.8. INSTALLING A PRIVATE CLUSTER ON GCP

In OpenShift Container Platform version 4.6, you can install a private cluster into an existing VPC on Google Cloud Platform (GCP). The installation program provisions the rest of the required infrastructure, which you can further customize. To customize the installation, you modify parameters in the `install-config.yaml` file before you install the cluster.

#### 4.8.1. Prerequisites

- Review details about the OpenShift Container Platform installation and update processes.
- Configure a GCP account to host the cluster.
- If you use a firewall, you must configure it to allow the sites that your cluster requires access to.
- If you do not allow the system to manage identity and access management (IAM), then a cluster administrator can manually create and maintain IAM credentials. Manual mode can also be used in environments where the cloud IAM APIs are not reachable.

#### 4.8.2. Private clusters

You can deploy a private OpenShift Container Platform cluster that does not expose external endpoints. Private clusters are accessible from only an internal network and are not visible to the Internet.
By default, OpenShift Container Platform is provisioned to use publicly-accessible DNS and endpoints. A private cluster sets the DNS, Ingress Controller, and API server to private when you deploy your cluster. This means that the cluster resources are only accessible from your internal network and are not visible to the internet.

To deploy a private cluster, you must use existing networking that meets your requirements. Your cluster resources might be shared between other clusters on the network.

Additionally, you must deploy a private cluster from a machine that has access the API services for the cloud you provision to, the hosts on the network that you provision, and to the internet to obtain installation media. You can use any machine that meets these access requirements and follows your company’s guidelines. For example, this machine can be a bastion host on your cloud network or a machine that has access to the network through a VPN.

4.8.2.1. Private clusters in GCP

To create a private cluster on Google Cloud Platform (GCP), you must provide an existing private VPC and subnets to host the cluster. The installation program must also be able to resolve the DNS records that the cluster requires. The installation program configures the Ingress Operator and API server for only internal traffic.

The cluster still requires access to Internet to access the GCP APIs.

The following items are not required or created when you install a private cluster:

- Public subnets
- Public network load balancers, which support public ingress
- A public DNS zone that matches the `baseDomain` for the cluster

The installation program does use the `baseDomain` that you specify to create a private DNS zone and the required records for the cluster. The cluster is configured so that the Operators do not create public records for the cluster and all cluster machines are placed in the private subnets that you specify.

Because it is not possible to limit access to external load balancers based on source tags, the private cluster uses only internal load balancers to allow access to internal instances.

The internal load balancer relies on instance groups rather than the target pools that the network load balancers use. The installation program creates instance groups for each zone, even if there is no instance in that group.

- The cluster IP address is internal only.
- One forwarding rule manages both the Kubernetes API and machine config server ports.
- The backend service is comprised of each zone’s instance group and, while it exists, the bootstrap instance group.
- The firewall uses a single rule that is based on only internal source ranges.

4.8.2.1.1. Limitations

No health check for the Machine config server, `/healthz`, runs because of a difference in load balancer functionality. Two internal load balancers cannot share a single IP address, but two network load balancers can share a single external IP address. Instead, the health of an instance is determined entirely by the `/readyz` check on port 6443.
4.8.3. About using a custom VPC

In OpenShift Container Platform 4.6, you can deploy a cluster into an existing VPC in Google Cloud Platform (GCP). If you do, you must also use existing subnets within the VPC and routing rules.

By deploying OpenShift Container Platform into an existing GCP VPC, you might be able to avoid limit constraints in new accounts or more easily abide by the operational constraints that your company’s guidelines set. This is a good option to use if you cannot obtain the infrastructure creation permissions that are required to create the VPC yourself.

4.8.3.1. Requirements for using your VPC

The installation program will no longer create the following components:

- VPC
- Subnets
- Cloud router
- Cloud NAT
- NAT IP addresses

If you use a custom VPC, you must correctly configure it and its subnets for the installation program and the cluster to use. The installation program cannot subdivide network ranges for the cluster to use, set route tables for the subnets, or set VPC options like DHCP, so you must do so before you install the cluster.

Your VPC and subnets must meet the following characteristics:

- The VPC must be in the same GCP project that you deploy the OpenShift Container Platform cluster to.
- To allow access to the Internet from the control plane and compute machines, you must configure cloud NAT on the subnets to allow egress to it. These machines do not have a public address. Even if you do not require access to the Internet, you must allow egress to the VPC network to obtain the installation program and images. Because multiple cloud NATs cannot be configured on the shared subnets, the installation program cannot configure it.

To ensure that the subnets that you provide are suitable, the installation program confirms the following data:

- All the subnets that you specify exist and belong to the VPC that you specified.
- The subnet CIDRs belong to the machine CIDR.
- You must provide a subnet to deploy the cluster control plane and compute machines to. You can use the same subnet for both machine types.

If you destroy a cluster that uses an existing VPC, the VPC is not deleted.

4.8.3.2. Division of permissions

Starting with OpenShift Container Platform 4.3, you do not need all of the permissions that are required for an installation program-provisioned infrastructure cluster to deploy a cluster. This change mimics the division of permissions that you might have at your company: some individuals can create different
resources in your clouds than others. For example, you might be able to create application-specific items, like instances, buckets, and load balancers, but not networking-related components such as VPCs, subnets, or Ingress rules.

The GCP credentials that you use when you create your cluster do not need the networking permissions that are required to make VPCs and core networking components within the VPC, such as subnets, routing tables, internet gateways, NAT, and VPN. You still need permission to make the application resources that the machines within the cluster require, such as load balancers, security groups, storage, and nodes.

4.8.3.3. Isolation between clusters

If you deploy OpenShift Container Platform to an existing network, the isolation of cluster services is preserved by firewall rules that reference the machines in your cluster by the cluster’s infrastructure ID. Only traffic within the cluster is allowed.

If you deploy multiple clusters to the same VPC, the following components might share access between clusters:

- The API, which is globally available with an external publishing strategy or available throughout the network in an internal publishing strategy
- Debugging tools, such as ports on VM instances that are open to the machine CIDR for SSH and ICMP access

4.8.4. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.6, you require access to the Internet to install your cluster.

You must have Internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

4.8.5. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your ssh-agent and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.
NOTE
In a production environment, you require disaster recovery and debugging.

You can use this key to SSH into the master nodes as the user core. When you deploy the cluster, the key is added to the core user’s ~/.ssh/authorized_keys list.

NOTE
You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

Procedure

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   $ ssh-keygen -t ed25519 -N " \n   -f <path>/<file_name>  

   Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   Running this command generates an SSH key that does not require a password in the location that you specified.

   NOTE
   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the ssh-agent process as a background task:

   $ eval "$(ssh-agent -s)"

   Example output

   Agent pid 31874

   NOTE
   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the ssh-agent:

   $ ssh-add <path>/<file_name>  

   1
Example output

Identity added: /home/<you>/<path>/<file_name> (<computer_name>)

1. Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa

4. Set the `GOOGLE_APPLICATION_CREDENTIALS` environment variable to the full path to your service account private key file.

   $ export GOOGLE_APPLICATION_CREDENTIALS="<your_service_account_file>"

5. Verify that the credentials were applied.

   $ gcloud auth list

Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

4.8.6. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on a local computer.

Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

   IMPORTANT

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   IMPORTANT

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.
4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```bash
$ tar xvf openshift-install-linux.tar.gz
```

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

### 4.8.7. Manually creating the installation configuration file

For installations of a private OpenShift Container Platform cluster that are only accessible from an internal network and are not visible to the Internet, you must manually generate your installation configuration file.

**Prerequisites**

- Obtain the OpenShift Container Platform installation program and the access token for your cluster.

**Procedure**

1. Create an installation directory to store your required installation assets in:

   ```bash
   $ mkdir <installation_directory>
   ```

   **IMPORTANT**

   You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the following `install-config.yaml` file template and save it in the `<installation_directory>`.

   **NOTE**

   You must name this configuration file `install-config.yaml`.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

   **IMPORTANT**

   The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.

### 4.8.7.1. Installation configuration parameters
Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster’s platform. When you create the `install-config.yaml` installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the `install-config.yaml` file to provide more details about the platform.

**NOTE**

After installation, you cannot modify these parameters in the `install-config.yaml` file.

**IMPORTANT**

The `openshift-install` command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

### 4.8.7.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

**Table 4.25. Required parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is v1. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the <code>baseDomain</code> and <code>metadata.name</code> parameter values that uses the <code>&lt;metadata.name&gt;</code>.&lt;br&gt;<code>&lt;baseDomain&gt;</code> format.</td>
<td>A fully-qualified domain or subdomain name, such as <code>example.com</code>.</td>
</tr>
<tr>
<td>metadata</td>
<td>Kubernetes resource <code>ObjectMeta</code>, from which only the <code>name</code> parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>---------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------</td>
</tr>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of</td>
<td>String of lowercase letters, hyphens (-), and periods (.), such as dev.</td>
</tr>
<tr>
<td></td>
<td>{{.metadata.name}}. {{.baseDomain}}.</td>
<td></td>
</tr>
<tr>
<td>platform</td>
<td>The configuration for the specific platform upon which to perform the</td>
<td>Object</td>
</tr>
<tr>
<td></td>
<td>installation: aws, baremetal, azure, openstack, ovirt, vsphere. For</td>
<td></td>
</tr>
<tr>
<td></td>
<td>additional information about platform.&lt;platform&gt; parameters, consult the</td>
<td></td>
</tr>
<tr>
<td></td>
<td>following table for your specific platform.</td>
<td></td>
</tr>
<tr>
<td>pullSecret</td>
<td>Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate</td>
<td>{</td>
</tr>
<tr>
<td></td>
<td>downloading container images for OpenShift Container Platform components</td>
<td>&quot;auths&quot;:{</td>
</tr>
<tr>
<td></td>
<td>from services such as Quay.io.</td>
<td>&quot;cloud.openshift.com&quot;:{</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;auth&quot;:&quot;b3Blb=&quot;&quot;,</td>
</tr>

</tr>
</tbody>
</table>

4.8.7.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

Table 4.26. Network parameters
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td></td>
<td></td>
<td>NOTE</td>
</tr>
<tr>
<td></td>
<td></td>
<td>You cannot modify parameters specified by the <code>networking</code> object after installation.</td>
</tr>
<tr>
<td>networking.networkType</td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN.</td>
</tr>
<tr>
<td>networking.clusterNetwork</td>
<td>The IP address blocks for pods.</td>
<td>An array of objects. For example:</td>
</tr>
</tbody>
</table>
|                               |                                                                              | networking:
|                               |                                                                              |   clusterNetwork:
|                               |                                                                              |     cidr: 10.128.0.0/14
|                               |                                                                              |     hostPrefix: 23                                                     |
| networking.clusterNetwork.cidr| Required if you use `networking.clusterNetwork`. An IP address block.        | An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32. |
|                               |                                                                              | An IPv4 network.                                                      |
|                               |                                                                              |                                                                       |
|                               | The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given cidr. A hostPrefix value of 23 provides 510 (2^(32 – 23) – 2) pod IP addresses. | A subnet prefix.                                                      |
|                               |                                                                              | The default value is 23.                                              |
| networking.serviceNetwork     | The IP address block for services. The default value is 172.30.0.0/16.       | An array with an IP address block in CIDR format. For example:         |
|                               |                                                                              | networking:
|                               |                                                                              |   serviceNetwork:
|                               |                                                                              |     - 172.30.0.0/16                                                    |
### networking.machine

The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap.

**Values**

An array of objects. For example:

```json
networking:
  machineNetwork:
    - cidr: 10.0.0.0/16
```

### networking.machineNetwork.cidr

Required if you use `networking.machineNetwork`. An IP address block. The default value is `10.0.0.0/16` for all platforms other than libvirt. For libvirt, the default value is `192.168.126.0/24`.

**Values**

An IP network block in CIDR notation.

For example, `10.0.0.0/16`.

**NOTE**

Set the `networking.machineNetwork` to match the CIDR that the preferred NIC resides in.

---

### 4.8.7.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of machine-pool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>compute.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
</tbody>
</table>
Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>compute.hyperthreading</code></td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td><code>compute.name</code></td>
<td>Required if you use <code>compute</code>. The name of the machine pool.</td>
<td>worker</td>
</tr>
<tr>
<td><code>compute.platform</code></td>
<td>Required if you use <code>compute</code>. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <code>controlPlane.platform</code> parameter value.</td>
<td>aws, azure, gcp, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td><code>compute.replicas</code></td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to 2. The default value is 3.</td>
</tr>
<tr>
<td><code>controlPlane</code></td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of <code>MachinePool</code> objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td><code>controlPlane.architecture</code></td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
</tbody>
</table>
Whether to enable or disable simultaneous multithreading, or hyperthreading, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.

**IMPORTANT**
If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>controlPlane.hypertreading</td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>controlPlane.name</td>
<td>Required if you use controlPlane. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use controlPlane. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the compute.platform parameter value.</td>
<td>aws, azure, gcp, openstack, ovirt, vsphere, or {}</td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
</tbody>
</table>
The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.

**NOTE**

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Red Hat Operators reference content.

---

<table>
<thead>
<tr>

<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>credentialsMode</td>
<td>The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.</td>
<td>Mint, Passthrough, Manual, or an empty string (&quot;&quot;').</td>
</tr>
</tbody>
</table>
Enable or disable FIPS mode. The default is false (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.

<td>Array of strings</td>
</tr>
</tbody>
</table>
### publish

How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.

**Internal** or **External**. To deploy a private cluster, which cannot be accessed from the internet, set `publish` to **Internal**. The default value is **External**.

### sshKey

The SSH key or keys to authenticate access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

One or more keys. For example:

```plaintext
sshKey:
  <key1>
  <key2>
  <key3>
```

---

### 4.8.7.14. Additional Google Cloud Platform (GCP) configuration parameters

Additional GCP configuration parameters are described in the following table:

#### Table 4.28. Additional GCP parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>platform.gcp.network</code></td>
<td>The name of the existing VPC that you want to deploy your cluster to.</td>
<td>String.</td>
</tr>
<tr>
<td><code>platform.gcp.region</code></td>
<td>The name of the GCP region that hosts your cluster.</td>
<td>Any valid region name, such as <code>us-central1</code>.</td>
</tr>
<tr>
<td><code>platform.gcp.type</code></td>
<td>The GCP machine type.</td>
<td>The GCP machine type.</td>
</tr>
<tr>
<td><code>platform.gcp.zones</code></td>
<td>The availability zones where the installation program creates machines for the specified MachinePool.</td>
<td>A list of valid GCP availability zones, such as <code>us-central1-a</code>, in a YAML sequence.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td>platform.gcp.controlPlaneSubnet</td>
<td>The name of the existing subnet in your VPC that you want to deploy your control plane machines to.</td>
<td>The subnet name.</td>
</tr>
<tr>
<td>platform.gcp.computeSubnet</td>
<td>The name of the existing subnet in your VPC that you want to deploy your compute machines to.</td>
<td>The subnet name.</td>
</tr>
<tr>
<td>platform.gcp.licenses</td>
<td>A list of license URLs that must be applied to the compute images. IMPORTANT The licenses parameter is a deprecated field and nested virtualization is enabled by default. It is not recommended to use this field.</td>
<td>Any license available with the license API, such as the license to enable nested virtualization. You cannot use this parameter with a mechanism that generates pre-built images. Using a license URL forces the installer to copy the source image before use.</td>
</tr>
<tr>
<td>platform.gcp.osDisk.diskSizeGB</td>
<td>The size of the disk in gigabytes (GB).</td>
<td>Any size between 16 GB and 65536 GB.</td>
</tr>
<tr>
<td>platform.gcp.osDisk.diskType</td>
<td>The type of disk.</td>
<td>Either the default pd-ssd or the pd-standard disk type. The control plane nodes must be the pd-ssd disk type. The worker nodes can be either type.</td>
</tr>
</tbody>
</table>

### 4.8.7.2. Sample customized install-config.yaml file for GCP

You can customize the install-config.yaml file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.

**IMPORTANT**

This sample YAML file is provided for reference only. You must obtain your install-config.yaml file by using the installation program and modify it.
apiVersion: v1
baseDomain: example.com
controlPlane:
  hyperthreading: Enabled
  name: master
  platform:
    gcp:
      type: n2-standard-4
      zones:
        - us-central1-a
        - us-central1-c
      osDisk:
        diskType: pd-ssd
        diskSizeGB: 1024
      replicas: 3
compute:
  - hyperthreading: Enabled
  name: worker
  platform:
    gcp:
      type: n2-standard-4
      zones:
        - us-central1-a
        - us-central1-c
      osDisk:
        diskType: pd-standard
        diskSizeGB: 128
      replicas: 3
metadata:
  name: test-cluster
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
  hostPrefix: 23
  machineNetwork:
    - cidr: 10.0.0.0/16
  networkType: OpenShiftSDN
  serviceNetwork:
    - 172.30.0.0/16
platform:
  gcp:
    region: us-central1
    network: existing_vpc
    controlPlaneSubnet: control_plane_subnet
    computeSubnet: compute_subnet
  pullSecret: '{"auths": ...}'
fips: false
sshKey: ssh-ed25519 AAAA...
publish: Internal

Required. The installation program prompts you for this value.
2. If you do not provide these parameters and values, the installation program provides the default value.

3. The controlPlane section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the compute section must begin with a hyphen, -, and the first line of the controlPlane section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

4. Whether to enable or disable simultaneous multithreading, or hyperthreading. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores. You can disable it by setting the parameter value to Disabled. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

   IMPORTANT

   If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger machine types, such as n1-standard-8, for your machines if you disable simultaneous multithreading.

5. Specify the name of an existing VPC.

6. Specify the name of the existing subnet to deploy the control plane machines to. The subnet must belong to the VPC that you specified.

7. Specify the name of the existing subnet to deploy the compute machines to. The subnet must belong to the VPC that you specified.

8. Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

   IMPORTANT

   The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

9. You can optionally provide the sshKey value that you use to access the machines in your cluster.

   NOTE

   For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

10. How to publish the user-facing endpoints of your cluster. Set publish to Internal to deploy a private cluster, which cannot be accessed from the Internet. The default value is External.

4.8.7.3. Configuring the cluster-wide proxy during installation
Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**Prerequisites**

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

**Procedure**

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
     httpProxy: http://<username>:<pswd>@<ip>:<port>  
     httpsProxy: https://<username>:<pswd>@<ip>:<port>  
     noProxy: example.com
   additionalTrustBundle: | 
     -----BEGIN CERTIFICATE-----
     <MY_TRUSTED_CA_CERT>
     -----END CERTIFICATE-----
   ...
   ``

   - A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.
   - A proxy URL to use for creating HTTPS connections outside the cluster.
   - A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, `.y.com` matches `x.y.com`, but not `y.com`. Use * to bypass the proxy for all destinations.
   - If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace to hold the additional CA certificates. If you provide `additionalTrustBundle` and at least one proxy setting, the `Proxy` object is configured to reference the `user-ca-bundle` config map in the `trustedCA` field. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges the contents.
specified for the trustedCA parameter with the RHCOS trust bundle. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

**NOTE**

The installation program does not support the proxy readinessEndpoints field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

**NOTE**

Only the Proxy object named cluster is supported, and no additional proxies can be created.

### 4.8.8. Deploying the cluster

You can install OpenShift Container Platform on a compatible cloud platform.

**IMPORTANT**

You can run the create cluster command of the installation program only once, during initial installation.

**Prerequisites**

- Configure an account with the cloud platform that hosts your cluster.
- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

**Procedure**

1. Change to the directory that contains the installation program and initialize the cluster deployment:

```
$ ./openshift-install create cluster --dir <installation_directory> \ 1
--log-level=info 2
```

   1 For <installation_directory>, specify the
   2 To view different installation details, specify warn, debug, or error instead of info.
NOTE

If the cloud provider account that you configured on your host does not have sufficient permissions to deploy the cluster, the installation process stops, and the missing permissions are displayed.

When the cluster deployment completes, directions for accessing your cluster, including a link to its web console and credentials for the kubeadmin user, display in your terminal.

Example output

```
INFO Install complete!
INFO To access the cluster as the system:admin user when using 'oc', run 'export KUBECONFIG=/home/myuser/install_dir/auth/kubeconfig'
INFO Access the OpenShift web-console here: https://console-openshift-console.apps.mycluster.example.com
INFO Login to the console with user: "kubeadmin", and password: "4vYBz-Ee6gm-ymBZj-Wi5AL"
INFO Time elapsed: 36m22s
```

NOTE

The cluster access and credential information also outputs to `<installation_directory>/openshift_install.log` when an installation succeeds.

IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

IMPORTANT

You must not delete the installation program or the files that the installation program creates. Both are required to delete the cluster.

4.8.9. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) in order to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.
**IMPORTANT**

If you installed an earlier version of `oc`, you cannot use it to complete all of the commands in OpenShift Container Platform 4.6. Download and install the new version of `oc`.

### 4.8.9.1. Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (`oc`) binary on Linux by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.

3. Click **Download Now** next to the **OpenShift v4.6 Linux Client** entry and save the file.

4. Unpack the archive:

   ```
   $ tar xvzf <file>
   ```

5. Place the `oc` binary in a directory that is on your **PATH**.
   
   To check your **PATH**, execute the following command:

   ```
   $ echo $PATH
   ```

After you install the OpenShift CLI, it is available using the `oc` command:

```
$ oc <command>
```
4.8.9.3. Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.6 MacOSX Client entry and save the file.

4. Unpack and unzip the archive.

5. Move the oc binary to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:
   
   ```
   $ echo $PATH
   ```

After you install the OpenShift CLI, it is available using the oc command:

```
$ oc <command>
```

4.8.10. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster kubeconfig file. The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the oc CLI.

Procedure

1. Export the kubeadmin credentials:

   ```
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run oc commands successfully using the exported configuration:

   ```
   $ oc whoami
   ```
4.8.11. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.6, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources

- See About remote health monitoring for more information about the Telemetry service

4.8.12. Next steps

- Customize your cluster.
- If necessary, you can opt out of remote health reporting.

4.9. INSTALLING A CLUSTER ON USER-PROVISIONED INFRASTRUCTURE IN GCP BY USING DEPLOYMENT MANAGER TEMPLATES

In OpenShift Container Platform version 4.6, you can install a cluster on Google Cloud Platform (GCP) that uses infrastructure that you provide.

The steps for performing a user-provided infrastructure install are outlined here. Several Deployment Manager templates are provided to assist in completing these steps or to help model your own. You are also free to create the required resources through other methods.

**IMPORTANT**

The steps for performing a user-provisioned infrastructure installation are provided as an example only. Installing a cluster with infrastructure you provide requires knowledge of the cloud provider and the installation process of OpenShift Container Platform. Several Deployment Manager templates are provided to assist in completing these steps or to help model your own. You are also free to create the required resources through other methods; the templates are just an example.

4.9.1. Prerequisites

- Review details about the OpenShift Container Platform installation and update processes.
If you use a firewall and plan to use telemetry, you must configure the firewall to allow the sites that your cluster requires access to.

If you do not allow the system to manage identity and access management (IAM), then a cluster administrator can manually create and maintain IAM credentials. Manual mode can also be used in environments where the cloud IAM APIs are not reachable.

NOTE
Be sure to also review this site list if you are configuring a proxy.

4.9.2. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The kube-controller-manager only approves the kubelet client CSRs. The machine-approver cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

4.9.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.6, you require access to the Internet to install your cluster.

You must have Internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.

- Access Quay.io to obtain the packages that are required to install your cluster.

- Obtain the packages that are required to perform cluster updates.

IMPORTANT

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

4.9.4. Configuring your GCP project

Before you can install OpenShift Container Platform, you must configure a Google Cloud Platform (GCP) project to host it.

4.9.4.1. Creating a GCP project

To install OpenShift Container Platform, you must create a project in your Google Cloud Platform (GCP) account to host the cluster.
Procedure

- Create a project to host your OpenShift Container Platform cluster. See Creating and Managing Projects in the GCP documentation.

**IMPORTANT**

Your GCP project must use the Premium Network Service Tier if you are using installer-provisioned infrastructure. The Standard Network Service Tier is not supported for clusters installed using the installation program. The installation program configures internal load balancing for the `api-int.<cluster_name>.<base_domain>` URL; the Premium Tier is required for internal load balancing.

### 4.9.4.2. Enabling API services in GCP

Your Google Cloud Platform (GCP) project requires access to several API services to complete OpenShift Container Platform installation.

**Prerequisites**

- You created a project to host your cluster.

**Procedure**

- Enable the following required API services in the project that hosts your cluster. See Enabling services in the GCP documentation.

<table>
<thead>
<tr>
<th>API service</th>
<th>Console service name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cloud Deployment Manager V2 API</td>
<td>deploymentmanager.googleapis.com</td>
</tr>
<tr>
<td>Compute Engine API</td>
<td>compute.googleapis.com</td>
</tr>
<tr>
<td>Google Cloud APIs</td>
<td>cloudapis.googleapis.com</td>
</tr>
<tr>
<td>Cloud Resource Manager API</td>
<td>cloudresourcemanager.googleapis.com</td>
</tr>
<tr>
<td>Google DNS API</td>
<td>dns.googleapis.com</td>
</tr>
<tr>
<td>IAM Service Account Credentials API</td>
<td>iamcredentials.googleapis.com</td>
</tr>
<tr>
<td>Identity and Access Management (IAM) API</td>
<td>iam.googleapis.com</td>
</tr>
<tr>
<td>Service Management API</td>
<td>servicemanagement.googleapis.com</td>
</tr>
<tr>
<td>Service Usage API</td>
<td>serviceusage.googleapis.com</td>
</tr>
<tr>
<td>Google Cloud Storage JSON API</td>
<td>storage-api.googleapis.com</td>
</tr>
</tbody>
</table>
4.9.4.3. Configuring DNS for GCP

To install OpenShift Container Platform, the Google Cloud Platform (GCP) account you use must have a dedicated public hosted zone in the same project that you host the OpenShift Container Platform cluster. This zone must be authoritative for the domain. The DNS service provides cluster DNS resolution and name lookup for external connections to the cluster.

Procedure

1. Identify your domain, or subdomain, and registrar. You can transfer an existing domain and registrar or obtain a new one through GCP or another source.

   **NOTE**
   
   If you purchase a new domain, it can take time for the relevant DNS changes to propagate. For more information about purchasing domains through Google, see Google Domains.

2. Create a public hosted zone for your domain or subdomain in your GCP project. See Creating public zones in the GCP documentation.
   Use an appropriate root domain, such as openshiftcorp.com, or subdomain, such as clusters.openshiftcorp.com.

3. Extract the new authoritative name servers from the hosted zone records. See Look up your Cloud DNS name servers in the GCP documentation.
   You typically have four name servers.

4. Update the registrar records for the name servers that your domain uses. For example, if you registered your domain to Google Domains, see the following topic in the Google Domains Help: How to switch to custom name servers.

5. If you migrated your root domain to Google Cloud DNS, migrate your DNS records. See Migrating to Cloud DNS in the GCP documentation.

6. If you use a subdomain, follow your company’s procedures to add its delegation records to the parent domain. This process might include a request to your company’s IT department or the division that controls the root domain and DNS services for your company.

4.9.4.4. GCP account limits

The OpenShift Container Platform cluster uses a number of Google Cloud Platform (GCP) components, but the default Quotas do not affect your ability to install a default OpenShift Container Platform cluster.

A default cluster, which contains three compute and three control plane machines, uses the following resources. Note that some resources are required only during the bootstrap process and are removed after the cluster deploys.

**Table 4.30. GCP resources used in a default cluster**
<table>
<thead>
<tr>
<th>Service</th>
<th>Component</th>
<th>Location</th>
<th>Total resources required</th>
<th>Resources removed after bootstrap</th>
</tr>
</thead>
<tbody>
<tr>
<td>Service account</td>
<td>IAM</td>
<td>Global</td>
<td>5</td>
<td>0</td>
</tr>
<tr>
<td>Firewall rules</td>
<td>Networking</td>
<td>Global</td>
<td>11</td>
<td>1</td>
</tr>
<tr>
<td>Forwarding rules</td>
<td>Compute</td>
<td>Global</td>
<td>2</td>
<td>0</td>
</tr>
<tr>
<td>Health checks</td>
<td>Compute</td>
<td>Global</td>
<td>2</td>
<td>0</td>
</tr>
<tr>
<td>Images</td>
<td>Compute</td>
<td>Global</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>Networks</td>
<td>Networking</td>
<td>Global</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>Routers</td>
<td>Networking</td>
<td>Global</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>Routes</td>
<td>Networking</td>
<td>Global</td>
<td>2</td>
<td>0</td>
</tr>
<tr>
<td>Subnetworks</td>
<td>Compute</td>
<td>Global</td>
<td>2</td>
<td>0</td>
</tr>
<tr>
<td>Target pools</td>
<td>Networking</td>
<td>Global</td>
<td>2</td>
<td>0</td>
</tr>
</tbody>
</table>

**NOTE**

If any of the quotas are insufficient during installation, the installation program displays an error that states both which quota was exceeded and the region.

Be sure to consider your actual cluster size, planned cluster growth, and any usage from other clusters that are associated with your account. The CPU, static IP addresses, and persistent disk SSD (storage) quotas are the ones that are most likely to be insufficient.

If you plan to deploy your cluster in one of the following regions, you will exceed the maximum storage quota and are likely to exceed the CPU quota limit:

- asia-east2
- asia-northeast2
- asia-south1
- australia-southeast1
- europe-north1
- europe-west2
- europe-west3
- europe-west6
You can increase resource quotas from the GCP console, but you might need to file a support ticket. Be sure to plan your cluster size early so that you can allow time to resolve the support ticket before you install your OpenShift Container Platform cluster.

### 4.9.4.5. Creating a service account in GCP

OpenShift Container Platform requires a Google Cloud Platform (GCP) service account that provides authentication and authorization to access data in the Google APIs. If you do not have an existing IAM service account that contains the required roles in your project, you must create one.

**Prerequisites**

- You created a project to host your cluster.

**Procedure**

1. Create a service account in the project that you use to host your OpenShift Container Platform cluster. See [Creating a service account](#) in the GCP documentation.

2. Grant the service account the appropriate permissions. You can either grant the individual permissions that follow or assign the **Owner** role to it. See [Granting roles to a service account for specific resources](#).

   **NOTE**

   While making the service account an owner of the project is the easiest way to gain the required permissions, it means that service account has complete control over the project. You must determine if the risk that comes from offering that power is acceptable.

3. Create the service account key in JSON format. See [Creating service account keys](#) in the GCP documentation.
   The service account key is required to create a cluster.

### 4.9.4.5.1. Required GCP permissions

When you attach the **Owner** role to the service account that you create, you grant that service account all permissions, including those that are required to install OpenShift Container Platform. To deploy an OpenShift Container Platform cluster, the service account requires the following permissions. If you deploy your cluster into an existing VPC, the service account does not require certain networking permissions, which are noted in the following lists:

**Required roles for the installation program**

- Compute Admin
- Security Admin
- Service Account Admin
Required roles for creating network resources during installation

- DNS Administrator

Required roles for user-provisioned GCP infrastructure

- Deployment Manager Editor
- Service Account Key Admin

Optional roles

For the cluster to create new limited credentials for its Operators, add the following role:

- Service Account Key Admin

The roles are applied to the service accounts that the control plane and compute machines use:

**Table 4.31. GCP service account permissions**

<table>
<thead>
<tr>
<th>Account</th>
<th>Roles</th>
</tr>
</thead>
<tbody>
<tr>
<td>Control Plane</td>
<td>roles/compute.instanceAdmin</td>
</tr>
<tr>
<td></td>
<td>roles/compute.networkAdmin</td>
</tr>
<tr>
<td></td>
<td>roles/compute.securityAdmin</td>
</tr>
<tr>
<td></td>
<td>roles/storage.admin</td>
</tr>
<tr>
<td></td>
<td>roles/iam.serviceAccountUser</td>
</tr>
<tr>
<td>Compute</td>
<td>roles/compute.viewer</td>
</tr>
<tr>
<td></td>
<td>roles/storage.admin</td>
</tr>
</tbody>
</table>

**4.9.4.6. Supported GCP regions**

You can deploy an OpenShift Container Platform cluster to the following Google Cloud Platform (GCP) regions:

- **asia-east1** (Changhua County, Taiwan)
- **asia-east2** (Hong Kong)
- **asia-northeast1** (Tokyo, Japan)
- **asia-northeast2** (Osaka, Japan)
4.9.4.7. Installing and configuring CLI tools for GCP

To install OpenShift Container Platform on Google Cloud Platform (GCP) using user-provisioned infrastructure, you must install and configure the CLI tools for GCP.

**Prerequisites**

- You created a project to host your cluster.
- You created a service account and granted it the required permissions.

**Procedure**

1. Install the following binaries in $PATH:
   
   - gcloud
4.9.5. Creating the installation files for GCP

To install OpenShift Container Platform on Google Cloud Platform (GCP) using user-provisioned infrastructure, you must generate the files that the installation program needs to deploy your cluster and modify them so that the cluster creates only the machines that it will use. You generate and customize the `install-config.yaml` file, Kubernetes manifests, and Ignition config files. You also have the option to first set up a separate `var` partition during the preparation phases of installation.

4.9.5.1. Optional: Creating a separate `/var` partition

It is recommended that disk partitioning for OpenShift Container Platform be left to the installer. However, there are cases where you might want to create separate partitions in a part of the filesystem that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the `/var` partition or a subdirectory of `/var`. For example:

- `/var/lib/containers`: Holds container-related content that can grow as more images and containers are added to a system.
- `/var/lib/etcd`: Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.
- `/var`: Holds data that you might want to keep separate for purposes such as auditing.

Storing the contents of a `/var` directory separately makes it easier to grow storage for those areas as needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

Because `/var` must be in place before a fresh installation of Red Hat Enterprise Linux CoreOS (RHCOS), the following procedure sets up the separate `/var` partition by creating a machine config that is inserted during the `openshift-install` preparation phases of an OpenShift Container Platform installation.

**IMPORTANT**

If you follow the steps to create a separate `/var` partition in this procedure, it is not necessary to create the Kubernetes manifest and Ignition config files again as described later in this section.

**Procedure**

1. Create a directory to hold the OpenShift Container Platform installation files:

   ```
   $ mkdir $HOME/clusterconfig
   ```

2. Run `openshift-install` to create a set of files in the `manifest` and `openshift` subdirectories. Answer the system questions as you are prompted:
$ openshift-install create manifests --dir $HOME/clusterconfig

Example output

? SSH Public Key ...
INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
INFO Consuming Install Config from target directory
INFO Manifests created in: $HOME/clusterconfig/manifests and $HOME/clusterconfig/openshift

3. Optional: Confirm that the installation program created manifests in the clusterconfig/openshift directory:

$ ls $HOME/clusterconfig/openshift/

Example output

99_kubeadmin-password-secret.yaml
99_openshift-cluster-api_master-machines-0.yaml
99_openshift-cluster-api_master-machines-1.yaml
99_openshift-cluster-api_master-machines-2.yaml
...

4. Create a MachineConfig object and add it to a file in the openshift directory. For example, name the file 98-var-partition.yaml, change the disk device name to the name of the storage device on the worker systems, and set the storage size as appropriate. This example places the /var directory on a separate partition:

```
apiVersion: machineconfiguration.openshift.io/v1
kind: MachineConfig
metadata:
  labels:
    machineconfiguration.openshift.io/role: worker
name: 98-var-partition
spec:
  config:
    ignition:
      version: 3.1.0
    storage:
      disks:
        - device: /dev/<device_name>  
          partitions:
            - label: var
              startMiB: <partition_start_offset>  
              sizeMiB: <partition_size>  
          filesystems:
            - device: /dev/disk/by-partlabel/var
              path: /var
              format: xfs
    systemd:
      units:
        - name: var.mount  
          enabled: true
```
The storage device name of the disk that you want to partition.

When adding a data partition to the boot disk, a minimum value of 25000 MiB (Mebibytes) is recommended. The root file system is automatically resized to fill all available space up to the specified offset. If no value is specified, or if the specified value is smaller than the recommended minimum, the resulting root file system will be too small, and future reinstalls of RHCOS might overwrite the beginning of the data partition.

The size of the data partition in mebibytes.

The name of the mount unit must match the directory specified in the Where= directive. For example, for a filesystem mounted on /var/lib/containers, the unit must be named var-lib-containers.mount.

The prjquota mount option must be enabled for filesystems used for container storage.

NOTE
When creating a separate /var partition, you cannot use different instance types for worker nodes, if the different instance types do not have the same device name.

5. Run openshift-install again to create Ignition configs from a set of files in the manifest and openshift subdirectories:

```
$ openshift-install create ignition-configs --dir $HOME/clusterconfig
$ ls $HOME/clusterconfig/
auth  bootstrap.ign  master.ign  metadata.json  worker.ign
```

Now you can use the Ignition config files as input to the installation procedures to install Red Hat Enterprise Linux CoreOS (RHCOS) systems.

4.9.5.2. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Google Cloud Platform (GCP).

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.

Procedure
1. Create the `install-config.yaml` file.
   
a. Change to the directory that contains the installation program and run the following command:

   ```bash
   $ ./openshift-install create install-config --dir <installation_directory> 1
   ```

   For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

   **IMPORTANT**

   Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

b. At the prompts, provide the configuration details for your cloud:

   i. Optional: Select an SSH key to use to access your cluster machines.

      **NOTE**

      For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

   ii. Select `gcp` as the platform to target.

   iii. If you have not configured the service account key for your GCP account on your computer, you must obtain it from GCP and paste the contents of the file or enter the absolute path to the file.

   iv. Select the project ID to provision the cluster in. The default value is specified by the service account that you configured.

   v. Select the region to deploy the cluster to.

   vi. Select the base domain to deploy the cluster to. The base domain corresponds to the public DNS zone that you created for your cluster.

   vii. Enter a descriptive name for your cluster.

   viii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

c. Optional: If you do not want the cluster to provision compute machines, empty the compute pool by editing the resulting `install-config.yaml` file to set `replicas` to 0 for the `compute` pool:

   ```yaml
   compute:
   - hyperthreading: Enabled
   ```
1. Set to 0.

2. Modify the `install-config.yaml` file. You can find more information about the available parameters in the Installation configuration parameters section.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

   **IMPORTANT**

   The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

### 4.9.5.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

#### Prerequisites

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the Proxy object’s `spec.noProxy` field to bypass the proxy if necessary.

   **NOTE**

   The Proxy object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

   For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

#### Procedure

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
     httpProxy: http://<username>:<pswd>@<ip>:<port> 1
     httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
     noProxy: example.com 3
   additionalTrustBundle: | 4
   ```
1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.

2. A proxy URL to use for creating HTTPS connections outside the cluster.

3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with `.` to match subdomains only. For example, `.y.com` matches `x.y.com`, but not `y.com`. Use `*` to bypass the proxy for all destinations.

4. If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace to hold the additional CA certificates. If you provide `additionalTrustBundle` and at least one proxy setting, the `Proxy` object is configured to reference the `user-ca-bundle` config map in the `trustedCA` field. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges the contents specified for the `trustedCA` parameter with the RHCOS trust bundle. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

**NOTE**

The installation program does not support the proxy `readinessEndpoints` field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

**NOTE**

Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

### 4.9.5.4. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to make its machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to create the cluster.
The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

Prerequisites

- You obtained the OpenShift Container Platform installation program.
- You created the `install-config.yaml` installation configuration file.

Procedure

1. Change to the directory that contains the installation program and generate the Kubernetes manifests for the cluster:

   ```
   $ ./openshift-install create manifests --dir <installation_directory>
   ```

   Example output

   ```
   INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
   INFO Consuming Install Config from target directory
   INFO Manifests created in: install_dir/manifests and install_dir/openshift
   ```

   For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.

2. Remove the Kubernetes manifest files that define the control plane machines:

   ```
   $ rm -f <installation_directory>/openshift/99_openshift-cluster-api_master-machines-*.yaml
   ```

   By removing these files, you prevent the cluster from automatically generating control plane machines.

3. Optional: If you do not want the cluster to provision compute machines, remove the Kubernetes manifest files that define the worker machines:

   ```
   $ rm -f <installation_directory>/openshift/99_openshift-cluster-api_worker-machineset-*.yaml
   ```

   Because you create and manage the worker machines yourself, you do not need to initialize these machines.
4. Check that the `mastersSchedulable` parameter in the 
<installation_directory>/manifests/cluster-scheduler-02-config.yml Kubernetes manifest 
file is set to `false`. This setting prevents pods from being scheduled on the control plane 
machines:

   a. Open the <installation_directory>/manifests/cluster-scheduler-02-config.yml file.

   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.

   c. Save and exit the file.

5. Optional: If you do not want the Ingress Operator to create DNS records on your behalf, remove 
the `privateZone` and `publicZone` sections from the 
<installation_directory>/manifests/cluster-dns-02-config.yml DNS configuration file:

   ```yaml
   apiVersion: config.openshift.io/v1
   kind: DNS
   metadata:
     creationTimestamp: null
     name: cluster
   spec:
     baseDomain: example.openshift.com
     privateZone: 1
     id: mycluster-100419-private-zone
     publicZone: 2
     id: example.openshift.com
   status: {}
   ``

   Remove this section completely.

   If you do so, you must add ingress DNS records manually in a later step.

6. To create the Ignition configuration files, run the following command from the directory that 
contains the installation program:

   ```bash
   $ ./openshift-install create ignition-configs --dir <installation_directory> 1
   ``

   For `<installation_directory>`, specify the same installation directory.

   The following files are generated in the directory:

   ```none
   ├── auth
   │   └── kubeadmin-password
   │       └── kubeconfig
   │   └── bootstrap.ign
   │   └── master.ign
   │   └── metadata.json
   │   └── worker.ign
   ```

### Additional resources

- Optional: Adding the ingress DNS records
4.9.6. Exporting common variables

4.9.6.1. Extracting the infrastructure name

The Ignition config files contain a unique cluster identifier that you can use to uniquely identify your cluster in Google Cloud Platform (GCP). The infrastructure name is also used to locate the appropriate GCP resources during an OpenShift Container Platform installation. The provided Deployment Manager templates contain references to this infrastructure name, so you must extract it.

Prerequisites

- You obtained the OpenShift Container Platform installation program and the pull secret for your cluster.
- You generated the Ignition config files for your cluster.
- You installed the `jq` package.

Procedure

- To extract and view the infrastructure name from the Ignition config file metadata, run the following command:

  ```
  $ jq -r .infraID <installation_directory>/metadata.json
  ```

  For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

  Example output

  ```
  openshift-vw9j6
  ```

  The output of this command is your cluster name and a random string.

4.9.6.2. Exporting common variables for Deployment Manager templates

You must export a common set of variables that are used with the provided Deployment Manager templates used to assist in completing a user-provided infrastructure install on Google Cloud Platform (GCP).

NOTE

Specific Deployment Manager templates can also require additional exported variables, which are detailed in their related procedures.

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.
- Generate the Ignition config files for your cluster.
• Install the jq package.

Procedure

1. Export the following common variables to be used by the provided Deployment Manager templates:

   ```bash
   $ export BASE_DOMAIN='<base_domain>'
   $ export BASE_DOMAIN_ZONE_NAME='<base_domain_zone_name>'
   $ export NETWORK_CIDR='10.0.0.0/16'
   $ export MASTER_SUBNET_CIDR='10.0.0.0/19'
   $ export WORKER_SUBNET_CIDR='10.0.32.0/19'
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   $ export CLUSTER_NAME=`jq -r .clusterName <installation_directory>/metadata.json`
   $ export INFRA_ID=`jq -r .infraID <installation_directory>/metadata.json`
   $ export PROJECT_NAME=`jq -r .gcp.projectID <installation_directory>/metadata.json`
   $ export REGION=`jq -r .gcp.region <installation_directory>/metadata.json`
   ```

   1. For <installation_directory>, specify the path to the directory that you stored the installation files in.

4.9.7. Creating a VPC in GCP

You must create a VPC in Google Cloud Platform (GCP) for your OpenShift Container Platform cluster to use. You can customize the VPC to meet your requirements. One way to create the VPC is to modify the provided Deployment Manager template.

**NOTE**

If you do not use the provided Deployment Manager template to create your GCP infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

Prerequisites

• Configure a GCP account.

• Generate the Ignition config files for your cluster.

Procedure

1. Copy the template from the Deployment Manager template for the VPC section of this topic and save it as 01_vpc.py on your computer. This template describes the VPC that your cluster requires.

2. Create a 01_vpc.yaml resource definition file:

   ```bash
   $ cat <<EOF >01_vpc.yaml
   imports:
   - path: 01_vpc.py
   EOF
   ```
resources:
- name: cluster-vpc
type: 01_vpc.py
properties:
  infra_id: '$(INFRA_ID)'
  region: '$(REGION)'
  master_subnet_cidr: '$(MASTER_SUBNET_CIDR)'
  worker_subnet_cidr: '$(WORKER_SUBNET_CIDR)'
EOF

1. infra_id is the INFRA_ID infrastructure name from the extraction step.
2. region is the region to deploy the cluster into, for example us-central1.
3. master_subnet_cidr is the CIDR for the master subnet, for example 10.0.0.0/19.
4. worker_subnet_cidr is the CIDR for the worker subnet, for example 10.0.32.0/19.

3. Create the deployment by using the gcloud CLI:

   $ gcloud deployment-manager deployments create $(INFRA_ID)-vpc --config 01_vpc.yaml

### 4.9.7.1. Deployment Manager template for the VPC

You can use the following Deployment Manager template to deploy the VPC that you need for your OpenShift Container Platform cluster:

**Example 4.1. 01_vpc.py Deployment Manager template**

```python
def GenerateConfig(context):

    resources = [{
        'name': context.properties['infra_id'] + '-network',
        'type': 'compute.v1.network',
        'properties': {
            'region': context.properties['region'],
            'autoCreateSubnetworks': False
        }
    }, {
        'name': context.properties['infra_id'] + '-master-subnet',
        'type': 'compute.v1.subnetwork',
        'properties': {
            'region': context.properties['region'],
            'network': '$(ref. + context.properties[infra_id] + -network.selfLink)',
            'ipCidrRange': context.properties['master_subnet_cidr']
        }
    }, {
        'name': context.properties['infra_id'] + '-worker-subnet',
        'type': 'compute.v1.subnetwork',
        'properties': {
            'region': context.properties['region'],
            'network': '$(ref. + context.properties[infra_id] + -network.selfLink)',
            'ipCidrRange': context.properties['worker_subnet_cidr']
        }
    }
```
All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require network in initramfs during boot to fetch Ignition config from the machine config server. You must configure the network connectivity between machines to allow cluster components to communicate. Each machine must be able to resolve the host names of all other machines in the cluster.

### Table 4.32. All machines to all machines

Network topology requirements
The infrastructure that you provision for your cluster must meet the following network topology requirements.

**IMPORTANT**
OpenShift Container Platform requires all nodes to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

Load balancers
Before you install OpenShift Container Platform, you must provision two load balancers that meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.
   - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

**IMPORTANT**
Do not configure session persistence for an API load balancer.
Configure the following ports on both the front and back of the load balancers:

### Table 4.35. API load balancer

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the <code>/readyz</code> endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
</tbody>
</table>

| 22623 | Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. | X | | Machine config server |

**NOTE**

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the `/readyz` endpoint to the removal of the API server instance from the pool. Within the time frame after `/readyz` returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application Ingress load balancer**: Provides an Ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

- **Layer 4 load balancing only.** This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the Ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

Configure the following ports on both the front and back of the load balancers:

### Table 4.36. Application Ingress load balancer

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress router pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
</tbody>
</table>

| 80 | The machines that run the Ingress router pods, compute, or worker, by default. | X | X | HTTP traffic |
TIP

If the true IP address of the client can be seen by the load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

NOTE

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

4.9.9. Creating load balancers in GCP

You must configure load balancers in Google Cloud Platform (GCP) for your OpenShift Container Platform cluster to use. One way to create these components is to modify the provided Deployment Manager template.

NOTE

If you do not use the provided Deployment Manager template to create your GCP infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.

Procedure

1. Copy the template from the Deployment Manager template for the internal load balancer section of this topic and save it as `02_lb_int.py` on your computer. This template describes the internal load balancing objects that your cluster requires.

2. For an external cluster, also copy the template from the Deployment Manager template for the external load balancer section of this topic and save it as `02_lb_ext.py` on your computer. This template describes the external load balancing objects that your cluster requires.

3. Export the variables that the deployment template uses:
   a. Export the cluster network location:
      
      ```
      $ export CLUSTER_NETWORK=(`gcloud compute networks describe ${INFRA_ID}-network --format json | jq -r .selfLink`)
      ```
   
   b. Export the control plane subnet location:
      
      ```
      $ export CONTROL_SUBNET=(`gcloud compute networks subnets describe ${INFRA_ID}-master-subnet --region=${REGION} --format json | jq -r .selfLink`)
      ```
   
   c. Export the three zones that the cluster uses:
      
      ```
      ```
Create a **02_infra.yaml** resource definition file:

```bash
$ cat <<EOF >02_infra.yaml
imports:
- path: 02_lb_ext.py
- path: 02_lb_int.py
resources:
- name: cluster-lb-ext
  type: 02_lb_ext.py
  properties:
    infra_id: '${INFRA_ID}'
    region: '${REGION}'
- name: cluster-lb-int
  type: 02_lb_int.py
  properties:
    cluster_network: '${CLUSTER_NETWORK}'
    control_subnet: '${CONTROL_SUBNET}'
    infra_id: '${INFRA_ID}'
    region: '${REGION}'
    zones:
    - '${ZONE_0}'
    - '${ZONE_1}'
    - '${ZONE_2}'
EOF
```

4. Create a **02_infra.yaml** resource definition file:

```bash
$ export ZONE_0=(`gcloud compute regions describe ${REGION} --format=json | jq -r .zones[0] | cut -d "" -f9`)
$ export ZONE_1=(`gcloud compute regions describe ${REGION} --format=json | jq -r .zones[1] | cut -d "" -f9`)
$ export ZONE_2=(`gcloud compute regions describe ${REGION} --format=json | jq -r .zones[2] | cut -d "" -f9`)
```

5. Create the deployment by using the **gcloud** CLI:

```bash
$ gcloud deployment-manager deployments create ${INFRA_ID}-infra --config 02_infra.yaml
```

6. Export the cluster IP address:

```bash
$ export ZONE_0=(`gcloud compute regions describe ${REGION} --format=json | jq -r .zones[0] | cut -d "" -f9`)
$ export ZONE_1=(`gcloud compute regions describe ${REGION} --format=json | jq -r .zones[1] | cut -d "" -f9`)
$ export ZONE_2=(`gcloud compute regions describe ${REGION} --format=json | jq -r .zones[2] | cut -d "" -f9`)
```

4. Create a **02_infra.yaml** resource definition file:

```bash
$ cat <<EOF >02_infra.yaml
imports:
- path: 02_lb_ext.py
- path: 02_lb_int.py
resources:
- name: cluster-lb-ext
  type: 02_lb_ext.py
  properties:
    infra_id: '${INFRA_ID}'
    region: '${REGION}'
- name: cluster-lb-int
  type: 02_lb_int.py
  properties:
    cluster_network: '${CLUSTER_NETWORK}'
    control_subnet: '${CONTROL_SUBNET}'
    infra_id: '${INFRA_ID}'
    region: '${REGION}'
    zones:
    - '${ZONE_0}'
    - '${ZONE_1}'
    - '${ZONE_2}'
EOF
```

4. Create a **02_infra.yaml** resource definition file:

```bash
$ export ZONE_0=(`gcloud compute regions describe ${REGION} --format=json | jq -r .zones[0] | cut -d "" -f9`)
$ export ZONE_1=(`gcloud compute regions describe ${REGION} --format=json | jq -r .zones[1] | cut -d "" -f9`)
$ export ZONE_2=(`gcloud compute regions describe ${REGION} --format=json | jq -r .zones[2] | cut -d "" -f9`)
```

5. Create the deployment by using the **gcloud** CLI:

```bash
$ gcloud deployment-manager deployments create ${INFRA_ID}-infra --config 02_infra.yaml
```

6. Export the cluster IP address:

```bash
$ export ZONE_0=(`gcloud compute regions describe ${REGION} --format=json | jq -r .zones[0] | cut -d "" -f9`)
$ export ZONE_1=(`gcloud compute regions describe ${REGION} --format=json | jq -r .zones[1] | cut -d "" -f9`)
$ export ZONE_2=(`gcloud compute regions describe ${REGION} --format=json | jq -r .zones[2] | cut -d "" -f9`)
```

4. Create a **02_infra.yaml** resource definition file:

```bash
$ cat <<EOF >02_infra.yaml
imports:
- path: 02_lb_ext.py
- path: 02_lb_int.py
resources:
- name: cluster-lb-ext
  type: 02_lb_ext.py
  properties:
    infra_id: '${INFRA_ID}'
    region: '${REGION}'
- name: cluster-lb-int
  type: 02_lb_int.py
  properties:
    cluster_network: '${CLUSTER_NETWORK}'
    control_subnet: '${CONTROL_SUBNET}'
    infra_id: '${INFRA_ID}'
    region: '${REGION}'
    zones:
    - '${ZONE_0}'
    - '${ZONE_1}'
    - '${ZONE_2}'
EOF
```

4. Create a **02_infra.yaml** resource definition file:

```bash
$ export ZONE_0=(`gcloud compute regions describe ${REGION} --format=json | jq -r .zones[0] | cut -d "" -f9`)
$ export ZONE_1=(`gcloud compute regions describe ${REGION} --format=json | jq -r .zones[1] | cut -d "" -f9`)
$ export ZONE_2=(`gcloud compute regions describe ${REGION} --format=json | jq -r .zones[2] | cut -d "" -f9`)
```

5. Create the deployment by using the **gcloud** CLI:

```bash
$ gcloud deployment-manager deployments create ${INFRA_ID}-infra --config 02_infra.yaml
```

6. Export the cluster IP address:
7. For an external cluster, also export the cluster public IP address:

```bash
$ export CLUSTER_PUBLIC_IP=\(`gcloud compute addresses describe \${INFRA_ID}-cluster-public-ip \--region=\${REGION} \--format json \| jq -r .address\`)
```

4.9.9.1. Deployment Manager template for the external load balancer

You can use the following Deployment Manager template to deploy the external load balancer that you need for your OpenShift Container Platform cluster:

Example 4.2. 02_lb_ext.py Deployment Manager template

```python
def GenerateConfig(context):
    resources = [
        {
            'name': context.properties["infra_id"] + '-cluster-public-ip',
            'type': 'compute.v1.address',
            'properties': {
                'region': context.properties["region"]
            }
        },
        {
            'name': context.properties['infra_id'] + '-api-http-health-check',
            'type': 'compute.v1.httpHealthCheck',
            'properties': {
                'port': 6080,
                'requestPath': '/readyz'
            }
        },
        {
            'name': context.properties['infra_id'] + '-api-target-pool',
            'type': 'compute.v1.targetPool',
            'properties': {
                'region': context.properties['region'],
                'healthChecks': ['$(ref. + context.properties['infra_id'] + '-api-http-health-check.selfLink)'],
                'instances': []
            }
        },
        {
            'name': context.properties['infra_id'] + '-api-forwarding-rule',
            'type': 'compute.v1.forwardingRule',
            'properties': {
                'region': context.properties['region'],
                'IPAddress': '$(ref. + context.properties['infra_id'] + '-cluster-public-ip.selfLink)',
                'target': '$(ref. + context.properties['infra_id'] + '-api-target-pool.selfLink)',
                'portRange': '6443'
            }
        }
    ]

    return {'resources': resources}
```
4.9.9.2. Deployment Manager template for the internal load balancer

You can use the following Deployment Manager template to deploy the internal load balancer that you need for your OpenShift Container Platform cluster:

Example 4.3. **02_lb_int.py** Deployment Manager template

```python
def GenerateConfig(context):
    backends = []
    for zone in context.properties['zones']:
        backends.append({
            'group': '$(ref. ' + context.properties['infra_id'] + '-master-' + zone + '-instance-group' + '.selfLink)'
        })

    resources = [
        {'name': context.properties['infra_id'] + '-cluster-ip',
         'type': 'compute.v1.address',
         'properties': {
             'addressType': 'INTERNAL',
             'region': context.properties['region'],
             'subnetwork': context.properties['control_subnet']
         }},
        {'name': context.properties['infra_id'] + '-api-internal-health-check',
         'type': 'compute.v1.healthCheck',
         'properties': {
             'httpsHealthCheck': {
                 'port': 6443,
                 'requestPath': '/readyz'
             },
             'type': "HTTPS"
         }},
        {'name': context.properties['infra_id'] + '-api-internal-backend-service',
         'type': 'compute.v1.regionBackendService',
         'properties': {
             'backends': backends,
             'healthChecks': ['$ref. ' + context.properties['infra_id'] + '-api-internal-health-check.selfLink]",
             'loadBalancingScheme': 'INTERNAL',
             'region': context.properties['region'],
             'protocol': 'TCP',
             'timeoutSec': 120
         }},
        {'name': context.properties['infra_id'] + '-api-internal-forwarding-rule',
         'type': 'compute.v1.forwardingRule',
         'properties': {
             'backendService': '$(ref. ' + context.properties['infra_id'] + '-api-internal-backend-service.selfLink)'
         }},
    # Refer to docs/dev/kube-apiserver-health-check.md on how to correctly setup health check
```
4.9.10. Creating a private DNS zone in GCP

You must configure a private DNS zone in Google Cloud Platform (GCP) for your OpenShift Container Platform cluster to use. One way to create this component is to modify the provided Deployment Manager template.

NOTE

If you do not use the provided Deployment Manager template to create your GCP infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.

Procedure

You will need this template in addition to the 02_lb_ext.py template when you create an external cluster.
1. Copy the template from the Deployment Manager template for the private DNS section of this topic and save it as 02_dns.py on your computer. This template describes the private DNS objects that your cluster requires.

2. Create a 02_dns.yaml resource definition file:

   ```
   $ cat <<EOF >02_dns.yaml
   imports:
   - path: 02_dns.py

   resources:
   - name: cluster-dns
     type: 02_dns.py
     properties:
       infra_id: '${INFRA_ID}'
       cluster_domain: '${CLUSTER_NAME}.${BASE_DOMAIN}'
       cluster_network: '${CLUSTER_NETWORK}'
   EOF
   ```

   - `infra_id` is the INFRA_ID infrastructure name from the extraction step.
   - `cluster_domain` is the domain for the cluster, for example openshift.example.com.
   - `cluster_network` is the selfLink URL to the cluster network.

3. Create the deployment by using the gcloud CLI:

   ```
   $ gcloud deployment-manager deployments create ${INFRA_ID}-dns --config 02_dns.yaml
   $ if [ -f transaction.yaml ]; then rm transaction.yaml; fi
   $ gcloud dns record-sets transaction start --zone ${INFRA_ID}-private-zone
   $ gcloud dns record-sets transaction add ${CLUSTER_IP} --name api.${CLUSTER_NAME}.${BASE_DOMAIN} --ttl 60 --type A --zone ${INFRA_ID}-private-zone
   $ gcloud dns record-sets transaction add ${CLUSTER_IP} --name api-int.${CLUSTER_NAME}.${BASE_DOMAIN} --ttl 60 --type A --zone ${INFRA_ID}-private-zone
   $ gcloud dns record-sets transaction execute --zone ${INFRA_ID}-private-zone
   $ if [ -f transaction.yaml ]; then rm transaction.yaml; fi
   $ gcloud dns record-sets transaction start --zone ${BASE_DOMAIN_ZONE_NAME}
   $ gcloud dns record-sets transaction add ${CLUSTER_PUBLIC_IP} --name api.${CLUSTER_NAME}.${BASE_DOMAIN} --ttl 60 --type A --zone ${BASE_DOMAIN_ZONE_NAME}
   $ gcloud dns record-sets transaction execute --zone ${BASE_DOMAIN_ZONE_NAME}
   ```

4. The templates do not create DNS entries due to limitations of Deployment Manager, so you must create them manually:

   a. Add the internal DNS entries:

   ```
   $ if [ -f transaction.yaml ]; then rm transaction.yaml; fi
   $ gcloud dns record-sets transaction start --zone ${INFRA_ID}-private-zone
   $ gcloud dns record-sets transaction add ${CLUSTER_IP} --name api-int.${CLUSTER_NAME}.${BASE_DOMAIN} --ttl 60 --type A --zone ${INFRA_ID}-private-zone
   $ gcloud dns record-sets transaction add ${CLUSTER_IP} --name api-int.${CLUSTER_NAME}.${BASE_DOMAIN} --ttl 60 --type A --zone ${INFRA_ID}-private-zone
   $ gcloud dns record-sets transaction execute --zone ${INFRA_ID}-private-zone
   $ if [ -f transaction.yaml ]; then rm transaction.yaml; fi
   ```

   b. For an external cluster, also add the external DNS entries:

   ```
   $ if [ -f transaction.yaml ]; then rm transaction.yaml; fi
   $ gcloud dns record-sets transaction start --zone ${BASE_DOMAIN_ZONE_NAME}
   $ gcloud dns record-sets transaction add ${CLUSTER_PUBLIC_IP} --name api.${CLUSTER_NAME}.${BASE_DOMAIN} --ttl 60 --type A --zone ${BASE_DOMAIN_ZONE_NAME}
   $ gcloud dns record-sets transaction execute --zone ${BASE_DOMAIN_ZONE_NAME}
   ```
4.9.10.1. Deployment Manager template for the private DNS

You can use the following Deployment Manager template to deploy the private DNS that you need for your OpenShift Container Platform cluster:

```
Example 4.4. 02_dns.py Deployment Manager template

def GenerateConfig(context):
    resources = [{
        'name': context.properties['infra_id'] + '-private-zone',
        'type': 'dns.v1.managedZone',
        'properties': {
            'description': '',
            'dnsName': context.properties['cluster_domain'] + '.',
            'visibility': 'private',
            'privateVisibilityConfig': {
                'networks': [{
                    'networkUrl': context.properties['cluster_network']
                }]
            }
        }
    }
    return {'resources': resources}
```

4.9.11. Creating firewall rules in GCP

You must create firewall rules in Google Cloud Platform (GCP) for your OpenShift Container Platform cluster to use. One way to create these components is to modify the provided Deployment Manager template.

**NOTE**

If you do not use the provided Deployment Manager template to create your GCP infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.

Procedure

1. Copy the template from the Deployment Manager template for firewall rules section of this topic and save it as `03_firewall.py` on your computer. This template describes the security groups that your cluster requires.
2. Create a `03_firewall.yaml` resource definition file:

```
$ cat <<EOF >03_firewall.yaml
imports:
- path: 03_firewall.py

resources:
- name: cluster-firewall
  type: 03_firewall.py
  properties:
    allowed_external_cidr: '0.0.0.0/0'
    infra_id: '${INFRA_ID}'
    cluster_network: '${CLUSTER_NETWORK}'
    network_cidr: '${NETWORK_CIDR}'
EOF
```

- `allowed_external_cidr` is the CIDR range that can access the cluster API and SSH to the bootstrap host. For an internal cluster, set this value to `${NETWORK_CIDR}`.
- `infra_id` is the INFRA_ID infrastructure name from the extraction step.
- `cluster_network` is the selfLink URL to the cluster network.
- `network_cidr` is the CIDR of the VPC network, for example `10.0.0.0/16`.

3. Create the deployment by using the `gcloud` CLI:

```
$ gcloud deployment-manager deployments create ${INFRA_ID}-firewall --config 03_firewall.yaml
```

### 4.9.11.1. Deployment Manager template for firewall rules

You can use the following Deployment Manager template to deploy the firewall rules that you need for your OpenShift Container Platform cluster:

**Example 4.5. 03_firewall.py Deployment Manager template**

```python
def GenerateConfig(context):

    resources = [
        {'name': context.properties['infra_id'] + '-bootstrap-in-ssh',
         'type': 'compute.v1.firewall',
         'properties': {
             'network': context.properties['cluster_network'],
             'allowed': [{
                 'IPProtocol': 'tcp',
                 'ports': ['22']
             }],
             'sourceRanges': [context.properties['allowed_external_cidr']],
             'targetTags': [context.properties['infra_id'] + '-bootstrap']
         }
     },
     {'name': context.properties['infra_id'] + '-api',
```
'type': 'compute.v1.firewall',
'properties': {
  'network': context.properties['cluster_network'],
  'allowed': [{
    'IPProtocol': 'tcp',
    'ports': ['6443']
  }],
  'sourceRanges': [context.properties['allowed_external_cidr']],
  'targetTags': [context.properties['infra_id'] + '-master']
}
},

{name: context.properties['infra_id'] + '-health-checks',
'type': 'compute.v1.firewall',
'properties': {
  'network': context.properties['cluster_network'],
  'allowed': [{
    'IPProtocol': 'tcp',
    'ports': ['6080', '6443', '22624']
  }],
  'sourceRanges': ['35.191.0.0/16', '130.211.0.0/22', '209.85.152.0/22', '209.85.204.0/22'],
  'targetTags': [context.properties['infra_id'] + '-master']
}
},

{name: context.properties['infra_id'] + '-etcd',
'type': 'compute.v1.firewall',
'properties': {
  'network': context.properties['cluster_network'],
  'allowed': [{
    'IPProtocol': 'tcp',
    'ports': ['2379-2380']
  }],
  'sourceTags': [context.properties['infra_id'] + '-master'],
  'targetTags': [context.properties['infra_id'] + '-master']
}
},

{name: context.properties['infra_id'] + '-control-plane',
'type': 'compute.v1.firewall',
'properties': {
  'network': context.properties['cluster_network'],
  'allowed': [{
    'IPProtocol': 'tcp',
    'ports': ['10257']
  }],
  'IPProtocol': 'tcp',
  'ports': ['10259']
}],
  'IPProtocol': 'tcp',
  'ports': ['22623']
}],
'sourceTags': [
  context.properties['infra_id'] + '-master',
  context.properties['infra_id'] + '-worker'
],
'targetTags': [context.properties['infra_id'] + '-master']
}
},

'}
4.9.12. Creating IAM roles in GCP

```json
return {
    'resources': resources
}
```
You must create IAM roles in Google Cloud Platform (GCP) for your OpenShift Container Platform cluster to use. One way to create these components is to modify the provided Deployment Manager template.

**NOTE**

If you do not use the provided Deployment Manager template to create your GCP infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.

Procedure

1. Copy the template from the Deployment Manager template for IAM roles section of this topic and save it as `03_iam.py` on your computer. This template describes the IAM roles that your cluster requires.

2. Create a `03_iam.yaml` resource definition file:

   ```
   $ cat <<EOF >03_iam.yaml
   imports:
   - path: 03_iam.py
   resources:
   - name: cluster-iam
     type: 03_iam.py
     properties:
       infra_id: '${INFRA_ID}'
   EOF
   ``

   `infra_id` is the `INFRA_ID` infrastructure name from the extraction step.

3. Create the deployment by using the `gcloud` CLI:

   ```
   $ gcloud deployment-manager deployments create ${INFRA_ID}-iam --config 03_iam.yaml
   ```

4. Export the variable for the master service account:

   ```
   $ export MASTER_SERVICE_ACCOUNT=`gcloud iam service-accounts list --filter "email~^${INFRA_ID}-m@$PROJECT_NAME." --format json | jq -r '.[0].email')
   ```

5. Export the variable for the worker service account:

   ```
   $ export WORKER_SERVICE_ACCOUNT=`gcloud iam service-accounts list --filter "email~^${INFRA_ID}-w@$PROJECT_NAME." --format json | jq -r '.[0].email')`
6. Export the variable for the subnet that hosts the compute machines:

```bash
$ export COMPUTE_SUBNET=('gcloud compute networks subnets describe ${INFRA_ID}-worker-subnet --region=${REGION} --format json | jq -r .selfLink')
```

7. The templates do not create the policy bindings due to limitations of Deployment Manager, so you must create them manually:

```bash
$ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member "serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role "roles/compute.instanceAdmin"
$ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member "serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role "roles/compute.networkAdmin"
$ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member "serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role "roles/compute.securityAdmin"
$ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member "serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role "roles/iam.serviceAccountUser"
$ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member "serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role "roles/storage.admin"
$ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member "serviceAccount:${WORKER_SERVICE_ACCOUNT}" --role "roles/compute.viewer"
$ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member "serviceAccount:${WORKER_SERVICE_ACCOUNT}" --role "roles/storage.admin"
```

8. Create a service account key and store it locally for later use:

```bash
$ gcloud iam service-accounts keys create service-account-key.json --iam-account=${MASTER_SERVICE_ACCOUNT}
```

4.9.12.1. Deployment Manager template for IAM roles

You can use the following Deployment Manager template to deploy the IAM roles that you need for your OpenShift Container Platform cluster:

**Example 4.6. 03_iam.py Deployment Manager template**

```python
def GenerateConfig(context):

    resources = [
        {'name': context.properties['infra_id'] + '-master-node-sa',
         'type': 'iam.v1.serviceAccount',
         'properties': {
             'accountId': context.properties['infra_id'] + '-m',
             'displayName': context.properties['infra_id'] + '-master-node'
         }
    ],
    [{'name': context.properties['infra_id'] + '-worker-node-sa',
      'type': 'iam.v1.serviceAccount',
      'properties': {
          'accountId': context.properties['infra_id'] + '-w',
          'displayName': context.properties['infra_id'] + '-worker-node'
      }
    ]
```
4.9.13. Creating the RHCOS cluster image for the GCP infrastructure

You must use a valid Red Hat Enterprise Linux CoreOS (RHCOS) image for Google Cloud Platform (GCP) for your OpenShift Container Platform nodes.

Procedure

1. Obtain the RHCOS image from the RHCOS image mirror page.

   IMPORTANT

   The RHCOS images might not change with every release of OpenShift Container Platform. You must download an image with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image version that matches your OpenShift Container Platform version if it is available.

   The file name contains the OpenShift Container Platform version number in the format `rhcos-<version>-<arch>-gcp.<arch>.tar.gz`.

2. Create the Google storage bucket:

   ```
   $ gsutil mb gs://<bucket_name>
   ```

3. Upload the RHCOS image to the Google storage bucket:

   ```
   $ gsutil cp <downloaded_image_file_path>/rhcos-<version>-x86_64-gcp.x86_64.tar.gz gs://<bucket_name>
   ```

4. Export the uploaded RHCOS image location as a variable:

   ```
   $ export IMAGE_SOURCE=`gs://<bucket_name>/rhcos-<version>-x86_64-gcp.x86_64.tar.gz`
   ```

5. Create the cluster image:

   ```
   $ gcloud compute images create "${INFRA_ID}-rhcos-image" \   --source-uri="${IMAGE_SOURCE}"
   ```

4.9.14. Creating the bootstrap machine in GCP

You must create the bootstrap machine in Google Cloud Platform (GCP) to use during OpenShift Container Platform cluster initialization. One way to create this machine is to modify the provided Deployment Manager template.
NOTE

If you do not use the provided Deployment Manager template to create your bootstrap machine, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.
- Create and configure networking and load balancers in GCP.
- Create control plane and compute roles.
- Ensure pyOpenSSL is installed.

Procedure

1. Copy the template from the Deployment Manager template for the bootstrap machine section of this topic and save it as `04_bootstrap.py` on your computer. This template describes the bootstrap machine that your cluster requires.

2. Export the location of the Red Hat Enterprise Linux CoreOS (RHCOS) image that the installation program requires:

   ```
   $ export CLUSTER_IMAGE=('gcloud compute images describe ${INFRA_ID}-rhcos-image --format json | jq -r .selfLink')
   ```

3. Create a bucket and upload the `bootstrap.ign` file:

   ```
   $ gsutil mb gs://${INFRA_ID}-bootstrap-ignition
   $ gsutil cp <installation_directory>/bootstrap.ign gs://${INFRA_ID}-bootstrap-ignition/
   ```

4. Create a signed URL for the bootstrap instance to use to access the Ignition config. Export the URL from the output as a variable:

   ```
   $ export BOOTSTRAP_IGN=`gsutil signurl -d 1h service-account-key.json gs://${INFRA_ID}-bootstrap-ignition/bootstrap.ign | grep "^gs:" | awk '{print $5}'`
   ```

5. Create a `04_bootstrap.yaml` resource definition file:

   ```
   $ cat <<EOF >04_bootstrap.yaml
   imports:
   - path: 04_bootstrap.py

   resources:
   - name: cluster-bootstrap
     type: 04_bootstrap.py
     properties:
       infra_id: '${INFRA_ID}'  # 1
   ```
infra_id is the INFRA_ID infrastructure name from the extraction step.

region is the region to deploy the cluster into, for example us-central1.

zone is the zone to deploy the bootstrap instance into, for example us-central1-b.

cluster_network is the `selfLink` URL to the cluster network.

control_subnet is the `selfLink` URL to the control subnet.

image is the `selfLink` URL to the RHCOS image.

machine_type is the machine type of the instance, for example n1-standard-4.

root_volume_size is the boot disk size for the bootstrap machine.

bootstrap_ign is the URL output when creating a signed URL.

6. Create the deployment by using the `gcloud` CLI:

```
$ gcloud deployment-manager deployments create ${INFRA_ID}-bootstrap --config 04_bootstrap.yaml
```

7. The templates do not manage load balancer membership due to limitations of Deployment Manager, so you must add the bootstrap machine manually.

   a. Add the bootstrap instance to the internal load balancer instance group:

```
$ gcloud compute instance-groups unmanaged add-instances
   $(INFRA_ID)-bootstrap-instance-group --zone=${ZONE_0} --instances=${INFRA_ID}-bootstrap
```

   b. Add the bootstrap instance group to the internal load balancer backend service:

```
$ gcloud compute backend-services add-backend
   $(INFRA_ID)-api-internal-backend-service --region=${REGION} --instance-group=${INFRA_ID}-bootstrap-instance-group --instance-group-zone=${ZONE_0}
```

4.9.14.1. Deployment Manager template for the bootstrap machine
You can use the following Deployment Manager template to deploy the bootstrap machine that you need for your OpenShift Container Platform cluster:

Example 4.7. 04_bootstrap.py Deployment Manager template

```python
def GenerateConfig(context):
    resources = [
        {'name': context.properties['infra_id'] + '-bootstrap-public-ip',
         'type': 'compute.v1.address',
         'properties': {
             'region': context.properties['region']
         }},
        {'name': context.properties['infra_id'] + '-bootstrap',
         'type': 'compute.v1.instance',
         'properties': {
             'disks': [{
                 'autoDelete': True,
                 'boot': True,
                 'initializeParams': {
                     'diskSizeGb': context.properties['root_volume_size'],
                     'sourceImage': context.properties['image']
                 }
             }],
             'machineType': 'zones/' + context.properties['zone'] + '/' + context.properties['machine_type'],
             'metadata': {
                 'items': [{
                     'key': 'user-data',
                     'value': '{"ignition":{"config":{"replace":{"source":"' + context.properties['bootstrap_ign'] + '"}}},"version":"3.1.0"}}
                 }],
             'networkInterfaces': [{
                 'subnetwork': context.properties['control_subnet'],
                 'accessConfigs': [{
                     'natIP': '$(ref.' + context.properties['infra_id'] + '-bootstrap-public-ip.address)'
                 }]
             }],
             'tags': {
                 'items': [
                     context.properties['infra_id'] + '-master',
                     context.properties['infra_id'] + '-bootstrap'
                 ],
                 'zone': context.properties['zone']
             }
         }},
        {'name': context.properties['infra_id'] + '-bootstrap-instance-group',
         'type': 'compute.v1.instanceGroup',
         'properties': {
             'namedPorts': [
                 {'name': 'ignition',
                  'port': 22623
             }
        }
```
4.9.15. Creating the control plane machines in GCP

You must create the control plane machines in Google Cloud Platform (GCP) for your cluster to use. One way to create these machines is to modify the provided Deployment Manager template.

**NOTE**

If you do not use the provided Deployment Manager template to create your control plane machines, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

**Prerequisites**

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.
- Create and configure networking and load balancers in GCP.
- Create control plane and compute roles.
- Create the bootstrap machine.

**Procedure**

1. Copy the template from the Deployment Manager template for control plane machines section of this topic and save it as `05_control_plane.py` on your computer. This template describes the control plane machines that your cluster requires.

2. Export the following variable required by the resource definition:

   ```bash
   $ export MASTER_IGNITION=`cat <installation_directory>/master.ign`
   ```

3. Create a `05_control_plane.yaml` resource definition file:

   ```bash
   $ cat <<EOF 05_control_plane.yaml
   imports:
   - path: 05_control_plane.py
   ```
infra_id is the INFRA_ID infrastructure name from the extraction step.

zones are the zones to deploy the control plane instances into, for example us-central1-a, us-central1-b, and us-central1-c.

control_subnet is the selfLink URL to the control subnet.

image is the selfLink URL to the RHCOS image.

machine_type is the machine type of the instance, for example n1-standard-4.

service_account_email is the email address for the master service account that you created.

ignition is the contents of the master.ign file.

4. Create the deployment by using the gcloud CLI:

   $ gcloud deployment-manager deployments create ${INFRA_ID}-control-plane --config 05_control_plane.yaml

5. The templates do not manage load balancer membership due to limitations of Deployment Manager, so you must add the control plane machines manually.

   - Run the following commands to add the control plane machines to the appropriate instance groups:

     $ gcloud compute instance-groups unmanaged add-instances ${INFRA_ID}-master-${ZONE_0}-instance-group --zone=${ZONE_0} --instances=${INFRA_ID}-master-0
     $ gcloud compute instance-groups unmanaged add-instances ${INFRA_ID}-master-${ZONE_1}-instance-group --zone=${ZONE_1} --instances=${INFRA_ID}-master-1
     $ gcloud compute instance-groups unmanaged add-instances ${INFRA_ID}-master-${ZONE_2}-instance-group --zone=${ZONE_2} --instances=${INFRA_ID}-master-2
For an external cluster, you must also run the following commands to add the control plane machines to the target pools:

```
$ gcloud compute target-pools add-instances $(INFRA_ID)-api-target-pool --instances-zone=""$ZONE_0"" --instances=$INFRA_ID-master-0
$ gcloud compute target-pools add-instances $(INFRA_ID)-api-target-pool --instances-zone=""$ZONE_1"" --instances=$INFRA_ID-master-1
$ gcloud compute target-pools add-instances $(INFRA_ID)-api-target-pool --instances-zone=""$ZONE_2"" --instances=$INFRA_ID-master-2
```

### 4.9.15.1. Deployment Manager template for control plane machines

You can use the following Deployment Manager template to deploy the control plane machines that you need for your OpenShift Container Platform cluster:

**Example 4.8. 05_control_plane.py Deployment Manager template**

```python
def GenerateConfig(context):

    resources = [
        {
            'name': context.properties['infra_id'] + '-master-0',
            'type': 'compute.v1.instance',
            'properties': {
                'disks': [
                    {
                        'autoDelete': True,
                        'boot': True,
                        'initializeParams': {
                            'diskSizeGb': context.properties['root_volume_size'],
                            'diskType': 'zones/' + context.properties['zones'][0] + '/diskTypes/pd-ssd',
                            'sourceImage': context.properties['image']
                        }
                    }
                ],
                'machineType': 'zones/' + context.properties['zones'][0] + '/machineTypes/' + context.properties['machine_type'],
                'metadata': {
                    'items': [
                        {'key': 'user-data',
                         'value': context.properties['ignition']
                    ]
                },
                'networkInterfaces': [
                    {'subnetwork': context.properties['control_subnet']}
                ],
                'serviceAccounts': [
                    {'email': context.properties['service_account_email'],
                     'scopes': ['https://www.googleapis.com/auth/cloud-platform']
                ],
                'tags': {
                    'items': [
                        context.properties['infra_id'] + '-master',
                    ]
                },
                'zone': context.properties['zones'][0]
            }
        },
```
'name': context.properties['infra_id'] + '-master-1',
'type': 'compute.v1.instance',
'properties': {
'disks': [
  'autoDelete': True,
  'boot': True,
  'initializeParams': {
    'diskSizeGb': context.properties['root_volume_size'],
    'diskType': 'zones/' + context.properties['zones'][1] + '/diskTypes/pd-ssd',
    'sourceImage': context.properties['image']
  }
],
'machineType': 'zones/' + context.properties['zones'][1] + '/machineTypes/' + context.properties['machine_type'],
'metadata': {
  'items': [{
    'key': 'user-data',
    'value': context.properties['ignition']
  }]
},
'networkInterfaces': [{
  'subnetwork': context.properties['control_subnet']
}],
'serviceAccounts': [{
  'email': context.properties['service_account_email'],
  'scopes': ['https://www.googleapis.com/auth/cloud-platform']
}],
'tags': {
  'items': [context.properties['infra_id'] + '-master', ]
},
'zone': context.properties['zones'][1]
},
{
'name': context.properties['infra_id'] + '-master-2',
'type': 'compute.v1.instance',
'properties': {
'disks': [
  'autoDelete': True,
  'boot': True,
  'initializeParams': {
    'diskSizeGb': context.properties['root_volume_size'],
    'diskType': 'zones/' + context.properties['zones'][2] + '/diskTypes/pd-ssd',
    'sourceImage': context.properties['image']
  }
],
'machineType': 'zones/' + context.properties['zones'][2] + '/machineTypes/' + context.properties['machine_type'],
'metadata': {
  'items': [{
    'key': 'user-data',
    'value': context.properties['ignition']
  }]
},
'networkInterfaces': [{

4.9.16. Wait for bootstrap completion and remove bootstrap resources in GCP

After you create all of the required infrastructure in Google Cloud Platform (GCP), wait for the bootstrap process to complete on the machines that you provisioned by using the Ignition config files that you generated with the installation program.

Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.
- Create and configure networking and load balancers in GCP.
- Create control plane and compute roles.
- Create the bootstrap machine.
- Create the control plane machines.

Procedure

1. Change to the directory that contains the installation program and run the following command:

   ```
   $ ./openshift-install wait-for bootstrap-complete --dir <installation_directory> \  
   --log-level info
   ```

   **1** For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   **2** To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

   If the command exits without a **FATAL** warning, your production control plane has initialized.
2. Delete the bootstrap resources:

```bash
$ gcloud compute backend-services remove-backend ${INFRA_ID}-api-internal-backend-service --region=${REGION} --instance-group=${INFRA_ID}-bootstrap-instance-group --instance-group-zone=${ZONE_0}
$ gsutil rm gs://${INFRA_ID}-bootstrap-ignition/bootstrap.ign
$ gsutil rb gs://${INFRA_ID}-bootstrap-ignition
$ gcloud deployment-manager deployments delete ${INFRA_ID}-bootstrap
```

### 4.9.17. Creating additional worker machines in GCP

You can create worker machines in Google Cloud Platform (GCP) for your cluster to use by launching individual instances discretely or by automated processes outside the cluster, such as auto scaling groups. You can also take advantage of the built-in cluster scaling mechanisms and the machine API in OpenShift Container Platform.

In this example, you manually launch one instance by using the Deployment Manager template. Additional instances can be launched by including additional resources of type `06_worker.py` in the file.

**NOTE**

If you do not use the provided Deployment Manager template to create your worker machines, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

**Prerequisites**

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.
- Create and configure networking and load balancers in GCP.
- Create control plane and compute roles.
- Create the bootstrap machine.
- Create the control plane machines.

**Procedure**

1. Copy the template from the **Deployment Manager template for worker machines** section of this topic and save it as `06_worker.py` on your computer. This template describes the worker machines that your cluster requires.

2. Export the variables that the resource definition uses.
   a. Export the subnet that hosts the compute machines:

```bash
$ export COMPUTE_SUBNET=`(gcloud compute networks subnets describe ${INFRA_ID}-worker-subnet --region=${REGION} --format json | jq -r .selfLink)`
```
b. Export the email address for your service account:

```
$ export WORKER_SERVICE_ACCOUNT=`gcloud iam service-accounts list --filter "email~^${INFRA_ID}-w@${PROJECT_NAME}." --format json | jq -r ".[0].email"
```

c. Export the location of the compute machine Ignition config file:

```
$ export WORKER_IGNITION=`cat <installation_directory>/worker.ign`
```

3. Create a **06_worker.yaml** resource definition file:

```
$ cat <<EOF >06_worker.yaml
imports:
- path: 06_worker.py
resources:
- name: 'worker-0'
  type: 06_worker.py
  properties:
    infra_id: '${INFRA_ID}'
    zone: '${ZONE_0}'
    compute_subnet: '${COMPUTE_SUBNET}'
    image: '${CLUSTER_IMAGE}'
    machine_type: 'n1-standard-4'
    root_volume_size: '128'
    service_account_email: '${WORKER_SERVICE_ACCOUNT}'
- name: 'worker-1'
  type: 06_worker.py
  properties:
    infra_id: '${INFRA_ID}'
    zone: '${ZONE_1}'
    compute_subnet: '${COMPUTE_SUBNET}'
    image: '${CLUSTER_IMAGE}'
    machine_type: 'n1-standard-4'
    root_volume_size: '128'
    service_account_email: '${WORKER_SERVICE_ACCOUNT}'
EOF
```

1. **name** is the name of the worker machine, for example **worker-0**.
2. **infra_id** is the **INFRA_ID** infrastructure name from the extraction step.
3. **zone** is the zone to deploy the worker machine into, for example **us-central1-a**.
4. **compute_subnet** is the **selfLink** URL to the compute subnet.
5. **image** is the **selfLink** URL to the RHCOS image.
6. **machine_type** is the machine type of the instance, for example **n1-standard-4**.
7. **service_account_email** is the email address for the worker service account that you created.
4. Optional: If you want to launch additional instances, include additional resources of type `06_worker.py` in your `06_worker.yaml` resource definition file.

5. Create the deployment by using the `gcloud` CLI:

   ```
   $ gcloud deployment-manager deployments create ${INFRA_ID}-worker --config 06_worker.yaml
   ```

### 4.9.17.1. Deployment Manager template for worker machines

You can use the following Deployment Manager template to deploy the worker machines that you need for your OpenShift Container Platform cluster:

**Example 4.9. 06_worker.py Deployment Manager template**

```python
def GenerateConfig(context):

    resources = [{
        'name': context.properties['infra_id'] + '-' + context.env['name'],
        'type': 'compute.v1.instance',
        'properties': {
            'disks': [{
                'autoDelete': True,
                'boot': True,
                'initializeParams': {
                    'diskSizeGb': context.properties['root_volume_size'],
                    'sourceImage': context.properties['image']
                }
            }],
            'machineType': 'zones/' + context.properties['zone'] + '/machineTypes/' + context.properties['machine_type'],
            'metadata': {
                'items': [{
                    'key': 'user-data',
                    'value': context.properties['ignition']
                }]
            },
            'networkInterfaces': [{
                'subnetwork': context.properties['compute_subnet']
            }],
            'serviceAccounts': [{
                'email': context.properties['service_account_email'],
                'scopes': ['https://www.googleapis.com/auth/cloud-platform']
            }],
            'tags': {
                'items': [context.properties['infra_id'] + '-worker',
                ]
            },
            'zone': context.properties['zone']
        }
    }
```
4.9.18. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) in order to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.6. Download and install the new version of oc.

4.9.18.1. Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

**Procedure**

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.6 Linux Client entry and save the file.

4. Unpack the archive:

   ```
   $ tar xzvf <file>
   ```

5. Place the oc binary in a directory that is on your PATH.

   To check your PATH, execute the following command:

   ```
   $ echo $PATH
   ```

After you install the OpenShift CLI, it is available using the oc command:

```
$ oc <command>
```

4.9.18.2. Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version in the Version drop-down menu.
3. Click **Download Now** next to the **OpenShift v4.6 Windows Client** entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the **oc** binary to a directory that is on your **PATH**. To check your **PATH**, open the command prompt and execute the following command:

   ```
   C:\> path
   ```

After you install the OpenShift CLI, it is available using the **oc** command:

   ```
   C:\> oc <command>
   ```

### 4.9.18.3. Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (**oc**) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.

3. Click **Download Now** next to the **OpenShift v4.6 MacOSX Client** entry and save the file.

4. Unpack and unzip the archive.

5. Move the **oc** binary to a directory on your **PATH**. To check your **PATH**, open a terminal and execute the following command:

   ```
   $ echo $PATH
   ```

After you install the OpenShift CLI, it is available using the **oc** command:

   ```
   $ oc <command>
   ```

### 4.9.19. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster **kubeconfig** file. The **kubeconfig** file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the **oc** CLI.

**Procedure**

1. Export the **kubeadm** credentials:
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   $ oc whoami

   **Example output**
   
   system:admin

4.9.20. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

**Prerequisites**

- You added machines to your cluster.

**Procedure**

1. Confirm that the cluster recognizes the machines:

   $ oc get nodes

   **Example output**
   
   ```
   NAME      STATUS    ROLES   AGE  VERSION
   master-0  Ready     master  63m  v1.19.0
   master-1  Ready     master  63m  v1.19.0
   master-2  Ready     master  64m  v1.19.0
   ```

   The output lists all of the machines that you created.

   **NOTE**
   
   The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

   $ oc get csr

   **Example output**
In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in Pending status, approve the CSRs for your cluster machines:

NOTE

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. Once the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the machine-approver if the Kubelet requests a new certificate with identical parameters.

NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the oc exec, oc rsh, and oc logs commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the node-bootstrapper service account in the system:node or system:admin groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

$$ oc adm certificate approve <csr_name>$$

1 $<csr_name>$ is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

$$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve$$

NOTE

Some Operators might not become available until some CSRs are approved.
4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-c57lv</td>
<td>5m26s</td>
<td>system:node:ip-10-0-95-157.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
</tbody>
</table>

5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name>  
```

<csr_name> is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs oc adm certificate approve
```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>74m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>worker-0</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>worker-1</td>
<td>Ready</td>
<td>worker</td>
<td>11m</td>
<td>v1.20.0</td>
</tr>
</tbody>
</table>

**NOTE**

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

**Additional information**

- For more information on CSRs, see [Certificate Signing Requests](#).
4.9.21. Optional: Adding the ingress DNS records

If you removed the DNS zone configuration when creating Kubernetes manifests and generating Ignition configs, you must manually create DNS records that point at the ingress load balancer. You can create either a wildcard `*.apps.{baseDomain}`, or specific records. You can use A, CNAME, and other records per your requirements.

Prerequisites

- Configure a GCP account.
- Remove the DNS Zone configuration when creating Kubernetes manifests and generating Ignition configs.
- Create and configure a VPC and associated subnets in GCP.
- Create and configure networking and load balancers in GCP.
- Create control plane and compute roles.
- Create the bootstrap machine.
- Create the control plane machines.
- Create the worker machines.

Procedure

1. Wait for the Ingress router to create a load balancer and populate the **EXTERNAL-IP** field:

   ```
   $ oc -n openshift-ingress get service router-default
   
   NAME             TYPE           CLUSTER-IP      EXTERNAL-IP      PORT(S)                      AGE
   
   $ export ROUTER_IP=`oc -n openshift-ingress get service router-default --no-headers | awk '{print $4}'`
   
   $ if [ -f transaction.yaml ]; then rm transaction.yaml; fi
   $ gcloud dns record-sets transaction start --zone ${INFRA_ID}-private-zone
   $ gcloud dns record-sets transaction add ${ROUTER_IP} --name ".apps.${CLUSTER_NAME}.${BASE_DOMAIN}. --ttl 300 --type A --zone ${INFRA_ID}-private-zone
   $ gcloud dns record-sets transaction execute --zone ${INFRA_ID}-private-zone
   ```

2. Add the A record to your zones:

   - To use A records:
     
     i. Export the variable for the router IP address:
     
     ```
     $ export ROUTER_IP=`oc -n openshift-ingress get service router-default --no-headers | awk '{print $4}'`
     
     $ if [ -f transaction.yaml ]; then rm transaction.yaml; fi
     $ gcloud dns record-sets transaction start --zone ${INFRA_ID}-private-zone
     $ gcloud dns record-sets transaction add ${ROUTER_IP} --name ".apps.${CLUSTER_NAME}.${BASE_DOMAIN}. --ttl 300 --type A --zone ${INFRA_ID}-private-zone
     $ gcloud dns record-sets transaction execute --zone ${INFRA_ID}-private-zone
     ```

   ii. Add the A record to the private zones:
iii. For an external cluster, also add the A record to the public zones:

```sh
if [ -f transaction.yaml ]; then rm transaction.yaml; fi
$ gcloud dns record-sets transaction start --zone ${BASE_DOMAIN_ZONE_NAME}
$ gcloud dns record-sets transaction add ${ROUTER_IP} --name \
\*.apps.${CLUSTER_NAME}.${BASE_DOMAIN} --ttl 300 --type A --zone
${BASE_DOMAIN_ZONE_NAME}
$ gcloud dns record-sets transaction execute --zone
${BASE_DOMAIN_ZONE_NAME}
```

- To add explicit domains instead of using a wildcard, create entries for each of the cluster’s current routes:

```sh
$ oc get --all-namespaces -o jsonpath='{range .items[*]}
{range .status.ingress[*]}
{.host}
{"\n"}
{end}
{end}' routes
```

Example output

- `oauth-openshift.apps.your.cluster.domain.example.com`
- `console-openshift-console.apps.your.cluster.domain.example.com`
- `downloads-openshift-console.apps.your.cluster.domain.example.com`
- `alertmanager-main-openshift-monitoring.apps.your.cluster.domain.example.com`
- `grafana-openshift-monitoring.apps.your.cluster.domain.example.com`
- `prometheus-k8s-openshift-monitoring.apps.your.cluster.domain.example.com`

4.9.22. Completing a GCP installation on user-provisioned infrastructure

After you start the OpenShift Container Platform installation on Google Cloud Platform (GCP) user-provisioned infrastructure, you can monitor the cluster events until the cluster is ready.

**Prerequisites**

- Deploy the bootstrap machine for an OpenShift Container Platform cluster on user-provisioned GCP infrastructure.
- Install the `oc` CLI and log in.

**Procedure**

1. Complete the cluster installation:

```sh
$ ./openshift-install --dir <installation_directory> wait-for install-complete
```

**Example output**

```
INFO Waiting up to 30m0s for the cluster to initialize...
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.
IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

2. Observe the running state of your cluster.
   a. Run the following command to view the current cluster version and status:

   ```
   $ oc get clusterversion
   ```

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>SINCE</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>version</td>
<td>4.5.4</td>
<td>True</td>
<td>False</td>
<td>24m</td>
<td>Working towards 4.5.4: 99% complete</td>
</tr>
</tbody>
</table>

   b. Run the following command to view the Operators managed on the control plane by the Cluster Version Operator (CVO):

   ```
   $ oc get clusteroperators
   ```

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED</th>

</tbody>
</table>

When the current cluster version is **AVAILABLE**, the installation is complete.

4.9.23. Telemetry access for OpenShift Container Platform
In OpenShift Container Platform 4.6, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources
- See About remote health monitoring for more information about the Telemetry service

4.9.24. Next steps
- Customize your cluster.
- If necessary, you can opt out of remote health reporting.

4.10. INSTALLING A CLUSTER INTO A SHARED VPC ON GCP USING DEPLOYMENT MANAGER TEMPLATES

In OpenShift Container Platform version 4.6, you can install a cluster into a shared Virtual Private Cloud (VPC) on Google Cloud Platform (GCP) that uses infrastructure that you provide. In this context, a cluster installed into a shared VPC is a cluster that is configured to use a VPC from a project different from where the cluster is being deployed.

A shared VPC enables an organization to connect resources from multiple projects to a common VPC network. You can communicate within the organization securely and efficiently by using internal IPs from that network. For more information about shared VPC, see Shared VPC overview in the GCP documentation.

The steps for performing a user-provided infrastructure installation into a shared VPC are outlined here. Several Deployment Manager templates are provided to assist in completing these steps or to help model your own. You are also free to create the required resources through other methods.

IMPORTANT

The steps for performing a user-provisioned infrastructure installation are provided as an example only. Installing a cluster with infrastructure you provide requires knowledge of the cloud provider and the installation process of OpenShift Container Platform. Several Deployment Manager templates are provided to assist in completing these steps or to help model your own. You are also free to create the required resources through other methods; the templates are just an example.

4.10.1. Prerequisites
- Review details about the OpenShift Container Platform installation and update processes.
- If you use a firewall and plan to use telemetry, you must configure the firewall to allow the sites that your cluster requires access to.
- If you do not allow the system to manage identity and access management (IAM), then a cluster administrator can manually create and maintain IAM credentials. Manual mode can also be used in environments where the cloud IAM APIs are not reachable.
4.10.2. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The `kube-controller-manager` only approves the kubelet client CSRs. The `machine-approver` cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

4.10.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.6, you require access to the Internet to install your cluster.

You must have Internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

4.10.4. Configuring the GCP project that hosts your cluster

Before you can install OpenShift Container Platform, you must configure a Google Cloud Platform (GCP) project to host it.

4.10.4.1. Creating a GCP project

To install OpenShift Container Platform, you must create a project in your Google Cloud Platform (GCP) account to host the cluster.

**Procedure**

- Create a project to host your OpenShift Container Platform cluster. See Creating and Managing Projects in the GCP documentation.
4.10.4.2. Enabling API services in GCP

Your Google Cloud Platform (GCP) project requires access to several API services to complete OpenShift Container Platform installation.

**Prerequisites**

- You created a project to host your cluster.

**Procedure**

- Enable the following required API services in the project that hosts your cluster. See Enabling services in the GCP documentation.

**Table 4.37. Required API services**

<table>
<thead>
<tr>
<th>API service</th>
<th>Console service name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cloud Deployment Manager V2 API</td>
<td>deploymentmanager.googleapis.com</td>
</tr>
<tr>
<td>Compute Engine API</td>
<td>compute.googleapis.com</td>
</tr>
<tr>
<td>Google Cloud APIs</td>
<td>cloudapis.googleapis.com</td>
</tr>
<tr>
<td>Cloud Resource Manager API</td>
<td>cloudresourcemanager.googleapis.com</td>
</tr>
<tr>
<td>Google DNS API</td>
<td>dns.googleapis.com</td>
</tr>
<tr>
<td>IAM Service Account Credentials API</td>
<td>iamcredentials.googleapis.com</td>
</tr>
<tr>
<td>Identity and Access Management (IAM) API</td>
<td>iam.googleapis.com</td>
</tr>
<tr>
<td>Service Management API</td>
<td>servicemanagement.googleapis.com</td>
</tr>
<tr>
<td>Service Usage API</td>
<td>serviceusage.googleapis.com</td>
</tr>
<tr>
<td>Google Cloud Storage JSON API</td>
<td>storage-api.googleapis.com</td>
</tr>
<tr>
<td>Cloud Storage</td>
<td>storage-component.googleapis.com</td>
</tr>
</tbody>
</table>

4.10.4.3. GCP account limits
The OpenShift Container Platform cluster uses a number of Google Cloud Platform (GCP) components, but the default Quotas do not affect your ability to install a default OpenShift Container Platform cluster.

A default cluster, which contains three compute and three control plane machines, uses the following resources. Note that some resources are required only during the bootstrap process and are removed after the cluster deploys.

**Table 4.38. GCP resources used in a default cluster**

<table>
<thead>
<tr>
<th>Service</th>
<th>Component</th>
<th>Location</th>
<th>Total resources required</th>
<th>Resources removed after bootstrap</th>
</tr>
</thead>
<tbody>
<tr>
<td>Service account</td>
<td>IAM</td>
<td>Global</td>
<td>5</td>
<td>0</td>
</tr>
<tr>
<td>Firewall rules</td>
<td>Networking</td>
<td>Global</td>
<td>11</td>
<td>1</td>
</tr>
<tr>
<td>Forwarding rules</td>
<td>Compute</td>
<td>Global</td>
<td>2</td>
<td>0</td>
</tr>
<tr>
<td>Health checks</td>
<td>Compute</td>

<td>2</td>
<td>0</td>
</tr>
<tr>
<td>Images</td>
<td>Compute</td>
<td>Global</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>Networks</td>
<td>Networking</td>
<td>Global</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>Routers</td>
<td>Networking</td>
<td>Global</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>Routes</td>
<td>Networking</td>
<td>Global</td>
<td>2</td>
<td>0</td>
</tr>
<tr>
<td>Subnetworks</td>
<td>Compute</td>
<td>Global</td>
<td>2</td>
<td>0</td>
</tr>
<tr>
<td>Target pools</td>
<td>Networking</td>
<td>Global</td>
<td>2</td>
<td>0</td>
</tr>
</tbody>
</table>

**NOTE**

If any of the quotas are insufficient during installation, the installation program displays an error that states both which quota was exceeded and the region.

Be sure to consider your actual cluster size, planned cluster growth, and any usage from other clusters that are associated with your account. The CPU, static IP addresses, and persistent disk SSD (storage) quotas are the ones that are most likely to be insufficient.

If you plan to deploy your cluster in one of the following regions, you will exceed the maximum storage quota and are likely to exceed the CPU quota limit:

- asia-east2
- asia-northeast2
- asia-south1
4.10.4.4. Creating a service account in GCP

OpenShift Container Platform requires a Google Cloud Platform (GCP) service account that provides authentication and authorization to access data in the Google APIs. If you do not have an existing IAM service account that contains the required roles in your project, you must create one.

Prerequisites

- You created a project to host your cluster.

Procedure

1. Create a service account in the project that you use to host your OpenShift Container Platform cluster. See Creating a service account in the GCP documentation.

2. Grant the service account the appropriate permissions. You can either grant the individual permissions that follow or assign the Owner role to it. See Granting roles to a service account for specific resources.

   NOTE

   While making the service account an owner of the project is the easiest way to gain the required permissions, it means that service account has complete control over the project. You must determine if the risk that comes from offering that power is acceptable.

3. Create the service account key in JSON format. See Creating service account keys in the GCP documentation.
   The service account key is required to create a cluster.

4.10.4.4.1. Required GCP permissions

When you attach the Owner role to the service account that you create, you grant that service account all permissions, including those that are required to install OpenShift Container Platform. To deploy an OpenShift Container Platform cluster, the service account requires the following permissions. If you
deploy your cluster into an existing VPC, the service account does not require certain networking permissions, which are noted in the following lists:

**Required roles for the installation program**
- Compute Admin
- Security Admin
- Service Account Admin
- Service Account User
- Storage Admin

**Required roles for creating network resources during installation**
- DNS Administrator

**Required roles for user-provisioned GCP infrastructure**
- Deployment Manager Editor
- Service Account Key Admin

**Optional roles**
For the cluster to create new limited credentials for its Operators, add the following role:
- Service Account Key Admin

The roles are applied to the service accounts that the control plane and compute machines use:

<table>
<thead>
<tr>
<th>Account</th>
<th>Roles</th>
</tr>
</thead>
<tbody>
<tr>
<td>Control Plane</td>
<td>roles/compute.instanceAdmin</td>
</tr>
<tr>
<td></td>
<td>roles/compute.networkAdmin</td>
</tr>
<tr>
<td></td>
<td>roles/compute.securityAdmin</td>
</tr>
<tr>
<td></td>
<td>roles/storage.admin</td>
</tr>
<tr>
<td></td>
<td>roles/iam.serviceAccountUser</td>
</tr>
<tr>
<td>Compute</td>
<td>roles/compute.viewer</td>
</tr>
<tr>
<td></td>
<td>roles/storage.admin</td>
</tr>
</tbody>
</table>

**4.10.4.5. Supported GCP regions**
You can deploy an OpenShift Container Platform cluster to the following Google Cloud Platform (GCP) regions:

- **asia-east1** (Changhua County, Taiwan)
- **asia-east2** (Hong Kong)
- **asia-northeast1** (Tokyo, Japan)
- **asia-northeast2** (Osaka, Japan)
- **asia-northeast3** (Seoul, South Korea)
- **asia-south1** (Mumbai, India)
- **asia-southeast1** (Jurong West, Singapore)
- **asia-southeast2** (Jakarta, Indonesia)
- **australia-southeast1** (Sydney, Australia)
- **europe-north1** (Hamina, Finland)
- **europe-west1** (St. Ghislain, Belgium)
- **europe-west2** (London, England, UK)
- **europe-west3** (Frankfurt, Germany)
- **europe-west4** (Eemshaven, Netherlands)
- **europe-west6** (Zürich, Switzerland)
- **northamerica-northeast1** (Montréal, Québec, Canada)
- **southamerica-east1** (São Paulo, Brazil)
- **us-central1** (Council Bluffs, Iowa, USA)
- **us-east1** (Moncks Corner, South Carolina, USA)
- **us-east4** (Ashburn, Northern Virginia, USA)
- **us-west1** (The Dalles, Oregon, USA)
- **us-west2** (Los Angeles, California, USA)
- **us-west3** (Salt Lake City, Utah, USA)
- **us-west4** (Las Vegas, Nevada, USA)

### 4.10.4.6. Installing and configuring CLI tools for GCP

To install OpenShift Container Platform on Google Cloud Platform (GCP) using user-provisioned infrastructure, you must install and configure the CLI tools for GCP.

**Prerequisites**
You created a project to host your cluster.

You created a service account and granted it the required permissions.

**Procedure**

1. Install the following binaries in `$PATH`:
   - `gcloud`
   - `gsutil`

   See [Install the latest Cloud SDK version](#) in the GCP documentation.

2. Authenticate using the `gcloud` tool with your configured service account.

   See [Authorizing with a service account](#) in the GCP documentation.

### 4.10.5. Configuring the GCP project that hosts your shared VPC network

If you use a shared Virtual Private Cloud (VPC) to host your OpenShift Container Platform cluster in Google Cloud Platform (GCP), you must configure the project that hosts it.

**NOTE**

If you already have a project that hosts the shared VPC network, review this section to ensure that the project meets all of the requirements to install an OpenShift Container Platform cluster.

**Procedure**

1. Create a project to host the shared VPC for your OpenShift Container Platform cluster. See [Creating and Managing Projects](#) in the GCP documentation.

2. Create a service account in the project that hosts your shared VPC. See [Creating a service account](#) in the GCP documentation.

3. Grant the service account the appropriate permissions. You can either grant the individual permissions that follow or assign the **Owner** role to it. See [Granting roles to a service account for specific resources](#).
While making the service account an owner of the project is the easiest way to gain the required permissions, it means that service account has complete control over the project. You must determine if the risk that comes from offering that power is acceptable.

The service account for the project that hosts the shared VPC network requires the following roles:

- Compute Network User
- Compute Security Admin
- Deployment Manager Editor
- DNS Administrator
- Security Admin
- Network Management Admin

### 4.10.5.1. Configuring DNS for GCP

To install OpenShift Container Platform, the Google Cloud Platform (GCP) account you use must have a dedicated public hosted zone in the project that hosts the shared VPC that you install the cluster into. This zone must be authoritative for the domain. The DNS service provides cluster DNS resolution and name lookup for external connections to the cluster.

**Procedure**

1. Identify your domain, or subdomain, and registrar. You can transfer an existing domain and registrar or obtain a new one through GCP or another source.

   **NOTE**
   
   If you purchase a new domain, it can take time for the relevant DNS changes to propagate. For more information about purchasing domains through Google, see [Google Domains](https://domains.google). (59)

2. Create a public hosted zone for your domain or subdomain in your GCP project. See [Creating public zones](https://cloud.google.com/) in the GCP documentation.
   
   Use an appropriate root domain, such as `openshiftcorp.com`, or subdomain, such as `clusters.openshiftcorp.com`.

3. Extract the new authoritative name servers from the hosted zone records. See [Look up your Cloud DNS name servers](https://cloud.google.com/) in the GCP documentation.
   
   You typically have four name servers.

4. Update the registrar records for the name servers that your domain uses. For example, if you registered your domain to Google Domains, see the following topic in the Google Domains Help: [How to switch to custom name servers](https://domains.google). (59)

5. If you migrated your root domain to Google Cloud DNS, migrate your DNS records. See [Migrating to Cloud DNS](https://cloud.google.com/) in the GCP documentation.
6. If you use a subdomain, follow your company’s procedures to add its delegation records to the parent domain. This process might include a request to your company’s IT department or the division that controls the root domain and DNS services for your company.

### 4.10.5.2. Creating a VPC in GCP

You must create a VPC in Google Cloud Platform (GCP) for your OpenShift Container Platform cluster to use. You can customize the VPC to meet your requirements. One way to create the VPC is to modify the provided Deployment Manager template.

**NOTE**

If you do not use the provided Deployment Manager template to create your GCP infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

**Prerequisites**

- Configure a GCP account.

**Procedure**

1. Copy the template from the Deployment Manager template for the VPC section of this topic and save it as `01_vpc.py` on your computer. This template describes the VPC that your cluster requires.

2. Export the following variables required by the resource definition:
   
   a. Export the control plane CIDR:
      ```
      $ export MASTER_SUBNET_CIDR='10.0.0.0/19'
      ```
   
   b. Export the compute CIDR:
      ```
      $ export WORKER_SUBNET_CIDR='10.0.32.0/19'
      ```
   
   c. Export the region to deploy the VPC network and cluster to:
      ```
      $ export REGION='<region>'
      ```

3. Export the variable for the ID of the project that hosts the shared VPC:

   ```
   $ export HOST_PROJECT=<host_project>
   ```

4. Export the variable for the email of the service account that belongs to host project:

   ```
   $ export HOST_PROJECT_ACCOUNT=<host_service_account_email>
   ```

5. Create a `01_vpc.yaml` resource definition file:

   ```
   $ cat <<EOF >01_vpc.yaml
   imports:
   ```

   ```python
   ```
infra_id is the prefix of the network name.

region is the region to deploy the cluster into, for example us-central1.

master_subnet_cidr is the CIDR for the master subnet, for example 10.0.0.0/19.

worker_subnet_cidr is the CIDR for the worker subnet, for example 10.0.32.0/19.

6. Create the deployment by using the gcloud CLI:

   $ gcloud deployment-manager deployments create <vpc_deployment_name> --config 01_vpc.yaml --project ${HOST_PROJECT} --account ${HOST_PROJECT_ACCOUNT}

For <vpc_deployment_name>, specify the name of the VPC to deploy.

7. Export the VPC variable that other components require:

   a. Export the name of the host project network:

      $ export HOST_PROJECT_NETWORK=<vpc_network>

   b. Export the name of the host project control plane subnet:

      $ export HOST_PROJECT_CONTROL_SUBNET=<control_plane_subnet>

   c. Export the name of the host project compute subnet:

      $ export HOST_PROJECT_COMPUTE_SUBNET=<compute_subnet>

8. Set up the shared VPC. See Setting up Shared VPC in the GCP documentation.

4.10.5.2.1. Deployment Manager template for the VPC

You can use the following Deployment Manager template to deploy the VPC that you need for your OpenShift Container Platform cluster:

Example 4.10. 01_vpc.py Deployment Manager template

def GenerateConfig(context):

- path: 01_vpc.py
  resources:
    - name: cluster-vpc
      type: 01_vpc.py
      properties:
        infra_id: '<prefix>'
        region: '${REGION}'
        master_subnet_cidr: '${MASTER_SUBNET_CIDR}'
        worker_subnet_cidr: '${WORKER_SUBNET_CIDR}'

EOF
resources = [
    {'name': context.properties['infra_id'] + '-network',
     'type': 'compute.v1.network',
     'properties': {
         'region': context.properties['region'],
         'autoCreateSubnetworks': False
     }
    ],
    {'name': context.properties['infra_id'] + '-master-subnet',
     'type': 'compute.v1.subnetwork',
     'properties': {
         'region': context.properties['region'],
         'network': '${ref.' + context.properties['infra_id'] + '-network.selfLink}',
         'ipCidrRange': context.properties['master_subnet_cidr']
     }
    ],
    {'name': context.properties['infra_id'] + '-worker-subnet',
     'type': 'compute.v1.subnetwork',
     'properties': {
         'region': context.properties['region'],
         'network': '${ref.' + context.properties['infra_id'] + '-network.selfLink}',
         'ipCidrRange': context.properties['worker_subnet_cidr']
     }
    ],
    {'name': context.properties['infra_id'] + '-router',
     'type': 'compute.v1.router',
     'properties': {
         'region': context.properties['region'],
         'network': '${ref.' + context.properties['infra_id'] + '-network.selfLink}',
         'nats': [{
             'name': context.properties['infra_id'] + '-nat-master',
             'natIpAllocateOption': 'AUTO_ONLY',
             'minPortsPerVm': 7168,
             'sourceSubnetworkIpRangesToNat': 'LIST_OF_SUBNETWORKS',
             'subnetworks': [{
                 'name': '${ref.' + context.properties['infra_id'] + '-master-subnet.selfLink}',
                 'sourceIpRangesToNat': ['ALL_IP_RANGES']
             }]
         }, {
             'name': context.properties['infra_id'] + '-nat-worker',
             'natIpAllocateOption': 'AUTO_ONLY',
             'minPortsPerVm': 512,
             'sourceSubnetworkIpRangesToNat': 'LIST_OF_SUBNETWORKS',
             'subnetworks': [{
                 'name': '${ref.' + context.properties['infra_id'] + '-worker-subnet.selfLink}',
                 'sourceIpRangesToNat': ['ALL_IP_RANGES']
             }]
         }]
     }
    ]
]

return {'resources': resources}
To install OpenShift Container Platform on Google Cloud Platform (GCP) using user-provisioned infrastructure, you must generate the files that the installation program needs to deploy your cluster and modify them so that the cluster creates only the machines that it will use. You generate and customize the `install-config.yaml` file, Kubernetes manifests, and Ignition config files. You also have the option to first set up a separate `var` partition during the preparation phases of installation.

4.10.6.1. Manually creating the installation configuration file

For installations of OpenShift Container Platform that use user-provisioned infrastructure, you manually generate your installation configuration file.

Prerequisites

- Obtain the OpenShift Container Platform installation program and the access token for your cluster.

Procedure

1. Create an installation directory to store your required installation assets in:

   ```
   $ mkdir <installation_directory>
   ```

   **IMPORTANT**

   You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the following `install-config.yaml` file template and save it in the `<installation_directory>`.

   **NOTE**

   You must name this configuration file `install-config.yaml`.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

   **IMPORTANT**

   The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.

4.10.6.2. Sample customized `install-config.yaml` file for GCP

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.
IMPORTANT

This sample YAML file is provided for reference only. You must obtain your `install-config.yaml` file by using the installation program and modify it.

```yaml
apiVersion: v1
baseDomain: example.com
controlPlane:
  hyperthreading: Enabled
  name: master
  platform:
    gcp:
      type: n2-standard-4
      zones:
        - us-central1-a
        - us-central1-c
  replicas: 3
compute:
  - hyperthreading: Enabled
  name: worker
  platform:
    gcp:
      type: n2-standard-4
      zones:
        - us-central1-a
        - us-central1-c
  replicas: 0
metadata:
  name: test-cluster
networking:
  clusterNetwork:
    - cidr: 10.128.0.0/14
    hostPrefix: 23
  machineNetwork:
    - cidr: 10.0.0.0/16
  networkType: OpenShiftSDN
  serviceNetwork:
    - 172.30.0.0/16
platform:
  gcp:
    projectID: openshift-production
    region: us-central1
  pullSecret: '{"auths": ...}'
  fips: false
  sshKey: ssh-ed25519 AAAA...
publish: Internal
```

1. Specify the public DNS on the host project.
2. [If you do not provide these parameters and values, the installation program provides the default value.](#)
3. The `controlPlane` section is a single mapping, but the compute section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the `compute` section must begin with a hyphen `-`, and the first line of the `controlPlane` section must not. Although both...
must begin with a hyphen, `-`, and the first line of the `control-plane` section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading, or hyperthreading. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to Disabled. If you disable simultaneous multithreading in some cluster machines, you must disable it in all cluster machines.

**IMPORTANT**

If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance. Use larger machine types, such as `n1-standard-8`, for your machines if you disable simultaneous multithreading.

Specify the main project where the VM instances reside.

Specify the region that your VPC network is in.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the `x86_64` architecture.

You can optionally provide the `sshKey` value that you use to access the machines in your cluster.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

How to publish the user-facing endpoints of your cluster. Set `publish` to Internal to deploy a private cluster, which cannot be accessed from the Internet. The default value is External. To use a shared VPC in a cluster that uses infrastructure that you provision, you must set `publish` to Internal. The installation program will no longer be able to access the public DNS zone for the base domain in the host project.

### 4.10.6.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the `install-config.yaml` file.

**Prerequisites**
You have an existing `install-config.yaml` file.

You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

**NOTE**

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port> 1
  httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
  noProxy: example.com 3
additionalTrustBundle: |
    -----BEGIN CERTIFICATE-----
    <MY_TRUSTED_CA_CERT>
    -----END CERTIFICATE-----
    ...
```

1. A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.

2. A proxy URL to use for creating HTTPS connections outside the cluster.

3. A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, `.y.com` matches `x.y.com`, but not `y.com`. Use `*` to bypass the proxy for all destinations.

4. If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace to hold the additional CA certificates. If you provide `additionalTrustBundle` and at least one proxy setting, the `Proxy` object is configured to reference the `user-ca-bundle` config map in the `trustedCA` field. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges the contents specified for the `trustedCA` parameter with the RHCOS trust bundle. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.
NOTE

The installation program does not support the proxy `readinessEndpoints` field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

NOTE

Only the `Proxy` object named `cluster` is supported, and no additional proxies can be created.

4.10.6.4. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to make its machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to create the cluster.

IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

Prerequisites

- You obtained the OpenShift Container Platform installation program.
- You created the `install-config.yaml` installation configuration file.

Procedure

1. Change to the directory that contains the installation program and generate the Kubernetes manifests for the cluster:

   ```
   $ ./openshift-install create manifests --dir <installation_directory>
   ```

   Example output
For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.

2. Remove the Kubernetes manifest files that define the control plane machines:

   ```bash
   $ rm -f <installation_directory>/openshift/99_openshift-cluster-api_master-machines-*.yaml
   ```

   By removing these files, you prevent the cluster from automatically generating control plane machines.

3. Remove the Kubernetes manifest files that define the worker machines:

   ```bash
   $ rm -f <installation_directory>/openshift/99_openshift-cluster-api_worker-machineset-*.yaml
   ```

   Because you create and manage the worker machines yourself, you do not need to initialize these machines.

4. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:

   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.

   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.

   c. Save and exit the file.

5. Remove the `privateZone` sections from the `<installation_directory>/manifests/cluster-dns-02-config.yml` DNS configuration file:

   ```yaml
   apiVersion: config.openshift.io/v1
   kind: DNS
   metadata:
     creationTimestamp: null
     name: cluster
   spec:
     baseDomain: example.openshift.com
     privateZone: 1
     id: mycluster-100419-private-zone
     status: {}
   ```

   Remove this section completely.

6. Configure the cloud provider for your VPC.

   a. Open the `<installation_directory>/manifests/cloud-provider-config.yaml` file.

   b. Add the `network-project-id` parameter and set its value to the ID of project that hosts the shared VPC network.
c. Add the `network-name` parameter and set its value to the name of the shared VPC network that hosts the OpenShift Container Platform cluster.

d. Replace the value of the `subnetwork-name` parameter with the value of the shared VPC subnet that hosts your compute machines.

The contents of the `<installation_directory>/manifests/cloud-provider-config.yaml` resemble the following example:

```yaml
---
config: |
  [global]
  project-id = example-project
  regional = true
  multizone = true
  node-tags = opensh-ptzzx-master
  node-tags = opensh-ptzzx-worker
  node-instance-prefix = opensh-ptzzx
  external-instance-groups-prefix = opensh-ptzzx
  network-project-id = example-shared-vpc
  network-name = example-network
  subnetwork-name = example-worker-subnet
```

7. If you deploy a cluster that is not on a private network, open the `<installation_directory>/manifests/cluster-ingress-default-ingresscontroller.yaml` file and replace the value of the `scope` parameter with `External`. The contents of the file resemble the following example:

```yaml
apiVersion: operator.openshift.io/v1
kind: IngressController
metadata:
  creationTimestamp: null
  name: default
  namespace: openshift-ingress-operator
spec:
  endpointPublishingStrategy:
    loadBalancer:
      scope: External
      type: LoadBalancerService
status:
  availableReplicas: 0
  domain: '
  selector: ''
```

8. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

```
$ ./openshift-install create ignition-configs --dir `<installation_directory>`
```

For `<installation_directory>`, specify the same installation directory.

The following files are generated in the directory:

```
├── auth
```
4.10.7. Exporting common variables

4.10.7.1. Extracting the infrastructure name

The Ignition config files contain a unique cluster identifier that you can use to uniquely identify your cluster in Google Cloud Platform (GCP). The infrastructure name is also used to locate the appropriate GCP resources during an OpenShift Container Platform installation. The provided Deployment Manager templates contain references to this infrastructure name, so you must extract it.

Prerequisites

- You obtained the OpenShift Container Platform installation program and the pull secret for your cluster.
- You generated the Ignition config files for your cluster.
- You installed the `jq` package.

Procedure

- To extract and view the infrastructure name from the Ignition config file metadata, run the following command:

  ```bash
  $ jq -r .infraID <installation_directory>/metadata.json  
  ```

  1 For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

Example output

```
openshift-vw9j6
```

1 The output of this command is your cluster name and a random string.

4.10.7.2. Exporting common variables for Deployment Manager templates

You must export a common set of variables that are used with the provided Deployment Manager templates used to assist in completing a user-provided infrastructure install on Google Cloud Platform (GCP).

**NOTE**

Specific Deployment Manager templates can also require additional exported variables, which are detailed in their related procedures.
Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.
- Generate the Ignition config files for your cluster.
- Install the `jq` package.

Procedure

1. Export the following common variables to be used by the provided Deployment Manager templates:

```bash
$ export BASE_DOMAIN='<base_domain>'
$ export BASE_DOMAIN_ZONE_NAME='<base_domain_zone_name>'
$ export NETWORK_CIDR='10.0.0.0/16'
$ export KUBECONFIG=<installation_directory>/auth/kubeconfig
$ export CLUSTER_NAME=`jq -r .clusterName <installation_directory>/metadata.json`
$ export INFRA_ID=`jq -r .infraID <installation_directory>/metadata.json`
$ export PROJECT_NAME=`jq -r .gcp.projectID <installation_directory>/metadata.json`
```

1. Supply the values for the host project.
2. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

4.10.8. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require network in `initramfs` during boot to fetch Ignition config from the machine config server.

You must configure the network connectivity between machines to allow cluster components to communicate. Each machine must be able to resolve the host names of all other machines in the cluster.

</table>
### Network topology requirements

The infrastructure that you provision for your cluster must meet the following network topology requirements.

#### IMPORTANT

OpenShift Container Platform requires all nodes to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

#### Load balancers

Before you install OpenShift Container Platform, you must provision two load balancers that meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.
   - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

    #### IMPORTANT

    Do not configure session persistence for an API load balancer.

<td>Kubernetes API</td>
</tr>
</tbody>
</table>

**Table 4.42. Control plane machines to control plane machines**

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Port</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TCP</td>
<td>2379-2380</td>
<td>etcd server and peer ports</td>
</tr>
</tbody>
</table>
Configure the following ports on both the front and back of the load balancers:

### Table 4.43. API load balancer

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the <code>/readyz</code> endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>

**NOTE**

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the `/readyz` endpoint to the removal of the API server instance from the pool. Within the time frame after `/readyz` returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application Ingress load balancer**: Provides an Ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the Ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

Configure the following ports on both the front and back of the load balancers:

### Table 4.44. Application Ingress load balancer

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress router pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress router pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>
TIP

If the true IP address of the client can be seen by the load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

NOTE

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

4.10.9. Creating load balancers in GCP

You must configure load balancers in Google Cloud Platform (GCP) for your OpenShift Container Platform cluster to use. One way to create these components is to modify the provided Deployment Manager template.

NOTE

If you do not use the provided Deployment Manager template to create your GCP infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.

Procedure

1. Copy the template from the Deployment Manager template for the internal load balancer section of this topic and save it as `02_lb_int.py` on your computer. This template describes the internal load balancing objects that your cluster requires.

2. For an external cluster, also copy the template from the Deployment Manager template for the external load balancer section of this topic and save it as `02_lb_ext.py` on your computer. This template describes the external load balancing objects that your cluster requires.

3. Export the variables that the deployment template uses:
   a. Export the cluster network location:
      ```shell
      $ export CLUSTER_NETWORK=('gcloud compute networks describe
      $(HOST_PROJECT_NETWORK) --project $(HOST_PROJECT) --account
      $(HOST_PROJECT_ACCOUNT) --format json | jq -r .selfLink')
      ```
   b. Export the control plane subnet location:
      ```shell
      $ export CONTROL_SUBNET=('gcloud compute networks subnets describe
      $(HOST_PROJECT_CONTROL_SUBNET) --region=$(REGION) --project
      $(HOST_PROJECT) --account $(HOST_PROJECT_ACCOUNT) --format json | jq -r
      .selfLink')
      ```
c. Export the three zones that the cluster uses:

```bash
$ export ZONE_0=('gcloud compute regions describe ${REGION} --format=json | jq -r .zones[0] | cut -d "/" -f9')

$ export ZONE_1=('gcloud compute regions describe ${REGION} --format=json | jq -r .zones[1] | cut -d "/" -f9')

$ export ZONE_2=('gcloud compute regions describe ${REGION} --format=json | jq -r .zones[2] | cut -d "/" -f9')
```

4. Create a `02_infra.yaml` resource definition file:

```yaml
$ cat <<EOF >02_infra.yaml
imports:
- path: 02_lb_ext.py
- path: 02_lb_int.py
resources:
- name: cluster-lb-ext
  type: 02_lb_ext.py
  properties:
    infra_id: '${INFRA_ID}'
    region: '${REGION}'
- name: cluster-lb-int
  type: 02_lb_int.py
  properties:
    cluster_network: '${CLUSTER_NETWORK}'
    control_subnet: '${CONTROL_SUBNET}'
    infra_id: '${INFRA_ID}'
    region: '${REGION}'
    zones:
    - '${ZONE_0}'
    - '${ZONE_1}'
    - '${ZONE_2}'
EOF
```

1. Required only when deploying an external cluster.

2. `infra_id` is the INFRA_ID infrastructure name from the extraction step.

3. `region` is the region to deploy the cluster into, for example `us-central1`.

4. `control_subnet` is the URI to the control subnet.

5. `zones` are the zones to deploy the control plane instances into, like `us-east1-b`, `us-east1-c`, and `us-east1-d`.

5. Create the deployment by using the `gcloud` CLI:

```bash
$ gcloud deployment-manager deployments create ${INFRA_ID}-infra --config 02_infra.yaml
```

6. Export the cluster IP address:
$ export CLUSTER_IP=`gcloud compute addresses describe ${INFRA_ID}-cluster-ip --region=${REGION} --format json | jq -r .address`

7. For an external cluster, also export the cluster public IP address:

$ export CLUSTER_PUBLIC_IP=`gcloud compute addresses describe ${INFRA_ID}-cluster-public-ip --region=${REGION} --format json | jq -r .address`

### 4.10.9.1. Deployment Manager template for the external load balancer

You can use the following Deployment Manager template to deploy the external load balancer that you need for your OpenShift Container Platform cluster:

**Example 4.11. 02_lb_ext.py Deployment Manager template**

```python
def GenerateConfig(context):

    resources = [
        {
            'name': context.properties['infra_id'] + '-cluster-public-ip',
            'type': 'compute.v1.address',
            'properties': {
                'region': context.properties['region']
            }
        },
        {
            'name': context.properties['infra_id'] + '-api-http-health-check',
            'type': 'compute.v1.httpHealthCheck',
            'properties': {
                'port': 6080,
                'requestPath': '/readyz'
            }
        },
        {
            'name': context.properties['infra_id'] + '-api-target-pool',
            'type': 'compute.v1.targetPool',
            'properties': {
                'region': context.properties['region'],
                'healthChecks': ['$(ref.' + context.properties['infra_id'] + '-api-http-health-check.selfLink)'],
                'instances': []
            }
        },
        {
            'name': context.properties['infra_id'] + '-api-forwarding-rule',
            'type': 'compute.v1.forwardingRule',
            'properties': {
                'region': context.properties['region'],
                'IPAddress': '$(ref.' + context.properties['infra_id'] + '-cluster-public-ip.selfLink)',
                'target': '$(ref.' + context.properties['infra_id'] + '-api-target-pool.selfLink)',
                'portRange': '6443'
            }
        }
    ]

    return {'resources': resources}
```

CHAPTER 4. INSTALLING ON GCP
4.10.9.2. Deployment Manager template for the internal load balancer

You can use the following Deployment Manager template to deploy the internal load balancer that you need for your OpenShift Container Platform cluster:

Example 4.12. 02_lb_int.py Deployment Manager template

```python
def GenerateConfig(context):
    backends = []
    for zone in context.properties['zones']:
        backends.append(
            {'group': '$(ref. ' + context.properties['infra_id'] + '-master-' + zone + '-instance-group' + '.selfLink)'}
        )
    resources = [{
        'name': context.properties['infra_id'] + '-cluster-ip',
        'type': 'compute.v1.address',
        'properties': {
            'addressType': 'INTERNAL',
            'region': context.properties['region'],
            'subnetwork': context.properties['control_subnet']
        }
    }, {
        'name': context.properties['infra_id'] + '-api-internal-health-check',
        'type': 'compute.v1.healthCheck',
        'properties': {
            'httpsHealthCheck': {
                'port': 6443,
                'requestPath': '/readyz'
            }
        }
    }, {
        'name': context.properties['infra_id'] + '-api-internal-backend-service',
        'type': 'compute.v1.regionBackendService',
        'properties': {
            'backends': backends,
            'healthChecks': ['$(ref. ' + context.properties['infra_id'] + '-api-internal-health-check.selfLink)'],
            'loadBalancingScheme': 'INTERNAL',
            'region': context.properties['region'],
            'protocol': 'TCP',
            'timeoutSec': 120
        }
    }, {
        'name': context.properties['infra_id'] + '-api-internal-forwarding-rule',
        'type': 'compute.v1.forwardingRule',
        'properties': {
            'backendService': '$(ref. ' + context.properties['infra_id'] + '-api-internal-backend-service.selfLink)'
        }
    }]
```
You will need this template in addition to the 02_lb_ext.py template when you create an external cluster.

4.10.10. Creating a private DNS zone in GCP

You must configure a private DNS zone in Google Cloud Platform (GCP) for your OpenShift Container Platform cluster to use. One way to create this component is to modify the provided Deployment Manager template.

NOTE

If you do not use the provided Deployment Manager template to create your GCP infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.

Procedure
1. Copy the template from the Deployment Manager template for the private DNS section of this topic and save it as `02_dns.py` on your computer. This template describes the private DNS objects that your cluster requires.

2. Create a `02_dns.yaml` resource definition file:

```bash
$ cat <<EOF >02_dns.yaml
imports:
- path: 02_dns.py

resources:
- name: cluster-dns
type: 02_dns.py
properties:
  infra_id: '${INFRA_ID}'
  cluster_domain: '${CLUSTER_NAME}.${BASE_DOMAIN}'
  cluster_network: '${CLUSTER_NETWORK}'
EOF
```

1. `infra_id` is the INFRA_ID infrastructure name from the extraction step.

2. `cluster_domain` is the domain for the cluster, for example `openshift.example.com`.

3. `cluster_network` is the selfLink URL to the cluster network.

3. Create the deployment by using the `gcloud` CLI:

```bash
$ gcloud deployment-manager deployments create ${INFRA_ID}-dns --config 02_dns.yaml --project ${HOST_PROJECT} --account ${HOST_PROJECT_ACCOUNT}

$ if [ -f transaction.yaml ]; then rm transaction.yaml; fi
$ gcloud dns record-sets transaction start --zone ${INFRA_ID}-private-zone --project ${HOST_PROJECT} --account ${HOST_PROJECT_ACCOUNT}
$ gcloud dns record-sets transaction add ${CLUSTER_IP} --name api.${CLUSTER_NAME}.${BASE_DOMAIN}. --ttl 60 --type A --zone ${INFRA_ID}-private-zone --project ${HOST_PROJECT} --account ${HOST_PROJECT_ACCOUNT}
$ gcloud dns record-sets transaction add ${CLUSTER_IP} --name api-int.${CLUSTER_NAME}.${BASE_DOMAIN}. --ttl 60 --type A --zone ${INFRA_ID}-private-zone --project ${HOST_PROJECT} --account ${HOST_PROJECT_ACCOUNT}
$ gcloud dns record-sets transaction execute --zone ${INFRA_ID}-private-zone --project ${HOST_PROJECT} --account ${HOST_PROJECT_ACCOUNT}

$ if [ -f transaction.yaml ]; then rm transaction.yaml; fi
$ gcloud --account=${HOST_PROJECT_ACCOUNT} --project=${HOST_PROJECT} dns record-sets transaction start --zone ${BASE_DOMAIN_ZONE_NAME}
$ gcloud --account=${HOST_PROJECT_ACCOUNT} --project=${HOST_PROJECT} dns record-sets transaction add ${CLUSTER_PUBLIC_IP} --name
```

4. The templates do not create DNS entries due to limitations of Deployment Manager, so you must create them manually:

   a. Add the internal DNS entries:

   ```bash
   $ if [ -f transaction.yaml ]; then rm transaction.yaml; fi
   $ gcloud dns record-sets transaction start --zone ${INFRA_ID}-private-zone --project ${HOST_PROJECT} --account ${HOST_PROJECT_ACCOUNT}
   $ gcloud dns record-sets transaction add $(CLUSTER_IP) --name api.$(CLUSTER_NAME).$(BASE_DOMAIN) --ttl 60 --type A --zone $(INFRA_ID)-private-zone --project $(HOST_PROJECT) --account $(HOST_PROJECT_ACCOUNT)
   $ gcloud dns record-sets transaction add $(CLUSTER_IP) --name api-int.$(CLUSTER_NAME).$(BASE_DOMAIN) --ttl 60 --type A --zone $(INFRA_ID)-private-zone --project $(HOST_PROJECT) --account $(HOST_PROJECT_ACCOUNT)
   $ gcloud dns record-sets transaction execute --zone $(INFRA_ID)-private-zone --project $(HOST_PROJECT) --account $(HOST_PROJECT_ACCOUNT)
   
   $ if [ -f transaction.yaml ]; then rm transaction.yaml; fi
   $ gcloud --account=$(HOST_PROJECT_ACCOUNT) --project=$(HOST_PROJECT) dns record-sets transaction start --zone $(BASE_DOMAIN_ZONE_NAME)
   $ gcloud --account=$(HOST_PROJECT_ACCOUNT) --project=$(HOST_PROJECT) dns record-sets transaction add $(CLUSTER_PUBLIC_IP) --name
   ```

   b. For an external cluster, also add the external DNS entries:
4.10.10.1. Deployment Manager template for the private DNS

You can use the following Deployment Manager template to deploy the private DNS that you need for your OpenShift Container Platform cluster:

Example 4.13. 02_dns.py Deployment Manager template

```python
def GenerateConfig(context):
    resources = [{
        'name': context.properties['infra_id'] + '-private-zone',
        'type': 'dns.v1.managedZone',
        'properties': {
            'description': '',
            'dnsName': context.properties['cluster_domain'] + '.',
            'visibility': 'private',
            'privateVisibilityConfig': {
                'networks': [{
                    'networkUrl': context.properties['cluster_network']
                }]
            }
        }
    }]
    return {'resources': resources}
```

4.10.11. Creating firewall rules in GCP

You must create firewall rules in Google Cloud Platform (GCP) for your OpenShift Container Platform cluster to use. One way to create these components is to modify the provided Deployment Manager template.

**NOTE**

If you do not use the provided Deployment Manager template to create your GCP infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

**Prerequisites**

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.
Procedure

1. Copy the template from the Deployment Manager template for firewall rules section of this topic and save it as 03_firewall.py on your computer. This template describes the security groups that your cluster requires.

2. Create a 03_firewall.yaml resource definition file:

```bash
$ cat <<EOF >03_firewall.yaml
imports:
  - path: 03_firewall.py

resources:
  - name: cluster-firewall
    type: 03_firewall.py
    properties:
      allowed_external_cidr: '0.0.0.0/0'
      infra_id: '${INFRA_ID}'
      cluster_network: '${CLUSTER_NETWORK}'
      network_cidr: '${NETWORK_CIDR}'
EOF
```

1. **allowed_external_cidr** is the CIDR range that can access the cluster API and SSH to the bootstrap host. For an internal cluster, set this value to `${NETWORK_CIDR}`.

2. **infra_id** is the `INFRA_ID` infrastructure name from the extraction step.

3. **cluster_network** is the `selfLink` URL to the cluster network.

4. **network_cidr** is the CIDR of the VPC network, for example 10.0.0.0/16.

3. Create the deployment by using the `gcloud` CLI:

```bash
$ gcloud deployment-manager deployments create ${INFRA_ID}-firewall --config 03_firewall.yaml --project ${HOST_PROJECT} --account ${HOST_PROJECT_ACCOUNT}
```

4.10.11.1. Deployment Manager template for firewall rules

You can use the following Deployment Manager template to deploy the firewall rules that you need for your OpenShift Container Platform cluster:

**Example 4.14. 03_firewall.py Deployment Manager template**

```python
def GenerateConfig(context):

    resources = [
        {'name': context.properties['infra_id'] + '-bootstrap-in-ssh',
         'type': 'compute.v1.firewall',
         'properties': {
             'network': context.properties['cluster_network'],
             'allowed': [{
                 'IPProtocol': 'tcp',
                 'ports': ['22']
             }],
```
'sourceRanges': [context.properties['allowed_external_cidr']],
'targetTags': [context.properties['infra_id'] + '-bootstrap']
},

'name': context.properties['infra_id'] + '-api',
'type': 'compute.v1.firewall',
'properties': {
  'network': context.properties['cluster_network'],
  'allowed': [{
    'IPProtocol': 'tcp',
    'ports': ['6443']
  }],
  'sourceRanges': [context.properties['allowed_external_cidr']],
  'targetTags': [context.properties['infra_id'] + '-master']
},

'name': context.properties['infra_id'] + '-health-checks',
'type': 'compute.v1.firewall',
'properties': {
  'network': context.properties['cluster_network'],
  'allowed': [{
    'IPProtocol': 'tcp',
    'ports': ['6080', '6443', '22624']
  }],
  'sourceRanges': ['35.191.0.0/16', '130.211.0.0/22', '209.85.152.0/22', '209.85.204.0/22'],
  'targetTags': [context.properties['infra_id'] + '-master']
},

'name': context.properties['infra_id'] + '-etcd',
'type': 'compute.v1.firewall',
'properties': {
  'network': context.properties['cluster_network'],
  'allowed': [{
    'IPProtocol': 'tcp',
    'ports': ['2379-2380']
  }],
  'sourceTags': [context.properties['infra_id'] + '-master'],
  'targetTags': [context.properties['infra_id'] + '-master']
},

'name': context.properties['infra_id'] + '-control-plane',
'type': 'compute.v1.firewall',
'properties': {
  'network': context.properties['cluster_network'],
  'allowed': [{
    'IPProtocol': 'tcp',
    'ports': ['10257']
  }],
  'sourceTags': [context.properties['infra_id'] + '-master'],
  'targetTags': [context.properties['infra_id'] + '-master']
}
{ 'name': context.properties['infra_id'] + '-internal-network', 'type': 'compute.v1.firewall', 'properties': { 'network': context.properties['cluster_network'], 'allowed': [{ 'IPProtocol': 'icmp' }, { 'IPProtocol': 'tcp', 'ports': ['22'] }], 'sourceRanges': [context.properties['network_cidr']], 'targetTags': [    context.properties['infra_id'] + '-master',    context.properties['infra_id'] + '-worker'] },
{ 'name': context.properties['infra_id'] + '-internal-cluster', 'type': 'compute.v1.firewall', 'properties': { 'network': context.properties['cluster_network'], 'allowed': [{ 'IPProtocol': 'udp', 'ports': ['4789', '6081'] }, { 'IPProtocol': 'tcp', 'ports': ['9000-9999'] }, { 'IPProtocol': 'udp', 'ports': ['9000-9999'] }, { 'IPProtocol': 'tcp', 'ports': ['10250'] }, { 'IPProtocol': 'tcp', 'ports': ['30000-32767'] }, { 'IPProtocol': 'udp', 'ports': ['30000-32767'] }], 'sourceTags': [ context.properties['infra_id'] + '-master', context.properties['infra_id'] + '-worker' ], 'targetTags': [ context.properties['infra_id'] + '-master', context.properties['infra_id'] + '-worker' ] }
4.10.12. Creating IAM roles in GCP

You must create IAM roles in Google Cloud Platform (GCP) for your OpenShift Container Platform cluster to use. One way to create these components is to modify the provided Deployment Manager template.

**NOTE**

If you do not use the provided Deployment Manager template to create your GCP infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

**Prerequisites**

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.

**Procedure**

1. Copy the template from the Deployment Manager template for IAM roles section of this topic and save it as `03_iam.py` on your computer. This template describes the IAM roles that your cluster requires.

2. Create a `03_iam.yaml` resource definition file:

   ```sh
   $ cat <<EOF >03_iam.yaml
   imports:
   - path: 03_iam.py
   resources:
   - name: cluster-iam
     type: 03_iam.py
     properties:
     infra_id: '${INFRA_ID}'
   EOF
   ```

   1 `infra_id` is the `INFRA_ID` infrastructure name from the extraction step.

3. Create the deployment by using the `gcloud` CLI:

   ```sh
   $ gcloud deployment-manager deployments create ${INFRA_ID}-iam --config 03_iam.yaml
   ```

4. Export the variable for the master service account:
5. Export the variable for the worker service account:

```bash
$ export WORKER_SERVICE_ACCOUNT=('gcloud iam service-accounts list --filter "email~^${INFRA_ID}-w@$PROJECT_NAME." --format json | jq -r '.[0].email')
```

6. Assign the permissions that the installation program requires to the service accounts for the subnets that host the control plane and compute subnets:

   a. Grant the **networkViewer** role of the project that hosts your shared VPC to the master service account:

   ```bash
   $ gcloud --account=${HOST_PROJECT_ACCOUNT} --project=${HOST_PROJECT} projects add-iam-policy-binding ${HOST_PROJECT} --member "serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role "roles/compute.networkViewer"
   ```

   b. Grant the **networkUser** role to the master service account for the control plane subnet:

   ```bash
   $ gcloud --account=${HOST_PROJECT_ACCOUNT} --project=${HOST_PROJECT} compute networks subnets add-iam-policy-binding "${HOST_PROJECT_CONTROL_SUBNET}" --member "serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role "roles/compute.networkUser" --region ${REGION}
   ```

   c. Grant the **networkUser** role to the worker service account for the control plane subnet:

   ```bash
   $ gcloud --account=${HOST_PROJECT_ACCOUNT} --project=${HOST_PROJECT} compute networks subnets add-iam-policy-binding "${HOST_PROJECT_CONTROL_SUBNET}" --member "serviceAccount:${WORKER_SERVICE_ACCOUNT}" --role "roles/compute.networkUser" --region ${REGION}
   ```

   d. Grant the **networkUser** role to the master service account for the compute subnet:

   ```bash
   $ gcloud --account=${HOST_PROJECT_ACCOUNT} --project=${HOST_PROJECT} compute networks subnets add-iam-policy-binding "${HOST_PROJECT_COMPUTE_SUBNET}" --member "serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role "roles/compute.networkUser" --region ${REGION}
   ```

   e. Grant the **networkUser** role to the worker service account for the compute subnet:

   ```bash
   $ gcloud --account=${HOST_PROJECT_ACCOUNT} --project=${HOST_PROJECT} compute networks subnets add-iam-policy-binding "${HOST_PROJECT_COMPUTE_SUBNET}" --member "serviceAccount:${WORKER_SERVICE_ACCOUNT}" --role "roles/compute.networkUser" --region ${REGION}
   ```

7. The templates do not create the policy bindings due to limitations of Deployment Manager, so you must create them manually:
Create a service account key and store it locally for later use:

```bash
$ gcloud iam service-accounts keys create service-account-key.json --iam-account=${MASTER_SERVICE_ACCOUNT}
```

### 4.10.12.1. Deployment Manager template for IAM roles

You can use the following Deployment Manager template to deploy the IAM roles that you need for your OpenShift Container Platform cluster:

**Example 4.15. 03_iam.py Deployment Manager template**

```python
def GenerateConfig(context):
    resources = [
        {
            'name': context.properties['infra_id'] + '-master-node-sa',
            'type': 'iam.v1.serviceAccount',
            'properties': {
                'accountId': context.properties['infra_id'] + '-m',
                'displayName': context.properties['infra_id'] + '-master-node'
            }
        },
        {
            'name': context.properties['infra_id'] + '-worker-node-sa',
            'type': 'iam.v1.serviceAccount',
            'properties': {
                'accountId': context.properties['infra_id'] + '-w',
                'displayName': context.properties['infra_id'] + '-worker-node'
            }
        }
    ]
    return {'resources': resources}
```

### 4.10.13. Creating the RHCOS cluster image for the GCP infrastructure

You must use a valid Red Hat Enterprise Linux CoreOS (RHCOS) image for Google Cloud Platform (GCP) for your OpenShift Container Platform nodes.
Procedure

1. Obtain the RHCOS image from the RHCOS image mirror page.

   **IMPORTANT**

   The RHCOS images might not change with every release of OpenShift Container Platform. You must download an image with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image version that matches your OpenShift Container Platform version if it is available.

   The file name contains the OpenShift Container Platform version number in the format `rhcos-<version>-<arch>-gcp.<arch>.tar.gz`.

2. Create the Google storage bucket:

   ```
   $ gsutil mb gs://<bucket_name>
   ```

3. Upload the RHCOS image to the Google storage bucket:

   ```
   $ gsutil cp <downloaded_image_file_path>/rhcos-<version>-x86_64-gcp.x86_64.tar.gz gs://<bucket_name>
   ```

4. Export the uploaded RHCOS image location as a variable:

   ```
   $ export IMAGE_SOURCE=`gs://<bucket_name>/rhcos-<version>-x86_64-gcp.x86_64.tar.gz`
   ```

5. Create the cluster image:

   ```
   $ gcloud compute images create "${INFRA_ID}-rhcos-image" \
   --source-uri="${IMAGE_SOURCE}"
   ```

4.10.14. Creating the bootstrap machine in GCP

You must create the bootstrap machine in Google Cloud Platform (GCP) to use during OpenShift Container Platform cluster initialization. One way to create this machine is to modify the provided Deployment Manager template.

   **NOTE**

   If you do not use the provided Deployment Manager template to create your bootstrap machine, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

**Prerequisites**

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.
- Create and configure networking and load balancers in GCP.
- Create control plane and compute roles.
- Ensure pyOpenSSL is installed.

**Procedure**

1. Copy the template from the Deployment Manager template for the bootstrap machine section of this topic and save it as `04_bootstrap.py` on your computer. This template describes the bootstrap machine that your cluster requires.

2. Export the location of the Red Hat Enterprise Linux CoreOS (RHCOS) image that the installation program requires:

   ```
   $ export CLUSTER_IMAGE=('gcloud compute images describe ${INFRA_ID}-rhcos-image --format json | jq -r .selfLink')
   ```

3. Create a bucket and upload the `bootstrap.ign` file:

   ```
   $ gsutil mb gs://${INFRA_ID}-bootstrap-ignition
   $ gsutil cp <installation_directory>/bootstrap.ign gs://${INFRA_ID}-bootstrap-ignition/
   ```

4. Create a signed URL for the bootstrap instance to use to access the Ignition config. Export the URL from the output as a variable:

   ```
   $ export BOOTSTRAP_IGN=\`gsutil signurl -d 1h service-account-key.json gs://${INFRA_ID}-bootstrap-ignition/bootstrap.ign | grep "^gs:" | awk '{print $5}'\`
   ```

5. Create a `04_bootstrap.yaml` resource definition file:

   ```
   $ cat <<EOF >04_bootstrap.yaml
   imports:
   - path: 04_bootstrap.py

   resources:
   - name: cluster-bootstrap
     type: 04_bootstrap.py
     properties:
       infra_id: '${INFRA_ID}'
       region: '${REGION}'
       zone: '${ZONE_0}'
       cluster_network: '${CLUSTER_NETWORK}'
       control_subnet: '${CONTROL_SUBNET}'
       image: '${CLUSTER_IMAGE}'
       machine_type: 'n1-standard-4'
       root_volume_size: '128'
       bootstrap_ign: '${BOOTSTRAP_IGN}'

   EOF
   ```
infra_id is the INFRA_ID infrastructure name from the extraction step.

region is the region to deploy the cluster into, for example us-central1.

zone is the zone to deploy the bootstrap instance into, for example us-central1-b.

cluster_network is the selfLink URL to the cluster network.

control_subnet is the selfLink URL to the control subnet.

image is the selfLink URL to the RHCOS image.

machine_type is the machine type of the instance, for example n1-standard-4.

root_volume_size is the boot disk size for the bootstrap machine.

bootstrap_ign is the URL output when creating a signed URL.

6. Create the deployment by using the gcloud CLI:

   $ gcloud deployment-manager deployments create ${INFRA_ID}-bootstrap --config 04_bootstrap.yaml

7. Add the bootstrap instance to the internal load balancer instance group:

   $ gcloud compute instance-groups unmanaged add-instances ${INFRA_ID}-bootstrap-instance-group --zone=${ZONE_0} --instances=${INFRA_ID}-bootstrap

8. Add the bootstrap instance group to the internal load balancer backend service:

   $ gcloud compute backend-services add-backend ${INFRA_ID}-api-internal-backend-service --region=${REGION} --instance-group=${INFRA_ID}-bootstrap-instance-group --instance-group-zone=${ZONE_0}

4.10.14.1. Deployment Manager template for the bootstrap machine

You can use the following Deployment Manager template to deploy the bootstrap machine that you need for your OpenShift Container Platform cluster:

Example 4.16. 04_bootstrap.py Deployment Manager template

```python
def GenerateConfig(context):

    resources = [
        {
            'name': context.properties['infra_id'] + '-bootstrap-public-ip',
            'type': 'compute.v1.address',
            'properties': {
                'region': context.properties['region']
            }
        },
        {
            'name': context.properties['infra_id'] + '-bootstrap',
            'type': 'compute.v1.instance',
            'properties': {
                'disks': [
                    
```
4.10.15. Creating the control plane machines in GCP

You must create the control plane machines in Google Cloud Platform (GCP) for your cluster to use. One way to create these machines is to modify the provided Deployment Manager template.

```json
return {
    'resources': resources
}
```
NOTE

If you do not use the provided Deployment Manager template to create your control plane machines, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.
- Create and configure networking and load balancers in GCP.
- Create control plane and compute roles.
- Create the bootstrap machine.

Procedure

1. Copy the template from the Deployment Manager template for control plane machines section of this topic and save it as `05_control_plane.py` on your computer. This template describes the control plane machines that your cluster requires.

2. Export the following variable required by the resource definition:

   ```
   $ export MASTER_IGNITION=`cat <installation_directory>/master.ign`
   ```

3. Create a `05_control_plane.yaml` resource definition file:

   ```
   $ cat <<EOF >05_control_plane.yaml
   imports:
     - path: 05_control_plane.py
   resources:
     - name: cluster-control-plane
       type: 05_control_plane.py
       properties:
         infra_id: '${INFRA_ID}'
         zones: '${ZONE_0}', '${ZONE_1}', '${ZONE_2}'
         control_subnet: '${CONTROL_SUBNET}'
         image: '${CLUSTER_IMAGE}'
         machine_type: 'n1-standard-4'
         root_volume_size: '128'
         service_account_email: '${MASTER_SERVICE_ACCOUNT}'
         ignition: '${MASTER_IGNITION}'
   EOF
   ```
infra_id is the INFRA_ID infrastructure name from the extraction step.

zones are the zones to deploy the control plane instances into, for example us-central1-a, us-central1-b, and us-central1-c.

control_subnet is the selfLink URL to the control subnet.

image is the selfLink URL to the RHCOS image.

machine_type is the machine type of the instance, for example n1-standard-4.

service_account_email is the email address for the master service account that you created.

ignition is the contents of the master.ign file.

4. Create the deployment by using the gcloud CLI:

```bash
$ gcloud deployment-manager deployments create $(INFRA_ID)-control-plane --config 05_control_plane.yaml
```

5. The templates do not manage load balancer membership due to limitations of Deployment Manager, so you must add the control plane machines manually.

- Run the following commands to add the control plane machines to the appropriate instance groups:

  ```bash
  $ gcloud compute instance-groups unmanaged add-instances $(INFRA_ID)-master-$ZONE_0-instance-group --zone=$ZONE_0 --instances=$(INFRA_ID)-master-0
  $ gcloud compute instance-groups unmanaged add-instances $(INFRA_ID)-master-$ZONE_1-instance-group --zone=$ZONE_1 --instances=$(INFRA_ID)-master-1
  $ gcloud compute instance-groups unmanaged add-instances $(INFRA_ID)-master-$ZONE_2-instance-group --zone=$ZONE_2 --instances=$(INFRA_ID)-master-2
  ```

- For an external cluster, you must also run the following commands to add the control plane machines to the target pools:

  ```bash
  $ gcloud compute target-pools add-instances $(INFRA_ID)-api-target-pool --instances-zone="$ZONE_0" --instances=$(INFRA_ID)-master-0
  $ gcloud compute target-pools add-instances $(INFRA_ID)-api-target-pool --instances-zone="$ZONE_1" --instances=$(INFRA_ID)-master-1
  $ gcloud compute target-pools add-instances $(INFRA_ID)-api-target-pool --instances-zone="$ZONE_2" --instances=$(INFRA_ID)-master-2
  ```

4.10.15.1. Deployment Manager template for control plane machines

You can use the following Deployment Manager template to deploy the control plane machines that you need for your OpenShift Container Platform cluster:

```python
Example 4.17. 05_control_plane.py Deployment Manager template

def GenerateConfig(context):
```

resources = [
    {'name': context.properties['infra_id'] + '-master-0',
     'type': 'compute.v1.instance',
     'properties': {
        'disks': [
            {'autoDelete': True,
             'boot': True,
             'initializeParams': {
                'diskSizeGb': context.properties['root_volume_size'],
                'diskType': 'zones/' + context.properties['zones'][0] + '/diskTypes/pd-ssd',
                'sourceImage': context.properties['image']
            }
        ],
        'machineType': 'zones/' + context.properties['zones'][0] + '/machineTypes/' + context.properties['machine_type'],
        'metadata': {
            'items': [{
                'key': 'user-data',
                'value': context.properties['ignition']
            }]
        },
        'networkInterfaces': [{
            'subnetwork': context.properties['control_subnet']
        }],
        'serviceAccounts': [{
            'email': context.properties['service_account_email'],
            'scopes': ['https://www.googleapis.com/auth/cloud-platform']
        }],
        'tags': {
            'items': [
                context.properties['infra_id'] + '-master',
            ]
        }
    },
    'zone': context.properties['zones'][0]
},
    {'name': context.properties['infra_id'] + '-master-1',
     'type': 'compute.v1.instance',
     'properties': {
        'disks': [
            {'autoDelete': True,
             'boot': True,
             'initializeParams': {
                'diskSizeGb': context.properties['root_volume_size'],
                'diskType': 'zones/' + context.properties['zones'][1] + '/diskTypes/pd-ssd',
                'sourceImage': context.properties['image']
            }
        ],
        'machineType': 'zones/' + context.properties['zones'][1] + '/machineTypes/' + context.properties['machine_type'],
        'metadata': {
            'items': [{
                'key': 'user-data',
                'value': context.properties['ignition']
            }]
        }
    },
    'zone': context.properties['zones'][1]
}]
4.10.16. Wait for bootstrap completion and remove bootstrap resources in GCP

```
'networkInterfaces': [{
  'subnetwork': context.properties['control_subnet']
},
'serviceAccounts': [{
  'email': context.properties['service_account_email'],
  'scopes': ['https://www.googleapis.com/auth/cloud-platform']
}],
'tags': {
  'items': [
    context.properties['infra_id'] + '-master',
  ],
  'zone': context.properties['zones'][1]
}
},
{name}: context.properties['infra_id'] + '-master-2',
'type': 'compute.v1.instance',
'properties': {
  'disks': [{
    'autoDelete': True,
    'boot': True,
    'initializeParams': {
      'diskSizeGb': context.properties['root_volume_size'],
      'diskType': 'zones/' + context.properties['zones'][2] + '/diskTypes/pd-ssd',
      'sourceImage': context.properties['image']
    },
  }],
  'machineType': 'zones/' + context.properties['zones'][2] + '/machineTypes/' + context.properties['machine_type'],
  'metadata': {
    'items': [{'
      'key': 'user-data',
      'value': context.properties['ignition']
    }]
  },
'networkInterfaces': [{
  'subnetwork': context.properties['control_subnet']
}],
'serviceAccounts': [{
  'email': context.properties['service_account_email'],
  'scopes': ['https://www.googleapis.com/auth/cloud-platform']
}],
'tags': {
  'items': [
    context.properties['infra_id'] + '-master',
  ],
  'zone': context.properties['zones'][2]
}
}]

return {'resources': resources}
```
After you create all of the required infrastructure in Google Cloud Platform (GCP), wait for the bootstrap process to complete on the machines that you provisioned by using the Ignition config files that you generated with the installation program.

**Prerequisites**

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.
- Create and configure networking and load balancers in GCP.
- Create control plane and compute roles.
- Create the bootstrap machine.
- Create the control plane machines.

**Procedure**

1. Change to the directory that contains the installation program and run the following command:

   ```bash
   $ ./openshift-install wait-for bootstrap-complete --dir <installation_directory> \  
   --log-level info
   ```

   *For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   *To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

   If the command exits without a `FATAL` warning, your production control plane has initialized.

2. Delete the bootstrap resources:

   ```bash
   $ gcloud compute backend-services remove-backend $(INFRA_ID)-api-internal-backend-service --region=${REGION} --instance-group=$(INFRA_ID)-bootstrap-instance-group --instance-group-zone=${ZONE_0}
   $ gsutil rm gs://$(INFRA_ID)-bootstrap-ignition/bootstrap.ign
   $ gsutil rb gs://$(INFRA_ID)-bootstrap-ignition
   $ gcloud deployment-manager deployments delete $(INFRA_ID)-bootstrap
   ```

**4.10.17. Creating additional worker machines in GCP**

You can create worker machines in Google Cloud Platform (GCP) for your cluster to use by launching individual instances discretely or by automated processes outside the cluster, such as auto scaling groups. You can also take advantage of the built-in cluster scaling mechanisms and the machine API in OpenShift Container Platform.

In this example, you manually launch one instance by using the Deployment Manager template. Additional instances can be launched by including additional resources of type `06_worker.py` in the file.
NOTE
If you do not use the provided Deployment Manager template to create your worker machines, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.
- Create and configure networking and load balancers in GCP.
- Create control plane and compute roles.
- Create the bootstrap machine.
- Create the control plane machines.

Procedure

1. Copy the template from the Deployment Manager template for worker machines section of this topic and save it as 06_worker.py on your computer. This template describes the worker machines that your cluster requires.

2. Export the variables that the resource definition uses.
   a. Export the subnet that hosts the compute machines:

   ```bash
   $ export COMPUTE_SUBNET=`(gcloud compute networks subnets describe ${HOST_PROJECT_COMPUTE_SUBNET} --region=${REGION} --project ${HOST_PROJECT} --account ${HOST_ACCOUNT} --format json | jq -r .selfLink)`
   ``

   b. Export the email address for your service account:

   ```bash
   $ export WORKER_SERVICE_ACCOUNT=`(gcloud iam service-accounts list --filter "email~^${INFRA_ID}-w@${PROJECT_NAME}." --format json | jq -r '.[0].email')`
   ``

   c. Export the location of the compute machine Ignition config file:

   ```bash
   $ export WORKER_IGNITION=`cat <installation_directory>/worker.ign`
   ``

3. Create a 06_worker.yaml resource definition file:

   ```bash
   $ cat <<EOF >06_worker.yaml
   imports:
   - path: 06_worker.py

   resources:
   - name: 'worker-0'
   ```
**name** is the name of the worker machine, for example *worker-0*.

**infra_id** is the INFRA_ID infrastructure name from the extraction step.

**zone** is the zone to deploy the worker machine into, for example *us-central1-a*.

**compute_subnet** is the selfLink URL to the compute subnet.

**image** is the selfLink URL to the RHCOS image.

**machine_type** is the machine type of the instance, for example *n1-standard-4*.

**service_account_email** is the email address for the worker service account that you created.

**ignition** is the contents of the *worker.ign* file.

4. Optional: If you want to launch additional instances, include additional resources of type *06_worker.py* in your *06_worker.yaml* resource definition file.

5. Create the deployment by using the gcloud CLI:

   ```
   $ gcloud deployment-manager deployments create ${INFRA_ID}-worker --config 06_worker.yaml
   ```

### 4.10.17.1. Deployment Manager template for worker machines

You can use the following Deployment Manager template to deploy the worker machines that you need for your OpenShift Container Platform cluster:
4.10.18. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) in order to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

**IMPORTANT**

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.6. Download and install the new version of oc.

4.10.18.1. Installing the OpenShift CLI on Linux

Example 4.18. 06_worker.py Deployment Manager template

```python
def GenerateConfig(context):
    resources = [
        {
            'name': context.properties['infra_id'] + '-' + context.env['name'],
            'type': 'compute.v1.instance',
            'properties': {
                'disks': [
                    {
                        'autoDelete': True,
                        'boot': True,
                        'initializeParams': {
                            'diskSizeGb': context.properties['root_volume_size'],
                            'sourceImage': context.properties['image']
                        }
                    }
                ],
                'machineType': 'zones/' + context.properties['zone'] + '/machineTypes/' + context.properties['machine_type'],
                'metadata': {
                    'items': [
                        {
                            'key': 'user-data',
                            'value': context.properties['ignition']
                        }
                    ],
                    'networkInterfaces': [
                        {
                            'subnetwork': context.properties['compute_subnet']
                        }
                    ],
                    'serviceAccounts': [
                        {
                            'email': context.properties['service_account_email'],
                            'scopes': ['https://www.googleapis.com/auth/cloud-platform']
                        }
                    ],
                    'tags': {
                        'items': [
                            context.properties['infra_id'] + '-worker',
                        ],
                        'zone': context.properties['zone']
                    }
                },
                'zone': context.properties['zone']
            }
        }
    ]
    return {'resources': resources}
```
You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.

3. Click **Download Now** next to the **OpenShift v4.6 Linux Client** entry and save the file.

4. Unpack the archive:

   ```
   $ tar xvzf <file>
   ```

5. Place the `oc` binary in a directory that is on your **PATH**.
   
   To check your **PATH**, execute the following command:

   ```
   $ echo $PATH
   ```

After you install the OpenShift CLI, it is available using the `oc` command:

```
$ oc <command>
```

### 4.10.18.2. Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

**Procedure**

2. Select the appropriate version in the **Version** drop-down menu.

3. Click **Download Now** next to the **OpenShift v4.6 Windows Client** entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the `oc` binary to a directory that is on your **PATH**.
   
   To check your **PATH**, open the command prompt and execute the following command:

   ```
   C:\> path
   ```

After you install the OpenShift CLI, it is available using the `oc` command:

```
C:\> oc <command>
```

### 4.10.18.3. Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.
Procedure

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.6 MacOSX Client entry and save the file.

4. Unpack and unzip the archive.

5. Move the oc binary to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:
   
   ```
   $ echo $PATH
   ```

After you install the OpenShift CLI, it is available using the oc command:

```
$ oc <command>
```

### 4.10.19. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster kubeconfig file. The kubeconfig file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the oc CLI.

**Procedure**

1. Export the kubeadmin credentials:

   ```
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```

   1. For <installation_directory>, specify the path to the directory that you stored the installation files in.

2. Verify you can run oc commands successfully using the exported configuration:

   ```
   $ oc whoami
   ```

   **Example output**

   ```
   system:admin
   ```

### 4.10.20. Approving the certificate signing requests for your machines
When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

**Prerequisites**

- You added machines to your cluster.

**Procedure**

1. Confirm that the cluster recognizes the machines:

   ```sh
   $ oc get nodes
   ``

   **Example output**

   ```
   NAME      STATUS    ROLES   AGE  VERSION
   master-0  Ready     master  63m  v1.19.0
   master-1  Ready     master  63m  v1.19.0
   master-2  Ready     master  64m  v1.19.0
   ```

   The output lists all of the machines that you created.

   **NOTE**

   The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

   ```sh
   $ oc get csr
   ``

   **Example output**

   ```
   NAME        AGE     REQUESTOR                                                                   CONDITION
   csr-8b2br   15m     system:serviceaccount:openshift-machine-config-operator:node-bootstrapper   Pending
   csr-8vnps   15m     system:serviceaccount:openshift-machine-config-operator:node-bootstrapper   Pending
   ...
   ```

   In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:
NOTE

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. Once the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the `machine-approver` if the Kubelet requests a new certificate with identical parameters.

NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the `oc exec`, `oc rsh`, and `oc logs` commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the `node-bootstrapper` service account in the `system:node` or `system:admin` groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

  ```
  $ oc adm certificate approve <csr_name>
  
  1
  <csr_name> is the name of a CSR from the list of current CSRs.
  ```

- To approve all pending CSRs, run the following command:

  ```
  $ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
  
  NOTE
  Some Operators might not become available until some CSRs are approved.
  ```

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

  ```
  $ oc get csr
  
  Example output
  
<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-c57lv</td>
<td>5m26s</td>
<td>system:node:ip-10-0-95-157.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
</tbody>
</table>
5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

   - To approve them individually, run the following command for each valid CSR:

     ```
     $ oc adm certificate approve <csr_name>  
     ```

     `<csr_name>` is the name of a CSR from the list of current CSRs.

   - To approve all pending CSRs, run the following command:

     ```
     $ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs oc adm certificate approve  
     ```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

   ```
   $ oc get nodes  
   ```

   **Example output**

   ```
   NAME      STATUS    ROLES   AGE  VERSION
   master-0  Ready     master  73m  v1.20.0
   master-1  Ready     master  73m  v1.20.0
   master-2  Ready     master  74m  v1.20.0
   worker-0  Ready     worker  11m  v1.20.0
   worker-1  Ready     worker  11m  v1.20.0  
   ```

   **NOTE**

   It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

**Additional information**

   - For more information on CSRs, see [Certificate Signing Requests](#).

### 4.10.21. Adding the ingress DNS records

DNS zone configuration is removed when creating Kubernetes manifests and generating Ignition configs. You must manually create DNS records that point at the ingress load balancer. You can create either a wildcard `*.apps.{baseDomain}` or specific records. You can use A, CNAME, and other records per your requirements.

**Prerequisites**

   - Configure a GCP account.

   - Remove the DNS Zone configuration when creating Kubernetes manifests and generating Ignition configs.

   - Create and configure a VPC and associated subnets in GCP.
Create and configure networking and load balancers in GCP.

Create control plane and compute roles.

Create the bootstrap machine.

Create the control plane machines.

Create the worker machines.

Procedure

1. Wait for the Ingress router to create a load balancer and populate the **EXTERNAL-IP** field:

   ```bash
   $ oc -n openshift-ingress get service router-default
   
   NAME             TYPE           CLUSTER-IP      EXTERNAL-IP      PORT(S)                      AGE
   
   $ export ROUTER_IP=`oc -n openshift-ingress get service router-default --no-headers | awk '{print $4}'`
   
   $ if [ -f transaction.yaml ]; then rm transaction.yaml; fi
   $ gcloud dns record-sets transaction start --zone ${INFRA_ID}-private-zone --project
   $[HOST_PROJECT] --account $[HOST_PROJECT_ACCOUNT]
   $ gcloud dns record-sets transaction add ${ROUTER_IP} --name
   \*.apps.${CLUSTER_NAME}.${BASE_DOMAIN}. --ttl 300 --type A --zone
   ${INFRA_ID}-private-zone --project ${HOST_PROJECT} --account
   $[HOST_PROJECT_ACCOUNT]
   $ gcloud dns record-sets transaction execute --zone ${INFRA_ID}-private-zone --project
   $[HOST_PROJECT] --account $[HOST_PROJECT_ACCOUNT]
   
   $ if [ -f transaction.yaml ]; then rm transaction.yaml; fi
   $ gcloud dns record-sets transaction start --zone ${BASE_DOMAIN_ZONE_NAME} --project
   $[HOST_PROJECT] --account $[HOST_PROJECT_ACCOUNT]
   $ gcloud dns record-sets transaction add ${ROUTER_IP} --name
   \*.apps.${CLUSTER_NAME}.${BASE_DOMAIN}. --ttl 300 --type A --zone
   ${BASE_DOMAIN_ZONE_NAME} --project ${HOST_PROJECT} --account
   $[HOST_PROJECT_ACCOUNT]
   $ gcloud dns record-sets transaction execute --zone
   ${BASE_DOMAIN_ZONE_NAME} --project ${HOST_PROJECT} --account
   $[HOST_PROJECT_ACCOUNT]
   ```

2. Add the A record to your zones:

   - To use A records:
     
     i. Export the variable for the router IP address:

        ```bash
        $ export ROUTER_IP=`oc -n openshift-ingress get service router-default --no-headers | awk '{print $4}'`
        ```

     ii. Add the A record to the private zones:

        ```bash
        $ if [ -f transaction.yaml ]; then rm transaction.yaml; fi
        $ gcloud dns record-sets transaction start --zone ${INFRA_ID}-private-zone --project
        $[HOST_PROJECT] --account $[HOST_PROJECT_ACCOUNT]
        $ gcloud dns record-sets transaction add ${ROUTER_IP} --name
        \*.apps.${CLUSTER_NAME}.${BASE_DOMAIN}. --ttl 300 --type A --zone
        ${INFRA_ID}-private-zone --project ${HOST_PROJECT} --account
        $[HOST_PROJECT_ACCOUNT]
        $ gcloud dns record-sets transaction execute --zone ${INFRA_ID}-private-zone --project
        ${HOST_PROJECT} --account ${HOST_PROJECT_ACCOUNT}
        ```

     iii. For an external cluster, also add the A record to the public zones:

        ```bash
        $ if [ -f transaction.yaml ]; then rm transaction.yaml; fi
        $ gcloud dns record-sets transaction start --zone ${BASE_DOMAIN_ZONE_NAME} --project
        ${HOST_PROJECT} --account ${HOST_PROJECT_ACCOUNT}
        $ gcloud dns record-sets transaction add ${ROUTER_IP} --name
        \*.apps.${CLUSTER_NAME}.${BASE_DOMAIN}. --ttl 300 --type A --zone
        ${BASE_DOMAIN_ZONE_NAME} --project ${HOST_PROJECT} --account
        $[HOST_PROJECT_ACCOUNT]
        $ gcloud dns record-sets transaction execute --zone
        ${BASE_DOMAIN_ZONE_NAME} --project ${HOST_PROJECT} --account
        $[HOST_PROJECT_ACCOUNT]
        ```
To add explicit domains instead of using a wildcard, create entries for each of the cluster’s current routes:

$ oc get --all-namespaces -o jsonpath='{range .items[*]}{range .status.ingress[*]}{.host}{"\n"}{{end}{end}} routes

Example output

oauth-openshift.apps.your.cluster.domain.example.com
console-openshift-console.apps.your.cluster.domain.example.com
downloads-openshift-console.apps.your.cluster.domain.example.com
alertmanager-main-openshift-monitoring.apps.your.cluster.domain.example.com
grafana-openshift-monitoring.apps.your.cluster.domain.example.com
prometheus-k8s-openshift-monitoring.apps.your.cluster.domain.example.com

4.10.22. Adding ingress firewall rules

The cluster requires several firewall rules. If you do not use a shared VPC, these rules are created by the ingress controller via the GCP cloud provider. When you use a shared VPC, you can either create cluster-wide firewall rules for all services now or create each rule based on events, when the cluster requests access. By creating each rule when the cluster requests access, you know exactly which firewall rules are required. By creating cluster-wide firewall rules, you can apply the same rule set across multiple clusters.

If you choose to create each rule based on events, you must create firewall rules after you provision the cluster and during the life of the cluster when the console notifies you that rules are missing. Events that are similar to the following event are displayed, and you must add the firewall rules that are required:

$ oc get events -n openshift-ingress --field-selector="reason=LoadBalancerManualChange"

Example output

Firewall change required by security admin: `gcloud compute firewall-rules create k8s-fw-a26e631036a3f46cba28f8df67266d55 --network example-network --description "{"kubernetes.io/service-name":"openshift-ingress/router-default", "kubernetes.io/service-ip":"35.237.236.234"}" --allow tcp:443,tcp:80 --source-ranges 0.0.0.0/0 --target-tags exampl-fqzq7-master,exampl-fqzq7-worker --project example-project`

If you encounter issues when creating these rule-based events, you can configure the cluster-wide firewall rules while your cluster is running.

4.10.22.1. Creating cluster-wide firewall rules for a shared VPC in GCP

You can create cluster-wide firewall rules to allow the access that the OpenShift Container Platform cluster requires.
Prerequisites

- You exported the variables that the Deployment Manager templates require to deploy your cluster.
- You created the networking and load balancing components in GCP that your cluster requires.

Procedure

1. Add a single firewall rule to allow the Google Cloud Engine health checks to access all of the services. This rule enables the ingress load balancers to determine the health status of their instances.

```bash
$ gcloud compute firewall-rules create --allow=tcp:30000-32767,udp:30000-32767 --network="${CLUSTER_NETWORK}" --source-ranges='130.211.0.0/22,35.191.0.0/16,209.85.152.0/22,209.85.204.0/22' --target-tags="${INFRA_ID}-master,${INFRA_ID}-worker" ${INFRA_ID}-ingress-hc --account=${HOST_PROJECT_ACCOUNT} --project=${HOST_PROJECT}
```

2. Add a single firewall rule to allow access to all cluster services:

- For an external cluster:

```bash
$ gcloud compute firewall-rules create --allow=tcp:80,tcp:443 --network="${CLUSTER_NETWORK}" --source-ranges="0.0.0.0/0" --target-tags="${INFRA_ID}-master,${INFRA_ID}-worker" ${INFRA_ID}-ingress --account=${HOST_PROJECT_ACCOUNT} --project=${HOST_PROJECT}
```

- For a private cluster:

```bash
$ gcloud compute firewall-rules create --allow=tcp:80,tcp:443 --network="${CLUSTER_NETWORK}" --source-ranges=${NETWORK_CIDR} --target-tags="${INFRA_ID}-master,${INFRA_ID}-worker" ${INFRA_ID}-ingress --account=${HOST_PROJECT_ACCOUNT} --project=${HOST_PROJECT}
```

Because this rule only allows traffic on TCP ports 80 and 443, ensure that you add all the ports that your services use.

4.10.23. Completing a GCP installation on user-provisioned infrastructure

After you start the OpenShift Container Platform installation on Google Cloud Platform (GCP) user-provisioned infrastructure, you can monitor the cluster events until the cluster is ready.

Prerequisites
• Deploy the bootstrap machine for an OpenShift Container Platform cluster on user-provisioned GCP infrastructure.

• Install the oc CLI and log in.

Procedure

1. Complete the cluster installation:

   $ ./openshift-install --dir <installation_directory> wait-for install-complete

   Example output

   INFO Waiting up to 30m0s for the cluster to initialize...

   For <installation_directory>, specify the path to the directory that you stored the installation files in.

   IMPORTANT

   • The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

   • It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

2. Observe the running state of your cluster.

   a. Run the following command to view the current cluster version and status:

      $ oc get clusterversion

      Example output

      NAME VERSION AVAILABLE PROGRESSING SINCE STATUS
      version False True 24m Working towards 4.5.4: 99% complete

   b. Run the following command to view the Operators managed on the control plane by the Cluster Version Operator (CVO):

      $ oc get clusteroperators

      Example output
c. Run the following command to view your cluster pods:

```
$ oc get pods --all-namespaces
```

**Example output**

<table>
<thead>
<tr>
<th>NAMESPACE</th>
<th>NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>kube-system</td>
<td>etcd-member-ip-10-0-3-111.us-east-2.compute.internal</td>
</tr>
<tr>
<td>2.compute.internal</td>
<td>1/1 Running 0 35m</td>
</tr>
<tr>
<td>kube-system</td>
<td>etcd-member-ip-10-0-3-239.us-east-2.compute.internal</td>
</tr>
<tr>
<td>2.compute.internal</td>
<td>1/1 Running 0 37m</td>
</tr>
<tr>
<td>kube-system</td>
<td>etcd-member-ip-10-0-3-24.us-east-2.compute.internal</td>
</tr>
<tr>
<td>2.compute.internal</td>
<td>1/1 Running 0 35m</td>
</tr>
<tr>
<td>openshift-apiserver-operator</td>
<td>openshift-apiserver-operator-6d6674f414-h712t 1/1 Running 1 37m</td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apiserver-fm48r</td>
</tr>
<tr>
<td>1/1 Running 0 30m</td>
<td>apiserver-fxkvv</td>
</tr>
<tr>
<td>openshift-apiserver</td>
<td>apiserver-q85nm</td>
</tr>
<tr>
<td>1/1 Running 0 29m</td>
<td></td>
</tr>
</tbody>
</table>
When the current cluster version is **AVAILABLE**, the installation is complete.

### 4.10.24. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.6, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to **OpenShift Cluster Manager**.

After you confirm that your **OpenShift Cluster Manager** inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use `subscription watch` to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- See [*About remote health monitoring*](#) for more information about the Telemetry service

### 4.10.25. Next steps

- **Customize your cluster.**

- If necessary, you can **opt out of remote health reporting**.

### 4.11. INSTALLING A CLUSTER ON GCP IN A RESTRICTED NETWORK WITH USER-PROVISIONED INFRASTRUCTURE

In OpenShift Container Platform version 4.6, you can install a cluster on Google Cloud Platform (GCP) that uses infrastructure that you provide and an internal mirror of the installation release content.

**IMPORTANT**

While you can install an OpenShift Container Platform cluster by using mirrored installation release content, your cluster still requires internet access to use the GCP APIs.

The steps for performing a user-provided infrastructure install are outlined here. Several **Deployment Manager** templates are provided to assist in completing these steps or to help model your own. You are also free to create the required resources through other methods.
The steps for performing a user-provisioned infrastructure installation are provided as an example only. Installing a cluster with infrastructure you provide requires knowledge of the cloud provider and the installation process of OpenShift Container Platform. Several Deployment Manager templates are provided to assist in completing these steps or to help model your own. You are also free to create the required resources through other methods; the templates are just an example.

4.11.1. Prerequisites

- Create a registry on your mirror host and obtain the `imageContentSources` data for your version of OpenShift Container Platform.

**IMPORTANT**

Because the installation media is on the mirror host, you can use that computer to complete all installation steps.

- Review details about the OpenShift Container Platform installation and update processes.

- If you use a firewall, you must configure it to allow the sites that your cluster requires access to. While you might need to grant access to more sites, you must grant access to `*.googleapis.com` and `accounts.google.com`.

- If you do not allow the system to manage identity and access management (IAM), then a cluster administrator can manually create and maintain IAM credentials. Manual mode can also be used in environments where the cloud IAM APIs are not reachable.

4.11.2. About installations in restricted networks

In OpenShift Container Platform 4.6, you can perform an installation that does not require an active connection to the Internet to obtain software components. Restricted network installations can be completed using installer-provisioned infrastructure or user-provisioned infrastructure, depending on the cloud platform to which you are installing the cluster.

If you choose to perform a restricted network installation on a cloud platform, you still require access to its cloud APIs. Some cloud functions, like Amazon Web Service’s IAM service, require Internet access, so you might still require Internet access. Depending on your network, you might require less Internet access for an installation on bare metal hardware or on VMware vSphere.

To complete a restricted network installation, you must create a registry that mirrors the contents of the OpenShift Container Platform registry and contains the installation media. You can create this registry on a mirror host, which can access both the Internet and your closed network, or by using other methods that meet your restrictions.

**IMPORTANT**

Because of the complexity of the configuration for user-provisioned installations, consider completing a standard user-provisioned infrastructure installation before you attempt a restricted network installation using user-provisioned infrastructure. Completing this test installation might make it easier to isolate and troubleshoot any issues that might arise during your installation in a restricted network.
4.11.2.1. Additional limits

Clusters in restricted networks have the following additional limitations and restrictions:

- The ClusterVersion status includes an Unable to retrieve available updates error.
- By default, you cannot use the contents of the Developer Catalog because you cannot access the required image stream tags.

4.11.3. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.6, you require access to the Internet to obtain the images that are necessary to install your cluster.

You must have Internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

4.11.4. Configuring your GCP project

Before you can install OpenShift Container Platform, you must configure a Google Cloud Platform (GCP) project to host it.

4.11.4.1. Creating a GCP project

To install OpenShift Container Platform, you must create a project in your Google Cloud Platform (GCP) account to host the cluster.

**Procedure**

- Create a project to host your OpenShift Container Platform cluster. See Creating and Managing Projects in the GCP documentation.
IMPORTANT

Your GCP project must use the Premium Network Service Tier if you are using installer-provisioned infrastructure. The Standard Network Service Tier is not supported for clusters installed using the installation program. The installation program configures internal load balancing for the `api-int.<cluster_name>`.<base_domain> URL; the Premium Tier is required for internal load balancing.

4.11.4.2. Enabling API services in GCP

Your Google Cloud Platform (GCP) project requires access to several API services to complete OpenShift Container Platform installation.

**Prerequisites**

- You created a project to host your cluster.

**Procedure**

- Enable the following required API services in the project that hosts your cluster. See Enabling services in the GCP documentation.

<table>
<thead>
<tr>
<th>API service</th>
<th>Console service name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compute Engine API</td>
<td>compute.googleapis.com</td>
</tr>
<tr>
<td>Google Cloud APIs</td>
<td>cloudapis.googleapis.com</td>
</tr>
<tr>
<td>Cloud Resource Manager API</td>
<td>cloudresourcemanager.googleapis.com</td>
</tr>
<tr>
<td>Google DNS API</td>
<td>dns.googleapis.com</td>
</tr>
<tr>
<td>IAM Service Account Credentials API</td>
<td>iamcredentials.googleapis.com</td>
</tr>
<tr>
<td>Identity and Access Management (IAM) API</td>
<td>iam.googleapis.com</td>
</tr>
<tr>
<td>Service Management API</td>
<td>servicemanagement.googleapis.com</td>
</tr>
<tr>
<td>Service Usage API</td>
<td>serviceusage.googleapis.com</td>
</tr>
<tr>
<td>Google Cloud Storage JSON API</td>
<td>storage-api.googleapis.com</td>
</tr>
<tr>
<td>Cloud Storage</td>
<td>storage-component.googleapis.com</td>
</tr>
</tbody>
</table>

4.11.4.3. Configuring DNS for GCP

To install OpenShift Container Platform, the Google Cloud Platform (GCP) account you use must have a dedicated public hosted zone in the same project that you host the OpenShift Container Platform.
cluster. This zone must be authoritative for the domain. The DNS service provides cluster DNS resolution and name lookup for external connections to the cluster.

**Procedure**

1. Identify your domain, or subdomain, and registrar. You can transfer an existing domain and registrar or obtain a new one through GCP or another source.

   **NOTE**
   
   If you purchase a new domain, it can take time for the relevant DNS changes to propagate. For more information about purchasing domains through Google, see [Google Domains](#).

2. Create a public hosted zone for your domain or subdomain in your GCP project. See [Creating public zones](#) in the GCP documentation.

   Use an appropriate root domain, such as `openshiftcorp.com`, or subdomain, such as `clusters.openshiftcorp.com`.

3. Extract the new authoritative name servers from the hosted zone records. See [Look up your Cloud DNS name servers](#) in the GCP documentation.

   You typically have four name servers.

4. Update the registrar records for the name servers that your domain uses. For example, if you registered your domain to Google Domains, see the following topic in the Google Domains Help: [How to switch to custom name servers](#).

5. If you migrated your root domain to Google Cloud DNS, migrate your DNS records. See [Migrating to Cloud DNS](#) in the GCP documentation.

6. If you use a subdomain, follow your company’s procedures to add its delegation records to the parent domain. This process might include a request to your company’s IT department or the division that controls the root domain and DNS services for your company.

**4.11.4.4. GCP account limits**

The OpenShift Container Platform cluster uses a number of Google Cloud Platform (GCP) components, but the default Quotas do not affect your ability to install a default OpenShift Container Platform cluster.

A default cluster, which contains three compute and three control plane machines, uses the following resources. Note that some resources are required only during the bootstrap process and are removed after the cluster deploys.

<table>
<thead>
<tr>
<th>Service</th>
<th>Component</th>
<th>Location</th>
<th>Total resources required</th>
<th>Resources removed after bootstrap</th>
</tr>
</thead>
<tbody>
<tr>
<td>Service account</td>
<td>IAM</td>
<td>Global</td>
<td>5</td>
<td>0</td>
</tr>
<tr>
<td>Firewall rules</td>
<td>Networking</td>
<td>Global</td>
<td>11</td>
<td>1</td>
</tr>
</tbody>
</table>
NOTE

If any of the quotas are insufficient during installation, the installation program displays an error that states both which quota was exceeded and the region.

Be sure to consider your actual cluster size, planned cluster growth, and any usage from other clusters that are associated with your account. The CPU, static IP addresses, and persistent disk SSD (storage) quotas are the ones that are most likely to be insufficient.

If you plan to deploy your cluster in one of the following regions, you will exceed the maximum storage quota and are likely to exceed the CPU quota limit:

- asia-east2
- asia-northeast2
- asia-south1
- australia-southeast1
- europe-north1
- europe-west2
- europe-west3
- europe-west6
- northamerica-northeast1
- southamerica-east1
You can increase resource quotas from the GCP console, but you might need to file a support ticket. Be sure to plan your cluster size early so that you can allow time to resolve the support ticket before you install your OpenShift Container Platform cluster.

4.11.4.5. Creating a service account in GCP

OpenShift Container Platform requires a Google Cloud Platform (GCP) service account that provides authentication and authorization to access data in the Google APIs. If you do not have an existing IAM service account that contains the required roles in your project, you must create one.

Prerequisites

- You created a project to host your cluster.

Procedure

1. Create a service account in the project that you use to host your OpenShift Container Platform cluster. See Creating a service account in the GCP documentation.

2. Grant the service account the appropriate permissions. You can either grant the individual permissions that follow or assign the Owner role to it. See Granting roles to a service account for specific resources.

   NOTE

   While making the service account an owner of the project is the easiest way to gain the required permissions, it means that service account has complete control over the project. You must determine if the risk that comes from offering that power is acceptable.

3. Create the service account key in JSON format. See Creating service account keys in the GCP documentation. The service account key is required to create a cluster.

4.11.4.5.1. Required GCP permissions

When you attach the Owner role to the service account that you create, you grant that service account all permissions, including those that are required to install OpenShift Container Platform. To deploy an OpenShift Container Platform cluster, the service account requires the following permissions. If you deploy your cluster into an existing VPC, the service account does not require certain networking permissions, which are noted in the following lists:

Required roles for the installation program

- Compute Admin
- Security Admin
- Service Account Admin
- Service Account User
- Storage Admin
Required roles for creating network resources during installation

- DNS Administrator

Required roles for user-provisioned GCP infrastructure

- Deployment Manager Editor
- Service Account Key Admin

Optional roles

For the cluster to create new limited credentials for its Operators, add the following role:

- Service Account Key Admin

The roles are applied to the service accounts that the control plane and compute machines use:

**Table 4.47. GCP service account permissions**

<table>
<thead>
<tr>
<th>Account</th>
<th>Roles</th>
</tr>
</thead>
<tbody>
<tr>
<td>Control Plane</td>
<td>roles/compute.instanceAdmin</td>
</tr>
<tr>
<td></td>
<td>roles/compute.networkAdmin</td>
</tr>
<tr>
<td></td>
<td>roles/compute.securityAdmin</td>
</tr>
<tr>
<td></td>
<td>roles/storage.admin</td>
</tr>
<tr>
<td></td>
<td>roles/iam.serviceAccountUser</td>
</tr>
<tr>
<td>Compute</td>
<td>roles/compute.viewer</td>
</tr>
<tr>
<td></td>
<td>roles/storage.admin</td>
</tr>
</tbody>
</table>

4.11.4.6. Supported GCP regions

You can deploy an OpenShift Container Platform cluster to the following Google Cloud Platform (GCP) regions:

- **asia-east1** (Changhua County, Taiwan)
- **asia-east2** (Hong Kong)
- **asia-northeast1** (Tokyo, Japan)
- **asia-northeast2** (Osaka, Japan)
- **asia-northeast3** (Seoul, South Korea)
- **asia-south1** (Mumbai, India)
- **asia-southeast1** (Jurong West, Singapore)
4.11.4.7. Installing and configuring CLI tools for GCP

To install OpenShift Container Platform on Google Cloud Platform (GCP) using user-provisioned infrastructure, you must install and configure the CLI tools for GCP.

Prerequisites

- You created a project to host your cluster.
- You created a service account and granted it the required permissions.

Procedure

1. Install the following binaries in $PATH:
   - gcloud
   - gsutil

   See Install the latest Cloud SDK version in the GCP documentation.

2. Authenticate using the gcloud tool with your configured service account.
   See Authorizing with a service account in the GCP documentation.
4.11.5. Creating the installation files for GCP

To install OpenShift Container Platform on Google Cloud Platform (GCP) using user-provisioned infrastructure, you must generate the files that the installation program needs to deploy your cluster and modify them so that the cluster creates only the machines that it will use. You generate and customize the `install-config.yaml` file, Kubernetes manifests, and Ignition config files. You also have the option to first set up a separate `var` partition during the preparation phases of installation.

4.11.5.1. Optional: Creating a separate `/var` partition

It is recommended that disk partitioning for OpenShift Container Platform be left to the installer. However, there are cases where you might want to create separate partitions in a part of the filesystem that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the `/var` partition or a subdirectory of `/var`. For example:

- `/var/lib/containers`: Holds container-related content that can grow as more images and containers are added to a system.
- `/var/lib/etcd`: Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.
- `/var`: Holds data that you might want to keep separate for purposes such as auditing.

Storing the contents of a `/var` directory separately makes it easier to grow storage for those areas as needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

Because `/var` must be in place before a fresh installation of Red Hat Enterprise Linux CoreOS (RHCOS), the following procedure sets up the separate `/var` partition by creating a machine config that is inserted during the `openshift-install` preparation phases of an OpenShift Container Platform installation.

**IMPORTANT**

If you follow the steps to create a separate `/var` partition in this procedure, it is not necessary to create the Kubernetes manifest and Ignition config files again as described later in this section.

**Procedure**

1. Create a directory to hold the OpenShift Container Platform installation files:

   ```bash
   $ mkdir $HOME/clusterconfig
   ```

2. Run `openshift-install` to create a set of files in the `manifest` and `openshift` subdirectories. Answer the system questions as you are prompted:

   ```bash
   $ openshift-install create manifests --dir $HOME/clusterconfig
   ```

   **Example output**

   ```text
   ? SSH Public Key ...
   ```
3. Optional: Confirm that the installation program created manifests in the `clusterconfig/openshift` directory:

```
$ ls $HOME/clusterconfig/openshift/
```

**Example output**

```
99_kubeadmin-password-secret.yaml
99_openshift-cluster-api_master-machines-0.yaml
99_openshift-cluster-api_master-machines-1.yaml
99_openshift-cluster-api_master-machines-2.yaml
```

4. Create a MachineConfig object and add it to a file in the `openshift` directory. For example, name the file `98-var-partition.yaml`, change the disk device name to the name of the storage device on the worker systems, and set the storage size as appropriate. This example places the /var directory on a separate partition:

```yaml
apiVersion: machineconfiguration.openshift.io/v1
kind: MachineConfig
metadata:
  labels:
    machineconfiguration.openshift.io/role: worker
name: 98-var-partition
spec:
  config:
    ignition:
      version: 3.1.0
    storage:
      disks:
        -device: /dev/<device_name>  
        partitions:
          -label: var
            startMiB: <partition_start_offset>  
            sizeMiB: <partition_size>  
        filesystems:
          -device: /dev/disk/by-partlabel/var
            path: /var
            format: xfs
    systemd:
      units:
        -name: var.mount  
        enabled: true
        contents: |
          [Unit]
          Before=local-fs.target
          [Mount]
          What=/dev/disk/by-partlabel/var
          Where=/var
```
The storage device name of the disk that you want to partition.

When adding a data partition to the boot disk, a minimum value of 25000 MiB (Mebibytes) is recommended. The root file system is automatically resized to fill all available space up to the specified offset. If no value is specified, or if the specified value is smaller than the recommended minimum, the resulting root file system will be too small, and future reinstalls of RHCOS might overwrite the beginning of the data partition.

The size of the data partition in mebibytes.

The name of the mount unit must match the directory specified in the `Where=` directive. For example, for a filesystem mounted on `/var/lib/containers`, the unit must be named `var-lib-containers.mount`.

The `prjquota` mount option must be enabled for filesystems used for container storage.

**NOTE**

When creating a separate `/var` partition, you cannot use different instance types for worker nodes, if the different instance types do not have the same device name.

5. Run `openshift-install` again to create Ignition configs from a set of files in the `manifest` and `openshift` subdirectories:

```
$ openshift-install create ignition-configs --dir $HOME/clusterconfig
$ ls $HOME/clusterconfig/
auth bootstrap.ign master.ign metadata.json worker.ign
```

Now you can use the Ignition config files as input to the installation procedures to install Red Hat Enterprise Linux CoreOS (RHCOS) systems.

### 4.11.5.2. Creating the installation configuration file

You can customize the OpenShift Container Platform cluster you install on Google Cloud Platform (GCP).

**Prerequisites**

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster. For a restricted network installation, these files are on your mirror host.
- Have the `imageContentSources` values that were generated during mirror registry creation.
- Obtain the contents of the certificate for your mirror registry.

**Procedure**

1. Create the `install-config.yaml` file.
a. Change to the directory that contains the installation program and run the following command:

```
$ ./openshift-install create install-config --dir <installation_directory>
```

For `<installation_directory>`, specify the directory name to store the files that the installation program creates.

**IMPORTANT**

Specify an empty directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

b. At the prompts, provide the configuration details for your cloud:

i. Optional: Select an SSH key to use to access your cluster machines.

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your `ssh-agent` process uses.

ii. Select `gcp` as the platform to target.

iii. If you have not configured the service account key for your GCP account on your computer, you must obtain it from GCP and paste the contents of the file or enter the absolute path to the file.

iv. Select the project ID to provision the cluster in. The default value is specified by the service account that you configured.

v. Select the region to deploy the cluster to.

vi. Select the base domain to deploy the cluster to. The base domain corresponds to the public DNS zone that you created for your cluster.

vii. Enter a descriptive name for your cluster.

viii. Paste the pull secret from the Red Hat OpenShift Cluster Manager.

2. Edit the `install-config.yaml` file to provide the additional information that is required for an installation in a restricted network.

a. Update the `pullSecret` value to contain the authentication information for your registry:

```
pullSecret: '{"auhth":{"<mirror_host_name>:5000": {"auth": "<credentials>"", "email": "you@example.com"}}}
```
For `<mirror_host_name>`, specify the registry domain name that you specified in the certificate for your mirror registry, and for `<credentials>`, specify the base64-encoded user name and password for your mirror registry.

b. Add the `additionalTrustBundle` parameter and value.

```yaml
additionalTrustBundle: |
    -----BEGIN CERTIFICATE-----
    ZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZZ
    -----END CERTIFICATE-----
```

The value must be the contents of the certificate file that you used for your mirror registry, which can be an existing, trusted certificate authority or the self-signed certificate that you generated for the mirror registry.

c. Define the network and subnets for the VPC to install the cluster in under the parent `platform.gcp` field:

```yaml
network: <existing_vpc>
controlPlaneSubnet: <control_plane_subnet>
computeSubnet: <compute_subnet>
```

For `platform.gcp.network`, specify the name for the existing Google VPC. For `platform.gcp.controlPlaneSubnet` and `platform.gcp.computeSubnet`, specify the existing subnets to deploy the control plane machines and compute machines, respectively.

d. Add the image content resources, which look like this excerpt:

```yaml
imageContentSources:
  - mirrors:
    - `<mirror_host_name>:5000/<repo_name>/release`
      source: quay.example.com/openshift-release-dev/ocp-release
    - mirrors:
      - `<mirror_host_name>:5000/<repo_name>/release`
        source: registry.example.com/ocp/release
```

To complete these values, use the `imageContentSources` that you recorded during mirror registry creation.

3. Make any other modifications to the `install-config.yaml` file that you require. You can find more information about the available parameters in the `Installation configuration parameters` section.

4. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

**IMPORTANT**

The `install-config.yaml` file is consumed during the installation process. If you want to reuse the file, you must back it up now.

4.11.5.3. Configuring the cluster-wide proxy during installation
Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the install-config.yaml file.

Prerequisites

- You have an existing install-config.yaml file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the Proxy object’s spec.noProxy field to bypass the proxy if necessary.

NOTE

The Proxy object status.noProxy field is populated with the values of the networking.machineNetwork[].cidr, networking.clusterNetwork[].cidr, and networking.serviceNetwork[] fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the Proxy object status.noProxy field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your install-config.yaml file and add the proxy settings. For example:

```yaml
apiVersion: v1
baseDomain: my.domain.com
proxy:
  httpProxy: http://<username>:<pswd>@<ip>:<port> 1
  httpsProxy: https://<username>:<pswd>@<ip>:<port> 2
  noProxy: example.com 3
additionalTrustBundle: |
  -----BEGIN CERTIFICATE-----
  <MY_TRUSTED_CA_CERT>
  -----END CERTIFICATE-----
...
```

1 A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be http.
2 A proxy URL to use for creating HTTPS connections outside the cluster.
3 A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, .y.com matches x.y.com, but not y.com. Use * to bypass the proxy for all destinations.
4 If provided, the installation program generates a config map that is named user-ca-bundle in the openshift-config namespace to hold the additional CA certificates. If you provide additionalTrustBundle and at least one proxy setting, the Proxy object is configured to reference the user-ca-bundle config map in the trustedCA field. The Cluster Network Operator then creates a trusted-ca-bundle config map that merges the contents
specified for the trustedCA parameter with the RHCOS trust bundle. The additionalTrustBundle field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

**NOTE**

The installation program does not support the proxy readinessEndpoints field.

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named cluster that uses the proxy settings in the provided install-config.yaml file. If no proxy settings are provided, a cluster Proxy object is still created, but it will have a nil spec.

**NOTE**

Only the Proxy object named cluster is supported, and no additional proxies can be created.

4.11.5.4. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to make its machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to create the cluster.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

**Prerequisites**

- You obtained the OpenShift Container Platform installation program. For a restricted network installation, these files are on your mirror host.

- You created the install-config.yaml installation configuration file.

**Procedure**
1. Change to the directory that contains the installation program and generate the Kubernetes manifests for the cluster:

   $ ./openshift-install create manifests --dir <installation_directory> ①

   Example output

   INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
   INFO Consuming Install Config from target directory
   INFO Manifests created in: install_dir/manifests and install_dir/openshift

   ① For <installation_directory>, specify the installation directory that contains the install-config.yaml file you created.

2. Remove the Kubernetes manifest files that define the control plane machines:

   $ rm -f <installation_directory>/openshift/99_openshift-cluster-api_master-machines-*.yaml

   By removing these files, you prevent the cluster from automatically generating control plane machines.

3. Optional: If you do not want the cluster to provision compute machines, remove the Kubernetes manifest files that define the worker machines:

   $ rm -f <installation_directory>/openshift/99_openshift-cluster-api_worker-machineset-*.yaml

   Because you create and manage the worker machines yourself, you do not need to initialize these machines.

4. Check that the mastersSchedulable parameter in the <installation_directory>/manifests/cluster-scheduler-02-config.yml Kubernetes manifest file is set to false. This setting prevents pods from being scheduled on the control plane machines:

   a. Open the <installation_directory>/manifests/cluster-scheduler-02-config.yml file.
   b. Locate the mastersSchedulable parameter and ensure that it is set to false.
   c. Save and exit the file.

5. Optional: If you do not want the Ingress Operator to create DNS records on your behalf, remove the privateZone and publicZone sections from the <installation_directory>/manifests/cluster-dns-02-config.yml DNS configuration file:

   apiVersion: config.openshift.io/v1
   kind: DNS
   metadata:
     creationTimestamp: null
     name: cluster
   spec:
     baseDomain: example.openshift.com
     privateZone: ①
       id: mycluster-100419-private-zone
Remove this section completely.

If you do so, you must add ingress DNS records manually in a later step.

6. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

```
$ ./openshift-install create ignition-configs --dir <installation_directory>
```

For `<installation_directory>`, specify the same installation directory.

The following files are generated in the directory:

```
├── auth
│   └── kubeadmin-password
│       └── kubeconfig
├── bootstrap.ign
├── master.ign
├── metadata.json
└── worker.ign
```

Additional resources

- Optional: Adding the ingress DNS records

4.11.6. Exporting common variables

4.11.6.1. Extracting the infrastructure name

The Ignition config files contain a unique cluster identifier that you can use to uniquely identify your cluster in Google Cloud Platform (GCP). The infrastructure name is also used to locate the appropriate GCP resources during an OpenShift Container Platform installation. The provided Deployment Manager templates contain references to this infrastructure name, so you must extract it.

Prerequisites

- You obtained the OpenShift Container Platform installation program and the pull secret for your cluster.
- You generated the Ignition config files for your cluster.
- You installed the `jq` package.

Procedure

- To extract and view the infrastructure name from the Ignition config file metadata, run the following command:
For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

Example output

```
$ jq -r .infraID <installation_directory>/metadata.json
```

The output of this command is your cluster name and a random string.

4.11.6.2. Exporting common variables for Deployment Manager templates

You must export a common set of variables that are used with the provided Deployment Manager templates used to assist in completing a user-provided infrastructure install on Google Cloud Platform (GCP).

NOTE
Specific Deployment Manager templates can also require additional exported variables, which are detailed in their related procedures.

Prerequisites

- Obtain the OpenShift Container Platform installation program and the pull secret for your cluster.
- Generate the Ignition config files for your cluster.
- Install the `jq` package.

Procedure

1. Export the following common variables to be used by the provided Deployment Manager templates:

```
$ export BASE_DOMAIN='<base_domain>'
$ export BASE_DOMAIN_ZONE_NAME='<base_domain_zone_name>'
$ export NETWORK_CIDR='10.0.0.0/16'
$ export MASTER_SUBNET_CIDR='10.0.0.0/19'
$ export WORKER_SUBNET_CIDR='10.0.32.0/19'

$ export KUBECONFIG=<installation_directory>/auth/kubeconfig
$ export CLUSTER_NAME=`jq -r .clusterName <installation_directory>/metadata.json`
$ export INFRA_ID=`jq -r .infraID <installation_directory>/metadata.json`
$ export PROJECT_NAME=`jq -r .gcp.projectID <installation_directory>/metadata.json`
$ export REGION=`jq -r .gcp.region <installation_directory>/metadata.json`
```

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.
4.11.7. Creating a VPC in GCP

You must create a VPC in Google Cloud Platform (GCP) for your OpenShift Container Platform cluster to use. You can customize the VPC to meet your requirements. One way to create the VPC is to modify the provided Deployment Manager template.

**NOTE**

If you do not use the provided Deployment Manager template to create your GCP infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

**Prerequisites**

- Configure a GCP account.
- Generate the Ignition config files for your cluster.

**Procedure**

1. Copy the template from the Deployment Manager template for the VPC section of this topic and save it as `01_vpc.py` on your computer. This template describes the VPC that your cluster requires.

2. Create a `01_vpc.yaml` resource definition file:

   ```
   $ cat <<EOF >01_vpc.yaml
   imports:
     - path: 01_vpc.py
   resources:
     - name: cluster-vpc
       type: 01_vpc.py
       properties:
         infra_id: '${INFRA_ID}'  # 1
         region: '${REGION}'  # 2
         master_subnet_cidr: '${MASTER_SUBNET_CIDR}'  # 3
         worker_subnet_cidr: '${WORKER_SUBNET_CIDR}'  # 4
   EOF
   ```

   - **infra_id** is the INFRA_ID infrastructure name from the extraction step.
   - **region** is the region to deploy the cluster into, for example us-central1.
   - **master_subnet_cidr** is the CIDR for the master subnet, for example 10.0.0.0/19.
   - **worker_subnet_cidr** is the CIDR for the worker subnet, for example 10.0.32.0/19.

3. Create the deployment by using the `gcloud` CLI:

   ```
   $ gcloud deployment-manager deployments create ${INFRA_ID}-vpc --config 01_vpc.yaml
   ```
4.11.7.1. Deployment Manager template for the VPC

You can use the following Deployment Manager template to deploy the VPC that you need for your OpenShift Container Platform cluster:

Example 4.19. 01_vpc.py Deployment Manager template

```python
def GenerateConfig(context):

    resources = [{
        'name': context.properties['infra_id'] + '-network',
        'type': 'compute.v1.network',
        'properties': {
            'region': context.properties['region'],
            'autoCreateSubnetworks': False
        }
    }, {
        'name': context.properties['infra_id'] + '-master-subnet',
        'type': 'compute.v1.subnetwork',
        'properties': {
            'region': context.properties['region'],
            'network': '$(ref.' + context.properties['infra_id'] + '-network.selfLink)',
            'ipCidrRange': context.properties['master_subnet_cidr']
        }
    }, {
        'name': context.properties['infra_id'] + '-worker-subnet',
        'type': 'compute.v1.subnetwork',
        'properties': {
            'region': context.properties['region'],
            'network': '$(ref.' + context.properties['infra_id'] + '-network.selfLink)',
            'ipCidrRange': context.properties['worker_subnet_cidr']
        }
    }, {
        'name': context.properties['infra_id'] + '-router',
        'type': 'compute.v1.router',
        'properties': {
            'region': context.properties['region'],
            'network': '$(ref.' + context.properties['infra_id'] + '-network.selfLink)',
            'nats': [
                '
                'name': context.properties['infra_id'] + '-nat-master',
                'natIpAllocateOption': 'AUTO_ONLY',
                'minPortsPerVm': 7168,
                'sourceSubnetworkIpRangesToNat': 'LIST_OF_SUBNETWORKS',
                'subnetworks': [
                    '
                    'name': '$(ref.' + context.properties['infra_id'] + '-master-subnet.selfLink)',
                    'sourceIpRangesToNat': ['ALL_IP_RANGES']
                ]
            ],
            'nats': [
                '
                'name': context.properties['infra_id'] + '-nat-worker',
                'natIpAllocateOption': 'AUTO_ONLY',
                'minPortsPerVm': 512,
                'sourceSubnetworkIpRangesToNat': 'LIST_OF_SUBNETWORKS',
                'subnetworks': [
                    '
                    'name': '$(ref.' + context.properties['infra_id'] + '-worker-subnet.selfLink)',
                    'sourceIpRangesToNat': ['ALL_IP_RANGES']
                ]
            ]
        }
    }
```

OpenShift Container Platform 4.6 Installing
4.11.8. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require network in initramfs during boot to fetch ignition config from the machine config server.

You must configure the network connectivity between machines to allow cluster components to communicate. Each machine must be able to resolve the host names of all other machines in the cluster.

Table 4.48. All machines to all machines

Table 4.50. Control plane machines to control plane machines
**Network topology requirements**
The infrastructure that you provision for your cluster must meet the following network topology requirements.

**Load balancers**
Before you install OpenShift Container Platform, you must provision two load balancers that meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.
   - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

   **IMPORTANT**
   Do not configure session persistence for an API load balancer.

Configure the following ports on both the front and back of the load balancers:

**Table 4.51. API load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the <code>/readyz</code> endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>
The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the `/readyz` endpoint to the removal of the API server instance from the pool. Within the time frame after `/readyz` returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application Ingress load balancer**: Provides an Ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the Ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

Configure the following ports on both the front and back of the load balancers:

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress router pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress router pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>

**TIP**

If the true IP address of the client can be seen by the load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

**NOTE**

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

4.11.9. **Creating load balancers in GCP**

You must configure load balancers in Google Cloud Platform (GCP) for your OpenShift Container Platform cluster to use. One way to create these components is to modify the provided Deployment Manager template.
NOTE

If you do not use the provided Deployment Manager template to create your GCP infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.

Procedure

1. Copy the template from the Deployment Manager template for the internal load balancer section of this topic and save it as 02_lb_int.py on your computer. This template describes the internal load balancing objects that your cluster requires.

2. For an external cluster, also copy the template from the Deployment Manager template for the external load balancer section of this topic and save it as 02_lb_ext.py on your computer. This template describes the external load balancing objects that your cluster requires.

3. Export the variables that the deployment template uses:
   a. Export the cluster network location:
      
      ```bash
      $ export CLUSTER_NETWORK=('gcloud compute networks describe ${INFRA_ID}-network --format json | jq -r .selfLink')
      ```
   
   b. Export the control plane subnet location:
      
      ```bash
      $ export CONTROL_SUBNET=('gcloud compute networks subnets describe ${INFRA_ID}-master-subnet --region=${REGION} --format json | jq -r .selfLink')
      ```
   
   c. Export the three zones that the cluster uses:
      
      ```bash
      $ export ZONE_0=('gcloud compute regions describe ${REGION} --format=json | jq -r .zones[0] | cut -d "/" -f9')
      $ export ZONE_1=('gcloud compute regions describe ${REGION} --format=json | jq -r .zones[1] | cut -d "/" -f9')
      $ export ZONE_2=('gcloud compute regions describe ${REGION} --format=json | jq -r .zones[2] | cut -d "/" -f9')
      ```

4. Create a 02_infra.yaml resource definition file:

   ```bash
   $ cat <<EOF >02_infra.yaml
   imports:
   - path: 02_lb_ext.py
   - path: 02_lb_int.py
   EOF
   ```
Required only when deploying an external cluster.

**infra_id** is the **INFRA_ID** infrastructure name from the extraction step.

**region** is the region to deploy the cluster into, for example **us-central1**.

**control_subnet** is the URI to the control subnet.

**zones** are the zones to deploy the control plane instances into, like **us-east1-b, us-east1-c**, and **us-east1-d**.

5. Create the deployment by using the **gcloud** CLI:

```bash
$ gcloud deployment-manager deployments create ${INFRA_ID}-infra --config 02_infra.yaml
```

6. Export the cluster IP address:

```bash
$ export CLUSTER_IP=(`gcloud compute addresses describe ${INFRA_ID}-cluster-ip --region=${REGION} --format json | jq -r .address`)
```

7. For an external cluster, also export the cluster public IP address:

```bash
$ export CLUSTER_PUBLIC_IP=('gcloud compute addresses describe ${INFRA_ID}-cluster-public-ip --region=${REGION} --format json | jq -r .address')
```

### 4.11.9.1. Deployment Manager template for the external load balancer

You can use the following Deployment Manager template to deploy the external load balancer that you need for your OpenShift Container Platform cluster:

**Example 4.20. 02_lb_ext.py Deployment Manager template**

```python
def GenerateConfig(context):
```
4.11.9.2. Deployment Manager template for the internal load balancer

You can use the following Deployment Manager template to deploy the internal load balancer that you need for your OpenShift Container Platform cluster:

Example 4.21. 02_lb_int.py Deployment Manager template

def GenerateConfig(context):

    backends = []
    for zone in context.properties['zones']:
        backends.append({
            'group': $(ref. + context.properties['infra_id'] + '-master-' + zone + '-instance-group') + '.selfLink'
        })

    resources = [{
        'name': context.properties['infra_id'] + '-cluster-ip',
        'type': 'compute.v1.forwardingRule',
        'properties': {
            'region': context.properties['region'],
            'IPAddress': $(ref. + context.properties['infra_id'] + '-cluster-public-ip.selfLink'),
            'target': $(ref. + context.properties['infra_id'] + '-api-forwarding-rule.selfLink'),
            'portRange': '6443'
        }
    }]

    return {'resources': resources}
'type': 'compute.v1.address',
'properties': {
    'addressType': 'INTERNAL',
    'region': context.properties['region'],
    'subnetwork': context.properties['control_subnet']
}
}, {
    # Refer to docs/dev/kube-apiserver-health-check.md on how to correctly setup health check probe for kube-apiserver
    'name': context.properties['infra_id'] + '-api-internal-health-check',
    'type': 'compute.v1.healthCheck',
    'properties': {
        'httpsHealthCheck': {
            'port': 6443,
            'requestPath': '/readyz'
        },
        'type': "HTTPS"
    }
}, {
    'name': context.properties['infra_id'] + '-api-internal-backend-service',
    'type': 'compute.v1.regionBackendService',
    'properties': {
        'backends': backends,
        'healthChecks': ["$(ref. + context.properties['infra_id'] + '-api-internal-health-check.selfLink')"],
        'loadBalancingScheme': 'INTERNAL',
        'region': context.properties['region'],
        'protocol': 'TCP',
        'timeoutSec': 120
    }
}, {
    'name': context.properties['infra_id'] + '-api-internal-forwarding-rule',
    'type': 'compute.v1.forwardingRule',
    'properties': {
        'backendService': "$(ref. + context.properties['infra_id'] + '-api-internal-backend-service.selfLink')",
        'IPAddress': "$(ref. + context.properties['infra_id'] + '-cluster-ip.selfLink')",
        'loadBalancingScheme': 'INTERNAL',
        'ports': ['6443', '22623'],
        'region': context.properties['region'],
        'subnetwork': context.properties['control_subnet']
    }
}
for zone in context.properties['zones']:
resources.append({
    'name': context.properties['infra_id'] + '-master-' + zone + '-instance-group',
    'type': 'compute.v1.instanceGroup',
    'properties': {
        'namedPorts': [
            {
                'name': 'ignition',
                'port': 22623
            }, {
                'name': 'https',
                'port': 6443
            }
        ]
    },
You will need this template in addition to the 02_lb_ext.py template when you create an external cluster.

4.11.10. Creating a private DNS zone in GCP

You must configure a private DNS zone in Google Cloud Platform (GCP) for your OpenShift Container Platform cluster to use. One way to create this component is to modify the provided Deployment Manager template.

**NOTE**

If you do not use the provided Deployment Manager template to create your GCP infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

**Prerequisites**

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.

**Procedure**

1. Copy the template from the Deployment Manager template for the private DNS section of this topic and save it as 02_dns.py on your computer. This template describes the private DNS objects that your cluster requires.

2. Create a 02_dns.yaml resource definition file:

   ```
   $ cat <<EOF >02_dns.yaml
   imports:
     - path: 02_dns.py
   resources:
     - name: cluster-dns
       type: 02_dns.py
       properties:
         infra_id: '${INFRA_ID}'
         cluster_domain: '${CLUSTER_NAME}.${BASE_DOMAIN}'
         cluster_network: '${CLUSTER_NETWORK}'
   EOF
   ```
1. **infra_id** is the INFRA_ID infrastructure name from the extraction step.

2. **cluster_domain** is the domain for the cluster, for example openshift.example.com.

3. **cluster_network** is the selfLink URL to the cluster network.

3. Create the deployment by using the **gcloud** CLI:

   ```
   $ gcloud deployment-manager deployments create ${INFRA_ID}-dns --config 02_dns.yaml
   ```

4. The templates do not create DNS entries due to limitations of Deployment Manager, so you must create them manually:

   a. Add the internal DNS entries:

   ```
   $ if [ -f transaction.yaml ]; then rm transaction.yaml; fi
   $ gcloud dns record-sets transaction start --zone ${INFRA_ID}-private-zone
   $ gcloud dns record-sets transaction add ${CLUSTER_IP} --name api.$(CLUSTER_NAME).$(BASE_DOMAIN). --ttl 60 --type A --zone ${INFRA_ID}-private-zone
   $ gcloud dns record-sets transaction add ${CLUSTER_IP} --name api-int.$(CLUSTER_NAME).$(BASE_DOMAIN). --ttl 60 --type A --zone ${INFRA_ID}-private-zone
   $ gcloud dns record-sets transaction execute --zone ${INFRA_ID}-private-zone
   ```

   b. For an external cluster, also add the external DNS entries:

   ```
   $ if [ -f transaction.yaml ]; then rm transaction.yaml; fi
   $ gcloud dns record-sets transaction start --zone ${BASE_DOMAIN_ZONE_NAME}
   $ gcloud dns record-sets transaction add ${CLUSTER_PUBLIC_IP} --name api.$(CLUSTER_NAME).$(BASE_DOMAIN). --ttl 60 --type A --zone ${BASE_DOMAIN_ZONE_NAME}
   $ gcloud dns record-sets transaction execute --zone ${BASE_DOMAIN_ZONE_NAME}
   ```

4.11.10.1. Deployment Manager template for the private DNS

You can use the following Deployment Manager template to deploy the private DNS that you need for your OpenShift Container Platform cluster:

**Example 4.22. 02_dns.py Deployment Manager template**

```python
def GenerateConfig(context):
    resources = [{
        'name': context.properties['infra_id'] + '-private-zone',
        'type': 'dns.v1.managedZone',
        'properties': {
            'description': '',
            'dnsName': context.properties['cluster_domain'] + '.',
            'visibility': 'private',
            'privateVisibilityConfig': {
                'networks': [{
                    'networkUrl': context.properties['cluster_network']
                }]
            }
        }
    }
```
4.11.1 Creating firewall rules in GCP

You must create firewall rules in Google Cloud Platform (GCP) for your OpenShift Container Platform cluster to use. One way to create these components is to modify the provided Deployment Manager template.

**NOTE**

If you do not use the provided Deployment Manager template to create your GCP infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

**Prerequisites**

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.

**Procedure**

1. Copy the template from the Deployment Manager template for firewall rules section of this topic and save it as `03_firewall.py` on your computer. This template describes the security groups that your cluster requires.

2. Create a `03_firewall.yaml` resource definition file:

   ```
   $ cat <<EOF >03_firewall.yaml
   imports:
    - path: 03_firewall.py

   resources:
    - name: cluster-firewall
      type: 03_firewall.py
      properties:
        allowed_external_cidr: '0.0.0.0/0'
        infra_id: '${INFRA_ID}'
        cluster_network: '${CLUSTER_NETWORK}'
        network_cidr: '${NETWORK_CIDR}'
   EOF
   
   1 *allowed_external_cidr* is the CIDR range that can access the cluster API and SSH to the bootstrap host. For an internal cluster, set this value to *${NETWORK_CIDR}*.  
   2 *infra_id* is the *INFRA_ID* infrastructure name from the extraction step.
cluster_network is the selfLink URL to the cluster network.

network_cidr is the CIDR of the VPC network, for example 10.0.0.0/16.

3. Create the deployment by using the gcloud CLI:

```bash
$ gcloud deployment-manager deployments create ${INFRA_ID}-firewall --config 03_firewall.yaml
```

4.11.1.1. Deployment Manager template for firewall rules

You can use the following Deployment Manager template to deploy the firewall rules that you need for your OpenShift Container Platform cluster:

Example 4.23. 03_firewall.py Deployment Manager template

```python
def GenerateConfig(context):
    resources = [
        {
            'name': context.properties['infra_id'] + '-bootstrap-in-ssh',
            'type': 'compute.v1.firewall',
            'properties': {
                'network': context.properties['cluster_network'],
                'allowed': [{
                    'IPProtocol': 'tcp',
                    'ports': ['22']
                }],
                'sourceRanges': [context.properties['allowed_external_cidr']],
                'targetTags': [context.properties['infra_id'] + '-bootstrap']
            }
        },
        {
            'name': context.properties['infra_id'] + '-api',
            'type': 'compute.v1.firewall',
            'properties': {
                'network': context.properties['cluster_network'],
                'allowed': [{
                    'IPProtocol': 'tcp',
                    'ports': ['6443']
                }],
                'sourceRanges': [context.properties['allowed_external_cidr']],
                'targetTags': [context.properties['infra_id'] + '-master']
            }
        },
        {
            'name': context.properties['infra_id'] + '-health-checks',
            'type': 'compute.v1.firewall',
            'properties': {
                'network': context.properties['cluster_network'],
                'allowed': [{
                    'IPProtocol': 'tcp',
                    'ports': ['6080', '6443', '22624']
                }],
                'sourceRanges': ['35.191.0.0/16', '130.211.0.0/22', '209.85.152.0/22', '209.85.204.0/22'],
                'targetTags': [context.properties['infra_id'] + '-master']
            }
        }
    ]
```
', 'name': context.properties['infra_id'] + '-etcd',
    'type': 'compute.v1.firewall',
    'properties': {
        'network': context.properties['cluster_network'],
        'allowed': [{
            'IPProtocol': 'tcp',
            'ports': ['2379-2380']
        }],
        'sourceTags': [context.properties['infra_id'] + '-master'],
        'targetTags': [context.properties['infra_id'] + '-master']
    }
},
{name': context.properties['infra_id'] + '-control-plane',
'type': 'compute.v1.firewall',
'properties': {
    'network': context.properties['cluster_network'],
    'allowed': [
        {
            'IPProtocol': 'tcp',
            'ports': ['10257']
        },
        {
            'IPProtocol': 'tcp',
            'ports': ['10259']
        },
        {
            'IPProtocol': 'tcp',
            'ports': ['22623']
        }
    ],
    'sourceTags': [
        context.properties['infra_id'] + '-master',
        context.properties['infra_id'] + '-worker'
    ],
    'targetTags': [context.properties['infra_id'] + '-master']
},
{name': context.properties['infra_id'] + '-internal-network',
'type': 'compute.v1.firewall',
'properties': {
    'network': context.properties['cluster_network'],
    'allowed': [
        {
            'IPProtocol': 'icmp'
        },
        {
            'IPProtocol': 'tcp',
            'ports': ['22']
        }
    ],
    'sourceRanges': [context.properties['network_cidr']],
    'targetTags': [
        context.properties['infra_id'] + '-master',
        context.properties['infra_id'] + '-worker'
    ]
},
{name': context.properties['infra_id'] + '-internal-cluster',
'type': 'compute.v1.firewall',
'properties': {
    'network': context.properties['cluster_network'],
    'allowed': [{

4.11.12. Creating IAM roles in GCP

You must create IAM roles in Google Cloud Platform (GCP) for your OpenShift Container Platform cluster to use. One way to create these components is to modify the provided Deployment Manager template.

NOTE

If you do not use the provided Deployment Manager template to create your GCP infrastructure, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.

Procedure

```json
"IPProtocol": "udp",
'ports': ['4789', '6081']
},
'IPProtocol": "tcp",
'ports': ['9000-9999']
},
'IPProtocol": "udp",
'ports': ['9000-9999']
},
'IPProtocol": "tcp",
'ports': ['10250']
},
'IPProtocol": "tcp",
'ports': ['30000-32767']
},
'IPProtocol": "udp",
'ports': ['30000-32767']
],
'sourceTags': [context.properties[infra_id] + '-master', context.properties[infra_id] + '-worker']
},
'targetTags': [context.properties[infra_id] + '-master', context.properties[infra_id] + '-worker']
}

return {'resources': resources}
```
1. Copy the template from the Deployment Manager template for IAM roles section of this topic and save it as 03_iam.py on your computer. This template describes the IAM roles that your cluster requires.

2. Create a 03_iam.yaml resource definition file:

   ```
   $ cat <<EOF >03_iam.yaml
   imports:
   - path: 03_iam.py
   resources:
   - name: cluster-iam
     type: 03_iam.py
     properties:
       infra_id: '${INFRA_ID}'
   EOF
   ```

   **infra_id** is the INFRA_ID infrastructure name from the extraction step.

3. Create the deployment by using the gcloud CLI:

   ```
   $ gcloud deployment-manager deployments create ${INFRA_ID}-iam --config 03_iam.yaml
   ```

4. Export the variable for the master service account:

   ```
   $ export MASTER_SERVICE_ACCOUNT=('gcloud iam service-accounts list --filter
   "email~^${INFRA_ID}-m@$\{PROJECT_NAME\}" --format json | jq -r '.[0].email')
   ```

5. Export the variable for the worker service account:

   ```
   $ export WORKER_SERVICE_ACCOUNT=('gcloud iam service-accounts list --filter
   "email~^${INFRA_ID}-w@$\{PROJECT_NAME\}" --format json | jq -r '.[0].email')
   ```

6. Export the variable for the subnet that hosts the compute machines:

   ```
   $ export COMPUTE_SUBNET=('gcloud compute networks subnets describe ${INFRA_ID}-
   worker-subnet --region=${REGION} --format json | jq -r .selfLink')
   ```

7. The templates do not create the policy bindings due to limitations of Deployment Manager, so you must create them manually:

   ```
   $ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member
   "serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role "roles/compute.instanceAdmin"
   $ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member
   "serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role "roles/compute.networkAdmin"
   $ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member
   "serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role "roles/compute.securityAdmin"
   $ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member
   "serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role "roles/iam.serviceAccountUser"
   $ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member
   "serviceAccount:${MASTER_SERVICE_ACCOUNT}" --role "roles/storage.admin"
   $ gcloud projects add-iam-policy-binding ${PROJECT_NAME} --member
   ```
Create a service account key and store it locally for later use:

```
$ gcloud iam service-accounts keys create service-account-key.json --iam-account=${MASTER_SERVICE_ACCOUNT}
```

### 4.11.12.1. Deployment Manager template for IAM roles

You can use the following Deployment Manager template to deploy the IAM roles that you need for your OpenShift Container Platform cluster:

**Example 4.24. 03_iam.py Deployment Manager template**

```python
def GenerateConfig(context):
    resources = [
        {
            'name': context.properties['infra_id'] + '-master-node-sa',
            'type': 'iam.v1.serviceAccount',
            'properties': {
                'accountId': context.properties['infra_id'] + '-m',
                'displayName': context.properties['infra_id'] + '-master-node'
            }
        },
        {
            'name': context.properties['infra_id'] + '-worker-node-sa',
            'type': 'iam.v1.serviceAccount',
            'properties': {
                'accountId': context.properties['infra_id'] + '-w',
                'displayName': context.properties['infra_id'] + '-worker-node'
            }
        }
    ];
    return {'resources': resources}
```

### 4.11.13. Creating the RHCOS cluster image for the GCP infrastructure

You must use a valid Red Hat Enterprise Linux CoreOS (RHCOS) image for Google Cloud Platform (GCP) for your OpenShift Container Platform nodes.

**Procedure**

1. Obtain the RHCOS image from the [RHCOS image mirror](https://mirror.openshift.com) page.

**IMPORTANT**

The RHCOS images might not change with every release of OpenShift Container Platform. You must download an image with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image version that matches your OpenShift Container Platform version if it is available.
The file name contains the OpenShift Container Platform version number in the format `rhcos-<version>-<arch>-gcp.<arch>.tar.gz`.

2. Create the Google storage bucket:

   ```bash
   $ gsutil mb gs://<bucket_name>
   ``

3. Upload the RHCOS image to the Google storage bucket:

   ```bash
   $ gsutil cp <downloaded_image_file_path>/rhcos-<version>-x86_64-gcp.x86_64.tar.gz gs://<bucket_name>
   ``

4. Export the uploaded RHCOS image location as a variable:

   ```bash
   $ export IMAGE_SOURCE=`gs://<bucket_name>/rhcos-<version>-x86_64-gcp.x86_64.tar.gz`
   ``

5. Create the cluster image:

   ```bash
   $ gcloud compute images create "${INFRA_ID}-rhcos-image" \
   --source-uri="${IMAGE_SOURCE}"
   ``

### 4.11.14. Creating the bootstrap machine in GCP

You must create the bootstrap machine in Google Cloud Platform (GCP) to use during OpenShift Container Platform cluster initialization. One way to create this machine is to modify the provided Deployment Manager template.

**NOTE**

If you do not use the provided Deployment Manager template to create your bootstrap machine, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

**Prerequisites**

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.
- Create and configure networking and load balancers in GCP.
- Create control plane and compute roles.
- Ensure pyOpenSSL is installed.

**Procedure**

1. Copy the template from the Deployment Manager template for the bootstrap machine section of this topic and save it as `04_bootstrap.py` on your computer. This template describes the bootstrap machine that your cluster requires.
2. Export the location of the Red Hat Enterprise Linux CoreOS (RHCOS) image that the installation program requires:

```bash
$ export CLUSTER_IMAGE=\('gcloud compute images describe ${INFRA_ID}-rhcos-image --format json | jq -r .selfLink'\)
```

3. Create a bucket and upload the `bootstrap.ign` file:

```bash
$ gsutil mb gs://${INFRA_ID}-bootstrap-ignition
$ gsutil cp <installation_directory>/bootstrap.ign gs://${INFRA_ID}-bootstrap-ignition/
```

4. Create a signed URL for the bootstrap instance to use to access the Ignition config. Export the URL from the output as a variable:

```bash
$ export BOOTSTRAP_IGN=`gsutil signurl -d 1h service-account-key.json gs://${INFRA_ID}-bootstrap-ignition/bootstrap.ign | grep "^gs:" | awk '{print $5}'`
```

5. Create a `04_bootstrap.yaml` resource definition file:

```bash
$ cat <<EOF >04_bootstrap.yaml
imports:
- path: 04_bootstrap.py

resources:
- name: cluster-bootstrap
type: 04_bootstrap.py
properties:
  infra_id: '${INFRA_ID}'
  region: '${REGION}'
  zone: '${ZONE_0}'
  cluster_network: '${CLUSTER_NETWORK}'
  control_subnet: '${CONTROL_SUBNET}'
  image: '${CLUSTER_IMAGE}'
  machine_type: 'n1-standard-4'
  root_volume_size: '128'
  bootstrap_ign: '${BOOTSTRAP_IGN}'
EOF
```

- **infra_id** is the `INFRA_ID` infrastructure name from the extraction step.
- **region** is the region to deploy the cluster into, for example `us-central1`.
- **zone** is the zone to deploy the bootstrap instance into, for example `us-central1-b`.
- **cluster_network** is the `selfLink` URL to the cluster network.
- **control_subnet** is the `selfLink` URL to the control subnet.
- **image** is the `selfLink` URL to the RHCOS image.
- **machine_type** is the machine type of the instance, for example `n1-standard-4`.  

CHAPTER 4. INSTALLING ON GCP
root_volume_size is the boot disk size for the bootstrap machine.

bootstrap_ign is the URL output when creating a signed URL.

6. Create the deployment by using the gcloud CLI:

   $ gcloud deployment-manager deployments create ${INFRA_ID}-bootstrap --config
   04_bootstrap.yaml

7. The templates do not manage load balancer membership due to limitations of Deployment Manager, so you must add the bootstrap machine manually.

   a. Add the bootstrap instance to the internal load balancer instance group:

      $ gcloud compute instance-groups unmanaged add-instances \
          ${INFRA_ID}-bootstrap-instance-group --zone=${ZONE_0} --instances=${INFRA_ID}-
          bootstrap

   b. Add the bootstrap instance group to the internal load balancer backend service:

      $ gcloud compute backend-services add-backend \
          ${INFRA_ID}-api-internal-backend-service --region=${REGION} --instance-
          group=${INFRA_ID}-bootstrap-instance-group --instance-group-zone=${ZONE_0}

4.11.14.1. Deployment Manager template for the bootstrap machine

You can use the following Deployment Manager template to deploy the bootstrap machine that you need for your OpenShift Container Platform cluster:

Example 4.25. 04_bootstrap.py Deployment Manager template

```python
def GenerateConfig(context):

    resources = [{
        'name': context.properties['infra_id'] + '-bootstrap-public-ip',
        'type': 'compute.v1.address',
        'properties': {
            'region': context.properties['region']
        }
    }, {
        'name': context.properties['infra_id'] + '-bootstrap',
        'type': 'compute.v1.instance',
        'properties': {
            'disks': [{
                'autoDelete': True,
                'boot': True,
                'initializeParams': {
                    'diskSizeGb': context.properties['root_volume_size'],
                    'sourceImage': context.properties['image']
                }
            }],
            'machineType': 'zones/' + context.properties['zone'] + '/machineTypes/' + 
                            context.properties['machine_type'],
```
4.11.15. Creating the control plane machines in GCP

You must create the control plane machines in Google Cloud Platform (GCP) for your cluster to use. One way to create these machines is to modify the provided Deployment Manager template.

NOTE

If you do not use the provided Deployment Manager template to create your control plane machines, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.
Prerequisites

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.
- Create and configure networking and load balancers in GCP.
- Create control plane and compute roles.
- Create the bootstrap machine.

Procedure

1. Copy the template from the Deployment Manager template for control plane machines section of this topic and save it as `05_control_plane.py` on your computer. This template describes the control plane machines that your cluster requires.

2. Export the following variable required by the resource definition:

   ```
   $ export MASTER_IGNITION=`cat <installation_directory>/master.ign`
   ```

3. Create a `05_control_plane.yaml` resource definition file:

   ```
   $ cat <<EOF >05_control_plane.yaml
   imports:
   - path: 05_control_plane.py

   resources:
   - name: cluster-control-plane
     type: 05_control_plane.py
     properties:
       infra_id: '${INFRA_ID}'  
       zones:  
         - '${ZONE_0}'
         - '${ZONE_1}'
         - '${ZONE_2}'
       control_subnet: '${CONTROL_SUBNET}'
       image: '${CLUSTER_IMAGE}'
       machine_type: 'n1-standard-4'
       root_volume_size: '128'
       service_account_email: '${MASTER_SERVICE_ACCOUNT}'
       ignition: '${MASTER_IGNITION}'
   EOF
   ```

   - `infra_id` is the `INFRA_ID` infrastructure name from the extraction step.
   - `zones` are the zones to deploy the control plane instances into, for example `us-central1-a`, `us-central1-b`, and `us-central1-c`.
   - `control_subnet` is the `selfLink` URL to the control subnet.
**image** is the **selfLink** URL to the RHCOS image.

**machine_type** is the machine type of the instance, for example **n1-standard-4**.

**service_account_email** is the email address for the master service account that you created.

**ignition** is the contents of the **master.ign** file.

4. Create the deployment by using the **gcloud** CLI:

```
$ gcloud deployment-manager deployments create ${INFRA_ID}-control-plane --config
05_control_plane.yaml
```

5. The templates do not manage load balancer membership due to limitations of Deployment Manager, so you must add the control plane machines manually.

- Run the following commands to add the control plane machines to the appropriate instance groups:

  ```
  $ gcloud compute instance-groups unmanaged add-instances
  ${INFRA_ID}-master-$(ZONE_0)-instance-group --zone=${ZONE_0} --instances=${INFRA_ID}-master-0
  $ gcloud compute instance-groups unmanaged add-instances
  ${INFRA_ID}-master-$(ZONE_1)-instance-group --zone=${ZONE_1} --instances=${INFRA_ID}-master-1
  $ gcloud compute instance-groups unmanaged add-instances
  ${INFRA_ID}-master-$(ZONE_2)-instance-group --zone=${ZONE_2} --instances=${INFRA_ID}-master-2
  ```

- For an external cluster, you must also run the following commands to add the control plane machines to the target pools:

  ```
  $ gcloud compute target-pools add-instances
  ${INFRA_ID}-api-target-pool --instances-zone="${ZONE_0}" --instances=${INFRA_ID}-master-0
  $ gcloud compute target-pools add-instances
  ${INFRA_ID}-api-target-pool --instances-zone="${ZONE_1}" --instances=${INFRA_ID}-master-1
  $ gcloud compute target-pools add-instances
  ${INFRA_ID}-api-target-pool --instances-zone="${ZONE_2}" --instances=${INFRA_ID}-master-2
  ```

4.11.15.1. Deployment Manager template for control plane machines

You can use the following Deployment Manager template to deploy the control plane machines that you need for your OpenShift Container Platform cluster:

**Example 4.26. 05_control_plane.py Deployment Manager template**

```
def GenerateConfig(context):
  resources = [
    {'name': context.properties['infra_id'] + '-master-0',
     'type': 'compute.v1.instance',
     'properties': {
        'disks': [{'
          'autoDelete': True,
          'boot': True,
          'initializeParams': {
```

---

4. Create the deployment by using the **gcloud** CLI:

```
$ gcloud deployment-manager deployments create ${INFRA_ID}-control-plane --config
05_control_plane.yaml
```

5. The templates do not manage load balancer membership due to limitations of Deployment Manager, so you must add the control plane machines manually.

- Run the following commands to add the control plane machines to the appropriate instance groups:

  ```
  $ gcloud compute instance-groups unmanaged add-instances
  ${INFRA_ID}-master-$(ZONE_0)-instance-group --zone=${ZONE_0} --instances=${INFRA_ID}-master-0
  $ gcloud compute instance-groups unmanaged add-instances
  ${INFRA_ID}-master-$(ZONE_1)-instance-group --zone=${ZONE_1} --instances=${INFRA_ID}-master-1
  $ gcloud compute instance-groups unmanaged add-instances
  ${INFRA_ID}-master-$(ZONE_2)-instance-group --zone=${ZONE_2} --instances=${INFRA_ID}-master-2
  ```

- For an external cluster, you must also run the following commands to add the control plane machines to the target pools:

  ```
  $ gcloud compute target-pools add-instances
  ${INFRA_ID}-api-target-pool --instances-zone="${ZONE_0}" --instances=${INFRA_ID}-master-0
  $ gcloud compute target-pools add-instances
  ${INFRA_ID}-api-target-pool --instances-zone="${ZONE_1}" --instances=${INFRA_ID}-master-1
  $ gcloud compute target-pools add-instances
  ${INFRA_ID}-api-target-pool --instances-zone="${ZONE_2}" --instances=${INFRA_ID}-master-2
  ```

4.11.15.1. Deployment Manager template for control plane machines

You can use the following Deployment Manager template to deploy the control plane machines that you need for your OpenShift Container Platform cluster:

**Example 4.26. 05_control_plane.py Deployment Manager template**

```
def GenerateConfig(context):
  resources = [
    {'name': context.properties['infra_id'] + '-master-0',
     'type': 'compute.v1.instance',
     'properties': {
        'disks': [{'
          'autoDelete': True,
          'boot': True,
          'initializeParams': {
```
{'diskSizeGb': context.properties['root_volume_size'],
'diskType': 'zones' + context.properties['zones'][0] + '/diskTypes/pd-ssd',
'sourceImage': context.properties['image']
},
'machineType': 'zones' + context.properties['zones'][0] + '/machineTypes/' + context.properties['machine_type'],
'metadata': {
'items': [
  {'key': 'user-data',
   'value': context.properties['ignition']
  }
],
'networkInterfaces': [
  {'subnetwork': context.properties['control_subnet']}
],
'serviceAccounts': [
  {'email': context.properties['service_account_email'],
   'scopes': ['https://www.googleapis.com/auth/cloud-platform']}
],
'tags': {
'items': [
  context.properties['infra_id'] + '-master',
]
},
'zone': context.properties['zones'][0]
},
{'name': context.properties['infra_id'] + '-master-1',
'type': 'compute.v1.instance',
'properties': {
'disks': [
  {'autoDelete': True,
   'boot': True,
   'initializeParams': {
     'diskSizeGb': context.properties['root_volume_size'],
     'diskType': 'zones' + context.properties['zones'][1] + '/diskTypes/pd-ssd',
     'sourceImage': context.properties['image']
   }
  ],
'machineType': 'zones' + context.properties['zones'][1] + '/machineTypes/' + context.properties['machine_type'],
'metadata': {
'items': [
  {'key': 'user-data',
   'value': context.properties['ignition']
  }
],
'networkInterfaces': [
  {'subnetwork': context.properties['control_subnet']}
],
'serviceAccounts': [
  {'email': context.properties['service_account_email'],
   'scopes': ['https://www.googleapis.com/auth/cloud-platform']}
],
'tags': {
}
4.11.16. Wait for bootstrap completion and remove bootstrap resources in GCP

After you create all of the required infrastructure in Google Cloud Platform (GCP), wait for the bootstrap process to complete on the machines that you provisioned by using the Ignition config files that you generated with the installation program.

**Prerequisites**

- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.
- Create and configure networking and load balancers in GCP.
- Create control plane and compute roles.
- Create the bootstrap machine.
- Create the control plane machines.

**Procedure**

1. Change to the directory that contains the installation program and run the following command:

   ```bash
   $ ./openshift-install wait-for bootstrap-complete --dir <installation_directory> \  
   --log-level info
   ```

   1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   2. To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

   If the command exits without a **FATAL** warning, your production control plane has initialized.

2. Delete the bootstrap resources:

   ```bash
   $ gcloud compute backend-services remove-backend $(INFRA_ID)-api-internal-backend-service --region=$(REGION) --instance-group=$(INFRA_ID)-bootstrap-instance-group --instance-group-zone=$(ZONE_0)
   $ gsutil rm gs://$(INFRA_ID)-bootstrap-ignition/bootstrap.ign
   $ gsutil rb gs://$(INFRA_ID)-bootstrap-ignition
   $ gcloud deployment-manager deployments delete $(INFRA_ID)-bootstrap
   ```

4.11.17. Creating additional worker machines in GCP

You can create worker machines in Google Cloud Platform (GCP) for your cluster to use by launching individual instances discretely or by automated processes outside the cluster, such as auto scaling groups. You can also take advantage of the built-in cluster scaling mechanisms and the machine API in OpenShift Container Platform.

In this example, you manually launch one instance by using the Deployment Manager template. Additional instances can be launched by including additional resources of type `06_worker.py` in the file.

**NOTE**

If you do not use the provided Deployment Manager template to create your worker machines, you must review the provided information and manually create the infrastructure. If your cluster does not initialize correctly, you might have to contact Red Hat support with your installation logs.

**Prerequisites**
- Configure a GCP account.
- Generate the Ignition config files for your cluster.
- Create and configure a VPC and associated subnets in GCP.
- Create and configure networking and load balancers in GCP.
- Create control plane and compute roles.
- Create the bootstrap machine.
- Create the control plane machines.

**Procedure**

1. Copy the template from the **Deployment Manager template for worker machines** section of this topic and save it as `06_worker.py` on your computer. This template describes the worker machines that your cluster requires.

2. Export the variables that the resource definition uses.
   
   a. Export the subnet that hosts the compute machines:
      ```bash
      $ export COMPUTE_SUBNET=`gcloud compute networks subnets describe ${INFRA_ID}-worker-subnet --region=${REGION} --format json | jq -r .selfLink`
      ```
   
   b. Export the email address for your service account:
      ```bash
      $ export WORKER_SERVICE_ACCOUNT=`gcloud iam service-accounts list --filter "email~^${INFRA_ID}-w@${PROJECT_NAME}." --format json | jq -r '.[0].email'`
      ```
   
   c. Export the location of the compute machine Ignition config file:
      ```bash
      $ export WORKER_IGNITION=`cat <installation_directory>/worker.ign`
      ```

3. Create a `06_worker.yaml` resource definition file:

   ```yaml
   $ cat <<EOF >06_worker.yaml
   imports:
   - path: 06_worker.py
   
   resources:
   - name: 'worker-0'
     type: 06_worker.py
     properties:
       infra_id: '${INFRA_ID}'
       zone: '${ZONE_0}'
       compute_subnet: '${COMPUTE_SUBNET}'
       image: '${CLUSTER_IMAGE}'
       machine_type: 'n1-standard-4'
       root_volume_size: '128'
       service_account_email: '${WORKER_SERVICE_ACCOUNT}'
       ignition: '${WORKER_IGNITION}'
   ```
name is the name of the worker machine, for example worker-0.

infra_id is the INFRA_ID infrastructure name from the extraction step.

zone is the zone to deploy the worker machine into, for example us-central1-a.

compute_subnet is the selfLink URL to the compute subnet.

image is the selfLink URL to the RHCOS image.

machine_type is the machine type of the instance, for example n1-standard-4.

service_account_email is the email address for the worker service account that you created.

ignition is the contents of the worker.ign file.

4. Optional: If you want to launch additional instances, include additional resources of type 06_worker.py in your 06_worker.yaml resource definition file.

5. Create the deployment by using the gcloud CLI:

```
$ gcloud deployment-manager deployments create ${INFRA_ID}-worker --config 06_worker.yaml
```

4.11.17.1. Deployment Manager template for worker machines

You can use the following Deployment Manager template to deploy the worker machines that you need for your OpenShift Container Platform cluster:

```python
Example 4.27. 06_worker.py Deployment Manager template

def GenerateConfig(context):
    resources = [
        {'name': context.properties['infra_id'] + '-' + context.env['name'],
        'type': 'compute.v1.instance',
        'properties': {
            'disks': [{
                'autoDelete': True,
                'boot': True,
            }]
```
4.11.18. Logging in to the cluster by using the CLI

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

Prerequisites

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

Procedure

1. Export the `kubeadmin` credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```
   
   For `<installation_directory>`, specify the path to the directory that you stored the installation files in.
2. Verify you can run `oc` commands successfully using the exported configuration:

```
$ oc whoami
```

Example output

```
system:admin
```

### 4.11.19. Disabling the default OperatorHub sources

Operator catalogs that source content provided by Red Hat and community projects are configured for OperatorHub by default during an OpenShift Container Platform installation. In a restricted network environment, you must disable the default catalogs as a cluster administrator.

**Procedure**

- Disable the sources for the default catalogs by adding `disableAllDefaultSources: true` to the `OperatorHub` object:

```
$ oc patch OperatorHub cluster --type json -p '
  
  [{"op": "add", "path": "/spec/disableAllDefaultSources", "value": true}]
```

**TIP**

Alternatively, you can use the web console to manage catalog sources. From the Administration → Cluster Settings → Global Configuration → OperatorHub page, click the Sources tab, where you can create, delete, disable, and enable individual sources.

### 4.11.20. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

**Prerequisites**

- You added machines to your cluster.

**Procedure**

1. Confirm that the cluster recognizes the machines:

```
$ oc get nodes
```

Example output

```
NAME     STATUS   ROLES    AGE   VERSION
master-0 Ready  master  63m   v1.19.0
master-1 Ready  master  63m   v1.19.0
master-2 Ready  master  64m   v1.19.0
```

The output lists all of the machines that you created.
NOTE

The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the Pending or Approved status for each machine that you added to the cluster:

   $ oc get csr

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-8b2br</td>
<td>15m</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-8vnps</td>
<td>15m</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-bootstrapper</td>
<td>Pending</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in Pending status, approve the CSRs for your cluster machines:

   $ oc adm certificate approve <csr_name>

   1

CHAPTER 4. INSTALLING ON GCP

NOTE

Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. Once the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the machine-approver if the Kubelet requests a new certificate with identical parameters.

NOTE

For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the oc exec, oc rsh, and oc logs commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the node-bootstrapper service account in the system:node or system:admin groups, and confirm the identity of the node.

- To approve them individually, run the following command for each valid CSR:

   $ oc adm certificate approve <csr_name>
**<csr_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs --no-run-if-empty oc adm certificate approve
```

**NOTE**

Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:

```
$ oc get csr
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-c57lv</td>
<td>5m26s</td>
<td>system:node:ip-10-0-95-157.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

```
$ oc adm certificate approve <csr_name>
```

**<csr_name>** is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

```
$ oc get csr -o go-template="{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}" | xargs oc adm certificate approve
```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.20.0</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>73m</td>
<td>v1.20.0</td>
</tr>
</tbody>
</table>
NOTE
It can take a few minutes after approval of the server CSRs for the machines to transition to the `Ready` status.

Additional information

- For more information on CSRs, see Certificate Signing Requests.

4.11.21. Optional: Adding the ingress DNS records

If you removed the DNS zone configuration when creating Kubernetes manifests and generating Ignition configs, you must manually create DNS records that point at the ingress load balancer. You can create either a wildcard `*.apps.{baseDomain}`, or specific records. You can use A, CNAME, and other records per your requirements.

Prerequisites

- Configure a GCP account.
- Remove the DNS Zone configuration when creating Kubernetes manifests and generating Ignition configs.
- Create and configure a VPC and associated subnets in GCP.
- Create and configure networking and load balancers in GCP.
- Create control plane and compute roles.
- Create the bootstrap machine.
- Create the control plane machines.
- Create the worker machines.

Procedure

1. Wait for the Ingress router to create a load balancer and populate the `EXTERNAL-IP` field:

   ```bash
   $ oc -n openshift-ingress get service router-default
   ```

   **Example output**

   ```
   NAME             TYPE           CLUSTER-IP      EXTERNAL-IP      PORT(S)                      AGE
   ```

2. Add the A record to your zones:

   - To use A records:
i. Export the variable for the router IP address:

```
$ export ROUTER_IP="oc -n openshift-ingress get service router-default --no-headers | awk '{print $4}')"
```

ii. Add the A record to the private zones:

```
$ if [-f transaction.yaml]; then rm transaction.yaml; fi
$ gcloud dns record-sets transaction start --zone ${INFRA_ID}-private-zone
$ gcloud dns record-sets transaction add ${ROUTER_IP} --name \*.apps.${CLUSTER_NAME}.${BASE_DOMAIN}. --ttl 300 --type A --zone ${INFRA_ID}-private-zone
$ gcloud dns record-sets transaction execute --zone ${INFRA_ID}-private-zone
```

iii. For an external cluster, also add the A record to the public zones:

```
$ if [-f transaction.yaml]; then rm transaction.yaml; fi
$ gcloud dns record-sets transaction start --zone ${BASE_DOMAIN_ZONE_NAME}
$ gcloud dns record-sets transaction add ${ROUTER_IP} --name \*.apps.${CLUSTER_NAME}.${BASE_DOMAIN}. --ttl 300 --type A --zone ${BASE_DOMAIN_ZONE_NAME}
$ gcloud dns record-sets transaction execute --zone ${BASE_DOMAIN_ZONE_NAME}
```

- To add explicit domains instead of using a wildcard, create entries for each of the cluster’s current routes:

```
$ oc get --all-namespaces -o jsonpath='{range .items[*]}{range .status.ingress[*]}{.host}\n"\n"{end}{end}' routes
```

**Example output**

```
oauth-openshift.apps.your.cluster.domain.example.com
console-openshift-console.apps.your.cluster.domain.example.com
downloads-openshift-console.apps.your.cluster.domain.example.com
alertmanager-main-openshift-monitoring.apps.your.cluster.domain.example.com
grafana-openshift-monitoring.apps.your.cluster.domain.example.com
prometheus-k8s-openshift-monitoring.apps.your.cluster.domain.example.com
```

### 4.11.22. Completing a GCP installation on user-provisioned infrastructure

After you start the OpenShift Container Platform installation on Google Cloud Platform (GCP) user-provisioned infrastructure, you can monitor the cluster events until the cluster is ready.

**Prerequisites**

- Deploy the bootstrap machine for an OpenShift Container Platform cluster on user-provisioned GCP infrastructure.
- Install the `oc` CLI and log in.

**Procedure**

- ```
  $ export ROUTER_IP="oc -n openshift-ingress get service router-default --no-headers | awk '{print $4}')"
  ```
- ```
  $ if [-f transaction.yaml]; then rm transaction.yaml; fi
  $ gcloud dns record-sets transaction start --zone ${INFRA_ID}-private-zone
  $ gcloud dns record-sets transaction add ${ROUTER_IP} --name \*.apps.${CLUSTER_NAME}.${BASE_DOMAIN}. --ttl 300 --type A --zone ${INFRA_ID}-private-zone
  $ gcloud dns record-sets transaction execute --zone ${INFRA_ID}-private-zone
  ```
- ```
  $ if [-f transaction.yaml]; then rm transaction.yaml; fi
  $ gcloud dns record-sets transaction start --zone ${BASE_DOMAIN_ZONE_NAME}
  $ gcloud dns record-sets transaction add ${ROUTER_IP} --name \*.apps.${CLUSTER_NAME}.${BASE_DOMAIN}. --ttl 300 --type A --zone ${BASE_DOMAIN_ZONE_NAME}
  $ gcloud dns record-sets transaction execute --zone ${BASE_DOMAIN_ZONE_NAME}
  ```
- To add explicit domains instead of using a wildcard, create entries for each of the cluster’s current routes:

  ```
  $ oc get --all-namespaces -o jsonpath='{range .items[*]}{range .status.ingress[*]}{.host}\n"\n"{end}{end}' routes
  ```

**Example output**

```
oauth-openshift.apps.your.cluster.domain.example.com
console-openshift-console.apps.your.cluster.domain.example.com
downloads-openshift-console.apps.your.cluster.domain.example.com
alertmanager-main-openshift-monitoring.apps.your.cluster.domain.example.com
grafana-openshift-monitoring.apps.your.cluster.domain.example.com
prometheus-k8s-openshift-monitoring.apps.your.cluster.domain.example.com
```
1. Complete the cluster installation:

```
$ ./openshift-install --dir <installation_directory> wait-for install-complete
```

Example output

INFO Waiting up to 30m0s for the cluster to initialize...

For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending node-bootstrapper certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

2. Observe the running state of your cluster.

a. Run the following command to view the current cluster version and status:

```
$ oc get clusterversion
```

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>SINCE</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>version</td>
<td></td>
<td>False</td>
<td>True</td>
<td>24m</td>
<td>Working towards 4.5.4: 99% complete</td>
</tr>
</tbody>
</table>

b. Run the following command to view the Operators managed on the control plane by the Cluster Version Operator (CVO):

```
$ oc get clusteroperators
```

Example output

<table>
<thead>
<tr>
<th>NAME</th>
<th>VERSION</th>
<th>AVAILABLE</th>
<th>PROGRESSING</th>
<th>DEGRADED SINCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>authentication</td>
<td>4.5.4</td>
<td>True</td>
<td>False</td>
<td>False    7m56s</td>
</tr>
<tr>
<td>cloud-credential</td>
<td>4.5.4</td>
<td>True</td>
<td>False</td>
<td>False    31m</td>
</tr>
<tr>
<td>cluster-autoscaler</td>
<td>4.5.4</td>
<td>True</td>
<td>False</td>
<td>False    16m</td>
</tr>
<tr>
<td>console</td>
<td>4.5.4</td>
<td>True</td>
<td>False</td>
<td>False    10m</td>
</tr>
</tbody>
</table>
c. Run the following command to view your cluster pods:

```
$ oc get pods --all-namespaces
```

### Example output

```
NAMESPACE                                               NAME
READY     STATUS      RESTARTS   AGE
kube-system                                             etcd-member-ip-10-0-3-111.us-east-2.compute.internal                1/1       Running     0          35m
kube-system                                             etcd-member-ip-10-0-3-239.us-east-2.compute.internal                1/1       Running     0          37m
kube-system                                             etcd-member-ip-10-0-3-24.us-east-2.compute.internal                 1/1       Running     0          35m
openshift-apiserver-operator                            openshift-apiserver-operator-6d6674f4f4-h7t2t                       1/1       Running     1          37m
openshift-apiserver                                     apiserver-fm48r
1/1       Running     0          30m
openshift-apiserver                                     apiserver-fxkvv
1/1       Running     0          29m
openshift-apiserver                                     apiserver-q85nm
1/1       Running     0          29m
... openshift-service-ca-operator                         openshift-service-ca-operator-66ff6dc6cd-9r257                      1/1       Running     0          37m
openshift-service-ca                                     apiservice-cabundle-injector-695b6bcbc-cl5hm 1/1       Running     0          35m
openshift-service-ca                                     configmap-cabundle-injector-8498544d7-
```
When the current cluster version is **AVAILABLE**, the installation is complete.

### 4.11.23. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.6, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to **OpenShift Cluster Manager**.

After you confirm that your **OpenShift Cluster Manager** inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use `subscription watch` to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

**Additional resources**

- See [About remote health monitoring](#) for more information about the Telemetry service.

### 4.11.24. Next steps

- Customize your cluster.
- Configure image streams for the Cluster Samples Operator and the `must-gather` tool.
- Learn how to use [Operator Lifecycle Manager (OLM) on restricted networks](#).
- If the mirror registry that you used to install your cluster has a trusted CA, add it to the cluster by configuring additional trust stores.
- If necessary, you can opt out of remote health reporting.

### 4.12. UNINSTALLING A CLUSTER ON GCP

You can remove a cluster that you deployed to Google Cloud Platform (GCP).

#### 4.12.1. Removing a cluster that uses installer-provisioned infrastructure

You can remove a cluster that uses installer-provisioned infrastructure from your cloud.

**NOTE**

After uninstallation, check your cloud provider for any resources not removed properly, especially with User Provisioned Infrastructure (UPI) clusters. There might be resources that the installer did not create or that the installer is unable to access. For example, some Google Cloud resources require **IAM permissions** in shared VPC host projects, or there might be unused health checks that must be deleted.

**Prerequisites**
- Have a copy of the installation program that you used to deploy the cluster.
- Have the files that the installation program generated when you created your cluster.

**Procedure**

1. From the directory that contains the installation program on the computer that you used to install the cluster, run the following command:

   ```
   $ ./openshift-install destroy cluster \
   --dir <installation_directory> --log-level info ① ②
   ```

   ① For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   ② To view different details, specify **warn**, **debug**, or **error** instead of **info**.

   **NOTE**

   You must specify the directory that contains the cluster definition files for your cluster. The installation program requires the **metadata.json** file in this directory to delete the cluster.

2. Optional: Delete the `<installation_directory>` directory and the OpenShift Container Platform installation program.
CHAPTER 5. INSTALLING ON BARE METAL

5.1. INSTALLING A CLUSTER ON BARE METAL

In OpenShift Container Platform version 4.6, you can install a cluster on bare metal infrastructure that you provision.

**IMPORTANT**

While you might be able to follow this procedure to deploy a cluster on virtualized or cloud environments, you must be aware of additional considerations for non-bare metal platforms. Review the information in the [guidelines for deploying OpenShift Container Platform on non-tested platforms](#) before you attempt to install an OpenShift Container Platform cluster in such an environment.

5.1.1. Prerequisites

- Review details about the OpenShift Container Platform installation and update processes.
- If you use a firewall, you must configure it to allow the sites that your cluster requires access to.

**NOTE**

Be sure to also review this site list if you are configuring a proxy.

5.1.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.6, you require access to the Internet to install your cluster.

You must have Internet access to:

- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.

**IMPORTANT**

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

5.1.3. Machine requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.
5.1.3.1. Required machines

The smallest OpenShift Container Platform clusters require the following hosts:

- One temporary bootstrap machine
- Three control plane, or master, machines
- At least two compute machines, which are also known as worker machines. If you are running a three-node cluster, running zero compute machines is supported. Running one compute machine is not supported.

**NOTE**

The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.

**IMPORTANT**

To maintain high availability of your cluster, use separate physical hosts for these cluster machines.

The bootstrap and control plane machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system. However, the compute machines can choose between Red Hat Enterprise Linux CoreOS (RHCOS) or Red Hat Enterprise Linux (RHEL) 7.9.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 8 and inherits all of its hardware certifications and requirements. See [Red Hat Enterprise Linux technology capabilities and limits](#).

5.1.3.2. Network connectivity requirements

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require network in initramfs during boot to fetch Ignition config files from the Machine Config Server. During the initial boot, the machines require either a DHCP server or that static IP addresses be set in order to establish a network connection to download their Ignition config files. Additionally, each OpenShift Container Platform node in the cluster must have access to a Network Time Protocol (NTP) server. If a DHCP server provides NTP servers information, the chrony time service on the Red Hat Enterprise Linux CoreOS (RHCOS) machines read the information and can sync the clock with the NTP servers.

5.1.3.3. Minimum resource requirements

Each cluster machine must meet the following minimum requirements:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS or RHEL 7.9</td>
<td>2</td>
<td>8 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>---------</td>
<td>------------------</td>
<td>---------</td>
<td>-----</td>
<td>---------</td>
<td>----------</td>
</tr>
</tbody>
</table>

1. One CPU is equivalent to one physical core when simultaneous multithreading (SMT), or hyperthreading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: \( \text{threads per core} \times \text{cores} \times \text{sockets} = \text{CPUs} \).

2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.

### 5.1.3.4. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The `kube-controller-manager` only approves the kubelet client CSRs. The `machine-approver` cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

### 5.1.4. Creating the user-provisioned infrastructure

Before you deploy an OpenShift Container Platform cluster that uses user-provisioned infrastructure, you must create the underlying infrastructure.

**Prerequisites**

- Review the [OpenShift Container Platform 4.x Tested Integrations](#) page before you create the supporting infrastructure for your cluster.

**Procedure**

1. Configure DHCP or set static IP addresses on each node.
2. Provision the required load balancers.
3. Configure the ports for your machines.
4. Configure DNS.
5. Ensure network connectivity.

#### 5.1.4.1. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require network in `initramfs` during boot to fetch Ignition config from the machine config server.
During the initial boot, the machines require either a DHCP server or that static IP addresses be set on each host in the cluster in order to establish a network connection, which allows them to download their Ignition config files.

It is recommended to use the DHCP server to manage the machines for the cluster long-term. Ensure that the DHCP server is configured to provide persistent IP addresses and host names to the cluster machines.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

You must configure the network connectivity between machines to allow cluster components to communicate. Each machine must be able to resolve the host names of all other machines in the cluster.

**Table 5.1. All machines to all machines**

<table>
<thead>
<tr>
<th>Protocol</th>
<th>Port</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

<td>Kubernetes API</td>
</tr>
</tbody>
</table>

**Table 5.3. Control plane machines to control plane machines**
**Network topology requirements**

The infrastructure that you provision for your cluster must meet the following network topology requirements.

**IMPORTANT**

OpenShift Container Platform requires all nodes to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

**Load balancers**

Before you install OpenShift Container Platform, you must provision two load balancers that meet the following requirements:

1. **API load balancer**: Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
   
   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.
   
   - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

**IMPORTANT**

Do not configure session persistence for an API load balancer.

Configure the following ports on both the front and back of the load balancers:

**Table 5.4. API load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6443</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane. You must configure the /readyz endpoint for the API server health check probe.</td>
<td>X</td>
<td>X</td>
<td>Kubernetes API server</td>
</tr>
<tr>
<td>22623</td>
<td>Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.</td>
<td>X</td>
<td></td>
<td>Machine config server</td>
</tr>
</tbody>
</table>
NOTE

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the `/readyz` endpoint to the removal of the API server instance from the pool. Within the time frame after `/readyz` returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application Ingress load balancer** Provides an Ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the Ingress routes.
- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

Configure the following ports on both the front and back of the load balancers:

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress router pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress router pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>

**TIP**

If the true IP address of the client can be seen by the load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

**NOTE**

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.

**NTP configuration**

OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for *Configuring chrony time service*.

If a DHCP server provides NTP server information, the chrony time service on the Red Hat Enterprise Linux CoreOS (RHCOS) machines read the information and can sync the clock with the NTP servers.

**Additional resources**
5.1.4.2. User-provisioned DNS requirements

DNS is used for name resolution and reverse name resolution. DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the host name for all the nodes. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

The following DNS records are required for an OpenShift Container Platform cluster that uses user-provisioned infrastructure. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the cluster base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>..<cluster_name>..<base_domain>`.

### Table 5.6. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes API</td>
<td><code>api.&lt;cluster_name&gt;..&lt;base_domain&gt;</code></td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the load balancer for the control plane machines. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td></td>
<td><code>api-int.&lt;cluster_name&gt;..&lt;base_domain&gt;</code></td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the load balancer for the control plane machines. These records must be resolvable from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Routes</td>
<td><code>*.apps.&lt;cluster_name&gt;..&lt;base_domain&gt;</code></td>
<td>Add a wildcard DNS A/AAAA or CNAME record that refers to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Bootstrap</td>
<td><code>bootstrap.&lt;cluster_name&gt;..&lt;base_domain&gt;</code></td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

The API server must be able to resolve the worker nodes by the host names that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.
### Component Record Description

| Master hosts | <master><n>.<cluster_name>.<base_domain>. | DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes (also known as the master nodes). These records must be resolvable by the nodes within the cluster. |
| Worker hosts | <worker><n>.<cluster_name>.<base_domain>. | Add DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster. |

#### TIP

You can use the `nslookup <hostname>` command to verify name resolution. You can use the `dig -x <ip_address>` command to verify reverse name resolution for the PTR records.

The following example of a BIND zone file shows sample A records for name resolution. The purpose of the example is to show the records that are needed. The example is not meant to provide advice for choosing one name resolution service over another.

**Example 5.1. Sample DNS zone database**

```
$TTL 1W
@ IN SOA ns1.example.com. root ( 2019070700 ; serial 3H ; refresh (3 hours) 30M ; retry (30 minutes) 2W ; expiry (2 weeks) 1W ) ; minimum (1 week)
IN NS ns1.example.com.
IN MX ns1.example.com.
; ;
ns1 IN A 192.168.1.5
smtp IN A 192.168.1.5
; helper IN A 192.168.1.5
helper.ocp4 IN A 192.168.1.5
; ; The api identifies the IP of your load balancer.
api.ocp4 IN A 192.168.1.5
api-int.ocp4 IN A 192.168.1.5
; ; The wildcard also identifies the load balancer.
*.apps.ocp4 IN A 192.168.1.5
; ; Create an entry for the bootstrap host.
bootstrap.ocp4 IN A 192.168.1.96
; ; Create entries for the master hosts.
master0.ocp4 IN A 192.168.1.97
master1.ocp4 IN A 192.168.1.98
```
The following example BIND zone file shows sample PTR records for reverse name resolution.

Example 5.2. Sample DNS zone database for reverse records

```plaintext
$TTL 1W
@ IN SOA ns1.example.com. root (2019070700 ; serial
  3H ; refresh (3 hours)
  30M ; retry (30 minutes)
  2W ; expiry (2 weeks)
  1W ) ; minimum (1 week)
IN NS ns1.example.com.
;
; The syntax is "last octet" and the host must have an FQDN
; with a trailing dot.
97 IN PTR master0.ocp4.example.com.
98 IN PTR master1.ocp4.example.com.
99 IN PTR master2.ocp4.example.com.
;
96 IN PTR bootstrap.ocp4.example.com.
;
5 IN PTR api.ocp4.example.com.
5 IN PTR api-int.ocp4.example.com.
;
11 IN PTR worker0.ocp4.example.com.
7 IN PTR worker1.ocp4.example.com.
;
;EOF
```

5.1.5. Generating an SSH private key and adding it to the agent

If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your `ssh-agent` and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

NOTE

In a production environment, you require disaster recovery and debugging.

You can use this key to SSH into the master nodes as the user `core`. When you deploy the cluster, the key is added to the `core` user’s `~/.ssh/authorized_keys` list.
NOTE
You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

Procedure

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

```
$ ssh-keygen -t ed25519 -N "" \n   -f <path>/<file_name>
```

Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

Running this command generates an SSH key that does not require a password in the location that you specified.

NOTE
If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the ssh-agent process as a background task:

```
$ eval "$(ssh-agent -s)"
```

Example output

```
Agent pid 31874
```

NOTE
If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.

3. Add your SSH private key to the ssh-agent:

```
$ ssh-add <path>/<file_name>
```

Example output

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

Specify the path and file name for your SSH private key, such as ~/.ssh/id_rsa
Next steps

- When you install OpenShift Container Platform, provide the SSH public key to the installation program. If you install a cluster on infrastructure that you provision, you must provide this key to your cluster’s machines.

5.1.6. Obtaining the installation program

Before you install OpenShift Container Platform, download the installation file on a local computer.

Prerequisites

- You have a computer that runs Linux or macOS, with 500 MB of local disk space

Procedure

1. Access the Infrastructure Provider page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

   IMPORTANT

   The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

   IMPORTANT

   Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

   $ tar xvf openshift-install-linux.tar.gz

5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

5.1.7. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) in order to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.
IMPORTANT

If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.6. Download and install the new version of oc.

5.1.7.1. Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.6 Linux Client entry and save the file.

4. Unpack the archive:

   $ tar xvzf <file>

5. Place the oc binary in a directory that is on your PATH.
   To check your PATH, execute the following command:

   $ echo $PATH

After you install the OpenShift CLI, it is available using the oc command:

$ oc <command>

5.1.7.2. Installing the OpenShift CLI on Windows

You can install the OpenShift CLI (oc) binary on Windows by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.6 Windows Client entry and save the file.

4. Unzip the archive with a ZIP program.

5. Move the oc binary to a directory that is on your PATH.
   To check your PATH, open the command prompt and execute the following command:

   C:\> path

After you install the OpenShift CLI, it is available using the oc command:
5.1.7.3. Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (oc) binary on macOS by using the following procedure.

Procedure

2. Select the appropriate version in the Version drop-down menu.
3. Click Download Now next to the OpenShift v4.6 MacOSX Client entry and save the file.
4. Unpack and unzip the archive.
5. Move the oc binary to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:

   ```bash
   $ echo $PATH
   ```

After you install the OpenShift CLI, it is available using the oc command:

```bash
$ oc <command>
```

5.1.8. Manually creating the installation configuration file

For installations of OpenShift Container Platform that use user-provisioned infrastructure, you manually generate your installation configuration file.

Prerequisites

- Obtain the OpenShift Container Platform installation program and the access token for your cluster.

Procedure

1. Create an installation directory to store your required installation assets in:

   ```bash
   $ mkdir <installation_directory>
   ```

   **IMPORTANT**

   You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.
2. Customize the following `install-config.yaml` file template and save it in the `<installation_directory>`.

   **NOTE**

   You must name this configuration file `install-config.yaml`.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

   **IMPORTANT**

   The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.

### 5.1.8.1. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster’s platform. When you create the `install-config.yaml` installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the `install-config.yaml` file to provide more details about the platform.

**NOTE**

After installation, you cannot modify these parameters in the `install-config.yaml` file.

**IMPORTANT**

The `openshift-install` command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

#### 5.1.8.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

**Table 5.7. Required parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the <code>install-config.yaml</code> content. The current version is v1. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>--------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------</td>
</tr>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the baseDomain and metadata.name parameter values that uses the <code>&lt;metadata.name&gt;.&lt;baseDomain&gt;</code> format.</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
</tr>
<tr>
<td>metadata</td>
<td>Kubernetes resource ObjectMeta, from which only the name parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of {{.metadata.name}}. {{.baseDomain}}.</td>
<td>String of lowercase letters, hyphens (-), and periods (.), such as dev.</td>
</tr>
<tr>
<td>platform</td>
<td>The configuration for the specific platform upon which to perform the installation: aws, baremetal, azure, openstack, ovirt, vsphere. For additional information about platform.&lt;platform&gt; parameters, consult the following table for your specific platform.</td>
<td>Object</td>
</tr>
<tr>
<td>pullSecret</td>
<td>Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.</td>
<td>{</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;auths&quot;:{</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;cloud.openshift.com&quot;:{</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;auth&quot;:&quot;b3Blb=&quot;,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;email&quot;:&quot;<a href="mailto:you@example.com">you@example.com</a>&quot;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>},</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;quay.io&quot;:{</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;auth&quot;:&quot;b3Blb=&quot;,</td>
</tr>
<tr>
<td></td>
<td></td>
<td>&quot;email&quot;:&quot;<a href="mailto:you@example.com">you@example.com</a>&quot;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>}</td>
</tr>
<tr>
<td></td>
<td></td>
<td>}</td>
</tr>
</tbody>
</table>
5.1.8.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

Table 5.8. Network parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>networking</td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td></td>
<td><strong>NOTE</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td>You cannot modify parameters specified by the</td>
<td></td>
</tr>
<tr>
<td></td>
<td>networking object after installation.</td>
<td></td>
</tr>
<tr>
<td>networking.network</td>
<td>The cluster network provider Container Network</td>
<td>Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN.</td>
</tr>
<tr>
<td>Type</td>
<td>Interface (CNI) plug-in to install.</td>
<td></td>
</tr>
<tr>
<td>networking.clusterNetwork</td>
<td>The IP address blocks for pods.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td>The default value is 10.128.0.0/14 with a host prefix of /23.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32.</td>
<td></td>
</tr>
<tr>
<td>networking.clusterNetwork.hostPrefix</td>
<td>The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23 then each node is assigned a /23 subnet out of the given cidr. A hostPrefix value of 23 provides 510 (2^(32 - 23) - 2) pod IP addresses.</td>
<td>A subnet prefix. The default value is 23.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>----------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>networking.serviceNetwork</td>
<td>The IP address block for services. The default value is <code>172.30.0.0/16</code>. The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.</td>
<td>An array with an IP address block in CIDR format. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>networking: serviceNetwork: - 172.30.0.0/16</code></td>
</tr>
<tr>
<td>networking.machineNetwork</td>
<td>The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap.</td>
<td>An array of objects. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td><code>networking: machineNetwork: - cidr: 10.0.0.0/16</code></td>
</tr>
<tr>
<td>networking.machineNetwork.cidr</td>
<td>Required if you use <code>networking.machineNetwork</code>. An IP address block. The default value is <code>10.0.0.0/16</code> for all platforms other than libvirt. For libvirt, the default value is <code>192.168.126.0/24</code>.</td>
<td>An IP network block in CIDR notation.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>For example, <code>10.0.0.0/16</code>.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>NOTE</strong></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Set the <code>networking.machineNetwork</code> to match the CIDR that the preferred NIC resides in.</td>
</tr>
</tbody>
</table>

**5.1.8.1.3. Optional configuration parameters**

Optional installation configuration parameters are described in the following table:

**Table 5.9. Optional parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>additionalTrustBundle</td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes’ trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
<td>String</td>
</tr>
<tr>
<td>compute</td>
<td>The configuration for the machines that comprise the compute nodes.</td>
<td>Array of machine-pool objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>----------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>-------------------------------</td>
</tr>
<tr>
<td><code>compute.architecture</code></td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td><code>compute.hyperthreading</code></td>
<td>Whether to enable or disable simultaneous multithreading, or hyperthreading, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines’ cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td><strong>IMPORTANT</strong></td>
<td>If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
<td></td>
</tr>
<tr>
<td><code>compute.name</code></td>
<td>Required if you use <code>compute</code>. The name of the machine pool.</td>
<td><code>worker</code></td>
</tr>
<tr>
<td><code>compute.platform</code></td>
<td>Required if you use <code>compute</code>. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <code>controlPlane.platform</code> parameter value.</td>
<td><code>aws, azure, gcp, openstack, ovirt, vsphere, or {}</code></td>
</tr>
<tr>
<td><code>compute.replicas</code></td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
<td>A positive integer greater than or equal to <code>2</code>. The default value is <code>3</code>.</td>
</tr>
<tr>
<td><code>controlPlane</code></td>
<td>The configuration for the machines that comprise the control plane.</td>
<td>Array of <code>MachinePool</code> objects. For details, see the following &quot;Machine-pool&quot; table.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>---------------------------------</td>
</tr>
<tr>
<td>controlPlane.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
<td>String</td>
</tr>
<tr>
<td>controlPlane.hypertreading</td>
<td>Whether to enable or disable simultaneous multithreading, or <code>hypertreading</code>, on control plane machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
<td>Enabled or Disabled</td>
</tr>
<tr>
<td>controlPlane.name</td>
<td>Required if you use <code>controlPlane</code>. The name of the machine pool.</td>
<td>master</td>
</tr>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use <code>controlPlane</code>. Use this parameter to specify the cloud provider that hosts the control plane machines. This parameter value must match the <code>compute.platform</code> parameter value.</td>
<td><code>aws</code>, <code>azure</code>, <code>gcp</code>, <code>openstack</code>, <code>ovirt</code>, <code>vsphere</code>, or <code>{}</code></td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
<td>The only supported value is 3, which is the default value.</td>
</tr>
</tbody>
</table>
### credentialsMode

The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.

- **Mint**, **Passthrough**, **Manual**, or an empty string ("").

#### NOTE

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Red Hat Operators reference content.

### fips

Enable or disable FIPS mode. The default is **false** (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

- **false** or **true**

#### IMPORTANT

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the **x86_64** architecture.

#### NOTE

If you are using Azure File storage, you cannot enable FIPS mode.

### imageContentSources

Sources and repositories for the release-image content.

- Array of objects. Includes a **source** and, optionally, **mirrors**, as described in the following rows of this table.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>imageContentSources.source</code></td>
<td>Required if you use <code>imageContentSources</code>. Specify the repository that users refer to, for example, in image pull specifications.</td>
<td>String</td>
</tr>
<tr>
<td><code>imageContentSources.mirrors</code></td>
<td>Specify one or more repositories that may also contain the same images.</td>
<td>Array of strings</td>
</tr>
<tr>
<td><code>publish</code></td>
<td>How to publish or expose the user-facing endpoints of your cluster, such as the Kubernetes API, OpenShift routes.</td>

### 5.1.8.2. Sample `install-config.yaml` file for bare metal

You can customize the `install-config.yaml` file to specify more details about your OpenShift Container Platform cluster’s platform or modify the values of the required parameters.
The base domain of the cluster. All DNS records must be sub-domains of this base and include the cluster name.

The **controlPlane** section is a single mapping, but the **compute** section is a sequence of mappings. To meet the requirements of the different data structures, the first line of the **compute** section must begin with a hyphen, -, and the first line of the **controlPlane** section must not. Although both sections currently define a single machine pool, it is possible that future versions of OpenShift Container Platform will support defining multiple compute pools during installation. Only one control plane pool is used.

Whether to enable or disable simultaneous multithreading (SMT), or **hyperthreading**. By default, SMT is enabled to increase the performance of your machines’ cores. You can disable it by setting the parameter value to **Disabled**. If you disable SMT, you must disable it in all cluster machines; this includes both control plane and compute machines.

**NOTE**

Simultaneous multithreading (SMT) is enabled by default. If SMT is not enabled in your BIOS settings, the **hyperthreading** parameter has no effect.

**IMPORTANT**

If you disable **hyperthreading**, whether in the BIOS or in the **install-config.yaml**, ensure that your capacity planning accounts for the dramatically decreased machine performance.

You must set the value of the **replicas** parameter to 0. This parameter controls the number of
The number of control plane machines that you add to the cluster. Because the cluster uses this values as the number of etcd endpoints in the cluster, the value must match the number of control

The cluster name that you specified in your DNS records.

A block of IP addresses from which pod IP addresses are allocated. This block must not overlap with existing physical networks. These IP addresses are used for the pod network. If you need to access the pods from an external network, you must configure load balancers and routers to manage the traffic.

The subnet prefix length to assign to each individual node. For example, if hostPrefix is set to 23, then each node is assigned a /23 subnet out of the given cidr, which allows for 510 \((2^{32 - 23} - 2)\) pod IPs addresses. If you are required to provide access to nodes from an external network, configure load balancers and routers to manage the traffic.

The IP address pool to use for service IP addresses. You can enter only one IP address pool. This block must not overlap with existing physical networks. If you need to access the services from an external network, configure load balancers and routers to manage the traffic.

You must set the platform to none. You cannot provide additional platform configuration variables for your platform.

Whether to enable or disable FIPS mode. By default, FIPS mode is not enabled. If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the x86_64 architecture.

The pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

The public portion of the default SSH key for the core user in Red Hat Enterprise Linux CoreOS (RHCOS).

**NOTE**

For production OpenShift Container Platform clusters on which you want to perform installation debugging or disaster recovery, specify an SSH key that your ssh-agent process uses.

5.1.8.3. Configuring the cluster-wide proxy during installation

Production environments can deny direct access to the Internet and instead have an HTTP or HTTPS proxy available. You can configure a new OpenShift Container Platform cluster to use a proxy by configuring the proxy settings in the install-config.yaml file.
NOTE

For bare metal installations, if you do not assign node IP addresses from the range that is specified in the `networking.machineNetwork[].cidr` field in the `install-config.yaml` file, you must include them in the `proxy.noProxy` field.

Prerequisites

- You have an existing `install-config.yaml` file.
- You reviewed the sites that your cluster requires access to and determined whether any of them need to bypass the proxy. By default, all cluster egress traffic is proxied, including calls to hosting cloud provider APIs. You added sites to the `Proxy` object’s `spec.noProxy` field to bypass the proxy if necessary.

NOTE

The `Proxy` object `status.noProxy` field is populated with the values of the `networking.machineNetwork[].cidr`, `networking.clusterNetwork[].cidr`, and `networking.serviceNetwork[]` fields from your installation configuration.

For installations on Amazon Web Services (AWS), Google Cloud Platform (GCP), Microsoft Azure, and Red Hat OpenStack Platform (RHOSP), the `Proxy` object `status.noProxy` field is also populated with the instance metadata endpoint (169.254.169.254).

Procedure

1. Edit your `install-config.yaml` file and add the proxy settings. For example:

   ```yaml
   apiVersion: v1
   baseDomain: my.domain.com
   proxy:
     httpProxy: http://<username>:<pswd>@<ip>:<port> ¹
     httpsProxy: https://<username>:<pswd>@<ip>:<port> ²
     noProxy: example.com ³
     additionalTrustBundle: |
       -----BEGIN CERTIFICATE-----
       <MY_TRUSTED_CA_CERT>
       -----END CERTIFICATE-----
   ...
   
   ¹ A proxy URL to use for creating HTTP connections outside the cluster. The URL scheme must be `http`.
   ² A proxy URL to use for creating HTTPS connections outside the cluster.
   ³ A comma-separated list of destination domain names, IP addresses, or other network CIDRs to exclude from proxying. Preface a domain with . to match subdomains only. For example, `.y.com` matches `x.y.com`, but not `y.com`. Use `*` to bypass the proxy for all destinations.
   ⁴ If provided, the installation program generates a config map that is named `user-ca-bundle` in the `openshift-config` namespace to hold the additional CA certificates. If you provide `additionalTrustBundle` and at least one proxy setting, the `Proxy` object is configured to
reference the `user-ca-bundle` config map in the `trustedCA` field. The Cluster Network Operator then creates a `trusted-ca-bundle` config map that merges the contents specified for the `trustedCA` parameter with the RHCOS trust bundle. The `additionalTrustBundle` field is required unless the proxy’s identity certificate is signed by an authority from the RHCOS trust bundle.

```
NOTE

The installation program does not support the proxy `readinessEndpoints` field.
```

2. Save the file and reference it when installing OpenShift Container Platform.

The installation program creates a cluster-wide proxy that is named `cluster` that uses the proxy settings in the provided `install-config.yaml` file. If no proxy settings are provided, a `cluster Proxy` object is still created, but it will have a nil `spec`.

```
NOTE

Only the Proxy object named `cluster` is supported, and no additional proxies can be created.
```

5.1.9. Configuring a three-node cluster

You can optionally install and run three-node clusters in OpenShift Container Platform with no workers. This provides smaller, more resource efficient clusters for cluster administrators and developers to use for development, production, and testing.

```
Procedure

- Edit the `install-config.yaml` file to set the number of compute replicas, which are also known as worker replicas, to 0, as shown in the following `compute` stanza:

  ```yaml
  compute:
    - name: worker
      platform: {}
      replicas: 0
  ```
```

5.1.10. Creating the Kubernetes manifest and Ignition config files

Because you must modify some cluster definition files and manually start the cluster machines, you must generate the Kubernetes manifest and Ignition config files that the cluster needs to make its machines.

The installation configuration file transforms into the Kubernetes manifests. The manifests wrap into the Ignition configuration files, which are later used to create the cluster.
IMPORTANT

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

Prerequisites

- You obtained the OpenShift Container Platform installation program.
- You created the `install-config.yaml` installation configuration file.

Procedure

1. Change to the directory that contains the installation program and generate the Kubernetes manifests for the cluster:

   ```bash
   $ ./openshift-install create manifests --dir <installation_directory>
   ```

   Example output

   ```bash
   INFO Credentials loaded from the "myprofile" profile in file "/home/myuser/.aws/credentials"
   INFO Consuming Install Config from target directory
   INFO Manifests created in: install_dir/manifests and install_dir/openshift
   ```

   For `<installation_directory>`, specify the installation directory that contains the `install-config.yaml` file you created.

   WARNING

   If you are installing a three-node cluster, skip the following step to allow the control plane nodes to be schedulable.
**IMPORTANT**

When you configure control plane nodes from the default unschedulable to schedulable, additional subscriptions are required. This is because control plane nodes then become worker nodes.

1. Check that the `mastersSchedulable` parameter in the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` Kubernetes manifest file is set to `false`. This setting prevents pods from being scheduled on the control plane machines:
   a. Open the `<installation_directory>/manifests/cluster-scheduler-02-config.yml` file.
   b. Locate the `mastersSchedulable` parameter and ensure that it is set to `false`.
   c. Save and exit the file.

2. To create the Ignition configuration files, run the following command from the directory that contains the installation program:

   ```bash
   $ ./openshift-install create ignition-configs --dir <installation_directory>
   ```

   For `<installation_directory>`, specify the same installation directory.

   The following files are generated in the directory:

   - `auth`
     - `kubeadmin-password`
     - `kubeconfig`
   - `bootstrap.ign`
   - `master.ign`
   - `metadata.json`
   - `worker.ign`

**Additional resources**

- See [Recovering from expired control plane certificates](#) for more information about recovering kubelet certificates.

### 5.1.11. Installing RHCOS and starting the OpenShift Container Platform bootstrap process

To install OpenShift Container Platform on bare metal infrastructure that you provision, you must install Red Hat Enterprise Linux CoreOS (RHCOS) on the machines. When you install RHCOS, you must provide the Ignition config file that was generated by the OpenShift Container Platform installation program for the type of machine you are installing. If you have configured suitable networking, DNS, and load balancing infrastructure, the OpenShift Container Platform bootstrap process begins automatically after the RHCOS machines have rebooted.

To install RHCOS on the machines, follow either the steps to use an ISO image or network PXE booting.
NOTE

The compute node deployment steps included in this installation document are RHCOS-specific. If you choose instead to deploy RHEL-based compute nodes, you take responsibility for all operating system life cycle management and maintenance, including performing system updates, applying patches, and completing all other required tasks. Use of RHEL 7 compute machines is deprecated and planned for removal in a future release of OpenShift Container Platform 4.

You can configure RHCOS during ISO and PXE installations by using the following methods:

- **Kernel arguments**: You can use kernel arguments to provide installation-specific information. For example, you can specify the locations of the RHCOS installation files that you uploaded to your HTTP server and the location of the Ignition config file for the type of node you are installing. For a PXE installation, you can use the `APPEND` parameter to pass the arguments to the kernel of the live installer. For an ISO installation, you can interrupt the live installation boot process to add the kernel arguments. In both installation cases, you can use special `coreos.inst.*` arguments to direct the live installer, as well as standard installation boot arguments for turning standard kernel services on or off.

- **Ignition configs**: OpenShift Container Platform Ignition config files (*.ign) are specific to the type of node you are installing. You pass the location of a bootstrap, control plane, or compute node Ignition config file during the RHCOS installation so that it takes effect on first boot. In special cases, you can create a separate, limited Ignition config to pass to the live system. That Ignition config could do a certain set of tasks, such as reporting success to a provisioning system after completing installation. This special Ignition config is consumed by the `coreos-installer` to be applied on first boot of the installed system. Do not provide the standard control plane and compute node Ignition configs to the live ISO directly.

- **coreos-installer**: You can boot the live ISO installer to a shell prompt, which allows you to prepare the permanent system in a variety of ways before first boot. In particular, you can run the `coreos-installer` command to identify various artifacts to include, work with disk partitions, and set up networking. In some cases, you can configure features on the live system and copy them to the installed system.

Whether to use an ISO or PXE install depends on your situation. A PXE install requires an available DHCP service and more preparation, but can make the installation process more automated. An ISO install is a more manual process and can be inconvenient if you are setting up more than a few machines.

NOTE

As of OpenShift Container Platform 4.6, the RHCOS ISO and other installation artifacts provide support for installation on disks with 4K sectors.

5.11.1. Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines using an ISO image

Before you install a cluster on infrastructure that you provision, you must create RHCOS machines for it to use. You can use an ISO image to create the machines.

**Prerequisites**

- Obtain the Ignition config files for your cluster.
- Have access to an HTTP server that can be accessed from your computer, and from the machines that you create.
Procedure

1. Upload the control plane, compute, and bootstrap Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

**IMPORTANT**

If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

2. Obtain the RHCOS images that are required for your preferred method of installing operating system instances from the RHCOS image mirror page.

**IMPORTANT**

The RHCOS images might not change with every release of OpenShift Container Platform. You must download images with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Use the image versions that match your OpenShift Container Platform version if they are available. Use only ISO images for this procedure. RHCOS qcow2 images are not supported for this installation type.

ISO file names resemble the following example:

`rhcos-<version>-live.<architecture>.iso`

3. Use the ISO to start the RHCOS installation. Use one of the following installation options:

   - Burn the ISO image to a disk and boot it directly.
   - Use ISO redirection via a LOM interface.

4. Boot the ISO image. You can interrupt the installation boot process to add kernel arguments. However, for this ISO procedure you should use the `coreos-installer` command instead of adding kernel arguments. If you run the live installer without options or interruption, the installer boots up to a shell prompt on the live system, ready for you to install RHCOS to disk.

5. Review the Advanced RHCOS installation reference section for different ways of configuring features, such as networking and disk partitions, before running the `coreos-installer`.

6. Run the `coreos-installer` command. At a minimum, you must identify the Ignition config file location for your node type, and the location of the disk you are installing to. Here is an example:

   ```sh
   $ sudo coreos-installer install \
   --ignition-url=https://host/worker.ign /dev/sda
   ```

7. After RHCOS installs, the system reboots. During the system reboot, it applies the Ignition config file that you specified.

8. Continue to create the other machines for your cluster.
IMPORTANT

You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, which is the default, also create at least two compute machines before you install the cluster.

5.1.11.2. Creating Red Hat Enterprise Linux CoreOS (RHCOS) machines by PXE or iPXE booting

Before you install a cluster that uses manually-provisioned RHCOS nodes, such as bare metal, you must create RHCOS machines for it to use. You can use PXE or iPXE booting to create the machines.

Prerequisites

- Obtain the Ignition config files for your cluster.
- Configure suitable PXE or iPXE infrastructure.
- Have access to an HTTP server that you can access from your computer.

Procedure

1. Upload the master, worker, and bootstrap Ignition config files that the installation program created to your HTTP server. Note the URLs of these files.

IMPORTANT

You can add or change configuration settings in your Ignition configs before saving them to your HTTP server. If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

2. Obtain the RHCOS kernel, initramfs and rootfs files from the RHCOS image mirror page.

IMPORTANT

The RHCOS artifacts might not change with every release of OpenShift Container Platform. You must download artifacts with the highest version that is less than or equal to the OpenShift Container Platform version that you install. Only use the appropriate kernel, initramfs, and rootfs artifacts described below for this procedure. RHCOS qcow2 images are not supported for this installation type.

The file names contain the OpenShift Container Platform version number. They resemble the following examples:

- kernel: rhcos-<version>-live-kernel-<architecture>
- initramfs: rhcos-<version>-live-initramfs.<architecture>.img
- rootfs: rhcos-<version>-live-rootfs.<architecture>.img

3. Upload the additional files that are required for your booting method:

- For traditional PXE, upload the kernel and initramfs files to your TFTP server and the rootfs file to your HTTP server.
• For iPXE, upload the **kernel**, **initramfs**, and **rootfs** files to your HTTP server.

**IMPORTANT**

If you plan to add more compute machines to your cluster after you finish installation, do not delete these files.

4. Configure the network boot infrastructure so that the machines boot from their local disks after RHCOS is installed on them.

5. Configure PXE or iPXE installation for the RHCOS images.
    Modify one of the following example menu entries for your environment and verify that the image and Ignition files are properly accessible:

• For PXE:

```
DEFAULT pxeboot
TIMEOUT 20
PROMPT 0
LABEL pxeboot
  KERNEL http://<HTTP_server>/rhcos-<version>-live-kernel-<architecture>
  coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign
```

1. Specify the location of the live **kernel** file that you uploaded to your HTTP server. The URL must be HTTP, TFTP, or FTP; HTTPS and NFS are not supported.

2. If you use multiple NICs, specify a single interface in the **ip** option. For example, to use DHCP on a NIC that is named `en01`, set `ip=en01:dhcp`.

3. Specify locations of the RHCOS files that you uploaded to your HTTP server. The **initrd** parameter value is the location of the **initramfs** file, the **coreos.live.roots_url** parameter value is the location of the **rootfs** file, and the **coreos.inst.ignition_url** parameter value is the location of the bootstrap Ignition config file. You can also add more kernel arguments to the **APPEND** line to configure networking or other boot options.

**NOTE**

This configuration does not enable serial console access on machines with a graphical console. To configure a different console, add one or more `console=` arguments to the **APPEND** line. For example, add `console=tt0 console=ttyS0` to set the first PC serial port as the primary console and the graphical console as a secondary console. For more information, see *How does one set up a serial terminal and/or console in Red Hat Enterprise Linux?*.

• For iPXE:

```
kernel http://<HTTP_server>/rhcos-<version>-live-kernel-<architecture> initrd=main
```
<architecture>.img coreos.inst.install_dev=/dev/sda
coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign
<architecture>.img

1. Specify locations of the RHCOS files that you uploaded to your HTTP server. The kernel parameter value is the location of the kernel file, the initrd=main argument is needed for booting on UEFI systems, the coreos.live.rootfs_url parameter value is the location of the rootfs file, and the coreos.inst.ignition_url parameter value is the location of the bootstrap Ignition config file.

2. If you use multiple NICs, specify a single interface in the ip option. For example, to use DHCP on a NIC that is named eno1, set ip=eno1:dhcp.

3. Specify the location of the initramfs file that you uploaded to your HTTP server.

**NOTE**

This configuration does not enable serial console access on machines with a graphical console. To configure a different console, add one or more console= arguments to the kernel line. For example, add console=tt0 console=ttS0 to set the first PC serial port as the primary console and the graphical console as a secondary console. For more information, see How does one set up a serial terminal and/or console in Red Hat Enterprise Linux?.

6. If you use PXE UEFI, perform the following actions:

   a. Provide the shimx64.efi and grubx64.efi EFI binaries and the grub.cfg file that are required for booting the system.

   - Extract the necessary EFI binaries by mounting the RHCOS ISO to your host and then mounting the images/efiboot.img file to your host:

     ```
     $ mkdir -p /mnt/iso
     $ mkdir -p /mnt/efiboot
     $ mount -o loop rhcos-installer.x86_64.iso /mnt/iso
     $ mount -o loop,ro /mnt/iso/images/efiboot.img /mnt/efiboot
     $ cp /mnt/efiboot/EFI/redhat/shimx64.efi .
     $ cp /mnt/efiboot/EFI/redhat/grubx64.efi .
     $ umount /mnt/efiboot
     ```

   - From the efiboot.img mount point, copy the EFI/redhat/shimx64.efi and EFI/redhat/grubx64.efi files to your TFTP server:
b. Edit the `grub.cfg` file to include arguments similar to the following:

```
menuentry 'Install Red Hat Enterprise Linux CoreOS' --class fedora --class gnu-linux --class gnu --class os {
  linuxefi rhcos-<version>-live-kernel-<architecture> coreos.inst.install_dev=/dev/sda
  <architecture>.img coreos.inst.ignition_url=http://<HTTP_server>/bootstrap.ign
  initrdelfi rhcos-<version>-live-initramfs.<architecture>.img
}
```

where:

- **rhcos-<version>-live-kernel-<architecture>**
  Specifies the `kernel` file that you uploaded to your TFTP server.

- **http://<HTTP_server>/rhcos-<version>-live-rootfs.<architecture>.img**
  Specifies the location of the live `rootfs` image that you uploaded to your HTTP server.

- **http://<HTTP_server>/bootstrap.ign**
  Specifies the location of the bootstrap Ignition config file that you uploaded to your HTTP server.

- **rhcos-<version>-live-initramfs.<architecture>.img**
  Specifies the location of the `initramfs` file that you uploaded to your TFTP server.

**NOTE**
For more information on how to configure a PXE server for UEFI boot, see the Red Hat Knowledgebase article: [How to configure/setup a PXE server for UEFI boot for Red Hat Enterprise Linux?](https://access.redhat.com/documentation/en-us/red_hat_enterprise_linux/8/html-single/uefi_boot_red_hat_enterprise_linux#how-to-configure-pxe-server)

7. Continue to create the machines for your cluster.

**IMPORTANT**
You must create the bootstrap and control plane machines at this time. If the control plane machines are not made schedulable, which is the default, also create at least two compute machines before you install the cluster.

### 5.11.3. Advanced Red Hat Enterprise Linux CoreOS (RHCOS) installation configuration

A key benefit for manually provisioning the Red Hat Enterprise Linux CoreOS (RHCOS) nodes for OpenShift Container Platform is to be able to do configuration that is not available through default OpenShift Container Platform installation methods. This section describes some of the configurations that you can do using techniques that include:

- Passing kernel arguments to the live installer
- Running `coreos-installer` manually from the live system
• Embedding Ignition configs in an ISO

The advanced configuration topics for manual Red Hat Enterprise Linux CoreOS (RHCOS) installations detailed in this section relate to disk partitioning, networking, and using Ignition configs in different ways.

5.1.11.3.1. Using advanced networking options for PXE and ISO installations

Networking for OpenShift Container Platform nodes uses DHCP by default to gather all necessary configuration settings. To set up static IP addresses or configure special settings, such as bonding, you can do one of the following:

• Pass special kernel parameters when you boot the live installer.
• Use a machine config to copy networking files to the installed system.
• Configure networking from a live installer shell prompt, then copy those settings to the installed system so that they take effect when the installed system first boots.

To configure a PXE or iPXE installation, use one of the following options:

• See the "Advanced RHCOS installation reference" tables.
• Use a machine config to copy networking files to the installed system.

To configure an ISO installation, use the following procedure.

Procedure

1. Boot the ISO installer.

2. From the live system shell prompt, configure networking for the live system using available RHEL tools, such as `nmcli` or `nmtui`.

3. Run the `coreos-installer` command to install the system, adding the `--copy-network` option to copy networking configuration. For example:

   ```sh
   $ coreos-installer install --copy-network \n   --ignition-url=http://host/worker.ign /dev/sda
   ```

   **IMPORTANT**

   The `--copy-network` option only copies networking configuration found under `/etc/NetworkManager/system-connections`. In particular, it does not copy the system hostname.

4. Reboot into the installed system.

5.1.11.3.2. Disk partitioning

The disk partitions are created on OpenShift Container Platform cluster nodes during the Red Hat Enterprise Linux CoreOS (RHCOS) installation. Each RHCOS node of a particular architecture uses the same partition layout, unless the default partitioning configuration is overridden. During the RHCOS installation, the size of the root file system is increased to use the remaining available space on the target device.
However, there are two cases where you might want to intervene to override the default partitioning when installing an OpenShift Container Platform node:

- Create separate partitions: For greenfield installations on an empty disk, you might want to add separate storage to a partition. This is officially supported for making `/var` or a subdirectory of `/var`, such as `/var/lib/etcd`, a separate partition, but not both.

  **IMPORTANT**

  Kubernetes supports only two filesystem partitions. If you add more than one partition to the original configuration, Kubernetes cannot monitor all of them.

- Retain existing partitions: For a brownfield installation where you are reinstalling OpenShift Container Platform on an existing node and want to retain data partitions installed from your previous operating system, there are both boot arguments and options to `coreos-installer` that allow you to retain existing data partitions.

### 5.1.11.3.2.1. Creating a separate `/var` partition

In general, disk partitioning for OpenShift Container Platform should be left to the installer. However, there are cases where you might want to create separate partitions in a part of the filesystem that you expect to grow.

OpenShift Container Platform supports the addition of a single partition to attach storage to either the `/var` partition or a subdirectory of `/var`. For example:

- `/var/lib/containers`: Holds container-related content that can grow as more images and containers are added to a system.

- `/var/lib/etcd`: Holds data that you might want to keep separate for purposes such as performance optimization of etcd storage.

- `/var`: Holds data that you might want to keep separate for purposes such as auditing.

Storing the contents of a `/var` directory separately makes it easier to grow storage for those areas as needed and reinstall OpenShift Container Platform at a later date and keep that data intact. With this method, you will not have to pull all your containers again, nor will you have to copy massive log files when you update systems.

Because `/var` must be in place before a fresh installation of Red Hat Enterprise Linux CoreOS (RHCOS), the following procedure sets up the separate `/var` partition by creating a machine config that is inserted during the `openshift-install` preparation phases of an OpenShift Container Platform installation.

**Procedure**

1. Create a directory to hold the OpenShift Container Platform installation files:

   ```
   $ mkdir $HOME/clusterconfig
   ```

2. Run `openshift-install` to create a set of files in the `manifest` and `openshift` subdirectories. Answer the system questions as you are prompted:

   ```
   $ openshift-install create manifests --dir $HOME/clusterconfig
   ? SSH Public Key ...
   $ ls $HOME/clusterconfig/openshift/
   ```
Create a `MachineConfig` object and add it to a file in the `openshift` directory. For example, name the file `98-var-partition.yaml`, change the disk device name to the name of the storage device on the `worker` systems, and set the storage size as appropriate. This example places the `/var` directory on a separate partition:

```yaml
apiVersion: machineconfiguration.openshift.io/v1
class: MachineConfig
metadata:
  labels:
    machineconfiguration.openshift.io/role: worker
  name: 98-var-partition
spec:
  config:
    ignition:
      version: 3.1.0
    storage:
      disks:
        - device: /dev/<device_name>  
          partitions:
            - label: var
              startMiB: <partition_start_offset>
              sizeMiB: <partition_size>
        filesystems:
          - device: /dev/disk/by-partlabel/var
            path: /var
            format: xfs
  systemd:
    units:
      - name: var.mount
        enabled: true
        contents:
        [Unit]
          Before=local-fs.target
        [Mount]
          What=/dev/disk/by-partlabel/var
          Where=/var
          Options=defaults,prjquota
        [Install]
          WantedBy=local-fs.target
```

1. The storage device name of the disk that you want to partition.
2. When adding a data partition to the boot disk, a minimum value of 25000 mebibytes is recommended. The root file system is automatically resized to fill all available space up to the specified offset. If no value is specified, or if the specified value is smaller than the recommended minimum, the resulting root file system will be too small, and future reinstalls of RHCOS might overwrite the beginning of the data partition.
3. The size of the data partition in mebibytes.
The name of the mount unit must match the directory specified in the `Where=` directive. For example, for a filesystem mounted on `/var/lib/containers`, the unit must be named `var-`

The `prjquota` mount option must be enabled for filesystems used for container storage.

**NOTE**

When creating a separate `/var` partition, you cannot use different instance types for worker nodes, if the different instance types do not have the same device name.

4. Run `openshift-install` again to create Ignition configs from a set of files in the `manifest` and `openshift` subdirectories:

```bash
$ openshift-install create ignition-configs --dir $HOME/clusterconfig
$ ls $HOME/clusterconfig/
auth bootstrap.ign master.ign metadata.json worker.ign
```

Now you can use the Ignition config files as input to the ISO or PXE manual installation procedures to install Red Hat Enterprise Linux CoreOS (RHCOS) systems.

5.1.11.3.2.2. Retaining existing partitions

For an ISO installation, you can add options to the `coreos-installer` command line that causes the installer to maintain one or more existing partitions. For a PXE installation, you can `APPEND coreos.inst.*` options to preserve partitions.

Saved partitions might be partitions from an existing OpenShift Container Platform system that has data partitions that you want to keep. Here are a few tips:

- If you save existing partitions, and those partitions do not leave enough space for RHCOS, installation will fail without damaging the saved partitions.
- Identify the disk partitions you want to keep either by partition label or by number.

**For an ISO installation**

This example preserves any partition in which the partition label begins with `data` (`data*`):

```bash
# coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign
  --save-partlabel 'data*' /dev/sda
```

The following example illustrates running the `coreos-installer` in a way that preserves the sixth (6) partition on the disk:

```bash
# coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign
  --save-partindex 6 /dev/sda
```

This example preserves partitions 5 and higher:

```bash`
# coreos-installer install --ignition-url http://10.0.2.2:8080/user.ign
  --save-partindex 5- /dev/sda
```
In the previous examples where partition saving is used, `coreos-installer` recreates the partition immediately.

**For a PXE installation**

This `APPEND` option preserves any partition in which the partition label begins with 'data' (`data*`):

```
coreos.inst.save_partlabel=data*
```

This `APPEND` option preserves partitions 5 and higher:

```
coreos.inst.save_partindex=5-
```

This `APPEND` option preserves partition 6:

```
coreos.inst.save_partindex=6
```

5.1.11.3.3. Identifying Ignition configs

When doing an RHCOS manual installation, there are two types of Ignition configs that you can provide, with different reasons for providing each one:

- **Permanent install Ignition config**: Every manual RHCOS installation needs to pass one of the Ignition config files generated by `openshift-installer`, such as `bootstrap.ign`, `master.ign` and `worker.ign`, to carry out the installation.

  **IMPORTANT**
  
  It is not recommended to modify these files.

For PXE installations, you pass the Ignition configs on the `APPEND` line using the `coreos.inst.ignition_url=` option. For ISO installations, after the ISO boots to the shell prompt, you identify the Ignition config on the `coreos-installer` command line with the `--ignition-url=` option. In both cases, only HTTP and HTTPS protocols are supported.

- **Live install Ignition config**: This type must be created manually and should be avoided if possible, as it is not supported by Red Hat. With this method, the Ignition config passes to the live install medium, runs immediately upon booting, and performs setup tasks before and/or after the RHCOS system installs to disk. This method should only be used for performing tasks that must be performed once and not applied again later, such as with advanced partitioning that cannot be done using a machine config.

  For PXE or ISO boots, you can create the Ignition config and `APPEND` the `ignition.config.url=` option to identify the location of the Ignition config. You also need to append `ignition.firstboot` `ignition.platform.id=metal` or the `ignition.config.url` option will be ignored.

5.1.11.3.3.1. Embedding an Ignition config in the RHCOS ISO

You can embed a live install Ignition config directly in an RHCOS ISO image. When the ISO image is booted, the embedded config will be applied automatically.

**Procedure**

2. Retrieve the RHCOS ISO image and the Ignition config file, and copy them into an accessible directory, such as /mnt:

```
# cp rhcos-<version>-live.x86_64.iso bootstrap.ign /mnt/
# chmod 644 /mnt/rhcos-<version>-live.x86_64.iso
```

3. Run the following command to embed the Ignition config into the ISO:

```
# ./coreos-installer iso ignition embed -i /mnt/bootstrap.ign \ 
   /mnt/rhcos-<version>-live.x86_64.iso
```

You can now use that ISO to install RHCOS using the specified live install Ignition config.

**IMPORTANT**

Using `coreos-installer iso ignition embed` to embed a file generated by `openshift-installer`, such as `bootstrap.ign`, `master.ign` and `worker.ign`, is unsupported and not recommended.

4. To show the contents of the embedded Ignition config and direct it into a file, run:

```
# ./coreos-installer iso ignition show /mnt/rhcos-<version>-live.x86_64.iso > mybootstrap.ign
# diff -s bootstrap.ign mybootstrap.ign
```

**Example output**

Files `bootstrap.ign` and `mybootstrap.ign` are identical

5. To remove the Ignition config and return the ISO to its pristine state so you can reuse it, run:

```
# ./coreos-installer iso ignition remove /mnt/rhcos-<version>-live.x86_64.iso
```

You can now embed another Ignition config into the ISO or use the ISO in its pristine state.

### 5.1.11.3.4. Advanced RHCOS installation reference

This section illustrates the networking configuration and other advanced options that allow you to modify the Red Hat Enterprise Linux CoreOS (RHCOS) manual installation process. The following tables describe the kernel arguments and command-line options you can use with the RHCOS live installer and the `coreos-installer` command.

**Routing and bonding options at RHCOS boot prompt**

If you install RHCOS from an ISO image, you can add kernel arguments manually when you boot that image to configure the node’s networking. If no networking arguments are used, the installation defaults to using DHCP.

**IMPORTANT**

When adding networking arguments, you must also add the `rd.neednet=1` kernel argument.
The following table describes how to use `ip=`, `nameserver=`, and `bond=` kernel arguments for live ISO installs.

**NOTE**
Ordering is important when adding kernel arguments: `ip=`, `nameserver=`, and then `bond=`.

**Routing and bonding options for ISO**

The following table provides examples for configuring networking of your Red Hat Enterprise Linux CoreOS (RHCOS) nodes. These are networking options that are passed to the `dracut` tool during system boot. For more information about the networking options supported by `dracut`, see the `dracut.cmdline` manual page.

<table>
<thead>
<tr>
<th>Description</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>To configure an IP address, either use DHCP (<code>ip=dhcp</code>) or set an individual static IP address (<code>ip= &lt;host_ip&gt;</code>). Then identify the DNS server IP address (<code>nameserver=&lt;dns_ip&gt;</code>) on each node. This example sets:</td>
<td><code>ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none</code>&lt;br&gt;<code>nameserver=4.4.4.41</code>&lt;br&gt;<strong>Route</strong>&lt;br&gt;The node's IP address to <strong>10.10.10.2</strong>&lt;br&gt;The gateway address to <strong>10.10.10.254</strong>&lt;br&gt;The netmask to <strong>255.255.255.0</strong>&lt;br&gt;The hostname to <strong>core0.example.com</strong>&lt;br&gt;The DNS server address to <strong>4.4.4.41</strong></td>
</tr>
</tbody>
</table>
| Specify multiple network interfaces by specifying multiple `ip=` entries. | `ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none`<br>`ip=10.10.10.3::10.10.10.254:255.255.255.0:core0.example.com:enp2s0:none`<br>Optional: You can configure routes to additional networks by setting an `rd.route=` value. If the additional network gateway is different from the primary network gateway, the default gateway must be the primary network gateway. | To configure the default gateway:<br>`ip=::10.10.10.254:::`<br>To configure the route for the additional network:<br>`rd.route=20.20.20.0/24:20.20.20.254:enp2s0`<br>Disable DHCP on a single interface, such as when there are two or more network interfaces and only one interface is being used. | `ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp1s0:none`<br>`ip=:::core0.example.com:enp2s0:none`<br>**Route**<br>`ip=::10.10.10.254:::`

<table>
<thead>
<tr>
<th>Description</th>
<th>Examples</th>
</tr>
</thead>
</table>
| You can combine DHCP and static IP configurations on systems with multiple network interfaces. | ip=enp1s0:dhcp  
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp2s0:none |
| Optional: You can configure VLANs on individual interfaces by using the `vlan=` parameter. | To configure a VLAN on a network interface and use a static IP address:  
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:enp2s0.100:none  
`vlan=enp2s0.100:enp2s0`  
To configure a VLAN on a network interface and to use DHCP:  
ip=enp2s0.100:dhcp  
`vlan=enp2s0.100:enp2s0` |
| You can provide multiple DNS servers by adding a `nameserver=` entry for each server. | `nameserver=1.1.1.1`  
`nameserver=8.8.8.8` |
| Optional: Bonding multiple network interfaces to a single interface is supported using the `bond=` option. In these two examples: | To configure the bonded interface to use DHCP, set the bond’s IP address to `dhcp`. For example:  
`bond=bond0:em1,em2:mode=active-backup  
`ip=bond0:dhcp`  
To configure the bonded interface to use a static IP address, enter the specific IP address you want and related information. For example:  
`bond=bond0:em1,em2:mode=active-backup  
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:bond0:none` |
|   - The syntax for configuring a bonded interface is:  
`bond=name[:network_interfaces] [:options]`  
   - `name` is the bonding device name (`bond0`),  
`network_interfaces` represents a comma-separated list of physical (ethernet) interfaces (`em1,em2`), and `options` is a comma-separated list of bonding options. Enter `modinfo bonding` to see available options.  
   - When you create a bonded interface using `bond=`, you must specify how the IP address is assigned and other information for the bonded interface. |
Optional: You can configure VLANs on bonded interfaces by using the `vlan=` parameter.

To configure the bonded interface with a VLAN and to use DHCP:

```
ip=bond0.100:dhcp
bond=bond0:em1,em2:mode=active-backup
vlan=bond0.100:bond0
```

To configure the bonded interface with a VLAN and to use a static IP address:

```
ip=10.10.10.2::10.10.10.254:255.255.255.0:core0.example.com:bond0.100:none
bond=bond0:em1,em2:mode=active-backup
vlan=bond0.100:bond0
```

Optional: Network teaming can be used as an alternative to bonding by using the `team=` parameter. In this example:

- The syntax for configuring a team interface is: `team=name[:network_interfaces]`
  - `name` is the team device name (team0) and `network_interfaces` represents a comma-separated list of physical (ethernet) interfaces (em1, em2).

```
NOTE
Teaming is planned to be deprecated when RHCOS switches to an upcoming version of RHEL. For more information, see this Red Hat Knowledgebase Article.
```

To configure a network team:

```
team=team0:em1,em2
ip=team0:dhcp
```

coreos.inst boot options for ISO or PXE install

While you can pass most standard installation boot arguments to the live installer, there are several arguments that are specific to the RHCOS live installer.

- For ISO, these options can be added by interrupting the RHCOS installer.
- For PXE or iPXE, these options must be added to the `APPEND` line before starting the PXE kernel. You cannot interrupt a live PXE install.

The following table shows the RHCOS live installer boot options for ISO and PXE installs.

Table 5.10. `coreos.inst` boot options
<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>coreos.inst.install_dev</td>
<td>Required. The block device on the system to install to. It is recommended to use the full path, such as /dev/sda, although sda is allowed.</td>
</tr>
<tr>
<td>coreos.inst.ignition_url</td>
<td>Optional: The URL of the Ignition config to embed into the installed system. If no URL is specified, no Ignition config is embedded.</td>
</tr>
<tr>
<td>coreos.inst.save_partlabel</td>
<td>Optional: Comma-separated labels of partitions to preserve during the install. Glob-style wildcards are permitted. The specified partitions do not need to exist.</td>
</tr>
<tr>
<td>coreos.inst.save_partindex</td>
<td>Optional: Comma-separated indexes of partitions to preserve during the install. Ranges m-n are permitted, and either m or n can be omitted. The specified partitions do not need to exist.</td>
</tr>
<tr>
<td>coreos.inst.insecure</td>
<td>Optional: Permits the OS image that is specified by coreos.inst.image_url to be unsigned.</td>
</tr>
<tr>
<td>coreos.inst.image_url</td>
<td>Optional: Download and install the specified RHCOS image.</td>
</tr>
<tr>
<td></td>
<td>- This argument should not be used in production environments and is intended for debugging purposes only.</td>
</tr>
<tr>
<td></td>
<td>- While this argument can be used to install a version of RHCOS that does not match the live media, it is recommended that you instead use the media that matches the version you want to install.</td>
</tr>
<tr>
<td></td>
<td>- If you are using coreos.inst.image_url, you must also use coreos.inst.insecure. This is because the bare-metal media are not GPG-signed for OpenShift Container Platform.</td>
</tr>
<tr>
<td></td>
<td>- Only HTTP and HTTPS protocols are supported.</td>
</tr>
<tr>
<td>coreos.inst.skip_reboot</td>
<td>Optional: The system will not reboot after installing. Once the install finishes, you will receive a prompt that allows you to inspect what is happening during installation. This argument should not be used in production environments and is intended for debugging purposes only.</td>
</tr>
</tbody>
</table>
coreos.inst.platform_id

Optional: The Ignition platform ID of the platform the RHCOS image is being installed on. Default is `metal`. This option determines whether or not to request an Ignition config from the cloud provider, such as VMware. For example:

```
coreos.inst.platform_id=vmware
```

ignition.config.url

Optional: The URL of the Ignition config for the live boot. For example, this can be used to customize how `coreos-installer` is invoked, or to run code before or after the installation. This is different from `coreos.inst.ignition_url`, which is the Ignition config for the installed system.

coreos-installer options for ISO install

You can also install RHCOS by invoking the `coreos-installer` command directly from the command line. The kernel arguments in the previous table provide a shortcut for automatically invoking `coreos-installer` at boot time, but you can pass similar arguments directly to `coreos-installer` when running it from a shell prompt.

The following table shows the options and subcommands you can pass to the `coreos-installer` command from a shell prompt during a live install.

**Table 5.11. coreos-installer command-line options, arguments, and subcommands**

<table>
<thead>
<tr>
<th>Command-line options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-u, --image-url &lt;url&gt;</code></td>
<td>Specify the image URL manually.</td>
</tr>
<tr>
<td><code>-f, --image-file &lt;path&gt;</code></td>
<td>Specify a local image file manually.</td>
</tr>
<tr>
<td><code>-i, --ignition-file &lt;path&gt;</code></td>
<td>Embed an Ignition config from a file.</td>
</tr>
<tr>
<td><code>-l, --ignition-url &lt;URL&gt;</code></td>
<td>Embed an Ignition config from a URL.</td>
</tr>
<tr>
<td><code>--ignition-hash &lt;digest&gt;</code></td>
<td>Digest type-value of the Ignition config.</td>
</tr>
<tr>
<td><code>-p, --platform &lt;name&gt;</code></td>
<td>Override the Ignition platform ID.</td>
</tr>
<tr>
<td><code>--append-karg &lt;arg&gt;...</code></td>
<td>Append the default kernel argument.</td>
</tr>
<tr>
<td><code>--delete-karg &lt;arg&gt;...</code></td>
<td>Delete the default kernel argument.</td>
</tr>
</tbody>
</table>
**-n, --copy-network**

Copy the network configuration from the install environment.

**IMPORTANT**

The **--copy-network** option only copies networking configuration found under `/etc/NetworkManager/system-connections`. In particular, it does not copy the system hostname.

<table>
<thead>
<tr>
<th><strong>--network-dir &lt;path&gt;</strong></th>
<th>For use with <code>-n</code>. Default is <code>/etc/NetworkManager/system-connections/</code>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>--save-partlabel &lt;lx&gt;..</strong></td>
<td>Save partitions with this label glob.</td>
</tr>
<tr>
<td><strong>--save-partindex &lt;id&gt;...</strong></td>
<td>Save partitions with this number or range.</td>
</tr>
<tr>
<td><strong>--offline</strong></td>
<td>Force offline installation.</td>
</tr>
<tr>
<td><strong>--insecure</strong></td>
<td>Skip signature verification.</td>
</tr>
<tr>
<td><strong>--insecure-ignition</strong></td>
<td>Allow Ignition URL without HTTPS or hash.</td>
</tr>
<tr>
<td><strong>--architecture &lt;name&gt;</strong></td>
<td>Target CPU architecture. Default is <code>x86_64</code>.</td>
</tr>
<tr>
<td><strong>--preserve-on-error</strong></td>
<td>Do not clear partition table on error.</td>
</tr>
<tr>
<td><strong>-h, --help</strong></td>
<td>Print help information.</td>
</tr>
</tbody>
</table>

**Command-line argument**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;device&gt;</td>
<td>The destination device.</td>
</tr>
</tbody>
</table>

**coreos-installer embedded Ignition commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>$ coreos-installer iso ignition embed &lt;options&gt; --ignition-file &lt;file_path&gt; &lt;ISO_image&gt;</code></td>
<td>Embed an Ignition config in an ISO image.</td>
</tr>
<tr>
<td><code>coreos-installer iso ignition show &lt;options&gt; &lt;ISO_image&gt;</code></td>
<td>Show the embedded Ignition config from an ISO image.</td>
</tr>
</tbody>
</table>
coreos-installer iso ignition remove
<options> <ISO_image>

Remove the embedded Ignition config from an ISO image.

coreos-installer ISO Ignition options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-f, --force</td>
<td>Overwrite an existing Ignition config.</td>
</tr>
<tr>
<td>-i, --ignition-file &lt;path&gt;</td>
<td>The Ignition config to be used. Default is stdin.</td>
</tr>
<tr>
<td>-o, --output &lt;path&gt;</td>
<td>Write the ISO to a new output file.</td>
</tr>
<tr>
<td>-h, --help</td>
<td>Print help information.</td>
</tr>
</tbody>
</table>

coreos-installer PXE Ignition commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>coreos-installer pxe ignition wrap &lt;options&gt;</td>
<td>Wrap an Ignition config in an image.</td>
</tr>
<tr>
<td>coreos-installer pxe ignition unwrap &lt;options&gt; &lt;image_name&gt;</td>
<td>Show the wrapped Ignition config in an image.</td>
</tr>
<tr>
<td>coreos-installer pxe ignition unwrap &lt;options&gt; &lt;initrd_name&gt;</td>
<td>Show the wrapped Ignition config in an initrd image.</td>
</tr>
</tbody>
</table>

coreos-installer PXE Ignition options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-i, --ignition-file &lt;path&gt;</td>
<td>The Ignition config to be used. Default is stdin.</td>
</tr>
<tr>
<td>-o, --output &lt;path&gt;</td>
<td>Write the ISO to a new output file.</td>
</tr>
<tr>
<td>-h, --help</td>
<td>Print help information.</td>
</tr>
</tbody>
</table>

5.1.12. Creating the cluster

To create the OpenShift Container Platform cluster, you wait for the bootstrap process to complete on the machines that you provisioned by using the Ignition config files that you generated with the installation program.

Prerequisites

- Create the required infrastructure for the cluster.
You obtained the installation program and generated the Ignition config files for your cluster.

You used the Ignition config files to create RHCOS machines for your cluster.

Your machines have direct Internet access or have an HTTP or HTTPS proxy available.

**Procedure**

1. Monitor the bootstrap process:

   ```bash
   $ ./openshift-install --dir <installation_directory> wait-for bootstrap-complete \   --log-level=info
   
   1 For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

   2 To view different installation details, specify `warn`, `debug`, or `error` instead of `info`.

   **Example output**

   INFO Waiting up to 30m0s for the Kubernetes API at https://api.test.example.com:6443...
   INFO API v1.19.0 up
   INFO Waiting up to 30m0s for bootstrapping to complete...
   INFO It is now safe to remove the bootstrap resources

   The command succeeds when the Kubernetes API server signals that it has been bootstrapped on the control plane machines.

2. After bootstrap process is complete, remove the bootstrap machine from the load balancer.

   **IMPORTANT**

   You must remove the bootstrap machine from the load balancer at this point.
   You can also remove or reformat the machine itself.

**5.1.13. Logging in to the cluster by using the CLI**

You can log in to your cluster as a default system user by exporting the cluster `kubeconfig` file. The `kubeconfig` file contains information about the cluster that is used by the CLI to connect a client to the correct cluster and API server. The file is specific to a cluster and is created during OpenShift Container Platform installation.

**Prerequisites**

- You deployed an OpenShift Container Platform cluster.
- You installed the `oc` CLI.

**Procedure**

1. Export the `kubeadmin` credentials:

   ```bash
   $ export KUBECONFIG=<installation_directory>/auth/kubeconfig
   ```
1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

2. Verify you can run `oc` commands successfully using the exported configuration:

   $ oc whoami

   **Example output**

   system:admin

### 5.1.14. Approving the certificate signing requests for your machines

When you add machines to a cluster, two pending certificate signing requests (CSRs) are generated for each machine that you added. You must confirm that these CSRs are approved or, if necessary, approve them yourself. The client requests must be approved first, followed by the server requests.

#### Prerequisites

- You added machines to your cluster.

#### Procedure

1. Confirm that the cluster recognizes the machines:

   $ oc get nodes

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>STATUS</th>
<th>ROLES</th>
<th>AGE</th>
<th>VERSION</th>
</tr>
</thead>
<tbody>
<tr>
<td>master-0</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.19.0</td>
</tr>
<tr>
<td>master-1</td>
<td>Ready</td>
<td>master</td>
<td>63m</td>
<td>v1.19.0</td>
</tr>
<tr>
<td>master-2</td>
<td>Ready</td>
<td>master</td>
<td>64m</td>
<td>v1.19.0</td>
</tr>
</tbody>
</table>

   The output lists all of the machines that you created.

   **NOTE**

   The preceding output might not include the compute nodes, also known as worker nodes, until some CSRs are approved.

2. Review the pending CSRs and ensure that you see the client requests with the **Pending** or **Approved** status for each machine that you added to the cluster:

   $ oc get csr

   **Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-8b2br</td>
<td>15m</td>
<td>system:serviceaccount:openshift-machine-config-operator:node-</td>
<td></td>
</tr>
</tbody>
</table>
In this example, two machines are joining the cluster. You might see more approved CSRs in the list.

3. If the CSRs were not approved, after all of the pending CSRs for the machines you added are in **Pending** status, approve the CSRs for your cluster machines:

   **NOTE**

   Because the CSRs rotate automatically, approve your CSRs within an hour of adding the machines to the cluster. If you do not approve them within an hour, the certificates will rotate, and more than two certificates will be present for each node. You must approve all of these certificates. Once the client CSR is approved, the Kubelet creates a secondary CSR for the serving certificate, which requires manual approval. Then, subsequent serving certificate renewal requests are automatically approved by the **machine approver** if the Kubelet requests a new certificate with identical parameters.

   **NOTE**

   For clusters running on platforms that are not machine API enabled, such as bare metal and other user-provisioned infrastructure, you must implement a method of automatically approving the kubelet serving certificate requests (CSRs). If a request is not approved, then the **oc exec**, **oc rsh**, and **oc logs** commands cannot succeed, because a serving certificate is required when the API server connects to the kubelet. Any operation that contacts the Kubelet endpoint requires this certificate approval to be in place. The method must watch for new CSRs, confirm that the CSR was submitted by the **node-bootstrapper** service account in the **system:node** or **system:admin** groups, and confirm the identity of the node.

   - To approve them individually, run the following command for each valid CSR:

     ```bash
     $ oc adm certificate approve <csr_name>
     ```

     `<csr_name>` is the name of a CSR from the list of current CSRs.

   - To approve all pending CSRs, run the following command:

     ```bash
     $ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs --no-run-if-empty oc adm certificate approve
     ```

     **NOTE**

     Some Operators might not become available until some CSRs are approved.

4. Now that your client requests are approved, you must review the server requests for each machine that you added to the cluster:
5. If the remaining CSRs are not approved, and are in the **Pending** status, approve the CSRs for your cluster machines:

- To approve them individually, run the following command for each valid CSR:

  ```
  $ oc adm certificate approve <csr_name>  
  ```

  `<csr_name>` is the name of a CSR from the list of current CSRs.

- To approve all pending CSRs, run the following command:

  ```
  $ oc get csr -o go-template='{{range .items}}{{if not .status}}{{.metadata.name}}{{"\n"}}{{end}}{{end}}' | xargs oc adm certificate approve  
  ```

6. After all client and server CSRs have been approved, the machines have the **Ready** status. Verify this by running the following command:

```
$ oc get nodes  
```

**Example output**

<table>
<thead>
<tr>
<th>NAME</th>
<th>AGE</th>
<th>REQUESTOR</th>
<th>CONDITION</th>
</tr>
</thead>
<tbody>
<tr>
<td>csr-bfd72</td>
<td>5m26s</td>
<td>system:node:ip-10-0-50-126.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
<tr>
<td>csr-c57lv</td>
<td>5m26s</td>
<td>system:node:ip-10-0-95-157.us-east-2.compute.internal</td>
<td>Pending</td>
</tr>
</tbody>
</table>

**NOTE**

It can take a few minutes after approval of the server CSRs for the machines to transition to the **Ready** status.

**Additional information**

- For more information on CSRs, see **Certificate Signing Requests**.

**5.1.15. Initial Operator configuration**
After the control plane initializes, you must immediately configure some Operators so that they all become available.

**Prerequisites**

- Your control plane has initialized.

**Procedure**

1. Watch the cluster components come online:

   ```bash
   $ watch -n5 oc get clusteroperators
   ```

   **Example output**

<table>

2. Configure the Operators that are not available.

**5.15.1. Image registry removed during installation**
On platforms that do not provide shareable object storage, the OpenShift Image Registry Operator bootstraps itself as **Removed**. This allows **openshift-installer** to complete installations on these platform types.

After installation, you must edit the Image Registry Operator configuration to switch the `managementState` from **Removed** to **Managed**.

**NOTE**

The Prometheus console provides an **ImageRegistryRemoved** alert, for example:

"Image Registry has been removed. **ImageStreamTags**, **BuildConfigs** and **DeploymentConfigs** which reference **ImageStreamTags** may not work as expected. Please configure storage and update the config to **Managed** state by editing configs.imageregistry.operator.openshift.io."

### 5.1.15.2. Image registry storage configuration

The Image Registry Operator is not initially available for platforms that do not provide default storage. After installation, you must configure your registry to use storage so that the Registry Operator is made available.

Instructions are shown for configuring a persistent volume, which is required for production clusters. Where applicable, instructions are shown for configuring an empty directory as the storage location, which is available for only non-production clusters.

Additional instructions are provided for allowing the image registry to use block storage types by using the **Recreate** rollout strategy during upgrades.

#### 5.1.15.2.1. Configuring registry storage for bare metal and other manual installations

As a cluster administrator, following installation you must configure your registry to use storage.

**Prerequisites**

- Cluster administrator permissions.
- A cluster that uses manually-provisioned Red Hat Enterprise Linux CoreOS (RHCOS) nodes, such as bare metal.
- Persistent storage provisioned for your cluster, such as Red Hat OpenShift Container Storage.

**IMPORTANT**

OpenShift Container Platform supports **ReadWriteOnce** access for image registry storage when you have only one replica. To deploy an image registry that supports high availability with two or more replicas, **ReadWriteMany** access is required.

- Must have 100Gi capacity.

**Procedure**

1. To configure your registry to use storage, change the `spec.storage.pvc` in the `configs.imageregistry/cluster` resource.
NOTE
When using shared storage, review your security settings to prevent outside access.

2. Verify that you do not have a registry pod:

   $ oc get pod -n openshift-image-registry

NOTE
If the storage type is emptyDir, the replica number cannot be greater than 1.

3. Check the registry configuration:

   $ oc edit configs.imageregistry.operator.openshift.io

Example output

```
storage:
  pvc:
    claim:
```

Leave the claim field blank to allow the automatic creation of an image-registry-storage PVC.

4. Check the clusteroperator status:

   $ oc get clusteroperator image-registry

5. Ensure that your registry is set to managed to enable building and pushing of images.
   - Run:
     $ oc edit configs.imageregistry/cluster
     Then, change the line
     managementState: Removed
     to
     managementState: Managed

5.15.2.2. Configuring storage for the image registry in non-production clusters

You must configure storage for the Image Registry Operator. For non-production clusters, you can set the image registry to an empty directory. If you do so, all images are lost if you restart the registry.

Procedure

- To set the image registry storage to an empty directory:
To allow the image registry to use block storage types during upgrades as a cluster administrator, you can use the **Recreate** rollout strategy. **IMPORTANT**

Block storage volumes are supported but not recommended for use with the image registry on production clusters. An installation where the registry is configured on block storage is not highly available because the registry cannot have more than one replica.

**Procedure**

1. To set the image registry storage as a block storage type, patch the registry so that it uses the **Recreate** rollout strategy and runs with only one (1) replica:

   ```
   $ oc patch config.imageregistry.operator.openshift.io/cluster --type=merge -p '{"spec":
   "{rolloutStrategy":"Recreate","replicas":1})'
   ```

2. Provision the PV for the block storage device, and create a PVC for that volume. The requested block volume uses the ReadWriteOnce (RWO) access mode.

3. Edit the registry configuration so that it references the correct PVC.

**5.1.16. Completing installation on user-provisioned infrastructure**

After you complete the Operator configuration, you can finish installing the cluster on infrastructure that you provide.

**Prerequisites**

- Your control plane has initialized.
- You have completed the initial Operator configuration.
Procedure

1. Confirm that all the cluster components are online with the following command:

   ```
   $ watch -n5 oc get clusteroperators
   ```

Example output

```
NAME          VERSION AVAILABLE PROGRESSING DEGRADED SINCE
authentication 4.6.0   True    False   False         3h56m
cloud-credential 4.6.0   True    False   False         29h

kube-controller-manager 4.6.0   True    False   False         29h
kube-scheduler 4.6.0   True    False   False         29h
kube-storage-version-migrator 4.6.0   True    False   False         4h2m
machine-api 4.6.0   True    False   False         29h
machine-approver 4.6.0   True    False   False         6h34m
machine-config 4.6.0   True    False   False         3h56m
marketplace 4.6.0   True    False   False         4h2m
monitoring 4.6.0   True    False   False         6h31m
network 4.6.0   True    False   False         29h
node-tuning 4.6.0   True    False   False         4h30m
openshift-apiserver 4.6.0   True    False   False         3h56m
openshift-controller-manager 4.6.0   True    False   False         4h36m
openshift-samples 4.6.0   True    False   False         4h30m
operator-lifecycle-manager 4.6.0   True    False   False         29h
operator-lifecycle-manager-catalog 4.6.0   True    False   False         29h
operator-lifecycle-manager-packageserver 4.6.0   True    False   False         3h59m
service-ca 4.6.0   True    False   False         29h
storage 4.6.0   True    False   False         4h30m
```

Alternatively, the following command notifies you when all of the clusters are available. It also retrieves and displays credentials:

```
$ ./openshift-install --dir <installation_directory> wait-for install-complete
```

1. For `<installation_directory>`, specify the path to the directory that you stored the installation files in.

Example output

```
INFO Waiting up to 30m0s for the cluster to initialize...
```
The command succeeds when the Cluster Version Operator finishes deploying the OpenShift Container Platform cluster from Kubernetes API server.

**IMPORTANT**

- The Ignition config files that the installation program generates contain certificates that expire after 24 hours, which are then renewed at that time. If the cluster is shut down before renewing the certificates and the cluster is later restarted after the 24 hours have elapsed, the cluster automatically recovers the expired certificates. The exception is that you must manually approve the pending `node-bootstrapper` certificate signing requests (CSRs) to recover kubelet certificates. See the documentation for Recovering from expired control plane certificates for more information.

- It is recommended that you use Ignition config files within 12 hours after they are generated because the 24-hour certificate rotates from 16 to 22 hours after the cluster is installed. By using the Ignition config files within 12 hours, you can avoid installation failure if the certificate update runs during installation.

2. Confirm that the Kubernetes API server is communicating with the pods.

   a. To view a list of all pods, use the following command:

   ```bash
   $ oc get pods --all-namespaces
   ```

   **Example output**

<table>
<thead>
<tr>
<th>NAMESPACE</th>
<th>NAME</th>
<th>READY</th>
<th>STATUS</th>
</tr>
</thead>
<tbody>
<tr>
<td>openshift-apiserver-operator</td>
<td>openshift-apiserver-operator-85cb746d55-zqhs8</td>

<td>0</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>5m</td>
</tr>
<tr>
<td></td>
<td>...</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

   b. View the logs for a pod that is listed in the output of the previous command by using the following command:

   ```bash
   $ oc logs <pod_name> -n <namespace>
   ```

   Specify the pod name and namespace, as shown in the output of the previous command.

   If the pod logs display, the Kubernetes API server can communicate with the cluster machines.
5.1.17. Telemetry access for OpenShift Container Platform

In OpenShift Container Platform 4.6, the Telemetry service, which runs by default to provide metrics about cluster health and the success of updates, requires internet access. If your cluster is connected to the internet, Telemetry runs automatically, and your cluster is registered to OpenShift Cluster Manager.

After you confirm that your OpenShift Cluster Manager inventory is correct, either maintained automatically by Telemetry or manually by using OpenShift Cluster Manager, use subscription watch to track your OpenShift Container Platform subscriptions at the account or multi-cluster level.

Additional resources
- See About remote health monitoring for more information about the Telemetry service.

5.1.18. Next steps
- Customize your cluster.
- If necessary, you can opt out of remote health reporting.
- Set up your registry and configure registry storage.

5.2. INSTALLING A CLUSTER ON BARE METAL WITH NETWORK CUSTOMIZATIONS

In OpenShift Container Platform version 4.6, you can install a cluster on bare metal infrastructure that you provision with customized network configuration options. By customizing your network configuration, your cluster can coexist with existing IP address allocations in your environment and integrate with existing MTU and VXL AN configurations.

You must set most of the network configuration parameters during installation, and you can modify only kubeProxy configuration parameters in a running cluster.

5.2.1. Prerequisites
- Review details about the OpenShift Container Platform installation and update processes.
- If you use a firewall, you must configure it to access Red Hat Insights.

5.2.2. Internet access for OpenShift Container Platform

In OpenShift Container Platform 4.6, you require access to the Internet to install your cluster.

You must have Internet access to:
- Access OpenShift Cluster Manager to download the installation program and perform subscription management. If the cluster has internet access and you do not disable Telemetry, that service automatically entitles your cluster.
- Access Quay.io to obtain the packages that are required to install your cluster.
- Obtain the packages that are required to perform cluster updates.
IMPORTANT

If your cluster cannot have direct Internet access, you can perform a restricted network installation on some types of infrastructure that you provision. During that process, you download the content that is required and use it to populate a mirror registry with the packages that you need to install a cluster and generate the installation program. With some installation types, the environment that you install your cluster in will not require Internet access. Before you update the cluster, you update the content of the mirror registry.

5.2.3. Machine requirements for a cluster with user-provisioned infrastructure

For a cluster that contains user-provisioned infrastructure, you must deploy all of the required machines.

5.2.3.1. Required machines

The smallest OpenShift Container Platform clusters require the following hosts:

- One temporary bootstrap machine
- Three control plane, or master, machines
- At least two compute machines, which are also known as worker machines. If you are running a three-node cluster, running zero compute machines is supported. Running one compute machine is not supported.

NOTE

The cluster requires the bootstrap machine to deploy the OpenShift Container Platform cluster on the three control plane machines. You can remove the bootstrap machine after you install the cluster.

IMPORTANT

To maintain high availability of your cluster, use separate physical hosts for these cluster machines.

The bootstrap and control plane machines must use Red Hat Enterprise Linux CoreOS (RHCOS) as the operating system. However, the compute machines can choose between Red Hat Enterprise Linux CoreOS (RHCOS) or Red Hat Enterprise Linux (RHEL) 7.9.

Note that RHCOS is based on Red Hat Enterprise Linux (RHEL) 8 and inherits all of its hardware certifications and requirements. See [Red Hat Enterprise Linux technology capabilities and limits](https://access.redhat.com/documentation/en-us/red_hat_enterprise_linux/8/html/technology_capabilities_and_limits/).  

5.2.3.2. Network connectivity requirements

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require network in `initramfs` during boot to fetch Ignition config files from the Machine Config Server. During the initial boot, the machines require either a DHCP server or that static IP addresses be set in order to establish a network connection to download their Ignition config files. Additionally, each OpenShift Container Platform node in the cluster must have access to a Network Time Protocol (NTP) server. If a DHCP server provides NTP servers information, the chrony time service on the Red Hat Enterprise Linux CoreOS (RHCOS) machines read the information and can sync the clock with the NTP servers.
5.2.3.3. Minimum resource requirements

Each cluster machine must meet the following minimum requirements:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Bootstrap</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Control plane</td>
<td>RHCOS</td>
<td>4</td>
<td>16 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
<tr>
<td>Compute</td>
<td>RHCOS or RHEL 7.9</td>
<td>2</td>
<td>8 GB</td>
<td>100 GB</td>
<td>300</td>
</tr>
</tbody>
</table>

1. One CPU is equivalent to one physical core when simultaneous multithreading (SMT), or hyperthreading, is not enabled. When enabled, use the following formula to calculate the corresponding ratio: (threads per core × cores) × sockets = CPUs.

2. OpenShift Container Platform and Kubernetes are sensitive to disk performance, and faster storage is recommended, particularly for etcd on the control plane nodes which require a 10 ms p99 fsync duration. Note that on many cloud platforms, storage size and IOPS scale together, so you might need to over-allocate storage volume to obtain sufficient performance.

5.2.3.4. Certificate signing requests management

Because your cluster has limited access to automatic machine management when you use infrastructure that you provision, you must provide a mechanism for approving cluster certificate signing requests (CSRs) after installation. The `kube-controller-manager` only approves the kubelet client CSRs. The `machine-approver` cannot guarantee the validity of a serving certificate that is requested by using kubelet credentials because it cannot confirm that the correct machine issued the request. You must determine and implement a method of verifying the validity of the kubelet serving certificate requests and approving them.

5.2.4. Creating the user-provisioned infrastructure

Before you deploy an OpenShift Container Platform cluster that uses user-provisioned infrastructure, you must create the underlying infrastructure.

**Prerequisites**

- Review the [OpenShift Container Platform 4.x Tested Integrations](#) page before you create the supporting infrastructure for your cluster.

**Procedure**

1. Configure DHCP or set static IP addresses on each node.
2. Provision the required load balancers.
3. Configure the ports for your machines.
4. Configure DNS.
5. Ensure network connectivity.

5.2.4.1. Networking requirements for user-provisioned infrastructure

All the Red Hat Enterprise Linux CoreOS (RHCOS) machines require network in initramfs during boot to fetch Ignition config from the machine config server.

During the initial boot, the machines require either a DHCP server or that static IP addresses be set on each host in the cluster in order to establish a network connection, which allows them to download their Ignition config files.

It is recommended to use the DHCP server to manage the machines for the cluster long-term. Ensure that the DHCP server is configured to provide persistent IP addresses and host names to the cluster machines.

The Kubernetes API server must be able to resolve the node names of the cluster machines. If the API servers and worker nodes are in different zones, you can configure a default DNS search zone to allow the API server to resolve the node names. Another supported approach is to always refer to hosts by their fully-qualified domain names in both the node objects and all DNS requests.

You must configure the network connectivity between machines to allow cluster components to communicate. Each machine must be able to resolve the host names of all other machines in the cluster.

### Table 5.12. All machines to all machines

</tbody>
</table>

### Table 5.13. All machines to control plane
Network topology requirements
The infrastructure that you provision for your cluster must meet the following network topology requirements.

**IMPORTANT**
OpenShift Container Platform requires all nodes to have internet access to pull images for platform containers and provide telemetry data to Red Hat.

Load balancers
Before you install OpenShift Container Platform, you must provision two load balancers that meet the following requirements:

1. **API load balancer.** Provides a common endpoint for users, both human and machine, to interact with and configure the platform. Configure the following conditions:
   - Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the API routes.
   - A stateless load balancing algorithm. The options vary based on the load balancer implementation.

   **IMPORTANT**
   Do not configure session persistence for an API load balancer.

Configure the following ports on both the front and back of the load balancers:

**Table 5.15. API load balancer**
Bootstrap and control plane. You remove the bootstrap machine from the load balancer after the bootstrap machine initializes the cluster control plane.

**NOTE**

The load balancer must be configured to take a maximum of 30 seconds from the time the API server turns off the /readyz endpoint to the removal of the API server instance from the pool. Within the time frame after /readyz returns an error or becomes healthy, the endpoint must have been removed or added. Probing every 5 or 10 seconds, with two successful requests to become healthy and three to become unhealthy, are well-tested values.

2. **Application Ingress load balancer** Provides an Ingress point for application traffic flowing in from outside the cluster. Configure the following conditions:

- Layer 4 load balancing only. This can be referred to as Raw TCP, SSL Passthrough, or SSL Bridge mode. If you use SSL Bridge mode, you must enable Server Name Indication (SNI) for the Ingress routes.

- A connection-based or session-based persistence is recommended, based on the options available and types of applications that will be hosted on the platform.

Configure the following ports on both the front and back of the load balancers:

**Table 5.16. Application Ingress load balancer**

<table>
<thead>
<tr>
<th>Port</th>
<th>Back-end machines (pool members)</th>
<th>Internal</th>
<th>External</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>443</td>
<td>The machines that run the Ingress router pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTPS traffic</td>
</tr>
<tr>
<td>80</td>
<td>The machines that run the Ingress router pods, compute, or worker, by default.</td>
<td>X</td>
<td>X</td>
<td>HTTP traffic</td>
</tr>
</tbody>
</table>

**TIP**

If the true IP address of the client can be seen by the load balancer, enabling source IP-based session persistence can improve performance for applications that use end-to-end TLS encryption.

**NOTE**

A working configuration for the Ingress router is required for an OpenShift Container Platform cluster. You must configure the Ingress router after the control plane initializes.
NTP configuration
OpenShift Container Platform clusters are configured to use a public Network Time Protocol (NTP) server by default. If you want to use a local enterprise NTP server, or if your cluster is being deployed in a disconnected network, you can configure the cluster to use a specific time server. For more information, see the documentation for Configuring chrony time service.

If a DHCP server provides NTP server information, the chrony time service on the Red Hat Enterprise Linux CoreOS (RHCOS) machines read the information and can sync the clock with the NTP servers.

Additional resources

- Configuring chrony time service

5.2.4.2. User-provisioned DNS requirements

DNS is used for name resolution and reverse name resolution. DNS A/AAAA or CNAME records are used for name resolution and PTR records are used for reverse name resolution. The reverse records are important because Red Hat Enterprise Linux CoreOS (RHCOS) uses the reverse records to set the host name for all the nodes. Additionally, the reverse records are used to generate the certificate signing requests (CSR) that OpenShift Container Platform needs to operate.

The following DNS records are required for an OpenShift Container Platform cluster that uses user-provisioned infrastructure. In each record, `<cluster_name>` is the cluster name and `<base_domain>` is the cluster base domain that you specify in the `install-config.yaml` file. A complete DNS record takes the form: `<component>.<cluster_name>.<base_domain>`.

Table 5.17. Required DNS records

<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kubernetes API</td>
<td>api.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the load balancer for the control plane machines. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td></td>
<td>api-int.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the load balancer for the control plane machines. These records must be resolvable from all the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

The API server must be able to resolve the worker nodes by the host names that are recorded in Kubernetes. If the API server cannot resolve the node names, then proxied API calls can fail, and you cannot retrieve logs from pods.
<table>
<thead>
<tr>
<th>Component</th>
<th>Record</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Routes</td>
<td>*.apps.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>Add a wildcard DNS A/AAAA or CNAME record that refers to the load balancer that targets the machines that run the Ingress router pods, which are the worker nodes by default. These records must be resolvable by both clients external to the cluster and from all the nodes within the cluster.</td>
</tr>
<tr>
<td>Bootstrap</td>
<td>bootstrap.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>Add a DNS A/AAAA or CNAME record, and a DNS PTR record, to identify the bootstrap machine. These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Master hosts</td>
<td>&lt;master&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the control plane nodes (also known as the master nodes). These records must be resolvable by the nodes within the cluster.</td>
</tr>
<tr>
<td>Worker hosts</td>
<td>&lt;worker&gt;&lt;n&gt;.&lt;cluster_name&gt;.&lt;base_domain&gt;</td>
<td>Add DNS A/AAAA or CNAME records and DNS PTR records to identify each machine for the worker nodes. These records must be resolvable by the nodes within the cluster.</td>
</tr>
</tbody>
</table>

**TIP**

You can use the `nslookup <hostname>` command to verify name resolution. You can use the `dig -x <ip_address>` command to verify reverse name resolution for the PTR records.

The following example of a BIND zone file shows sample A records for name resolution. The purpose of the example is to show the records that are needed. The example is not meant to provide advice for choosing one name resolution service over another.

**Example 5.3. Sample DNS zone database**

```
$TTL 1W
@ IN SOA ns1.example.com. root ( 2019070700 ; serial 3H ; refresh (3 hours) 30M ; retry (30 minutes) 2W ; expiry (2 weeks) 1W ) ; minimum (1 week)
IN NS ns1.example.com.
IN MX 10 smtp.example.com.
;
ns1 IN A 192.168.1.5
smtp IN A 192.168.1.5
;
helper IN A 192.168.1.5
helper.ocp4 IN A 192.168.1.5
;
The api identifies the IP of your load balancer.
```
The following example BIND zone file shows sample PTR records for reverse name resolution.

Example 5.4. Sample DNS zone database for reverse records

$TTL 1W
@ IN SOA ns1.example.com. root ( 
 2019070700 ; serial 
3H ; refresh (3 hours) 
30M ; retry (30 minutes) 
2W ; expiry (2 weeks) 
1W ) ; minimum (1 week)
IN NS ns1.example.com.
;
; The syntax is "last octet" and the host must have an FQDN
; with a trailing dot.
97 IN PTR master0.ocp4.example.com.
98 IN PTR master1.ocp4.example.com.
99 IN PTR master2.ocp4.example.com.
;
96 IN PTR bootstrap.ocp4.example.com.
;
5 IN PTR api.ocp4.example.com.
5 IN PTR api-int.ocp4.example.com.
;
11 IN PTR worker0.ocp4.example.com.
7 IN PTR worker1.ocp4.example.com.
;
;EOF

5.2.5. Generating an SSH private key and adding it to the agent
If you want to perform installation debugging or disaster recovery on your cluster, you must provide an SSH key to both your ssh-agent and the installation program. You can use this key to access the bootstrap machine in a public cluster to troubleshoot installation issues.

**NOTE**

In a production environment, you require disaster recovery and debugging.

You can use this key to SSH into the master nodes as the user core. When you deploy the cluster, the key is added to the core user’s ~/.ssh/authorized_keys list.

**NOTE**

You must use a local key, not one that you configured with platform-specific approaches such as AWS key pairs.

**Procedure**

1. If you do not have an SSH key that is configured for password-less authentication on your computer, create one. For example, on a computer that uses a Linux operating system, run the following command:

   ```
   $ ssh-keygen -t ed25519 -N "" -f <path>/<file_name>
   ```

   Specify the path and file name, such as ~/.ssh/id_rsa, of the new SSH key. If you have an existing key pair, ensure your public key is in the your ~/.ssh directory.

   Running this command generates an SSH key that does not require a password in the location that you specified.

   **NOTE**

   If you plan to install an OpenShift Container Platform cluster that uses FIPS Validated / Modules in Process cryptographic libraries on the x86_64 architecture, do not create a key that uses the ed25519 algorithm. Instead, create a key that uses the rsa or ecdsa algorithm.

2. Start the ssh-agent process as a background task:

   ```
   $ eval "$(ssh-agent -s)"
   ```

   **Example output**

   ```
   Agent pid 31874
   ```

   **NOTE**

   If your cluster is in FIPS mode, only use FIPS-compliant algorithms to generate the SSH key. The key must be either RSA or ECDSA.
3. Add your SSH private key to the **ssh-agent**:

```bash
$ ssh-add <path>/<file_name>
```

**Example output**

```
Identity added: /home/<you>/<path>/<file_name> (<computer_name>)
```

Specify the path and file name for your SSH private key, such as `~/.ssh/id_rsa`

**Next steps**

- When you install OpenShift Container Platform, provide the SSH public key to the installation program.

**5.2.6. Obtaining the installation program**

Before you install OpenShift Container Platform, download the installation file on a local computer.

**Prerequisites**

- You have a computer that runs Linux or macOS, with 500 MB of local disk space

**Procedure**

1. Access the **Infrastructure Provider** page on the OpenShift Cluster Manager site. If you have a Red Hat account, log in with your credentials. If you do not, create an account.

2. Select your infrastructure provider.

3. Navigate to the page for your installation type, download the installation program for your operating system, and place the file in the directory where you will store the installation configuration files.

**IMPORTANT**

The installation program creates several files on the computer that you use to install your cluster. You must keep the installation program and the files that the installation program creates after you finish installing the cluster. Both files are required to delete the cluster.

**IMPORTANT**

Deleting the files created by the installation program does not remove your cluster, even if the cluster failed during installation. To remove your cluster, complete the OpenShift Container Platform uninstallation procedures for your specific cloud provider.

4. Extract the installation program. For example, on a computer that uses a Linux operating system, run the following command:

```bash
$ tar xvf openshift-install-linux.tar.gz
```
5. Download your installation pull secret from the Red Hat OpenShift Cluster Manager. This pull secret allows you to authenticate with the services that are provided by the included authorities, including Quay.io, which serves the container images for OpenShift Container Platform components.

5.2.7. Installing the OpenShift CLI by downloading the binary

You can install the OpenShift CLI (oc) in order to interact with OpenShift Container Platform from a command-line interface. You can install oc on Linux, Windows, or macOS.

**IMPORTANT**
If you installed an earlier version of oc, you cannot use it to complete all of the commands in OpenShift Container Platform 4.6. Download and install the new version of oc.

5.2.7.1. Installing the OpenShift CLI on Linux

You can install the OpenShift CLI (oc) binary on Linux by using the following procedure.

**Procedure**

2. Select the appropriate version in the Version drop-down menu.
3. Click Download Now next to the OpenShift v4.6 Linux Client entry and save the file.
4. Unpack the archive:
   ```
   $ tar xvzf <file>
   ```
5. Place the oc binary in a directory that is on your PATH.
   To check your PATH, execute the following command:
   ```
   $ echo $PATH
   ```

After you install the OpenShift CLI, it is available using the oc command:

```
$ oc <command>
```
4. Unzip the archive with a ZIP program.

5. Move the `oc` binary to a directory that is on your PATH.
   To check your PATH, open the command prompt and execute the following command:

   ```
   C:\> path
   ```

   After you install the OpenShift CLI, it is available using the `oc` command:

   ```
   C:\> oc <command>
   ```

5.2.7.3. Installing the OpenShift CLI on macOS

You can install the OpenShift CLI (`oc`) binary on macOS by using the following procedure.

**Procedure**

2. Select the appropriate version in the Version drop-down menu.

3. Click Download Now next to the OpenShift v4.6 MacOSX Client entry and save the file.

4. Unpack and unzip the archive.

5. Move the `oc` binary to a directory on your PATH.
   To check your PATH, open a terminal and execute the following command:

   ```
   $ echo $PATH
   ```

   After you install the OpenShift CLI, it is available using the `oc` command:

   ```
   $ oc <command>
   ```

5.2.8. Manually creating the installation configuration file

For installations of OpenShift Container Platform that use user-provisioned infrastructure, you manually generate your installation configuration file.

**Prerequisites**

- Obtain the OpenShift Container Platform installation program and the access token for your cluster.

**Procedure**

1. Create an installation directory to store your required installation assets in:

   ```
   $ mkdir <installation_directory>
   ```
IMPORTANT

You must create a directory. Some installation assets, like bootstrap X.509 certificates have short expiration intervals, so you must not reuse an installation directory. If you want to reuse individual files from another cluster installation, you can copy them into your directory. However, the file names for the installation assets might change between releases. Use caution when copying installation files from an earlier OpenShift Container Platform version.

2. Customize the following `install-config.yaml` file template and save it in the `<installation_directory>`.

NOTE

You must name this configuration file `install-config.yaml`.

3. Back up the `install-config.yaml` file so that you can use it to install multiple clusters.

IMPORTANT

The `install-config.yaml` file is consumed during the next step of the installation process. You must back it up now.

5.2.8.1. Installation configuration parameters

Before you deploy an OpenShift Container Platform cluster, you provide parameter values to describe your account on the cloud platform that hosts your cluster and optionally customize your cluster’s platform. When you create the `install-config.yaml` installation configuration file, you provide values for the required parameters through the command line. If you customize your cluster, you can modify the `install-config.yaml` file to provide more details about the platform.

NOTE

After installation, you cannot modify these parameters in the `install-config.yaml` file.

IMPORTANT

The `openshift-install` command does not validate field names for parameters. If an incorrect name is specified, the related file or object is not created, and no error is reported. Ensure that the field names for any parameters that are specified are correct.

5.2.8.1.1. Required configuration parameters

Required installation configuration parameters are described in the following table:

Table 5.18. Required parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>apiVersion</td>
<td>The API version for the install-config.yaml content. The current version is v1. The installer may also support older API versions.</td>
<td>String</td>
</tr>
<tr>
<td>baseDomain</td>
<td>The base domain of your cloud provider. The base domain is used to create routes to your OpenShift Container Platform cluster components. The full DNS name for your cluster is a combination of the baseDomain and metadata.name parameter values that uses the &lt;metadata.name&gt;.&lt;baseDomain&gt; format.</td>
<td>A fully-qualified domain or subdomain name, such as example.com.</td>
</tr>
<tr>
<td>metadata</td>
<td>Kubernetes resource ObjectMeta, from which only the name parameter is consumed.</td>
<td>Object</td>
</tr>
<tr>
<td>metadata.name</td>
<td>The name of the cluster. DNS records for the cluster are all subdomains of {{.metadata.name}}.{{.baseDomain}}.</td>
<td>String of lowercase letters, hyphens (-), and periods (.), such as dev.</td>
</tr>
<tr>
<td>platform</td>
<td>The configuration for the specific platform upon which to perform the installation: aws, baremetal, azure, openstack, ovirt, vsphere. For additional information about platform.&lt;platform&gt; parameters, consult the following table for your specific platform.</td>
<td>Object</td>
</tr>
</tbody>
</table>
Get a pull secret from the Red Hat OpenShift Cluster Manager to authenticate downloading container images for OpenShift Container Platform components from services such as Quay.io.

```
{
  "auths":{
    "cloud.openshift.com":{
      "auth":"b3Blb=",
      "email":"you@example.com"
    },
    "quay.io":{
      "auth":"b3Blb=",
      "email":"you@example.com"
    }
  }
}
```

### 5.2.8.1.2. Network configuration parameters

You can customize your installation configuration based on the requirements of your existing network infrastructure. For example, you can expand the IP address block for the cluster network or provide different IP address blocks than the defaults.

Only IPv4 addresses are supported.

Table 5.19. Network parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>networking</strong></td>
<td>The configuration for the cluster network.</td>
<td>Object</td>
</tr>
<tr>
<td><strong>networking.network</strong></td>
<td>The cluster network provider Container Network Interface (CNI) plug-in to install.</td>
<td>Either OpenShiftSDN or OVNKubernetes. The default value is OpenShiftSDN.</td>
</tr>
<tr>
<td><strong>networking.clusterNetwork</strong></td>
<td>The IP address blocks for pods. The default value is 10.128.0.0/14 with a host prefix of /23.</td>
<td>An array of objects. For example: networking: clusterNetwork: - cidr: 10.128.0.0/14 hostPrefix: 23</td>
</tr>
<tr>
<td></td>
<td>NOTE: You cannot modify parameters specified by the networking object after installation.</td>
<td></td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-----------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>--------</td>
</tr>
<tr>
<td>networking.clusterNetwork.cidr</td>
<td>Required if you use <code>networking.clusterNetwork</code>. An IP address block.</td>
<td>An IP address block in Classless Inter-Domain Routing (CIDR) notation. The prefix length for an IPv4 block is between 0 and 32.</td>
</tr>
<tr>
<td></td>
<td>An IPv4 network.</td>
<td></td>
</tr>
<tr>
<td>networking.clusterNetwork.hostPrefix</td>
<td>The subnet prefix length to assign to each individual node. For example, if <code>hostPrefix</code> is set to 23 then each node is assigned a /23 subnet out of the given <code>cidr</code>. A <code>hostPrefix</code> value of 23 provides 510 $(2^{32 - 23} - 2)$ pod IP addresses.</td>
<td>A subnet prefix. The default value is 23.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>networking.serviceNetwork</td>
<td>The IP address block for services. The default value is 172.30.0.0/16.</td>
<td>An array with an IP address block in CIDR format. For example:</td>
</tr>
<tr>
<td></td>
<td>The OpenShift SDN and OVN-Kubernetes network providers support only a single IP address block for the service network.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>```</td>
</tr>
</tbody>
</table>
|                                               | networking:                                                                ồ
|                                               | serviceNetwork:                                                               | - 172.30.0.0/16 |
|                                               | networking:                                                                  |         |
|                                               | machineNetwork:                                                              |         |
|                                               | cidr: 10.0.0.0/16                                                           |         |
| networking.machineNetwork                     | The IP address blocks for machines. If you specify multiple IP address blocks, the blocks must not overlap.                                                                                               | An array of objects. For example: |
|                                               |                                                                                                                                                                                                             |         |
|                                               | networking:                                                                  |         |
|                                               | machineNetwork:                                                              |         |
|                                               | cidr: 10.0.0.0/16                                                           |         |
| networking.machineNetwork.cidr                | Required if you use `networking.machineNetwork`. An IP address block. The default value is 10.0.0.0/16 for all platforms other than libvirt. For libvirt, the default value is 192.168.126.0/24. | An IP network block in CIDR notation. For example, 10.0.0.0/16. |
|                                               |                                                                                                                                                                                                             |         |
|                                               | **NOTE**                                                                      | Set the `networking.machineNetwork` to match the CIDR that the preferred NIC resides in.                                                                                                               |         |

### 5.2.8.1.3. Optional configuration parameters

Optional installation configuration parameters are described in the following table:

<table>
<thead>
<tr>
<th>Table 5.20. Optional parameters</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>additionalTrustBundle</code></td>
<td>A PEM-encoded X.509 certificate bundle that is added to the nodes' trusted certificate store. This trust bundle may also be used when a proxy has been configured.</td>
</tr>
<tr>
<td><code>compute</code></td>
<td>The configuration for the machines that comprise the compute nodes.</td>
</tr>
<tr>
<td><code>compute.architecture</code></td>
<td>Determines the instruction set architecture of the machines in the pool. Currently, heterogeneous clusters are not supported, so all pools must specify the same architecture. Valid values are <code>amd64</code> (the default).</td>
</tr>
<tr>
<td><code>compute.hyperthreading</code></td>
<td>Whether to enable or disable simultaneous multithreading, or <strong>hyperthreading</strong>, on compute machines. By default, simultaneous multithreading is enabled to increase the performance of your machines' cores.</td>
</tr>
<tr>
<td></td>
<td><strong>IMPORTANT</strong> If you disable simultaneous multithreading, ensure that your capacity planning accounts for the dramatically decreased machine performance.</td>
</tr>
<tr>
<td><code>compute.name</code></td>
<td>Required if you use <code>compute</code>. The name of the machine pool.</td>
</tr>
<tr>
<td><code>compute.platform</code></td>
<td>Required if you use <code>compute</code>. Use this parameter to specify the cloud provider to host the worker machines. This parameter value must match the <code>controlPlane.platform</code> parameter value.</td>
</tr>
<tr>
<td><code>compute.replicas</code></td>
<td>The number of compute machines, which are also known as worker machines, to provision.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>controlPlane</td>
<td>The configuration for the machines that comprise the control plane.</td>
</tr>
<tr>
<td>controlPlane.architecture</td>
<td>Determines the instruction set architecture of the machines in the pool.</td>
</tr>
<tr>
<td></td>
<td>Currently, heterogeneous clusters are not supported, so all pools</td>
</tr>
<tr>
<td></td>

<td>planning accounts for the dramatically decreased machine performance.</td>
</tr>
<tr>
<td>controlPlane.name</td>
<td>Required if you use controlPlane. The name of the machine pool.</td>
</tr>
<tr>
<td>controlPlane.platform</td>
<td>Required if you use controlPlane. Use this parameter to specify the cloud</td>
</tr>
<tr>
<td></td>
<td>provider that hosts the control plane machines. This parameter value must</td>
</tr>
<tr>
<td></td>
<td>match the compute.platform parameter value.</td>
</tr>
<tr>
<td>controlPlane.replicas</td>
<td>The number of control plane machines to provision.</td>
</tr>
</tbody>
</table>
The Cloud Credential Operator (CCO) mode. If no mode is specified, the CCO dynamically tries to determine the capabilities of the provided credentials, with a preference for mint mode on the platforms where multiple modes are supported.

**NOTE**

Not all CCO modes are supported for all cloud providers. For more information on CCO modes, see the Cloud Credential Operator entry in the Red Hat Operators reference content.

### fips

Enable or disable FIPS mode. The default is **false** (disabled). If FIPS mode is enabled, the Red Hat Enterprise Linux CoreOS (RHCOS) machines that OpenShift Container Platform runs on bypass the default Kubernetes cryptography suite and use the cryptography modules that are provided with RHCOS instead.

**IMPORTANT**

The use of FIPS Validated / Modules in Process cryptographic libraries is only supported on OpenShift Container Platform deployments on the **x86_64** architecture.

**NOTE**

If you are using Azure File storage, you cannot enable FIPS mode.
